Proboscidea

The order Proboscidea comprises three suborders and about 300 species of terrestrial mammals. All but two species, the Asiatic, or Asian, elephant ***(Elephas maximus)*** and the African elephant ***(Loxodonta africana)***,are extinct. The elephants are the largest surviving land animals and, among the mammals, are exceeded only by the whales in size.

The Proboscidea are characterized by columnar limbs, bulky bodies, and elongated snouts. In recent forms, testes are internal. The snout is a long boneless proboscis, or trunk; it is a combination of the upper lips, palate, and nostrils. Some of the incisor teeth develop into tusks. One extinct suborder (Deinotherioidea) lost the upper tusks; certain others have lost the lower ones and evolved upper tusks of dentine from which the enamel has partially or completely disappeared. The canine teeth were generally repressed in all groups, and the cheek teeth developed rows of blunt cones or ridges. In later forms, the temporary teeth were replaced by permanent ones, which are pushed by an escalator-like movement along a horizontal plane, so that the front teeth were replaced by teeth moving forward from the rear. The skull, which originally was elongated, became shorter, higher, and bulkier in later forms. The back of the eye orbit remained open instead of forming a complete bony ring, and the nasal opening in all Proboscidea is at a higher horizontal plane than the eye sockets. The neck shortened as the animals evolved larger, higher bodies and an elongated trunk that also functions as a hand. The skull has enlarged out of proportion to the brain in order to serve as an anchor for the trunk and to support the heavy dentition. This order occurs in all the continents except Australia. Fossils of proboscideans provide valuable information about early humans who were their contemporaries.

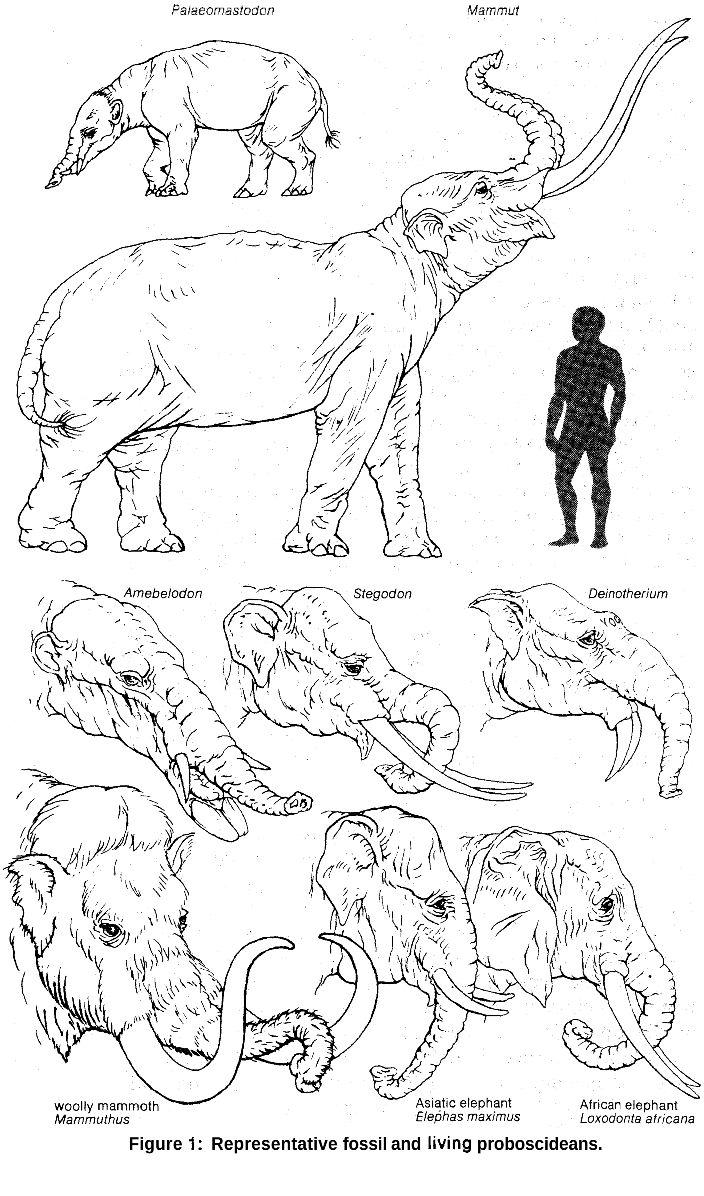

Figure 1: Representative fossil and living proboscideans.

GENERAL FEATURES

Size range and distribution. In Europe, the landmass that broke up to form the islands of the Mediterranean Sea harboured proboscideans. Three fossil species have been found in Malta; one had had a height of 2.1 metres, or 6.9 feet ***(Palaeoloxodon mindriensis)***, another a height of 1.5 metres, or 4.9 feet ***(P. melitensis)***, and the third was less than one metre, or about three feet ***(P. falconeri)***. ***P. creticus*** of Crete was 1.5 metres, and ***P. cypriotis*** of Cyprus was 0.9 metre (three feet) in height. In North America, a ***Mammuthus*** isolated on Santa Rosa Island, off the coast of southern California, was probably derived from ***Mammuthus meridionalis***, a species that stood **4.2** metres (13.8 feet) at the shoulders.

Early human records of elephants

Elephas maximus asurus lived in Iran and Syria. Early drawings of the animal and fragmentary skeletal remains indicate that it was the largest subspecies of the Asian elephant. The war elephants employed by Pyrrhus in 255 BC and engraved upon Roman seals show animals of unusual size. "Sarus," which signified "the Syrian," was the outstanding animal in the elephant battle squadron of the Carthaginian general Hannibal. In 1500 BC elephants ***(Elephas maximus rubridens)*** existed in China as far north as Anyang, in northern Honan Province. Writings from the 14th century state that elephants were still to be found in Kwangsi Province.

Man as well as other environmental factors exterminated the woolly mammoth ***(Mammuthus primigenius)*** and the imperial mammoth ***(M. imperator)*** about 10,000 years ago. Several races of the living species of Asian and African elephants also died out by about 1500 BC. The small North African race became extinct by the 2nd century AD, and some of the American mastodons, such as ***Cuvieronius postremus*** of South America, died out as recently as the 4th century AD. The large African bush elephants ***(Loxodonta africana)*** were exterminated from the Transvaal in South Africa early in the 20th century, but they still occur over much of the continent south of the Sahara Desert. A smaller elephant inhabits the forests of western equatorial Africa, particularly in the Congo region. It is considered by some to be a subspecies (***Loxodonta africana cyclotis)*** of the African elephant; others believe it to be represented by several subspecies; still others consider it to be a separate species (L. ***cyclotis)***.

In Asia, elephants have been exterminated from Iran, Iraq, Afghanistan, the northwestern part of India, and from much of the Malay Peninsula, Java, and the greater part of Borneo and Sri Lanka (formerly Ceylon). Isolated colonies remain in forest areas of Mysore in the peninsular part of India, in Assam, Nepal, Burma, Malaya, southern China, Sri Lanka, Sumatra, Borneo, and other islands of the East Indies.

Capture of elephants

Importance to man. Elephants constitute the chief source of commercial ivory. Because of the continuing demand for this commodity, the animals are in danger of extermination. Elephant "pearls" consist of concentric layers of ivory deposited over a foreign object that has been intruded into the soft ivory at the base of the growing tusk. From early times elephants have been used as beasts of burden in India and Burma. Since they do not breed freely in captivity, new stock for domestication is often captured from wild herds. One method is to drive them through a funnel-shaped stockade into a small enclosure; trained tame elephants help to subdue, noose, and train young captives for service. The training and handling of an elephant are usually entrusted to one man, called the mahout in India and the oozie in Burma; an elephant and its keeper frequently became inseparable companions.

Trained elephants carry humans in a howdah, or miniature hunting lodge, on their backs. They are used to move timber or other heavy materials.

In modern times, African elephants have been trained for labour only since late in the 19th century; however, they were used by the Carthaginians in wars with the Romans. Elephants depicted on Roman medals of the 2nd century AD have heads and bodies of the Asian but ears of the African species. This suggests that both species at that time were tamed. Elephants were used as executioners in Roman amphitheatres and for military pageants. They are still used in exhibitions at circuses, carnivals, and zoological parks. In warfare elephants have been used to drag heavy equipment, especially through mud and up steep slopes. As late as World War II, they were of value in military movements over the mud-clogged roads of Southeast Asia.

The association between man and elephants goes far back into mythology, and a rich folklore has developed. Bracelets of hairs from the tail of a freshly-killed or living elephant are prized as good-luck charms.

Attempts to locate the legendary "graveyards" to which old elephants allegedly resort when near death have been, for the most part, unsuccessful. The groups of buried elephant remains that have been found probably represent sites where elephants drowned in bogs or rivers or perished from imbibing poisonous water.

NATURAL HISTORY

Reproduction and life cycle. Tuskers, or tusked bulls, occasionally fight brief, savage duels that may end in death for the defeated animal. A duel between tuskless elephants may last for days, with occasional periods of rest. The female selected from the herd by the winner often makes an apparent attempt to escape from him. After a brief preliminary courting, the male mounts the female from behind, leaning over her back and either gripping her body or resting his forefeet upon her pelvis, and assumes a standing posture. Copulation lasts for about 20 seconds, with very little movement or noise. Mating continues promiscuously for about two days, after which the most powerful bull drives off the others and remains with the cow for about three weeks. The period of gestation varies from 20 months for a female calf to 22 months for a male. When parturition is about to occur, the herd surrounds the cow, who assumes a squatting position while giving birth.

In regions where large carnivores, such as tigers, prey upon newborn elephants, the cow seeks a female associate. The mother and the other elephants in the herd blow dust upon the moist, newborn calf to dry it. Two hours after birth, the baby is able to stand and is suckled. The mother and calf then join the herd.

Tame cows begin breeding at the age of eight or nine years; tame bulls begin when about 11 or 12 years of age. The interval between the birth of successive calves is 'about four years. In captivity cows are known to continue bearing calves until 60 or 70 years of age.

Appearance of elephant calf

The newborn elephant is about one metre (three feet) high and weighs about 90 kilograms (200 pounds). It is covered with yellow and brown hair. After a few months the hair on some parts of the body is as long as that in the extinct mammoth. In E. *maximus* there is also a pinkish patch around each eye, and when the calf is about five months old, a faint whitish patch develops on each cheekbone. As this patch spreads, similar patches appear upon the trunk and ears. In the more easterly races of Malaya and Sumatra there are only a few gray spots. The hoof nails, which are dark at first, gradually become lighter. When the elephant is about eight years old, a thick oily secretion known as musth, or must, begins to flow from a gland in the temporal, or temple, region. It occurs in both sexes, but is more active in males. The secretion increases each year until it drips into the elephant's mouth. Some authorities believe that the function of the secretion is to inhibit feeding; others believe it has some effect on sexual activity.

An elephant is not fully grown until it is about 25 years old. In the wild, the average life-span is about 80 years, but under optimum conditions an elephant may live for 120 years.

Behaviour. The organization of an elephant herd is often according to age and sex. In Elephas, although herds of 10 or 15 females and their young may appear to be under the leadership of a large female, and their organization matriarchal, young adult males are always in the vicinity, as is the real leader of the entire group, a large male. The leader may be accompanied by one young adult male who acts as a scout, warning the leader of danger. The herd also has a system of scouts, and, before emerging into an open area, one of the scouts usually explores it. If no danger is apparent, he signals by trumpeting to the herd to advance. Individuals often serve as guards while the rest of the herd feeds or bathes.

The herd is held together both by blood relationship and by a strong sense of companionship. If an individual is injured, three or four others surround it, shielding it from danger, supporting it, and helping it to move away. A calf that has lost its mother is adopted by the other cows in the herd even if they have their own calves to raise.

Ecology. Elephants clear paths through forests that are too dense for other animals. Many modern roads in elephant-inhabited countries originated in this manner. Elephants browse to a height of about five metres (16 feet), thereby increasing the amount of sunlight available for shrubs. Their uprooting of grass and roots aerates the soil and stimulates the growth of plants that replace the ones devoured. Mud wallows frequented by elephants are fertilized by their excreta.

Feeding habits

An elephant may destroy or discard as much vegetation as it consumes. An adult may eat between 250 to 350 kilograms (550 to 750 pounds) of solid food each day. When grazing, the animal uses its trunk or forefoot to gather grass, which is slapped against a forelimb to rid it of sand. In rainy weather, when soil is more difficult to shake off, the animal browses. Asian elephants break off branches; African elephants are more likely to push over trees. The wood apple (Feronia elephantorum) is a favourite food of the Asian elephant. The animal also eats wild rice that grows in forest lakes and various other aquatic plants. The African bush elephant eats the fruit of various palm trees. The spongy wood of the baobab tree provides some water during periods of drought.

FORM AND FUNCTION

Extant forms. The adult elephant has a tuft of hair at the tip of the tail and sometimes a patch of hair on the head. The limbs are adapted for bearing great weight: the legs are straight and pillar-like, and the bones of the joints are flat at the articular surfaces. Each toe has a heavy hoof nail; the weight is borne on thick pads behind the toes. The nose and upper lip are extended into a long trunk, which contains the nasal passages and has nostrils at the tip. Water for drinking is sucked into the trunk and then discharged directly into the mouth. The trunk is used for placing food into the mouth, for spraying and dusting the body, for lifting or moving heavy objects, and even for throwing objects at man.

The upper second incisors are typically developed into ivory tusks, the longest and heaviest teeth of any living animal. Canine teeth are absent. The complex molars are of the high-crowned type, with transverse rows of enamel ridges on the grinding surface, which is often traversed by a longitudinal median groove. There is normally only one complete functional tooth and half of a second one at a time on each side of each jaw. These are replaced horizontally from the rear as they wear away.

The Asian elephant (Elephas *maximus*) and its races are distinguished from the African elephants by being somewhat smaller and by having relatively small ears with the upper edge curled forward. The head is more domed, is structurally more complex, and has a greater development of diploe, or bony cell cavities. E. *maximus* also has high-crowned teeth and a relatively smooth trunk with a single fingerlike projection at the tip. Adult bulls weigh up to six tons and commonly stand 3.3 metres (10.8 feet) at the withers. Only the males develop tusks, which average 1.5 metres (4.9 feet) in length, the pair weighing about 32 kilograms (71 pounds). These develop flat, longitudinal planes of wear near the tip. Tusks 2.7 metres (8.9 feet) long and 68 kilograms (150 pounds) in weight have been recorded. About 90 percent of the males of the Ceylonese race lack tusks; Sumatran elephants are of slighter build and have longer trunks.

In contrast to the Asian species, the African bush elephant is generally larger. This and the forest form have extremely large ears (one metre in breadth), with the upper edge curled backward, and a roughened, heavily ringed trunk with two projections at the tip. The molars are of coarser construction, have fewer ridges, are less crenulated (scalloped), and consist of a thicker surface of enamel over thick plates of dentine. The top of the head is not domed, and the forehead is more convex. The tusk tips are usually conical, the legs are longer, and the eyes are relatively larger than those of the Asian elephant.

The average height of adult bull bush elephants is 3.3 metres (10.8 feet) at the shoulder, and the average weight is six tons. Cows are about 0.6 metre (two feet) shorter. Both sexes possess tusks, which average about 1.8 metres (5.9 feet) long, the pair weighing 36 to 55 kilograms (79 to 121 pounds). A pair of tusks in the British Museum weighs about 133 kilograms (293 pounds); the larger one of the two is 3.5 metres (11.5 feet) long, with a basal circumference of 46 centimetres (18 inches). The largest elephant on record, a bull bush elephant killed in the Cuando river district of southeastern Angola in 1955, is on display at the Smithsonian Institution in Washington, D.C.; it probably weighed 10 tons when alive and stood four metres (13 feet) at the shoulder. Adult forest elephants are about 2.1 metres (6.9 feet) tall and weigh 1,225 kilograms (2,700 pounds), with slender tusks that are often more than three metres long. The ears are relatively small and smoothly rounded at the margins.

Albinos

Albino, or "white," elephants occasionally occur, especially in Thailand and Burma, where they are regarded by some as semisacred.

The mammoth. The genus Mammuthus contains some of the largest members of the family Elephantidae. Certain ones reached a height of over 4.2 metres (13.8 feet) at the shoulders. One was M. meridionalis of Asia and Europe, and the other was M. imperator, which entered North America during the upper Pleistocene.

The genus also contains one of the most specialized members of the family, the woolly mammoth, M. *primigenius*, which probably became extinct about 10,000 years ago. It inhabited the sub-Arctic area of Asia and Europe and eventually entered North America over the Bering Strait; it travelled southward across western North America almost to Wyoming, then spread eastward toward Lake Michigan. Its height of 3.3 metres (10.8 feet) at the shoulders equalled that of a large *Elephas maximus,* but the body was relatively shorter, and the hindquarters sloped downward. Its skull was compressed from front to back. As an adaptation to its cold environment, the woolly mammoth evolved small ears, a short goatlike tail, and a coat of dense, furry, short hair overlain by longer, bristly hair. It also had a humplike reserve of fat upon the top of the head and on the shoulders. A subcutaneous layer of fat about eight centimetres thick covered the body. The molars had as many .as 27 lamellae, or plates. The tusks of the male were about 4.8 metres long. Their almost circular curvature and great size suggest that they may have functioned as shovels for exposing vegetation buried under snow. The mammoth is one of the few extinct proboscideans in which the carcass has often been completely preserved. Among the best known are two from Siberia—one discovered near the mouth of the Lena River in 1804; the other in the bank of the Beresovka River in 1900.

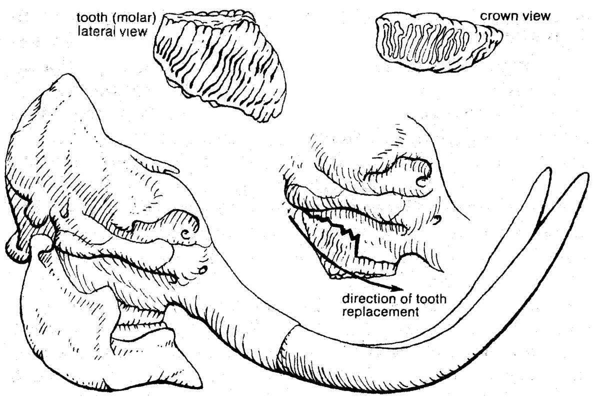

Figure 2: Skull and tooth movement in a mammoth *(Mammuthus primigenius).*

EVOLUTION AND CLASSIFICATION

Origin of the proboscis

Historical development and paleontology. The order Proboscidea has evolved from unknown ancestors that were not much larger than pigs. They flourished during the Paleocene Epoch (65,000,000 to 54,000,000 years ago). During the course of evolution, the lower jaw elongated beyond the upper, and the tusks projected well beyond the upper ones. At this stage the nose, palate, and upper lips developed into an elongated fleshy cover to the projecting lower jaw. It is probable that the nostrils opened well above the extremity of this flap and were near the eyes. A longer lower jaw proved less useful than a shorter one, so the upper flap was converted into a multipurpose tubular proboscis. Because the nostrils shifted to the tip of the proboscis, the animal was able to breathe while submerged in water. When so submerged, the animal had to rely on its sense of smell more than sight to detect approaching predators.

The suborder Deinotherioidea, consisting of one genus, is an early branch of the main proboscidean stock of the Eocene Epoch (54,000,000 to 38,000,000 years ago). They lost their upper tusks and developed a downward-hooked, tusk-tipped mandible. Numerous species of the suborder occurred in Asia, Europe, and Africa and persisted into Pleistocene times (2,500,000 to 10,000 years ago). The largest was the European Deinotherium *gigantissimum*, which reached a height of 3.8 metres (12.5 feet) at the shoulders and existed during the Pliocene Epoch (7,000,000 to 2,500,000 years ago).

In the suborder Mastodontoidea, the family Gomphotheriidae comprises 15 genera, including the earliest members of the order, Phiomia and *Palaeomastodon.* The former were the size of donkeys, but the latter were as large as a modern Asian cow elephant. In this family the skull and neck are elongated, and the teeth low crowned. The second incisors are enlarged; the upper ones are compressed and vertical, and they retain a band of enamel. In the later evolved genera, the lower pair are bent forward, depressed, and expanded into shovellike structures that do not meet the upper tusks. The canines are absent. Among this family are Cordillerion of North America and Cuvieronius of South America. The latter became extinct as recently as AD 200 to 400.

Phiomia, which occurred in Egypt and India, was an archaic shovel-tusked form with an elongated neck. It flourished during the Oligocene (38,000,000 to 26,000,000 years ago). The mandible and its tusks became more shovellike in *Amebelodon* and *Platybelodon* of the Miocene (26,000,000 to 7,000,000 years ago).

In *Palaeomastodon* the skull shortened, and the tusks assumed a cylindrical shape. The genus occurs in middle Oligocene deposits of Egypt. In some later genera, such as *Anancus* and *Stegomastodon,* the jaws shortened and the lower tusks disappeared. In some shovel-tuskers, the mandible remained enlarged and continued to function as a shovel for digging plant bulbs. It was probably protected by a horny pad.

Mastodontidae contains the single genus *Mastodon.* It lacked lower tusks. The tusks were about two metres (seven feet) long. Some species attained a height of about three metres (ten feet), and were covered with hair. Parts of carcasses of the recently extinct American species *Mastodon americanus* have been discovered in peat deposits and swamps.

The earliest proboscideans in Asia are *Phiomia, Gomphotherium, Platybelodon,* and *Serridentinus,* of the family Gomphotheriidae, and *Stegolophodon,* of the family Elephantidae. All occurred in the Miocene of China and some in Burma and India.

In the suborder Elephantoidea, *Stegolophodon* is intermediate between the mastodons and elephants proper. Although this genus first appeared during the Miocene of Europe, Asia, and Africa, it persisted into the upper Pleistocene of these continents.

Stegodon, which occurred during the Pliocene in Asia and during the Pleistocene in Africa and Asia, evolved from *Stegolophodon.* The skull enlarged, the jaws shortened, and the lower tusks disappeared. *Stegodon zhaolongensis* of China was a large species with the most primitive teeth in the genus. The tusks of some species such as *Stegodon magnidens* of India were about 3.3 metres (10.8 feet) in length; in others, however, they were feeble. The molars were usually low crowned, and the depression between each pair of dental folds or plates was Y-shaped, rather than V-shaped or U-shaped as in other elephants.

The genus *Mammuthus* includes all species formerly placed under *Archidiskodon, Metarchidiskodon, Parelephas,* and *Stegoloxodon.* Its species occurred in the Pleistocene of Asia, Europe, America, and Africa. Several species had great bulk and heavy tusk development.

Development of pygmy forms

On various occasions during the Pleistocene Epoch, normal-sized elephants that inhabited a continent were isolated when a part of the landmass was separated into islands by the submergence of low-lying land. As these isolated colonies of elephants multiplied, their fodder supply decreased, and the animals gradually became smaller—an unsuccessful measure against extinction. This process is evident in the East Indies and Philippines, in the islands of the Mediterranean Sea, and in certain islands off the coast of southern California.

Classification. *Distinguishing taxonomic features.* The proboscideans are classified largely according to body size; shape of the skull; dentition; and the shape, size, and degree of reduction of enamel in the tusks. Groups marked with a dagger (†) are extinct and known only from fossils.

Annotated classification.

ORDER PROBOSCIDEA

Oligocene to present; North America, Eurasia, and Africa. Heavy-bodied (graviportal) animals with snout prolonged into a fleshy proboscis (trunk). Tusks developed from upper or lower incisors or both; canines absent; cheek teeth with transverse rows of blunt cones or ridges. Skull short, high; nasal openings at a higher horizontal plane than eyes. Body size medium to large; shoulder height from about 1 m (about 3 ft) to more than 4 m (13 ft). About 300 species, all extinct but two.

†Suborder Deinotherioidea

†Family Deirtotheriidae

Lower Miocene to upper Pleistocene; Europe, Asia, Africa. Upper tusks lacking; lower tusks curving downward from tip of lower jaw. One genus *(Deinotherium);* many species; height to about 3 m.

†Suborder Mastodontoidea

†Family Gomphotheriidae

Lower Oligocene to Recent (AD 200–400); Europe, Asia, North and South America. Skull and neck elongated. Teeth low-crowned; succession vertical. Later genera with protruding, shovellike lower incisors, others with substantial upper tusks and no lowers; premolars with 2 transverse crests, molars with 3. About 15 genera, several dozen species; shoulder height about 1 to 3 m.

†Family Mastodontidae (mastodons)

Lower Miocene to upper Pleistocene (possibly to early historic times); Europe, Asia, Africa, North America. Molars with rounded prominences, but no ridges; lower tusks absent, but upper incisors substantial, reaching over 2 m in length in males of some species. One genus *(Mastodon),* many species; shoulder height to at least 3 m.

Suborder Elephantoidea

Family Elepharztidae (elephants and mammoths)

Lower Miocene to present; fossils from Europe, Asia, East Indies, Africa, and North America; Recent species from Africa *(Loxodonta)* and southern Asia *(Elephas)* which have probably evolved from *Stegolophodon.* Six genera, with several dozen fossil and 2 Recent species; shoulder height from 1 to about 3.5 m. The epiphyses (ends of long bones in limbs) do not fuse until the last molars appear. The molars are replaced at least three times. Marrow disappears from the limb bones early in adulthood.

Procedural Law

Law, to be effective, must go beyond the determination of the rights and obligations of individuals and collective bodies to an indication of how these rights and obligations can be enforced. It must do this, moreover, in a systematic and formal way. Otherwise, the numerous disputes that arise in a complex society cannot be handled efficiently, fairly, without favouritism, and, equally important for the maintenance of social peace, without the appearance of favouritism. This systematic and formal way is procedural law. Procedural law, then, constitutes the sum total of legal rules designed to insure the enforcement of rights by means of the courts, and thus contrasts with substantive law, the sum total of the rules determining the essence of the rights and obligations.

Since procedural law is only a means for enforcing substantive rules, there are different kinds of procedural law, corresponding to the various kinds of substantive law. Criminal law, for example, is the branch of substantive law dealing with punishment for offenses against the public and has as its corollary criminal procedure, which indicates how the sanctions of criminal law must be applied. In many countries there is an administrative procedure for the enforcement of various rights, obligations, and interests regulated by administrative law. Substantive private law, which deals with the relations between private (that is, nongovernmental) persons, whether individuals or corporate bodies, has as its corollary the rules of civil procedure, and it is civil procedure to which this article is limited. In many countries, private law itself is subdivided into two branches, civil law, the law dealing with nonbusiness relationships, and commercial law, dealing with business relationships. Each often has its own set of courts. In such countries, it is, then, possible to subdivide civil procedure in general into two branches, civil procedure in the strict sense and commercial procedure.

Private law, as opposed to criminal or administrative law, does not usually require the parties to choose the courts to resolve their disputes. They may, in fact, and frequently do submit the disputes to one or more private individuals for resolution. A private individual chosen to resolve a dispute in a binding (rather than merely advisory) fashion is usually referred to as an arbitrator, and the procedure under which he acts, as arbitration. At present, arbitration also is ordinarily clothed with some form of governmental sanction; indeed, in some countries, in particular in England, arbitration and ordinary civil procedure may be quite closely connected.

Since each system of substantive law in the world must obviously be accompanied by a system of procedural law, the different systems of civil procedure existing in the world are too numerous to be discussed within the framework of one article or, indeed, an entire volume. This article deals comparatively with some of those systems of civil procedure that have had more than local or temporary significance. Procedure under U.S. Federal Rules of Civil Procedure, which is a good example of a modern Anglo-American procedure, and those of the French and Austrian codes of civil procedure, which represent different European views of civil procedure, receive the main emphasis.

Historical growth of procedural law

ROMAN LAW

Civil procedure in ancient Rome had a marked influence on later development on the European continent and, to some extent, in England. The procedure of very early Roman law left little permanent impact on the law. Highly formalized, it was based on strict compliance with rules of pleadings and was replaced during the 1st century BC by the more flexible formulary procedure that in some respects bears marked similarity to Anglo-American civil procedure. Law suits were divided into two phases. In the first phase, devoted to defining the issues, the parties presented their claims and defenses orally to a judicial official called a praetor, whose main function was to hear the allegations of the parties and then to frame a formula or instruction applicable to the issue presented by the parties. The praetor did not decide the merits of the case. Instead, with the consent of the parties, he selected from a list of approved individuals a private individual (judex), whose duty it was to hear witnesses, examine the proof, and render a decision in accordance with the applicable law contained in the formula. There was no appeal. The procedure facilitated growth and change in the law: by adapting existing formulas, or modifying them, the praetors were, in effect, able to change substantive rules of law.

The formulary system

The formulary system with its separation of fact finding and determination of the law was not followed in the provinces conquered by the Romans. There, administrative officials rendered justice under general administrative powers. In the late imperial period, the procedure used in the provinces was also introduced in Rome itself. The creative role of the praetor came to an end, the formulas were abolished, and the division of a lawsuit into two phases was also terminated. Lawsuits were now initiated by a written pleading. Appeals from lower to higher judges became possible, and the procedure lent itself to delay. As a result, parties often submitted their disputes to arbitration or to religious leaders for settlement. Consequently, the leaders of various religious communities, including in particular those of the Christian Church, came to exercise judicial functions that in the very late Roman Empire received a degree of state recognition.

MEDIEVAL EUROPE

The Germanic tribes that conquered the Roman Empire in the 5th century carried their own procedure with them into the conquered territories. That procedure was quite formalistic: in court, which often was the assembly of all the freeborn men of the district, the parties had to formulate their allegations in precise, traditional language; the use of improper words could mean the loss of the case. At this point the court determined what method of proof should be used: ordeal, judicial combat between the parties or their champions, or wager of law (whereby each side had to attempt to obtain more persons who were willing to swear on their oaths as to the uprightness of the party they were supporting). Roman law procedure, however, never entirely disappeared from the territories conquered by the Germanic tribes. In addition, a modified form of late Roman procedure was in use in the ecclesiastical courts that applied the still-developing canon law. This late Roman and canonical procedure appears to have been preferable to the Germanic procedure and gradually supplanted it in Italy and France, and somewhat later in Germany, though all elements of the Germanic procedure did not disappear. In Scandinavia, on the other hand, indigenous procedure was able to resist displacement by foreign law.

The Roman-canonical procedure, with its heavy reliance on written, rather than oral, presentations, necessitated representation by learned counsel. The whole procedure was divided into rigid stages. Precise rules governed the presentation of evidence; thus the concordant testimony of two male witnesses usually amounted to "full proof," and one witness was ordinarily insufficient to prove any matter, unless he was a high ecclesiastic. A court order was needed before testimonial evidence could be used; witnesses were ordinarily examined not before the full court but by a judge, with a court clerk or notary committing the witnesses' testimony to writing for later submission to the court. This complex procedure was ill-suited to the day-to-day needs of commerce; as a result, special courts operated by and for businessmen sprang up in important mercantile centres (maritime courts, commercial courts) to deal with matters of inland and maritime commerce.

Early codifications

As the Middle Ages ended, there was an increasing tendency to favour written over oral evidence. At the same time, there was a tendency to "nationalize" the general Roman-canonical procedure prevalent in much of Europe and to create national procedural laws. In 1667 in France, this led to the enactment by Louis XIV of the Ordonnance Civile, also known as Code Louis, a comprehensive code regulating civil procedure in all of France in a uniform manner. The Code Louis continued, with some improvements, many of the basic principles of procedure that had prevailed since the late Middle Ages.

COMMON LAW IN ENGLAND

Originally, procedure in English local and feudal courts resembled quite closely that of other countries with a Germanic legal tradition. But unlike the countries on the continent of Europe, England never romanized its indigenous procedure once the latter had become inadequate but instead developed a procedure of its own capable of substantial growth and adjustment. That England was able to do this seems to have been due to two reiated factors, both the result of the strong monarchy that followed the Norman invasion: the growth of the jury system and the establishment of a centralized royal court system. The former offered a substitute for the antiquated methods of proof of the traditional Germanic law—-ordeal, trial by battle, and wager of law—and the latter led to the creation of a definite legal tradition, the common law, and to the administration of justice through permanent professional judges, and their attendant clerks, instead of the popular assemblies or groups of wise men who rendered justice elsewhere (see also JURY; COMMON LAW).

Development of the writ

Royal courts could be used only if permitted by a special royal writing, or writ, issued in the name of the king. Such writs were at first issued when there was a complaint that local or feudal courts were not rendering justice. Later, they were issued in cases involving land; such a writ might direct the defendant to return the land or explain why he refused to do so or, later on, direct the sheriff to bring the defendant before the court so that he might answer for his conduct. Eventually the writs became standardized. Through ingenious fictions (assumptions, for judicial purposes, of facts that do not exist), substantially all litigation not reserved to the ecclesiastical or other specialized courts could be brought before the royal courts, a situation preferred by suitors, since the royal courts abandoned much of the awkward Germanic law of proof in favour of trial by jury sooner than did local courts.

As the system of royal courts developed, the parties, or rather their counsel, formulated the issues to be settled through their "pleadings" before the court in London; after that the issues would be tried before a jury in the county where the facts arose. The mechanics of pleading gradually became quite complex. Originally, Germanic pleading practices, which involved oral formulation of issues in rather precise words, prevailed. Eventually, the clerks of the court wrote a summary of these oral pleadings and later recorded the entire substance. The plaintiff had to plead facts that came within the writ used to start the action; the defendant could either generally deny the facts asserted by plaintiff or assert specific defenses.

The complexities of the common-law procedure led some parties to request relief directly from the king, who in medieval theory was considered as the ultimate fountainhead of justice. These requests were transferred to the royal chancery—that is, the office of the lord chancellor—which, in this way, developed into another court; it was supposed to deal "equitably" with cases in which the strict rules of the common law failed. In the course of time this function of the chancery developed into a body of well-defined rules known as "equity." Until the 16th century, the chancellors were generally ecclesiastics; hence procedure in chancery to obtain equity was to some extent influenced by canonical procedures. In particular, there was no jury trial, no writ circumscribing a precise cause of action, and so forth.

Movement toward reform

The procedure of the common-law courts and the existence of a separate procedure for equity matters were both taken over in the United States. In the 19th century there developed in both England and the United States movements to simplify procedural complexities. These involved several related approaches: (1) a reform in court organization, doing away with separate courts of equity and, to the extent they existed, with coordinated common-law courts of general jurisdiction and establishing a more rational system of appeals courts; (2) a reform of pleading, abandoning largely the need to plead a specific cause of action based on writs, and giving judges power to promulgate rules of procedure.

The reforms were not entirely successful; early court decisions interpreted the revised pleading rules in a restrictive fashion, and the merger of common-law and equity courts did not result in a complete merger of procedures. U.S. federal and state constitutions, for example, guaranteed a jury trial in all cases at common law, but not in equity.

PERIOD OF NATIONAL CODIFICATIONS IN EUROPE

Dissatisfaction with the system of judicial administration was a major cause of the French Revolution of 1789. One of the earliest actions taken by the newly constituted National Assembly was the creation of a new court system (1790). But no reform of a lasting nature was undertaken in the field of civil procedure. The introduction of a jury system was debated but was adopted for criminal cases only.

Napoleon attempted to restore normality and unity to France after the Revolution through the creation of codes encompassing an entire field of law and containing the best of both the old pre-Revolutionary and the Revolutionary law. His Code of Civil Procedure of 1806, however, relied heavily on the 1667 code but continued certain procedures created during the Revolution.

During the 19th century, codifications of procedural law were enacted in other countries (Italy in 1865 and Germany in 1877). They usually retained large elements of the Roman-canonical or French procedure and were often cumbersome and slow. Austria departed from the Roman-canonical model in 1895 with the adoption of a new Code of Civil Procedure. The new code adopted comprehensively the principle of oral presentation: only matters presented orally in open court were important for a decision of the case; writings could have only a preparatory role; witnesses were no longer heard before a delegated judge who prepared a written record but by the court or judge that actually decided the case; finally, the parties were obligated to present their cases fully and truthfully, and the judge was directed to make certain that all relevant facts were stated. These notions were widely followed by other countries when they amended their codes of civil procedure. Recent changes made in the French Code of Civil Procedure (particularly in 1958 and 1965) were to some extent inspired by the Austrian model. A somewhat contrary trend occurred in Italy, however, where later amendments to the more progressive 1942 Code of Civil Procedure to some extent reemphasized written presentations. A step contrary to some modern European thinking was also taken by the new Belgian Judicial Code of 1967 (effective 1969). It reduces the role of the judge and correspondingly increases that of the parties and their counsel. Even more atypical have been developments in Japan. That country adopted a Code of Civil Procedure, very largely modelled on the German Code of 1877, in the year 1890. In 1926, the code was amended in order to expedite procedures. Austrian ideas about the role of the judge were heavily relied on. But after the defeat of Japan at the end of World War II, an attempt was made to introduce some of the features of the American civil trial, with its heavy reliance on the presentation of facts by the parties' attorneys and the correspondingly less significant role of the judge. For a variety of reasons, the attempt was not entirely successful. Present Japanese law blends a procedure largely based on the German model with some features of Anglo-American origin.

Elements of procedure

CONSIDERATIONS PRIOR TO TRIAL OR MAIN HEARING

Jurisdiction, competence, and venue. The words jurisdiction and competence refer generally to the power of an official body (legislative, judicial, or administrative) to deal with a specific matter. This article is concerned with judicial jurisdiction, the power of a court to act. That power may depend on the relationship of the court to the subject matter of the action; in such an instance one speaks generally of subject matter jurisdiction. The jurisdiction of a court may also depend on the relationship between the court and the defendant in the action. As to that relationship, important conceptual differences exist between the countries of the common-law orbit, which usually refer to this problem as the question of "jurisdiction over the defendant" and countries with a continental European tradition, which are likely to subdivide the problem into questions of "international jurisdiction" (*i.e.*, which country may take the case) and questions of "territorial jurisdiction" (*i.e.*, courts in which part of the country may take the case). In the United States, questions of jurisdiction are complicated by the due process clause of the Constitution, which imposes limits on the states' power to confer jurisdiction on their courts. It has been suggested that the word jurisdiction should be used only when discussing the power of the courts in a state generally to act in a given situation without violating the due process clause, whereas the word competence should be used to refer to the power of a particular court in a state to act pursuant to the laws of that state, but this distinction has not been widely followed; frequently, the terms jurisdiction and competence are used interchangeably. (For a more detailed discussion, especially in relation to matters containing foreign elements, see CONFLICT OF LAWS.)

Venue

For reasons having to do with the historical tradition of the common-law courts—especially with the practice of the royal courts in London to send out judges to conduct trials throughout the country with the help of locally selected juries—in common-law countries the various higher courts existing in a given state are not ordinarily viewed as completely separate tribunals but essentially as parts of one overall court. Hence the question of "venue," which is usually not so problematical as lack of jurisdiction. The most common venue rule is that the action may be initiated where either the plaintiff or defendant resides, where the cause of action arose, or, if real property is involved, where the real property is situated. Even when all formal legal requirements of jurisdiction and venue are fulfilled, American courts are sometimes authorized to dismiss an action on the ground that the choice of court will create serious inconvenience for the parties or the court itself.

Parties. In spite of differences in terminology, rules prevailing in various legal systems concerning the parties to a case show some basic similarities. It is quite generally recognized that in order to participate in a law suit as a plaintiff or as a defendant, a party must have the capacity to sue and must, in addition, be a "proper" party (that is, have standing before the court).

All persons recognized as such by law, including corporations and even groups of individuals without formal corporate status, may, at least in the abstract, assert their rights in court and are liable to suit by others. In practice, however, the law obliges certain persons to act through another person. These persons, such as minors and mental incompetents, are usually said to lack procedural capacity, or to have it only to a limited extent, and must act through parents or guardians. Corporations can frequently sue in their own name, though some countries (such as Sweden) require that actions be brought by or against the board of directors or similar body.

All legal systems limit in some respects the number of individuals who may engage in lawsuits; generally, only persons who have an actual interest in the outcome of the lawsuit may sue or be sued. Furthermore, only a person who owns (or claims to own) the right or obligation under suit can be a party to a suit involving that right. In the United States this rule is frequently called the real party in interest rule, and similar rules are found elsewhere—for example, in Italy and France. Frequently the real party in interest will be the person who will ultimately benefit from any recovery obtained, but this is not true in all cases. In the United States, for instance, the trustee of a trust is deemed the real party in interest in connection with suits involving the trust, though any recovery obtained by him will ultimately benefit the beneficiaries of the trust. Because of the problems inherent in the real parties in interest rule, some modern codifications have omitted any reference to it.

In connection with matters of public law, the ability to sue is sometimes restricted less narrowly than in pure private-law actions. In France, for instance, citizens are able to bring actions in court to attack municipal expenditures (though not expenditures of the national government).

Class suits

Ordinarily, only parties to an action are bound by its outcome. But when a very large group may be affected by a particular controversy, it is frequently impractical for all menibers of the group to join in the litigation. For this reason, the law in the United States sometimes authorizes so-called class actions, in which a limited number of persons sue to vindicate the rights of a much larger class; in the end all members are bound by the outcome of the suit. Class actions are frequently, but by no means exclusively, used in actions involving shareholders of a corporation. Countries with a Roman-law tradition generally do not authorize class actions, though in some limited situations proceedings brought by one person may affect the rights of other persons not party to the suit.

Although a person is ordinarily free to decide for himself whether or not he wants to attempt to enforce his rights by legal proceedings, his refusal to do so may cause harm to others. For this reason, the laws of many countries authorize creditors, for instance, to prosecute actions of their debtors if the debtors fail to do so.

Legal controversies are not necessarily limited to two persons, one plaintiff and one defendant. Sometimes, for instance, in actions involving co-ownership or joint obligations, the rights of several parties may be so inextricably intertwined that, for all practical purposes, it is impossible to adjudicate the rights of one person standing alone. In such cases, the procedural rules of many countries require that all such persons be made parties to the lawsuit. In other cases, however, the presence of several individuals may be merely useful, but not absolutely essential, to a resolution of a dispute. In such cases the law simply "permits" the individuals to join in, or be brought into, the lawsuit. It is also possible that persons not originally participating in a lawsuit may find that their rights are affected in some manner, directly or indirectly, by such suit. To avoid a multiplicity of actions, such persons will often be authorized to intervene in the pending lawsuit, if their own claim has a sufficiently close connection in law or fact with it. In civil-law countries a person wishing to support the claim of some other party must proceed by way of direct intervention. In the United States, an individual who wants to promote the claim of some other party may ask the court for leave to appear as amicus curiae (friend of the court) so that he may present arguments in favour of the person he supports. In certain cases, furthermore, defendants are authorized to bring third parties into an action when, for instance, these third parties are or may be liable to the defendants on account of the claim asserted against the defendants. This is known as impleader.

Amicus curiae

In general, a person's capacity to sue or be sued is not affected by the fact that he is an alien or nonresident, unless a state of war exists between his home country and the country he wishes to sue. Even a state of war generally will not destroy capacity to be sued. But an alien may experience some disadvantages. Many countries, for example, withhold legal aid from aliens, particularly if the alien's home country does not grant reciprocity. More importantly, many European and Latin American countries require alien plaintiffs to post security to guarantee that they will be able to reimburse the defendant for the expenses of the lawsuit, and sometimes even for additional damage, should they lose the case. As a result of the 1954 Hague Convention on Civil Procedure and numerous other treaties, this security for costs has been eliminated between many countries. In the United States, the nationality of a party is not material to the issue of whether security for costs is due; any nonresident of the state where the action is brought is required to post security. The rule in most other countries with an English legal tradition is analogous.

Provisional remedies. Lawsuits frequently take a long time. A judgment in an action concerning whether or not the defendant has the right to cut down certain trees, for instance, will be of little value if, while the suit is pending, the trees have already been cut down; in like manner, a judgment for a sum of money will be quite useless if the defendant is able to conceal or squander his funds while the parties litigate. For these reasons, legal systems quite generally provide so-called provisional remedies that enable the plaintiff to obtain some guarantees that any judgment obtained against the defendant will not be in vain. There appears to be a rather remarkable similarity between remedies in common-law and civil-law countries, although the legal technicalities are often different. The provisional remedies are frequently available even before an action has been initiated; but in such a case, an action must ordinarily be started within a short period of time after the grant of the remedy.

Attachment

Some remedies serve to prevent the disappearance either of funds required for the payment of the eventual judgment or of specific property involved in litigation. This purpose is served by attachment (bringing the property under the custody of the law), replevin (an action to recover property taken unlawfully), or other similar remedies. Usually, the remedy is granted by a judge at the request of the plaintiff, upon a showing that certain facts exist that make it probable that the plaintiff has a good claim and that the payment of the judgment by defendant may be threatened. Attachment ordinarily involves the seizure of the property by an officer of the court, who will hold it pending final disposition of the case, or, occasionally, involves merely an order to the person holding the property not to dispose of it. Attachment is not necessarily limited to tangible property but can also be used in connection with all sorts of intangible property (such as money due, or bank accounts). These remedies are granted in a proceeding in which the defendant is not heard (*i.e.*, ex parte).

Other remedies are intended to stabilize a situation pending the outcome of litigation. In such instances, courts are frequently authorized to issue orders (known in Anglo-American law as temporary injunctions) commanding the parties to do or not to do certain acts that may cause irreparable harm to the other side while the suit is pending. In both civil-law and common-law countries, orders of this nature ordinarily are granted only after a hearing in which both sides appear. Sometimes a court order of an even more temporary and short-lived nature (temporary restraining order) may be obtained without hearing the other side.

In countries with a common-law tradition a person disobeying an injunction issued by a court is guilty of "contempt of court" and can be punished quite severely. In civil-law countries, punishment for contempt is largely unknown, and since broad orders to defendants may therefore be difficult to enforce, such orders are sometimes limited to specific narrow situations. The Supreme Court of the United States has recently cast some doubt on the propriety of granting ex parte remedies.

The commencement of the action. In Anglo-American procedure, finding the facts has traditionally been the function of the jury, which cannot conveniently be kept together except for a brief period of time; proof taking therefore has to be concentrated in one continuous episode, the trial. As a result, a lawsuit is generally divided into two stages, the first, or pleading, stage and the trial stage. At the pleading stage the parties notify each other of their claims and defenses; at the trial stage, they or their counsel prove their factual contentions before the jury primarily through the oral examination of witnesses produced by them. The verdict of the jury and the judgment based on it follow immediately thereafter.

A different general pattern is followed in countries whose procedure is based on the Roman-canonical procedure. Since there is no jury, there is no need for a concentrated trial, and the procedure consists essentially of a series of hearings at which counsel argue their clients' position and submit documentary evidence; any other form of evidence can be utilized only with a special court order definitely describing the type of evidence and the matter to be proved by it. Hearings with argument continue after the evidence has been taken.

The nature of the summons and the requirements of service. In most countries when a civil action is initiated, some form of notice to that effect must be served immediately upon the defendant. This notice may consist merely of a statement to the effect that the plaintiff is suing the defendant and that the defendant must appear in court on a specified day or be in default. Such a notice is commonly referred to as a summons, the successor to the old English "writ" initiating the action. When the notice of the lawsuit consists only of the summons, it is necessary, either at the same or a subsequent time, to supply the defendant with more specific information about the nature of the claim against him. This information is contained in plantiff's first pleading, the complaint.

In common-law countries it was originally necessary to deliver the summons to the defendant in person (personal service). Now, other forms of service to notify the defendant, such as leaving the summons with an agent, employee, or a person of suitable age at his home, are also permissible provided their intent is to apprise the defendant that the suit is pending. Service by publication in a newspaper is generally authorized only when no other form of service is reasonably possible.

Formal rules

In civil-law countries the summons proper is often combined with the statement of plaintiff's claim in a single document (*assignation* in France, *citazione* in Italy). Other detailed formal rules must often be observed, and the documents sometimes must be written on paper bearing tax stamps, a requirement still in force in Italy; in France copies must be presented to a tax office for "registration" for tax purposes. The document need not be served to the individual himself; a member of the household, or even a neighbour or janitor, usually will be an adequate recipient. In Austria and several other countries, service can be effected through the use of the mail.

Pleadings. Pleadings are the formal written documents by which the parties set forth their contentions. They serve several functions including giving notice of the nature of the claim or defense, stating the facts that each party believes to exist, narrowing the number of issues that ultimately must be decided, providing a means to determine whether the party has a valid claim or defense, and serving as a record of what has been actually decided once the suit is ended.

In the English common law the pleadings were primarily designed to state the legal theory relied upon and to narrow the issues to be tried. Accordingly, in common-law proceedings, the plaintiff and defendant alternately submitted documents, each responding to the one that preceded it, and narrowed the field of conflict until there remained only one issue, upon which the trial would be based. Because narrowing the issues was deemed of great importance, the parties were not allowed to plead alternative or contradictory states of fact and the defendant was permitted to rely on only one defense at one time.

In the United States during the 19th century, numerous procedural reforms were instituted. The parties were no longer required to plead on the basis of legal theories but instead were to allege a statement of facts constituting the cause of action or defense; the court could then apply any legal theory that was applicable under the facts alleged and later proved. The insistence upon fact pleading had substantial drawbacks, however, especially since the courts demanded a high degree of specificity, made technical distinctions between fact and evidence (forbidding the insertion of the latter in the pleading), and bound the parties to prove the facts alleged or lose the lawsuit. This last rule was particularly harsh since it forced the party to allege detailed facts early in the proceedings when he frequently was not yet certain precisely what facts had occurred.

Modern reforms have gone a long way toward elimination of the injustices of the former system. U.S. federal rules require only "a short and plain statement of the claim showing that the pleader is entitled to relief"; the defendant "shall state in short and plain terms his defenses." There is no requirement that legal theory be stated in the pleading nor that only facts be alleged. Other rules specifically permit the parties to plead alternative or contradictory claims or defenses and provide that in the usual case, only two pleadings, the complaint and the answer, shall be permitted. The effect of these changes has been to substantially downgrade the importance of the pleading stage of the lawsuit. The primary function of the pleadings is now only to give a general notice of the subject matter of the suit to the opposing party.

European pleadings

Under modem European codes, pleading problems, for a variety of reasons, have not been as pronounced as in Anglo-American law. The narrowing of issues is generally an essentially judicial function, to be achieved either at a special preliminary hearing or even at a plenary hearing before the full court; the creation of a permanent record is a function of the final judgment, which unlike the general—and therefore uninformative—verdict in an American jury trial must ordinarily contain a description of the facts and legal reasons on which it is based. Pleadings therefore serve primarily to inform the court and parties concerning their respective claims, a function of limited importance, since under some codes (such as the Austrian Code of Civil Procedure of 1895) only statements by the parties or their counsel in open court are fully effective for this purpose. In addition, amendments or changes can ordinarily be made without difficulty, though, in order to avoid dilatory tactics and surprise, some limitations exist. In France, for instance, it is not permissible to add new claims unless they are related to the existing claim, but new facts and legal arguments are permissible.

European pleadings tend to be more general than English and American, with fewer distinctions between ultimate facts, evidentiary facts, and matters of law. In some countries, such as France, it is usual to start the action by pleadings of the utmost generality, subject to further elaboration later.

Appearance. The summons or analogous document by which the plaintiff initiates his action quite generally commands the defendant to appear in court a specified number of days after its service. In case of failure to appear, he is threatened with a "default" judgment. In both the Anglo-American and the continental European systems the appearance in court is normally a legal fiction. The defendant "appears" by serving plaintiff with a notice indicating that he will defend the lawsuit and giving the name of the attorney or similar representative who will act for him in this connection. Certain other procedural steps indicating a willingness to defend the lawsuit are sometimes considered the equivalent of such a notice.

The time limits for the appearance vary greatly. European countries frequently provide a great many different time periods varying with the distance between defendant and the court where the action is pending. In France, for instance, a defendant residing in that country must appear within eight days, whereas one residing elsewhere in Europe has eight days and one month; these time periods can be shortened by judicial decision in case of urgency. In some countries the time to appear is fixed by the court. Less attention is usually paid to geography in the United States. In New York, for instance, the defendant must appear in 20 days if the summons was served personally, and 30 days if some other form of service was employed.

In some countries, where appearance involves either actual presence in courts, or at least the delivery of documents to the court (Italy, Sweden), plaintiff and defendant may both be required to appear.

The preparatory stage. As noted above, there is a fundamental difference between Anglo-American procedure and the civil-law procedure, with the Scandinavian countries taking a somewhat intermediate position. In countries whose procedure is based on English common law, the concentrated trial, traditionally before a jury, serves as a climax to earlier procedures. At this time, the parties attempt to prove the facts at issue, primarily through the presentation of oral evidence. The climax of a European proceeding, however, is the hearing before the full bench of judges—a hearing that is essentially devoted to argument of counsel and the presentation of documentary evidence; any other type of evidence usually requires a specific court order for its utilization. In both legal systems there are procedures to prepare for the trial or hearing.

In Anglo-American procedure a preparatory phase can be devoted to numerous purposes. First, since a jury trial is required only when there are disputes as to matters of fact, the court may be asked to make a decision on those cases that can be decided purely on legal matters, without any regard to the facts in dispute. This will be true, for example, when the court lacks jurisdiction or when it is obvious that a dispute between the parties as to the facts is more apparent than real. In these cases the party concerned will address a motion to the court (either a motion to dismiss for lack of jurisdiction or a motion for summary judgment) that can be decided immediately by a judge sitting alone, without waiting for the availability of a trial date.

It should also be noted that there may be a pretrial hearing before a judge, at which the judge will attempt to narrow the issues in controversy and, if possible, try to settle the case, thus making the trial unnecessary.

If the suit has not come to an end as a result of such preliminaries, the parties must prepare for trial. At the trial, evidence is presented in an uninterrupted fashion, without any possibility for additional proof after its close; each side in the end must stand or fall on the testimony presented by it.

European preparatory phase

The European system is in some ways similar to the Anglo-American. Frequently, such questions as jurisdiction can be decided in the preliminary phase, without waiting for the full hearing. The preliminary phase may also serve to narrow issues and produce a settlement. But differences in basic structure in some of the European codes lead to variations in emphasis. The absence of a concentrated trial, for instance, makes it much less important for a party to have detailed knowledge of the facts known by the other side. Further, proof proceedings sometimes occur during the preliminary phases rather than at the main hearing; though in Austria the full court holds hearings devoted to all aspects of the case, without distinguishing between matters considered preliminary and those more pertinent to the main hearing.

Pretrial motions. Because court calendars for jury trials are often extremely crowded, especially in the larger cities, the parties involved in a case often will resort to pretrial motions if there is any remote possibility that such an action would lead to a resolution of the dispute without trial. The party making the motion summons his opponent to appear before a judge designated for that purpose and transmits at that time copies of the papers pertaining to the motion, such as sworn statements (affidavits) of persons having knowledge of the facts or memorandums concerning the applicable law; the other side may submit opposing papers. At the time the judge hears the motion, attorneys for both sides argue briefly concerning the matter in question; no witnesses are heard. In addition to cases in which there may be a lack of jurisdiction, it may also occur that the right asserted by the plaintiff does not exist and that he is not entitled by law to relief; in either case a motion for dismissal would be made.

Summary judgment

On a somewhat different plane stands the motion for summary judgment. Frequently it appears that the issues of fact raised in the pleadings do not really exist. In such a case, since the outcome would not be in any reasonable doubt, a trial would be a mere formality. To avoid the needless expense and delay of a trial, a motion for summary judgment can be made. (The rules relating to this motion are strict so as to abridge neither the right of every man to his day in court nor the constitutionally guaranteed right to a jury trial.) The sole function of the judge is to determine if, from all the available evidence, there exists a material issue of fact that is honestly disputed; he is not to determine what the true facts are. If he finds a material issue of fact to be in dispute, he must deny the motion and set the case down for a future trial. If he finds no such issue, he may grant a final and binding judgment.

In those civil-law countries that have a preparatory phase before a single judge and a final hearing before a three-judge bench, procedural defenses similar to pretrial motions are ordinarily raised before the single judge. Sometimes, however, in cases of lack of jurisdiction or lack of competence a hearing is held before the full court. Where the issue is one of territorial competence the result may be the transfer of the case to the proper court. General summary proceedings have lost considerable importance in France and have been abandoned completely in Italy, but in actions involving claims based on negotiable or other written instruments, for instance, special procedures have been developed that permit a judgment to be obtained with great dispatch, particularly if the defendant has no effective defense on the merits.

Discovery procedures. In general, English common law lacked procedural devices aimed at giving the parties and the court advance notice of the factual contentions of both sides prior to the trial of the action. Whatever information was obtained by a party about the opposing party's case was received from the pleadings. This absence of discovery devices was a reflection of a judicial philosophy that held that surprise was a proper tactical device and that withholding information from one's opponent until trial would prevent an unscrupulous adversary from fabricating evidence. Limited discovery devices were, however, available in the equity courts.

Reforms were instituted in the 19th and 20th centuries. A mid-19th-century New York code, for example, provided that each party could serve written questionnaires on its adversary, could compel the adversary to produce documents prior to the trial, and could, under some circumstances, take the oral deposition of any witness, whether or not a party to the action. Even with these changes, discovery proceedings were limited. In 1938 new U.S. federal rules expanded the discovery process further. It was hoped that more complete disclosure would result in a more thorough preparation and presentation of cases, encourage pretrial settlement by making each party cognizant of the true value of his claim, and expose, at an early stage in the proceedings, insubstantial claims that should not go to trial.

Thus, a party may seek discovery not only of information that would be admissible at trial but also any information that, though not admissible, might lead to the discovery of admissible testimony. Some limitations remain, however; materials prepared in anticipation of the pending litigation by or for a party, for instance, are not discoverable unless the party seeking discovery shows a substantial need for the information and an inability to obtain substantially equivalent information by alternative means. Most discovery devices may be utilized without prior court approval and the procedures take place in lawyers' offices; judicial intervention must ordinarily be sought only when there is a dispute concerning the permissible scope of discovery or when there is a need to impose sanctions for failure to obey a court order compelling discovery.

European procedures to secure information

With the exception of procedures to secure, in advance of lawsuit, evidence that is in danger of being lost (for instance, because a witness may die), there are few procedures in civil-law countries to enable a party to secure information to use later. There are several reasons for this. Sometimes it has been viewed improper to compel a party to disclose information that may help his adversary. The absence of a concentrated trial makes it less important to have all information available at once, even more so because appeals ordinarily involve a rehearing of the whole case. The greater role given the judge in some countries (such as Austria and Germany) in bringing out factual matters further reduces the need to obtain information in anticipation of the hearing.

Consequently, discovery of documents is usually possible only in very limited cases, although a party that actually intends to use a document has to make it available to the other side. In France, for instance, production of documents to the other side is possible in bankruptcy and related commercial matters, and it is required in commercial cases generally that books be produced for inspection by the court. Traditionally, discovery of documents has been unavailable in noncommercial cases; legislation in **1965** did authorize the judge to request the parties to produce any documents, but this is production before the court, not for a party's use as such.

Pretrial conference. The discovery process frequently makes the parties aware of significant issues not previously considered or may make it clear that an issue considered important before discovery is no longer so. In order to provide a means for reflecting these changes and also to assist in simplifying the issues to be tried, shortening the time for trial, and possibly eliminating the need for trial completely, the court may direct the parties to appear before it for a pretrial conference.

At the conference, no testimony of witnesses is heard, and no formal adversary proceeding takes place. The attorneys representing the litigants, with the assistance of the judge, try to reach agreement on amendments to the pleadings, the elimination of issues raised at an earlier stage that are no longer deemed pertinent, and the crystallization of the real, controversial issues that must be determined at the trial.

An indirect benefit of the pretrial conference is the possibility that a settlement of the case will be reached by the parties without the necessity of trial. Although some authorities feel that this should be a primary goal of the pretrial conference, the prevailing view is that "settlements must be a by-product rather than the object of pre-trial, the primary aim being to improve the quality of the expected trial rather than to avoid it." It should be noted, however, that a considerable number of lawsuits, and the vast majority of personal injury cases, are settled before a final verdict.

In civil-law countries, procedures somewhat analogous in purpose to pretrial conferences are fairly prevalent. Since such preliminary hearings are ordinarily held before a single judge, rather than a formal three-judge court, a considerable saving of judicial time may result. In **1965,** France, for instance, reformed its practice in this respect. There, each case is assigned to a special "prehearing" judge, who sets time limits for the exchange of pleadings, decides how many pleadings after the original summons and complaint shall be used and when they shall be submitted, and may penalize dilatory parties by delivering a default judgment or, if both sides are dilatory, by striking the case off the calendar. In addition, he may call in the parties' counsel for a conference and must make sure that all documents that the parties intend to use at the main hearing have been filed. He may also call in the parties themselves for a conference concerning a possible settlement. He must, in short, either settle the case or put it in shape for the formal hearing.

THE TRIAL AND THE MAIN HEARING

The climactic and decisive part of an Anglo-American civil action is the trial, in which the parties present their proof in a concentrated fashion. The climactic event in a lawsuit based on European codes is the hearing before the full court. The differences between these two procedures are so fundamental that discussion of the two will be essentially separate.

The jury system. The following discussion will deal with the jury in terms of specific aspects of trial procedure. For a more detailed presentation of the jury system, see **JURY.**

Many of the procedural rules governing trials in civil actions have been designed to reflect the basic premise that the function of the jury is to determine the facts of the case, whereas the function of the judge is to determine the applicable law and to oversee the parties' presentation of the facts to the court. The consequences of the presence of the jury have been so pervasive that even in cases tried by a judge without a jury, the procedural rules designed to accommodate jury trials remain largely intact, with the important exception, of course, that the judge will determine both the facts and the law.

The order of trial. Although some variations may exist, a trial is conducted most frequently in the following manner. The attorneys for plaintiff and the defendant make opening statements to the jury, outlining what each conceives to be the nature of the case and what each hopes to prove as the trial proceeds. Next, the attorney for the plaintiff presents his case by calling witnesses, questioning them, and permitting them to be cross-examined by the attorney for the defense; when the former has concluded his presentation, the latter frequently will ask for a dismissal of the suit for failure of plaintiff to establish a prima facie case (that is, a case sufficient until contradicted by evidence); if this is unsuccessful, he will call and examine witnesses in order to establish his defenses, and these witnesses are subject to cross-examination by the plaintiff's attorney. The attorneys for each side then make a closing argument to the jury, marshalling the evidence presented in a light most favourable to their respective clients; the judge will instruct the jury on the applicable law; and the jury will retire to deliberate in private until it reaches a verdict, which will then be announced in open court.

The rules of evidence. Although the parties, and not the judge, are charged with the primary obligation to call and question the witnesses, the judge must act as arbiter in all disputes between the parties concerning the admissibility of evidence. When one party objects to the introduction of testimony, the judge will decide whether or not, in accordance with established rules of admissibility, the evidence sought to be introduced is to he heard by the jury. In general, the rules of evidence are designed to screen from the jury evidence that is either deemed not reliable or, if reliable, considered to be capable of confusing the jury in some way. As a consequence, evidence based on hearsay and, to some extent, opinion is prohibited. In keeping with the adversary system, the judge is not entitled to rule that evidence is inadmissible unless a party objects to its introduction. The party objecting to the evidence must state the grounds for his objection and the judge must permit the jury to hear the evidence unless the specified grounds given by the attorney are applicable. Even within this narrow framework, the judge's role is limited, for the rules of evidence leave little room for discretion on the part of the judge.

Directed verdicts. When the party having the burden of proof of an issue has completed its presentation to the jury, the opposing side may ask the court to rule as a matter of law that the evidence presented does not provide sufficient proof for a reasonable jury to find for the party who presented the evidence. When a judge so finds, he may "direct a verdict," thus in effect withholding from the jury the right to rule independently on the issues at all. It has been held that this device, if properly applied, is not a violation of the constitutional right to jury trial because similar devices have historically been available to judges and because a verdict is directed only when there has not been sufficient evidence introduced to create a material issue of disputed fact for the jury to decide. The granting of a directed verdict results in a final judgment, and the termination of the trial.

Instructions to the jury. It is the obligation of the judge, at the conclusion of the trial, to instruct the jury as to the applicable law governing the case in order to guide it in arriving at a just verdict. Although this is solely the judge's obligation, in practice the parties will propose instructions for his consideration. The judge then selects among the proposals that have been submitted and offers the parties the opportunity, out of the hearing of the jury, to object to any proposed instruction that they deem to be incorrect. Failure at this time to object generally precludes a party from arguing later that the instructions given were incorrect.

There has been much debate as to the relevance of jury instructions generally, some commentators urging that the jury seldom understands the instructions given or often ignores them. The charge, however, that the judge gave improper instructions to the jury is one of the most frequent grounds of error offered by parties when appealing an adverse decision.

Comments on evidence

In addition to the judge's obligation to charge the jury on the law, U.S. federal rules and some other procedural codes permit the judge to comment on the evidence. When it is permitted, the judge may give his opinion with regard to the merits of the case so long as he makes clear to the jury that this opinion is not binding and that the jury, not he, is solely responsible for finding the truth as to the facts in dispute.

Types of verdict. Most frequently the jury will be requested to return a general verdict—that is, a decision merely stating in general terms the ultimate conclusion that it has reached (for example, the award of X dollars to plaintiff). This form of verdict gives considerable leeway to the jury and permits, if it does not encourage, some deviation from a strictly logical and technical application of the law to the facts. An alternative that offers greater control over the decision-making process is the special verdict whereby the jury is instructed merely to answer a series of specific factual questions proposed by the judge, who will then himself determine the verdict, based upon the jury's responses to the questions asked. Because of the difficulty in drawing up questions that would cover completely the issues of the case, the special verdict is cumbersome and not frequently used.

New trial and other relief. After the trial is completed, either party may request the trial judge to vacate the verdict and grant a new trial. Innumerable grounds are available for requesting a new trial, including, for example, judicial error, excessiveness of the verdict, and jury misconduct. Considerable discretion is given the judge, and a decision to grant a new trial will seldom be overturned on appeal. The grant of a new trial, unlike the directed verdict, does not result in the judge substituting his opinion for that of the jury but only mandates another jury to hear the case at another trial. But in the very limited cases in which a judge may grant a directed verdict, he can also substitute his decision for that of the jury by a judgment not on the verdict.

The main hearing. In civil-law countries the hearing before the full court is the essential part of a civil action. At that hearing, counsel for both sides present argument as to the law and the facts of the case and submit documentary evidence. The hearing serves several purposes: it informs the court of the contentions of the parties, both legal and factual; it narrows the issues that may have been raised by the original pleadings; and it leads to the submission of at least one type of evidence, namely, documentary evidence. The extent of proof presentation and the narrowing of issues vary from country to country.

In such countries as Italy and France, which divide the lawsuit into a preparatory and a final stage, the judge in charge of the preparatory proceedings attempts to narrow the issues and may, for this purpose, examine the parties. In countries where there is only one stage, this process takes place during the full hearing. In general, in civil-law countries, evidence other than documentary evidence may be introduced only pursuant to a specific court order specifying the matter on which such evidence is to be received and the form that such evidence is to take (witness, experts, etc.). But again two forms are possible. Under the Austrian code of civil procedure, the court that decides the case must hear the witness, expert, or whatever. In such a case, an order will be made at the hearing and will be implemented by the calling of the witness or expert. Subsequently the arguments of counsel may continue, interrupted perhaps by a new proof order, should the court feel this to be necessary. In France and Italy the court or the judge of the prehearing phase will make an order for the hearing of a witness or expert, but the witness or expert will be heard by a single judge not ordinarily part of the court, who will prepare a summary of the testimony. Latei on, that summary will be submitted to the court; there will be additional argument and finally a decision will be made based on the record so made. Because witnesses or experts are always acting pursuant to court order, they are never considered a party's witness.

Types of proof proceedings. Various types of proof proceedings are generally available, including (1) hearing of witnesses who are not themselves parties; (2) the expert's report; (3) the examination of parties, either informally or pursuant to formal interrogatories.

A party wishing a witness to be heard must make an appropriate request, informing the other side of the name of the witness and the subject on which the witness is to be heard; this is to enable the party to prepare its own side of the case. At the examination the judge will ask the witness to state in narrative form what he knows about the precise issue mentioned in the proof order; subsequently, the judge may ask additional, clarifying questions. If counsel for both sides wish to propose questions, they must ordinarily put them to the judge, who presents them to the witness. A more or less extensive summary of the testimony is prepared immediately by a clerk under the direction of the judge and signed by the witness, the judge, and the clerk. In the case of witnesses who live too far away from the court where the action is pending, interrogation sometimes takes place in a local court.

The examination of an expert is obtained in the same manner as that of a witness. Although the parties may suggest an expert to the court, those chosen are ordinarily taken from a list of experts approved by the court. The expert is considered an impartial auxiliary of the court; his use is ordinarily limited to cases involving some technical or scientific problem. The court or judge issuing the proof order may authorize him to make certain scientific investigations (*e.g.,* in an automobile accident case, to examine the car involved) and to report thereon.

Parties not considered witnesses

Parties are not considered witnesses, and different procedures for parties ordinarily exist. **A** court is usually authorized informally to question parties, ordinarily not under oath, either on the court's own motion or on the request of a party. Though this questioning is designed mainly to narrow issues, it does also have a function in terms of evidence. In Austria and some other countries the judge questioning a party may put the party under oath if he feels this to be necessary for an elucidation of the truth. In other countries, a party may be challenged by his adversary to make a statement under oath.

Rules of evidence. In European courts, rules as to the admission of evidence are ordinarily quite liberal since there has been no need to develop complex rules to keep certain evidence from a jury. It is generally required that evidence relate directly to the facts in issue and be neither superfluous nor unduly repetitious. But since judicial review of lower court decisions on the admission of evidence is frequently quite limited, these requirements have never been developed into the detailed rules existing in Anglo-American law.

There are, however, some rules restricting testimonial evidence. In the first place, certain groups of persons, including parties and frequently close relatives of parties, may not be witnesses. Furthermore, confidential information acquired by certain professions (clergymen, doctors, lawyers, public officials, and others) may not ordinarily be divulged. In addition, there are rules requiring written proof in certain cases, such as birth, marriage, death, and some legal transactions.

Hearsay

The hearsay rule and its numerous exceptions are quite unknown in countries whose procedure is based on the European codes. That an individual may have only indirect knowledge of an event will not usually prevent his testimony as to the event, although it will affect the weight given it; at times, however, courts will refuse to hear testimony of a witness whose connection with the events in issue is utterly remote. The absence of a hearsay rule makes it possible to utilize many forms of documentary evidence not available in Anglo-American countries, such as written, unsworn statements of witnesses who do not later testify, written opinions of experts, and so on, though the courts do not necessarily give much credence to such items.

All modern European codes reject the Roman-canonical principle according to which a predetermined weight must be given to the various kinds of evidence; instead the court gives each item of evidence whatever weight seems reasonable under the circumstances of the individual case. There are some exceptions to this, however. Countries with a Latin tradition frequently accord great weight to public and notarial documents.

In general, it can be said that because the free evaluation of evidence is normally possible and because the production of evidence is so largely under judicial control, questions of burden of proof are much less important in countries governed by European procedural codes than in the Anglo-American system.

It is sometimes said that civil procedure in continental European countries is inquisitory in nature and that the strongly accusatory features of Anglo-American civil procedure have not found favour there. European courts often have an affirmative duty to clarify the issue and are frequently authorized to call witnesses or experts on their own motion, though the extent to which they make use of this power may vary. But the basic impetus for the lawsuit always comes from the parties. There are thus inquisitorial elements, but no true inquisitorial procedure.

Judgment and execution. *Drafting and form of judgment.* When proceedings are terminated, the court that has considered the case will render a judgment. In such a case one speaks of a final judgment. Judgments deciding some procedural matter but not terminating the proceedings are known as interlocutory judgments.

In American practice, the judgment of a court after a jury trial is presented in a stylized document that merely recites certain data relating to the lawsuit, such as the names of the parties, the fact that a jury verdict has been rendered, and the disposition to be made. No detailed grounds are given for the decision. If a judge decides a case without a jury, he is often required to indicate the factual and legal bases for his decision in order to facilitate appellate review; in practice, such findings, too, are often of a rather stylized nature. Courts sitting without juries sometimes prepare, in addition, an opinion in which their reasoning is explained in narrative form.

Judgments in civil-law countries quite generally consist of not only statements indicating the names of the parties and the like and the decision of the court but also an opinion in which the court explains its decision. The opinion may vary in style. In Germany and Austria, it is narrative in nature, as in the United States; in France, it is traditionally cast in the form of one long sentence consisting of a syllogism using the facts and the applicable law as premises. When the court consists of several judges, it is frequent practice in Anglo-American countries for judges who disagree with the decision of the majority to prepare and file dissenting opinions, in which they explain the reasons for their disagreements. In civil-law countries, such dissenting opinions are rarely allowed; indeed, the courts are generally forbidden from disclosing the position taken by an individual member.

Filing of judgment

Quite generally, originals of judgments are filed in court clerks' offices; the parties may then procure copies to use as they see fit. In some countries, the rules for the formal preparation, signing, and filing of judgments tend to be quite technical and complex; this is much less so in the United States. Furthermore, judgments must frequently be written on stamped paper or presented to some tax office for the payment of a tax.

The effect of judgments: res judicata; collateral estoppel. Judgments generally have a continuing effect on parties and others long after they are rendered. In some situations the doctrine of res judicata will grant a binding effect on issues determined in the lawsuit. The doctrine is intended to avoid excessive litigation and is known in some form in most countries. Thus, it is uniformly held in the United States that when a valid and final personal judgment in an action for the recovery of money is rendered in favour of the plaintiff, the plaintiff or his legal successors are prevented from instituting an action against the defendant on the *same* cause. In effect, what was considered in the first action, or even that which should have been considered but was not, cannot form the basis of a second action. This does not preclude a second lawsuit based on a *different* cause of action or claim, but the related doctrine of "collateral estoppel" will preclude the parties from relitigating in the second suit based on a different cause of action any issue of fact common to both suits that was actually litigated and necessarily determined in the first suit.

The doctrine of collateral estoppel traditionally had been limited to the parties to the past action. For instance, A, as the driver of B's truck, is involved in an accident with a car driven by C. If A sues C and recovers a judgment because of the negligence of C, the traditional rule has been that in a subsequent suit filed by B against C for damage to the truck, C is not precluded from claiming that he was not negligent since B was not a party to the first suit and would not be bound by the decision in it. Many courts now, however, are holding that even though the same parties are not involved, when the issues are the same and when the defendant has presented a complete and full defense in the first trial, collateral estoppel will now bind him to the finding in the first suit that he was negligent in the occurrence.

Res judicata in civil-law countries

The principle of res judicata is followed in civil-law countries as well, but there are differences. Substantively, res judicata applies generally only in new proceedings between the same parties (or their heirs or successors in interest), and the new proceedings must involve the same type of action (the same bases for the action and the same demand for relief). There is, however, no collateral estoppel, though a judgment that is no longer subject to any form of review (appeal, etc.) is binding as to all procedural rulings. In effect, res judicata becomes procedurally operative only after all normal means of review have been exhausted or the time limit to use them has lapsed.

Enforcement of judgment. All countries have procedures intended to overcome the resistance of a party who fails to comply with the judgment of a court. This is usually known as the enforcement or execution of a judgment. Rules vary greatly, and they are usually highly technical and thus can only be dealt with generally. In the

United States a party who obtains a judgment for a sum of money is entitled normally to avail himself at once of the procedural devices designed to enforce the judgment. The fact that the period for appeal has not yet passed or that an appeal is filed does not, of itself, affect the right to enforce the judgment; the losing party, seeking to postpone enforcement of the judgment pending appeal, must request such relief either from the trial court or the court to which the appeal is taken. Frequently, such a request will be granted if the losing party posts a bond or other security to ensure that the delay in enforcement will not adversely affect the rights of the winning party should the appellate court affirm the judgment of the trial court.

When the judgment results in an order to the losing party to do or refrain from doing some act, the court has the power to enforce the judgment by punishing a party who fails to comply, by a fine or a jail sentence, on the grounds that his disobedience constitutes "contempt of court."

When the judgment results in an award of money damages, the usual procedures for enforcement are the "levy of execution" on property belonging to the defendant or an execution against his income. All property that is not exempt by a specific statute, as well as income earned and debts owed by third persons, are subject to this enforcement process. Exemptions generally are given for such necessities as wearing apparel, tools and implements used in earning a living, and household furniture, and such personal items as wedding rings, family Bibles, and family photographs. The attorney for the party in whose favour the judgment has been rendered or the clerk of the court in which the judgment was obtained issues a command to the sheriff to seize the property, Once the sheriff has taken possession of the property he sells it at public auction and, after deducting his fees, turns over to the judgment creditor only those proceeds of the sale necessary to satisfy the judgment; any excess is returned to the defendant.

Garnishment of wages

The remedy of garnishing the earnings of the defendant, although generally permitted, is accompanied by certain safeguards to prevent oppression. Thus, only if the debtor fails to make payments voluntarily, can his wages be seized, and even then only a limited percentage of the wages.

Rules for the enforcement of judgments in civil-law countries are in some respects similar to those in the United States or other common-law countries, although some differences do exist. Frequently, judgments cannot be enforced by execution or in some other way until all appeals have been heard or until the time for such appeals has run out, but the precise rules differ greatly from country to country and often depend on the subject matter of the action or the court to which an appeal is taken. In Germany, for instance, it is sometimes possible to receive an execution on a judgment still subject to appeal, but the money recovered on execution must be paid into the court clerk's office pending determination of the appeal.

In all countries there are detailed rules exempting certain types of property from seizure, but continental European rules are much less generous toward the debtor than corresponding rules in the United States. In France, for instance, all wages exceeding the equivalent of about $3,000 per year may be seized, whereas in New York no more than 10 percent of wages may ever be taken. If several judgments, which threaten to exceed a debtor's available assets, exist against him, other procedures are available to insure that these assets will be distributed fairly. To some extent, such procedures replace bankruptcy, which in some European countries is available only to businessmen and not to private debtors.

Problems arise in connection with judgments ordering a party to do or not to do a certain act, since contempt procedures, outside of mild fines or jail sentences available to secure the maintenance of order in the courtroom, are generally unknown in Europe. For this reason, Italian judgments will order the performance of a specified act only when, in the case of disobedience by the party, the act can be performed by a substitute appointed by the court. For instance, if the defendant is ordered to tear down a wall and refuses to do so, the court may appoint a contractor to perform this operation. French courts have not limited themselves so narrowly and have developed a kind of civil penalty in order to compel compliance with their judgments.

Costs and disbursements. Generally, the prevailing party recovers not only the amount of the judgment but also the costs and expenses of the suit. These include filing fees, government taxes, witness fees, and the like. but not funds spent in the preparation of the case. In countries like Austria and Germany that regulate the fees of attorneys by an official schedule, such fees are ordinarily recoverable. In countries where such fees are not regulated by schedule, they usually must be borne by the party that has incurred them. In countries such as England or France, where a party is often represented by an agent for litigation (a solicitor, or *avoué*) and a separate attorney to handle oral argument and trial (a barrister, or *avocat*), the fees of the former, but not of the latter, are reimbursable in most situations.

APPEALS AND OTHER METHODS OF REVIEW

A judgment of a court of first instance may be attacked either by appeal to a higher court or by a request for some form of review of the judgment by the court that rendered it. Thus, it is quite generally possible for a defendant who has defaulted to ask a court to reopen the case and hear it on its merits. As noted above, in Anglo-American courts, it is frequently possible to ask for a new trial. In some cases (if, for example, there is newly discovered evidence) procedures analogous to motions for a new trial exist in European countries. In certain countries and in some states of the United States, an appeal of a judgment that is not a final decision can be made in addition to appeals of final decisions.

The appeal process is somewhat different in civil-law and common-law countries. In Europe the appeal from the court of first instance to the intermediate appellate court ordinarily involves a reexamination of the entire case, both the law and the facts, and new evidence frequently can be introduced. An appeal to the supreme or highest court is restricted to matters of law, and the facts found by the lower court are not re-examined. In the Anglo-American system, on the other hand, both the intermediate appellate court and the supreme court examine only the written record created in the court below and do not receive new evidence. Furthermore, review is generally restricted to matters of law, though the scope of review is broader in the intermediate appellate court than the supreme court. Rules of appeal in all systems tend to combine the desire that justice be done and error be corrected with the desire to find some point at which the proceedings will end and judgment will be deemed final.

Common-law appellate procedure. A fundamental principle underlying the function of appellate courts in the United States is the concept that the court serves only to review allegations that errors of law were committed at the trial. In no sense can the appeal be considered a retrial of the entire case. Factual determinations made at a jury trial are not reviewable on appeal except when presented in the context of a legal question. Factual determinations made by a judge in cases tried without a jury are reviewable on appeal, but even in such cases, appellate courts are reluctant to set aside such determinations unless clearly erroneous.

The party appealing the judgment must specify the errors that allegedly occurred at the trial; generally, the appellate court will consider only those points advanced by the appealing party. Moreover, the court will, with few exceptions, refuse to consider an allegation of error, unless the issue had been raised during the initial trial.

Because appellate courts do not hear witnesses or permit the introduction of new evidence on appeal, it is necessary that the record of the trial be made available and include a transcript of the proceedings, original papers, and exhibits. Both parties are required to submit written "briefs" to the court containing legal precedents and the arguments in support of their contentions that error did or did not occur, and each party has an opportunity to present oral legal arguments supporting his position.

Most jurisdictions provide a second appellate court to which a party may appeal from an adverse decision of the first appellate court. The right to such a second appeal is usually limited to certain types of cases raising particularly important issues, and only a small percentage of litigants pursue a second appeal. In the U.S. Supreme Court, a petition to authorize an appeal in certain cases involving the public interest, when it is not available as a matter of right, is known as a petition for a writ of certiorari.

Civil-law appellate procedure. Appeals to intermediate appellate courts from courts of first instance are available quite broadly in Europe, frequently for all judgments exceeding a certain amount (*e.g.*, 2,500 francs, or about $460 U.S., in France) and at times for certain types of judgments, regardless of amount. Since the appeal involves a new hearing of the case, the procedure is essentially similar to that in use in courts of first instance. In the case of a review of a nonfinal judgment, the appellate court frequently limits its review to an examination of the legal correctness of that judgment and then remands the case, so that proceedings in the court below may be completed. Occasionally, appellate courts are authorized to use the occasion of an appeal of a nonfinal judgment in order to decide the entire case themselves. Though an appeal involves a rehearing of the entire case and though parties are, generally speaking, entitled to introduce new evidence, the appeal may not be used to bring forth entirely new claims. The broad availability of a new hearing on appeal encourages appeals to intermediate appellate courts and explains their frequently very heavy case load.

By way of contrast, appeals to the supreme courts of the various countries are generally limited to questions of law. The facts are not ordinarily re-examined, and no new evidence may be introduced. The procedure involves essentially the presentation of written or oral argument by counsel for both sides on the alleged substantive or procedural errors made by the lower court. In several countries, such as France and Italy, the partisan argument by the parties is augmented by independent argument by an officer of the Ministry of Justice representing the law as such. The Court either affirms or reverses the judgment submitted to it for review. If it reverses, it does not, generally, substitute its own judgment for the erroneous judgment below but merely annuls the erroneous judgment and remands the case for new proceedings, frequently to a court different from that from which the case came. Review by supreme courts can usually be sought for all final (and sometimes even nonfinal) decisions of intermediate appellate courts, and frequently also of decisions of courts of first instance if no appeal to an intermediate appellate court is possible. No special permission of the court analogous to the grant of certiorari is ordinarily required. Consequently, case loads are extremely heavy, and to handle them the full court does not usually sit together but instead is divided into panels. In important matters two or more panels may sit together. The court to which the case is remanded is not bound by the view of the law expressed by the appellate court.

Procellariiformes

The Procellariiformes are a distinct natural order of oceanic birds with about 87 living and 36 fossil species. Of diverse size and range, they are divided into four families: albatrosses, sheanvaters, storm petrels, and diving petrels. All are recognizable by their conspicuous tubular nostrils, which project upon the culmen (upper bill), giving the order its alternative name, Tubinares, "tube nosed." The feet are webbed, and the hind toe is vestigial or missing. All species have a characteristic powerful musky odour caused by the excretion of stomach oil; the oil can be used as a defensive discharge through the mouth when the bird is alarmed.

GENERAL FEATURES

Importance to man. The tube-nosed birds have been of considerable local economic importance as a source of protein food, feathers, and oil wherever man has colonized or has been able to raid the coastal and oceanic islands where they breed; this has resulted in the partial or complete extermination locally of certain species. Man has also been responsible for the introduction of predators, such as rats, pigs, and cats. In regions where bird populations have survived, man has continued to harvest the eggs, the plump young birds (at fledging time), or both. Many thousands of slender-billed, or short-tailed, shearwaters (*Puffinus tenuirostris)* are taken on the Bass Strait islands off Tasmania and sold fresh, salted, or deep-frozen as "muttonbirds." The name muttonbird was most likely derived from the use of the flesh as a supplement for mutton by the early settlers of New South Wales. The numbers of muttonbirds now harvested are regulated so as to preserve a substantial breeding stock.

"Mutton-birds"

In New Zealand the Maori people have harvested young *titi* (sheanvaters of several species) from time immemorial, a right assured them in perpetuity by treaty with Queen Victoria. On the other side of the world, hundreds of Manx shearwaters (*Puffinus puffinus*) were formerly collected for food and as lobster bait on the Welsh islands of Skomer and Skokholm, which are now nature preserves estimated to contain about 200,000 Manx sheanvaters and 2,000 storm petrels *(Hydrobates pelagicus)*. On the Tristan da Cunha Islands in the South Atlantic, resident islanders harvest the eggs and squab (young) of a large, mixed seabird population, which includes more than 6,000,000 greater sheanvaters (*Puffinus gravis*).

The harvesting of northern fulmar petrels (*Fulmarus glacialis*) is an ancient practice among peoples of the cool northern coasts where the birds breed. In Iceland about 50,000 fulmars were taken annually between 1897 and 1925; the occurrence in 1939 of psittacosis (a virulent avian disease) among processors of the birds resulted in prohibition of the use of fulmars for food.

During the early 17th-century colonization of Bermuda, millions of cahows, or Bermuda petrels (Pterodroma *cahow*), were exterminated by the colonists. For nearly 300 years the species was believed extinct, but in 1951 a few pairs were discovered nesting on an offshore islet, where a remnant survives under strict protection. The related black-capped petrel, or diablotin (P. hasitata), of the West Indies was also thought extinct (due to predation by man, rats, and mongooses) until in 1961 a substantial population, estimated to number at least 4,000 birds, was found breeding in the inaccessible forested crags of Hispaniola.

In the 18th and 19th centuries, huge numbers of albatrosses were taken for food (largely by whalers) and for the millinery trade. With the disappearance of sailing vessels, changes in fashions, and the establishment of many nesting grounds as sanctuaries, such predation has virtually disappeared, but albatrosses have not entirely escaped stress at the hands of man. On Sand Island in the Midway Atoll, Laysan albatrosses (Diomedea *immutabilis)* increased from a few pairs in 1900 to about 60,000 pairs in the early 1960s, the increase resulting from shelter provided by introduced vegetation. The use of the island by aircraft after 1935, air raids by the Japanese during World War II, and the loss of 30,000 birds humanely killed by the U.S. Navy (in a control program designed to reduce collisions between birds and aircraft) did not deter the albatrosses from this favoured nesting area. The control program was abandoned after the discovery that levelling certain sand dunes effected a 70 percent reduction in collisions by removing the updrafts near aircraft runways.

Distribution. The majority of procellariiforms breed in the Southern Hemisphere, but several species migrate thousands of miles north across the Equator to winter in the northern summer seas, where they molt, feed, and rest in preparation for the return home in the southern spring. Similarly, species that breed in the Northern Hemisphere also live in perpetual summer by migrating far south to winter in the southern summer. A number are less migratory and do not cross the Equator. Several species are almost sedentary, chiefly smaller petrels breeding in tropical and subtropical latitudes, and the sub-Antarctic prions (Pachyptila) and diving petrels. All latitudes of the unfrozen oceans are thus occupied, but there are fewer living in the calm equatorial region where there is little wind to lift their long wings and where the pelagic (open-ocean) crustacean food on which so many seabirds basically depend is scarce. The zone of upwelling water in the windy latitudes of the Antarctic covergence, between 40" and 60" south latitude, is richest in the shrimplike krill (Euphausia species), attracting surface-feeding tubinares and the diving penguins, prions, and diving petrels. Some feed along the edge of the ice of the Antarctic continent, and four tubinares actually breed on its shores: the Antarctic fulmar, the giant petrel, the snowy petrel, and the tiny but very numerous Wilson's petrel; the nesting burrows of the last may be blocked by snow for days during the protracted breeding season. The only tubinare nesting near the ice limits in the high Arctic is the fulmar, which reaches Franz Josef Land, Greenland, and the Arctic Circle north of the Aleutian Islands.

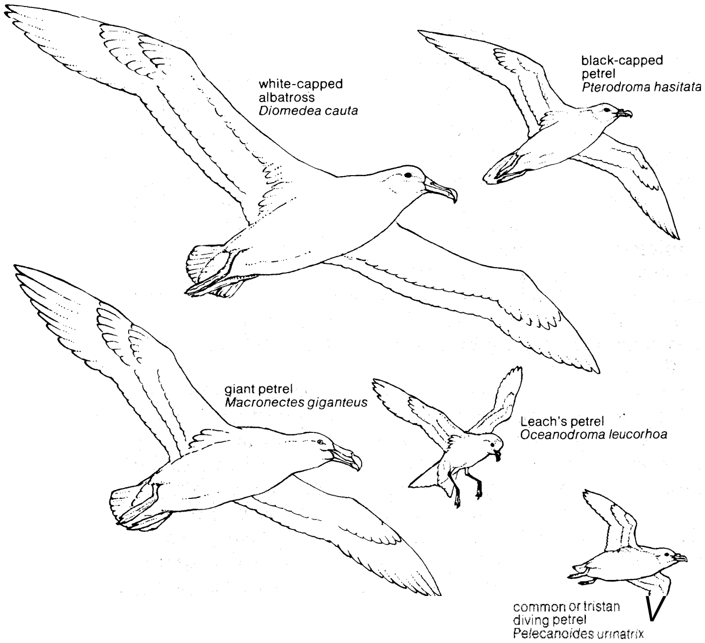

Figure 1: Representative procellartiform birds in flight.

Of the albatrosses (family Diomedeidae), only the two Midway species and the short-tailed albatross (Diomedea *albatrus)* nest well north of the equatorial doldrums. The latter was brought close to extinction by plume hunters and by a volcanic eruption at its nesting island of Torishima. There were enough immature birds at sea at the time to allow a partial recovery, and some 60 individuals were counted there in 1969. Nine albatross species range the Southern Hemisphere, gliding on the eternal winds of the "Roaring Forties" (the region between 40° and 50° latitude) and moving north with the food-rich cold currents along the west coasts of South America, South Africa, Australia, and New Zealand. One species, the waved albatross (Diomedea irrorata), is unique in that it breeds only in the Galápagos Archipelago at the Equator, where probably not more than 3,000 pairs nest on Hood Island.

The family Procellariidae includes the larger petrels, such as the northern and southern fulmars (*Fulmarus* glacialis and F. glacialoides), the gadfly petrels (*Pterodroma)*, several genera of shearwaters, and the prions or whalebirds. Several of the shearwaters and larger petrels breed in burrows far inland on mountain crags in the Andes, West Indies, Madeira, and New Zealand. The largest member of this family is the giant, or stinker, petrel (Macronectes giganteus), an albatross-like scavenger and circumpolar wanderer with a heavy beak and wing span of eight feet. Smallest are the prions, four species of small, stocky, little-studied birds, 22 to 30 centimetres (nine to 12 inches) long, with broad bills and a restricted cold-water range; they breed on sub-Antarctic islands, keeping much to the water, as do the diving petrels.

The storm-petrel family, Hydrobatidae, ranges both hemispheres but is strongest numerically in the Pacific, where Halocyptena microsoma, the least petrel of Baja California, rivals the Atlantic storm petrel as the smallest procellariiform. The word petrel ("little Peter") derives from a habit of the storm petrels of walking on the waves.

The diving petrels form a family (Pelecanoididae) and genus (Pelecanoides) with four species. They are small, rather sedentary, coast-dwelling birds confined to cool southern islands, including Tristan da Cunha, the Falklands, New Zealand, and southeastern Australia. The common diving petrel (P. urinatrix) is circumpolar; the largest species, the Peruvian (P. garnotii), has followed the Humboldt current along the west coast of South America and breeds from Chile to Peru; the Magellanic (P. *magellani*) is confined to the tip of South America; the Georgian (P. georgicus) breeds on South Georgia, Macquarie, and Auckland islands. Diving petrels are specialized birds with short, black-and-white bodies and closely resemble externally and in habits the small auks (family Alcidae, order Charadriiformes) of the Northem Hemisphere.

NATURAL HISTORY

Locomotion. All tube-nosed birds have a protracted life cycle conditioned by their evolution and oceanic environment. Because they spend most of their lives at sea, they are clumsy on land, laboriously using their wings as props to assist locomotion; their legs are too far to the rear to effect a well-balanced bipedal progress. The smaller species nest in burrows and rock crevices and are nocturnal, being helpless and unable to manoeuvre quickly on land when attacked by predators. As a rule, the incubating bird is tame and does not associate the approach of man with danger but will often allow him to stroke and fondle it. Albatrosses are especially docile, hence the name mollymawk (mallemuck), from the Dutch *mollemok* ("stupid gull").

Flight pattern of albatrosses

The long-winged tubinares require a smooth runway for takeoff on a calm day; over rough ground they will utilize the bill to hook along, and either climb a rock or tree to gain a launching height or flop over the edge of the nearest cliff. On the wing, they are perfect aviators, riding out the severest storms of their normally windy oceanic feeding grounds with ease and grace. The great albatrosses can overtake and circle a fast ship at sea, with long glides rarely interrupted by wingbeats. The ability of albatrosses to move upwind without flapping depends on the fact that wind velocity is appreciably lower near the waves than a few metres in the air. The flight pattern is a series of broad ellipses (Figure 2), characteristically including (1) a fast downwind glide beginning at the greater elevation, at which the wind velocity is higher, giving the bird considerable momentum with a small loss of altitude. As it reaches maximum speed, the bird turns crosswind (2), briefly skimming the waves, then moves upwind (3) on a long, level glide through the lower velocity air, maintaining altitude, but losing speed. As soon as its air speed reaches a critical low, the bird climbs steeply cross-wind (4) to complete the ellipse, now at the same altitude as at the start of the previous downwind leg but having gained in position upwind. It then glides downwind again to gather fresh momentum. The same flight pattern may be used, of course, to travel crosswind or downwind. The normal air speed of the royal and wandering albatrosses (*Diomedea* epornophora and *D. exulans),* whose wing spans reach about 3.4 metres (11 feet), is 80 to 110 kilometres (50 to 70 miles) per hour. Although the flight appears effortless, some energy is expended in the muscular action that keeps the long, narrow wings fully extended.

Figure 2: Flight pattern of the albatross.

The medium-sized tubinares (shearwaters and procellariid petrels) have a flight pattern similar to that of albatrosses, but their shorter wings are flapped regularly between the briefer gliding periods. The little storm petrels have an altogether more erratic darting, fluttering, and sometimes hovering flight, their feet hanging down to walk on the water surface.

Feeding habits. Shearwaters, storm petrels, and diving petrels feed by taking small fish and crustaceans close to the surface; they make short dives as necessary. Many of the larger procellariids consume substantial amounts of squid. Albatrosses, giant petrels, and fulmars dive little; they are surface feeders, often settling on the water. At night they devour squid that rise to the surface; during the day they take schooling fish; garbage from ships; wounded, exhausted, or dead birds; and carrion, including the flesh of dead whales and other cetaceans. The giant petrel is probably the only tubinare agile enough on land to kill other birds; at its nesting grounds it will attack young penguins inadequately guarded by their parents.

Reproduction and growth. As a general rule, the mature adults return to the established breeding site many weeks before the single white egg is laid. There is often severe competition for nesting territories in large crowded colonies on small islands. Returning each year to the same nest site, the male and female remain faithful to it and thus to each other for life. It is believed that some albatross pairs also remain together at sea in the nonbreeding season, but many of the burrowing shearwaters and petrels, meeting on land only at night, may never see their mates clearly when ashore (recognition being by voice, touch, and possibly smell) and probably do not deliberately consort in pairs at sea.

The greeting ceremony

At each fresh encounter ashore between breeding birds, there is an elaborate greeting ceremony; the birds clash and fence with the bills, cackling and screaming. These antics occur in both the nocturnal procellariids and the diurnal albatrosses, and in the latter there is also a bowing and dancing display. Such behaviour provides time for mate recognition and relieves and displaces any natural aggression or fear.

The nest type varies somewhat among species. Albatrosses scrape a shallow depression or build a mound of soil and vegetation; the fulmars and other diurnal procellariid petrels nest on ledges or on level ground; most shearwaters, diving petrels, and some storm petrels dig burrows in soft soil; other storm petrels utilize natural crevices.

Once the nest site has been adopted, one member of the pair usually remains on guard against usurpation by other home-hunting birds. The male may remain on guard for several days and nights, while the female feeds at sea to meet the requirements of the developing egg. In some species, the female may depart on a recuperative feeding cruise within a few hours after laying if her mate is there to take over incubation. Mated birds do not feed each other but incubate in spells of several days each, the bird at home fasting and losing weight while the bird at sea is feasting and fattening.

The egg is incubated for a long period, about 80 days in the wandering albatross, 52 days in the Manx shearwater, 40 days in the smallest petrels (the last about equal to the incubation period of the ostrich). For the first week or so after hatching, the helpless, downy chick requires the warmth of the parental body for survival. During this period it is brooded and fed tenderly on an oily broth of semidigested marine organisms pumped from the adult esophagus, which is muscularly constricted to control the flow to the infant's needs. Instinctively, the chick seeks the open, warm, fishy-smelling mouth of the parent, thrusting and groping blindly with its tiny bill crosswise in the open maw of the adult.

The down grows rapidly; a second down sprouts (to which the first remains attached), and the baby is soon homeothermic—*i.e.*, able to keep itself warm while its parents forage far at sea and return with increasingly large crop loads of food. Some of the fishing trips of the parents are real voyages, involving absences of several days; the Manx shearwater may travel nearly 1,000 kilometres (more than 600 miles) from Wales to the

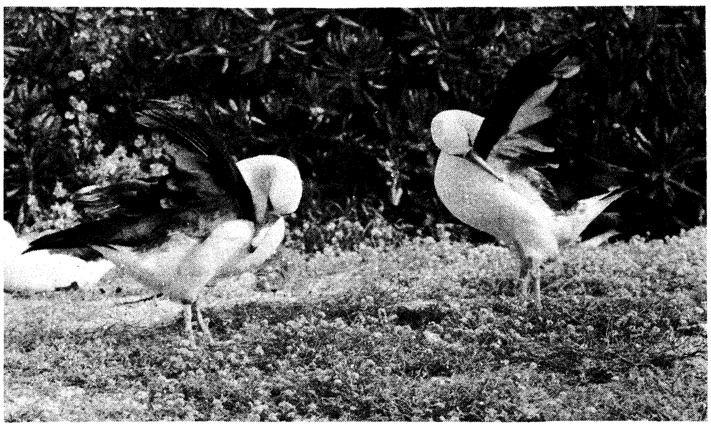

Figure 3: A pair of Laysan albatrosses (*Diomeda immutabilis*) in ritualized preening display, a part of the courtship that precedes nest building.

Period of fledgling starvation

Bay of Biscay and back to load up with its favourite food, sardines. Albatrosses may leave their well-developed nestling for a week or two. If both parents happen to return at the same time, the nestling may ingest food equal to its own weight in one meal. It becomes very fat in the later stages of the long fledgling period, which is not less than two months in the small petrels and reaches nine months in the largest albatrosses. Before it leaves the nest, the chick is deserted by the parents, who retire to molt at sea. This begins a starvation period which may last a week in the smallest petrels, twelve days in the medium-sized shearwaters, and considerably longer in the largest species, before the fledgling goes to sea. When deserted, it is well-feathered and fatter and heavier than the adult; it needs a period of thinning and exercise before it is capable of flight. After days of fasting and wing flapping, it may become airborne one windy night, especially if hatched in a burrow on a gale-swept mountain height from which it can flap and glide to the sea. Calm weather is its enemy; many island-born young tumble down to the sea, too heavy to take off again in still air. They are expert swimmers, however, and can dive deeply to avoid attacks by aerial predators.

Paddling rapidly away from the dangers of land and soon gaining flight, the young procellariiform sets off along the traditional migration route, alone and unguided by the long-departed adults. Driven by an innate impulse to keep flying, it reaches winter quarters that it has never seen before, often at a surprising speed. One Manx shearwater, banded in Wales as a fledgling, travelled 9,900 kilometres (6,200 miles) to southern Brazil in 16% days. Allowing half of each day for resting and feeding, this is equivalent to an average surface speed of 50 kilometres (30 miles) per hour over the period, a remarkable achievement for a bird just out of the nest.

The young albatross remains longest in the nest—so long in the case of the royal and wandering albatrosses that the nestling is overtaken by the Antarctic winter. It endures blizzards and savage winds that force it to grip the nesting mound tightly with its claws, yet it is warm enough under its oily plumage to survive fasting for many wintry days until a parent appears with food. Because of the protracted nesting period, these great albatrosses cannot rear more than one young every other year. To compensate for the slow rate of reproduction, albatrosses are long-lived; life expectancy, once breeding age is reached, appears to be several decades. Marking of Laysan albatrosses has shown that they do not breed successfully until seven years old. In order to maintain their numbers, the wandering and royal albatrosses, breeding for the first time even later, must have the highest average longevity among birds. The Manx and other medium-sized shearwaters lay the first egg when five years old, the least petrel in the third or fourth summer.

There is thus always a large proportion of each tubinare population that is nonbreeding. During its first year at sea, the young bird may not even approach the land. While the mature birds have completed their migration and settled to breed at home, the yearlings may lag far behind on the route, spending the summer at sea. In the next few years adolescents arrive at the breeding islands and shores too late to make more than a preliminary landing and exploration of the ground for a future partnership. At midsummer in the nesting colonies there is a considerable arrival of immature birds familiarizing themselves with prospective breeding territories. Where a colony is already overcrowded, it is always the young, eligible, but inexperienced, birds that leave to form new peripheral colonies in the region of their birthplace.

Ecology and conservation. The tubinares collectively occupy a position midway in the oceanic food chain. Their food is lower on the chain than that of animals which take subsurface fishes (*e.g.*, certain diving birds, seals, and medium-sized predatory fishes) but above that of the minute and larval fishes which feed on plankton. Insofar as man has overfished much of the oceans and removed or reduced competitors, such as the krill-feeding whales, and has taken fish species from the food chain, he might be said to have influenced the success and therefore the numbers of the tubinares, but there is no firm evidence for this. Although the numbers of some species are recorded as increasing, it is likely that the reason is stricter protection and reduction of exploitation at the nesting sites. It is generally accepted that the considerable increase of the fulmar in the North Atlantic and its spread south from the Arctic to new breeding grounds has resulted from the great development of fishing fleets, which fulmars follow in vast numbers to devour the fish offal thrown overboard.

Man's effect on the tubinare population

Only a few tubinares are rare and in danger of extinction. The majority are successful and often numerous. With their pelagic, aerial habits they are less liable to be trapped in oil slicks than are the Northern Hemisphere swimming seabirds (auks, ducks, and loons), which are killed by the thousands by oil. The diving petrels and prions, living in the cleaner Antarctic seas, are less exposed to this danger.

FORM AND FUNCTION

General features. The general body plan of procellariiform birds varies slightly from family to family. In general, they are long-winged, short-necked birds with short to moderate tails and legs. Webbing is present between the front toes, and the hindtoe (hallux) is small or lacking. In contrast to their strong-flying relatives, the diving petrels have short wings. At the other extreme, the aspect ratio (the ratio of wing span to the chord, or width) of the wing may exceed 14:1 in some albatrosses. This long, narrow wing, with a high-lift airfoil, is an extreme adaptation for fixed-wing gliding.

The bill varies from rather short and broad in diving petrels to medium in length (somewhat more than half the total length of the head) in some albatrosses. It is sheathed in horny plates and has a distinct hooked nail at the tip. In albatrosses the two nasal tubes lie separated on the right and left upper lateral surfaces of the bill; in all other procellariiforms, the nostrils are fused into a single tube lying on the dorsal midline of the bill and having a dividing wall or septum, which may end short of the end of the tube, resulting in a single opening.

Procellariiforms are totally lacking in bright plumage colours, being entirely black, white, or shades of brown or gray. Strikingly contrasting patterns of light and dark are often found, however, and the bills or feet of a few species are yellow or pink. A number of shearwaters and procellariid petrels and a few albatrosses are polymorphic; *i.e.*, they occur in light and dark phases (plumage types), some species also having intermediate forms. The polymorphism may be restricted to certain parts of

Drawing by R. Keane

the plumage, such as the underparts of the body or the upper surface of the wings.

Squirting oil as a defense mechanism

Stomach oil. Most tubinares, when handled or threatened, eject the oily contents of the stomach with some force. In some species, notably the cliff-nesting fulmars, this habit, a fear reaction that also serves to lighten the bird for flight, has been exploited as a defensive weapon. Facing an intruder, the disturbed bird ejects a spurt of evil-smelling fluid a metre or so in his direction, often with apparently planned accuracy. The habit is instinctive; a baby fulmar, on hatching, has been observed to squirt yellow oil before it is fully out of the shell. Later, the downy chick squirts oil at any visitor, even its parents. Mated fulmars may exchange little squirts of oil during the excitement of bill-fencing ceremonies.

Analysis of this unique oil shows that it is a waxy secretion of the proventriculus (the first chamber of the stomach), rich in vitamins A and D. In most birds, the walls of the proventriculus produce an acid fluid that rapidly breaks down raw food entering from the esophagus. In the tubinares, which feed their young a soup of predigested marine organisms, the proventriculus is much enlarged and internally folded, increasing the surface when dilated and enabling a larger number of glands to function. The latter are groups, or follicles, of oil-producing cells. The colour of the oil varies according to the type of food; it is often reddish from the presence of astacin, a pigment found in crustaceans.

The discharge of stomach oil is partly excretion of surplus fat, which might upset the bird's metabolism if retained in quantity. Ejected through the mouth and nose, it also disposes of excess vitamins and salt in the diet of marine food and seawater. Similar in character to the secretions of the oil glands of other birds, the crop oil may also assist in waterproofing the feathers as the tubinare preens its plumage with its oil-stained bill.

EVOLUTION AND CLASSIFICATION

Relationship to penguins

Evolution. The oldest tubinare fossil is a giant albatross *(Gigantornis)* from the Eocene of Nigeria (about 50,000,000 years ago). It may have had a wing span of six metres (20 feet) and was contemporary with the now extinct giant penguins (order Sphenisciformes). It is generally agreed that the two orders had a common ancestor from which they may have evolved. The penguins occupied the ecological niche of diving and feeding under the surface and became flightless; the tube noses specialized in flight and surface feeding. Support for a common origin (a view contested by some taxonomists) comes from the facts that the oldest fossil penguin had a bill with distinct tube-nosed apertures; the young of the blue penguin *Eudyptula,* considered to be the most primitive of penguins living today, exhibits tubelike openings to its nostrils. Mutual displays of bill fencing and wing movements in courtship, as well as the method of regurgitating digested food, are almost identical in tubinare and penguin. The short-winged diving petrels, which "fly" much underwater but little in air, seem to parallel an early stage in the evolution of penguins, especially when, during a few weeks of the annual molt, they lose their quills and must live in the water.

Classification. *Distinguishing taxonomic features.* The families of the Procellariiformes are separated mainly by the general body plan, the condition of the nostrils, and, in the case of the Procellariidae and Hydrobatidae (long considered one family), the osteology of the skull and sternum. At the genus level, characters used include the shape of the beak, wings, and tail; the degree of flattening of the tarsus (lower leg); size of the hallux; and the relative lengths of the leg bones.

Annotated classification. The following classification, proposed by American ornithologist Alexander Wetmore in 1930, is in nearly universal usage.

ORDER PROCELLARIIFORMES (tubinares)

Oceanic birds with tubular nostrils; bill covered with horny plates and hooked at the tip. Anterior toes webbed; hallux short or lacking. Wing with 11 primary feathers (the outer minute); secondaries short; diastataxic (*i.e.,* with the 5th secondary absent). Two coats of nestling down. Oil gland feathered. Strong musky smell. Single white egg; long incubation and nestling periods. About 87 living and 36 known fossil species; all marine; worldwide.

Family Diomedeidae (albatrosses)

Middle Eocene to present. Extremely long, narrow wings; short tail. Bill longer than remainder of head; nostrils semitubular, small, situated near the base of long groove. Two genera, 13 species; length 50–125 cm (20–50 in.); wing span to 340 cm (11 ft); North Pacific and all southern oceans.

Family Procellariidae
(large petrels, fulmars, prions, shearwaters)

Middle Oligocene to present. Long-winged, short-tailed. Nostrils united on top of bill. Twelve genera, about 50 species; length 22–75 cm (9–30 in.); all oceans, but greatest diversity in southern hemisphere.

Family Hydrobatidae (storm petrels)

Upper Miocene to present. Small black and brown birds, usually with conspicuous white rump; wings rounded; tail square or forked. Often walk on water. Eight genera, 20 species; length 15–20 cm (6–8 in.); all oceans, but more species breeding in Southern Hemisphere.

Family Pelecanoididae (diving petrels)

Upper Pleistocene to present. Small stocky birds, with short wings and tails. Black above; white below. One genus, four species; length 1620 cm (6%–8 in.); cool sub-Antarctic seas.

Critical appraisal. In a system of evolutionary relationships by structural affinities, the tube-nosed birds seem to fit conveniently between the penguins and the pelecaniform birds. But within the order, the arrangement of genera, species, and races of tubinares has been changed all too frequently by taxonomists. This disorder has resulted partly from new information on the structure, habits, and distribution of these birds, hitherto little studied because of their remote oceanic breeding grounds. The ordinal position occupied by the highly specialized prions and diving petrels is still in dispute. The fulmars are sometimes divided into three species because of their distinct differences in bill, body size and shape, and geographical range; but other taxonomists regard them as Arctic, Pacific, and Antarctic races of the species *Fulmarus glacialis.* Several authorities have recently placed several medium-sized shearwaters in one species *Puffinus puffinus,* with eight closely related forms or subspecies. Because there is no evidence of interbreeding between these populations, although they may mingle at sea on migration, and there are no intermediate forms even when they inhabit the same island (in which case, they nest at different times), other workers prefer to treat them as full species of *Puffinus.*

(R.M.L.)

Production, Theory of

In economics, the theory of production is an effort to explain the principles by which a business firm decides how much of each commodity that it sells (its "outputs" or "products") it will produce, and how much of each kind of labour, raw material, fixed capital good, etc., that it employs (its "inputs" or "factors of production") it will use. The theory involves some of the most fundamental principles of economics. These include the relationship between the prices of commodities and the prices (or wages or rents) of the productive factors used to produce them and also the relationships between the prices of commodities and productive factors, on the one hand, and the quantities of these commodities and productive factors that are produced or used, on the other.

Three kinds of business decisions

The various decisions a business enterprise makes about its productive activities can be classified into three layers of increasing complexity. The first layer includes decisions about methods of producing a given quantity of the output in a plant of given size and equipment. It involves the problem of what is called short-run cost minimization. The second layer, including the determination of the most profitable quantities of products to produce in any given plant, deals with what is called short-run profit maximization. The third layer, concerning the determination of the most profitable size and equipment of plant, relates to what is called long-run profit maximization.

The article covers the main principles involved in each of these problems in turn. For the sake of clarity, the essential principles will be considered within the context of a firm that produces only a single product or commodity, even though such firms in actuality are rare.

COSTS IN THE SHORT RUN

The relationship between input and output

The production function. However much of a commodity a business firm produces, it endeavours to produce it as cheaply as possible. Taking the quality of the product and the prices of the productive factors as given, which is the usual situation, the firm's task is to determine the cheapest combination of factors of production that can produce the desired output. This task is best understood in terms of what is called the production function; *i.e.*, an equation that expresses the relationship between the quantities of factors employed and the amount of product obtained. It states the amount of product that can be obtained from each and every combination of factors. This relationship can be written mathematically as $y = f(x_1, x_2, \ldots, x_n; k_1, k_2, \ldots, k_m)$. Here, y denotes the quantity of output. The firm is presumed to use n variable factors of production; that is, factors like hourly paid production workers and raw materials, the quantities of which can be increased or decreased. In the formula the quantity of the first variable factor is denoted by x_1 and so on. The firm is also presumed to use m fixed factors, or factors like fixed machinery, salaried staff, etc., the quantities of which cannot be varied readily or habitually. The available quantity of the first fixed factor is indicated in the formal by k_1 and so on. The entire formula expresses the amount of output that results when specified quantities of factors are employed. It must be noted that though the quantities of the factors determine the quantity of output, the reverse is not true, and as a general rule there will be many combinations of productive factors that could be used to produce the same output. Finding the cheapest of these is the problem of cost minimization.

The cost of production is simply the sum of the costs of all of the various factors. It can be written:

$$C = p_1x_1 + \ldots + p_nx_n + r_1k_1 + \ldots + r_nk_n,$$

in which p_1 denotes the price of a unit of the first variable factor, r_1 denotes the annual cost of owning and maintaining the first fixed factor, and so on. Here again one group of terms, the first, covers variable cost (roughly "direct costs" in accounting terminology), which can be changed readily; another group, the second, covers fixed cost (accountants' "overhead costs"), which includes items not easily varied. The discussion will deal first with variable cost.

The principles involved in selecting the cheapest combination of variable factors can be seen in terms of a simple example. If a firm manufactures gold necklace chains in such a way that there are only two variable factors: labour (specifically, goldsmith-hours) and gold wire; the production function for such a firm will be $y = f(x_1, x_2; k)$, in which the symbol k is included simply as a reminder that the number of chains producible by x_1 feet of gold wire and x_2 goldsmith-hours depends on the amount of machinery and other fixed capital available. Since there are only two variable factors, this production function can be portrayed graphically in a figure known as an isoquant diagram (Figure 1). In the graph, goldsmith-hours per month are plotted horizontally and the number of feet of gold wire used per month vertically. Each of the curved lines, called an isoquant, will then represent a certain number of necklace chains produced. The data displayed show that 100 goldsmith-hours plus 900 feet of gold wire can produce 200 necklace chains. But there are other combinations of variable inputs that could also produce 200 necklace chains per month. If the goldsmiths work more carefully and slowly, they can produce 200 chains from 850 feet of wire; but to produce so many chains more goldsmith-hours will be required, perhaps **130.** The isoquant labelled "200" shows all the combinations of the variable inputs that will just suffice to produce 200 chains. The other two isoquants shown are interpreted similarly. It is obvious that many more isoquants, in principle an infinite number, could also be drawn. This diagram is a graphic display of the relationships expressed in the production function.

Substitution of factors. The isoquants also illustrate an important economic phenomenon: that of factor substitution. This means that one variable factor can be substituted for others; as a general rule a more lavish use of one variable factor will permit an unchanged amount of output to be produced with fewer units of some or all of the others. In the example above, labour was literally as good as gold and could be substituted for it. If it were not for factor substitution there would be no room for further decision after y, the number of chains to be produced, had been established.

The shape of the isoquants shown, for which there is a good deal of empirical support, is very important. In moving along any one isoquant, the more of one factor that is employed, the less of the other will be needed to maintain the stated output; this is the graphic representation of factor substitutability. But there is a corollary: the more of one factor that is employed, the less it will be possible to reduce the use of the other by using more of the first. This is the property known as "diminishing marginal rates of substitution." The marginal rate of substitution of factor 1 for factor 2 is the number of units by

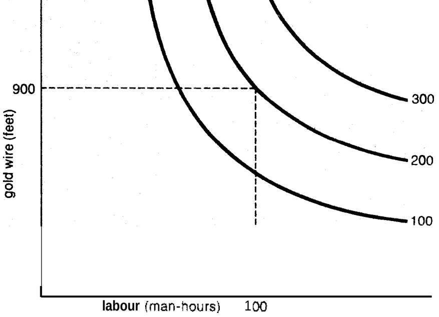

Figure 1: Isoquant diagram of hours of labour and feet of gold wire used per month.

which x_1 can be reduced per unit increase in x_2, output remaining unchanged. In the diagram, if feet of gold wire are indicated by x_1 and goldsmith hours by x_2, then the marginal rate of substitution is shown by the steepness (the negative of the slope) of the isoquant; and it will be seen that it diminishes steadily as x_2 increases because it becomes harder and harder to economize on the use of gold simply by taking more care. The remainder of the analysis rests heavily on the assumption that diminishing marginal rates of substitution are characteristic of the production process generally.

The cost data and the technological data can now be brought together. The variable cost of using x_1, x_2 units of the factors of production is written $p_1x_1 + p_2x_2$, and this information can be added to the isoquant diagram (Figure 2). The straight line labelled v_2, called the v_2-isocost line, shows all the combinations of input that can be purchased for a specified variable cost, v_2. The other two isocost lines shown are interpreted similarly. The general formula for an isocost line is $p_1x_1 + p_2x_2 = \mathrm{v}$, in which v is some particular variable cost. The slope of an isocost line is found by dividing p_2 by p_1 and depends only on the ratio of the prices of the two factors.

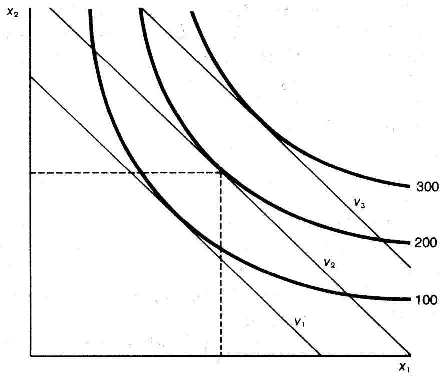

Figure 2: Isoquant diagram for two factors of production, x_1 and x_2 (see text).

The minimization of costs

Three isocost lines are shown, corresponding to variable costs amounting to v_1, v_2, and v_3. If 200 units are to be produced, expenditure of v_1 on variable factors will not suffice since the v_1-isocost line never reaches the isoquant for 200 units. An expenditure of v_3 is more than sufficient; and v_2 is the lowest variable cost for which 200 units can be produced. Thus v_2 is found to be the minimum variable cost of producing 200 units (as v_3 is of 300 units) and the coordinates of the point where the v_2 isocost line touches the 200-unit isoquant are the quantities of the two factors that will be used when 200 units are to be produced and the prices of the two factors are in the ratio p_2/p_1. It may be noted that the cheapest combination for the production of any quantity will be found at the point at which the relevant isoquant is tangent to an isocost line. Thus, since the slope of an isoquant is given by the marginal rate of substitution, any firm trying to produce as cheaply as possible will always purchase or hire factors in quantities such that the marginal rate of substitution will equal the ratio of their prices.

The isoquant-isocost diagram (or the corresponding solution by the alternative means of the calculus) solves the short-run cost minimization problem by determining the least-cost combination of variable factors that can produce a given output in a given plant. The variable cost incurred when the least-cost combination of inputs is used in conjunction with a given outfit of fixed equipment is called the variable cost of that quantity of output and denoted VC (y). The total cost incurred, variable plus fixed, is the short-run cost of that output, denoted $\mathrm{SRC}(y)$. Clearly $\mathrm{SRC}(y) = \mathrm{VC}(y) + \mathrm{R}(K)$, in which the second term symbolizes the sum of the annual costs of the fixed factors available.

Marginal *cost*. Two other concepts now become important. The average variable cost, written $\mathrm{AVC}(y)$, is the variable cost per unit of output. Algebraically, $\mathrm{AVC}(y) = \mathrm{VC}(y)/y$. The marginal variable cost, or simply marginal cost $[\mathrm{MC}(y)]$ is, roughly, the increase in variable cost incurred when output is increased by one unit; *i.e.*, $\mathrm{MC}(y) = \mathrm{VC}\ (y+1) - \mathrm{VC}(y)$. Though for theoretical purposes a more precise definition can be obtained by regarding $\mathrm{VC}(y)$ as a continuous function of output, this is not necessary in the present case.

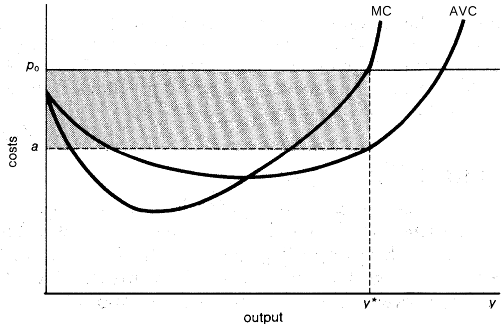

Figure 3: Average variable costs (AVC) and marginal variable costs (MC) in relation to output.

The usual behaviour of average and marginal variable costs in response to changes in the level of output from a given fixed plant is shown in Figure 3. In this figure costs (in dollars per unit) are measured vertically and output (in units per year) is shown horizontally. The figure is drawn for some particular fixed plant, and it can be seen that average costs are fairly high for very low levels of output relative to the size of the plant, largely because there is not enough work to keep a well-balanced work force fully occupied. People are either idle much of the time or shifting, expensively, from job to job. As output increases from a low level, average costs decline to a low plateau. But as the capacity of the plant is approached, the inefficiencies incident on plant congestion force average costs up quite rapidly. Overtime may be incurred, outmoded equipment and inexperienced hands may be called into use, there may not be time to take machinery off the line for routine maintenance; or minor breakdowns and delays may disrupt schedules seriously because of inadequate slack and reserves. Thus the AVC curve has the flat-bottomed U-shape shown. The MC curve, as might be expected, falls faster and rises more rapidly than the AVC curve.

OUTPUT IN THE SHORT RUN

The average and marginal cost curves just deduced are the keys to the solution of the second-level problem, the determination of the most profitable level of output to produce in a given plant. The only additional datum needed is the price of the product, say p_0.

How the firm maximizes its profit

The most profitable amount of output may be found by using these data. If the marginal cost of any given output (y) is less than the price, sales revenues will increase more than costs if output is increased by one unit (or even a few more); and profits will rise. Contrariwise, if the marginal cost is greater than the price, profits will be increased by cutting back output by at least one unit. It then follows that the output that maximizes profits is the one for which $\mathrm{MC}(y) = p_0$. This is the second basic finding: in response to any price the profit-maximizing firm will produce and offer the quantity for which the marginal cost equals that price.

Such a conclusion is shown in Figure 3. In response to the price, p_0, shown, the firm will offer the quantity y^* given by the value of y for which the ordinate of the MC curve equals the price. If a denotes the corresponding average variable cost, net revenue per unit will be equal to $p_0 - a$, and the total excess of revenues over variable costs will be $y^*(p_0 - a)$, which is represented graphically by the shaded rectangle in the figure.

Marginal cost and price. The conclusion that marginal cost tends to equal price is important in that it shows how the quantity of output produced by a firm is influenced by the market price. If the market price is lower than the lowest point on the average variable cost curve, the firm will "cut its losses" by not producing anything. At any higher market price, the firm will produce the quantity for which marginal cost equals that price. Thus the quantity that the firm will produce in response to any price can be found in Figure 3 by reading the marginal cost curve, and for this reason the marginal cost curve is said to be the short-run supply curve for the firm.

The short-run supply curve for a product—that is, the total amount that all the firms producing it will produce in response to any market price—follows immediately, and is seen to be the sum of the short-run supply curves (or marginal cost curves, except when the price is below the bottoms of the average variable cost curves for some firms) of all the firms in the industry. This curve is of fundamental importance for economic analysis, for together with the demand curve for the product it determines the market price of the commodity and the amount that will be produced and purchased.

One pitfall must, however, be ncted. In the demonstration of the supply curves for the firms, and hence of the industry, it was assumed that factor prices were fixed. Though this is fair enough for a single firm, the fact is that if all firms together attempt to increase their outputs in response to an increase in the price of the product, they are likely to bid up the prices of some or all of the factors of production that they use. In that event the product supply curve as calculated will overstate the increase in output that will be elicited by an increase in price. A more sophisticated type of supply curve, incorporating induced changes in factor prices, is therefore necessary. Such curves are discussed in the standard literature of this subject.

The returns to the factors of production

Marginal product. It is now possible to derive the relationship between product prices and factor prices, which is the basis of the theory of income distribution. To this end, the marginal product of a factor is defined as the amount that output would be increased if one more unit of the factor were employed. all other circumstances remaining the same. Algebraically, it may be expressed as the difference between the product of a given amount of the factor and the product when that factor is increased by an additional unit. Thus if $MP_1(x_1)$ denotes the marginal product of factor 1 when x_1 units are employed, then $MP_1(x_1) = f(x_1 + 1, x_2, \dots, x_n; k) - f(x_1, x_2 \dots, x_n;$ k). The marginal products are closely related to the marginal rates of substitution previously defined. If an additional unit of factor 1 will increase output by f_1 units, for example, then one more unit of output can be obtained by employing $1/f_1$ more units of factor 1. Similarly, if the marginal product of factor 2 is f_2, then output will fall by one unit if the use of factor 2 is reduced by $1/f_2$ units. Thus output will remain unchanged, to a good approximation, if $1/f_1$ units of factor 1 are used to replace $1/f_2$ units of factor 2. The marginal rate of substitution is therefore f_2/f_1, or the ratio of the marginal products of the two factors. It has already been shown that the marginal rate of substitution also equals the ratio of the prices of the factors, and it therefore follows that the prices (or wages) of the factors are proportional to their marginal products.

This is one of the most significant theoretical findings in economics. To restate it briefly: factors of production are paid in proportion to their marginal products. This is not a question of social equity but merely a consequence of the efforts of businessmen to produce as cheaply as possible.

Further, the marginal products of the factors are closely related to marginal costs and, therefore, to product prices. For if one more unit of factor 1 is employed, output will be increased by $MP_1(x_1)$ units and variable cost by p_1; so the marginal cost of additional units produced will be $p_1/MP_1(x_1)$. Similarly, if additional output is obtained by employing an additional unit of factor 2, the marginal cost will be $p_2/MP_2(x_2)$. But, as shown above, these two numbers are the same; whichever factor i is used to increase output, the marginal cost will be p_i/MP_i (x,) and, furthermore, the firm will choose its output level so that the marginal cost will be equal to the price, p_0.

Thus it has been found that $p_1 = p_0 MP_1(x_1)$, $p_2 = p_0 MP_2(x_2), \dots$, or the price of each factor is the price of the product multiplied by its marginal product, which is the value of its marginal product. This, also, is a fundamental theorem of income distribution and one of the most significant theorems in economics. Its logic can be perceived directly. If the equality is violated for any factor, the businessman can increase his profits either by hiring units of the factor or by laying them off until the equality is satisfied, and presumably the businessman will do so.

The theory of production decisions in the short run, as just outlined, leads to two conclusions (of fundamental importance throughout the field of economics) about the responses of business firms to the market prices of the commodities they produce and the factors of production they buy or hire: (1) the firm will produce the quantity of its product for which the marginal cost is equal to the market price and (2) it will purchase or hire factors of production in such quantities that the price of the commodity produced multiplied by the marginal product of the factor will be equal to the cost of a unit of the factor. The first of these conclusions explains the supply curves of the commodities produced in an economy. Though the conclusions were deduced within the context of a firm that uses two factors of production, they are clearly applicable in general.

LONG-RUN ADJUSTMENTS

The relationship between the short run and the long run

The theory of long-run profit-maximizing behaviour rests on the short-run theory that has just been presented but is considerably more complex because of two features: (1) long-run cost curves, to be defined below, are more varied in shape than the corresponding short-run cost curves, and (2) the long-run behaviour of an industry cannot be deduced simply from the long-run behaviour of the films in it because the roster of firms is subject to change. It is of the essence of long-run adjustments that they take place by the addition or dismantling of fixed productive capacity by both established firms and new or recently created firms.

At any one time an established firm with an existing plant will make its short-run decisions by comparing the ruling price of its commodity with cost curves corresponding to that plant. If the price is so high that the firm is operating on the rising leg of its short-run cost curve, its marginal costs will be high—higher than its average costs—and it will be enjoying operating profits, as shown in Figure 3. The firm will then consider whether it could increase its profits by enlarging its plant. The effect of plant enlargement is to reduce the variable cost of producing high levels of output by reducing the strain on limited production facilities, at the expense of increasing the level of fixed costs.

In response to any level of output that it expects to continue for some time, the firm will desire and eventually acquire the fixed plant for which the short-run costs of that level of output are as low as possible. This leads to the concept of the long-run cost curve: the long-run costs of any level of output are the short-run costs of producing that output in the plant that makes those short-run costs as low as possible. These result from balancing the fixed costs entailed by any plant against the shod-run costs of producing in that plant. 'The long-run costs of producing y are denoted by $LRC(y)$. The average long-run cost of y is the long-run cost per unit of y (algebraically $LAC(y) = LRC(y)/y$). The marginal long-run cost is the increase in long-run cost resulting from an increase of one unit in the level of output. It represents a combination of short-run and long-run adjustments to a slight increase in the rate of output. It can be shown that the long-run marginal cost equals the marginal cost as previously defined when the cost-minimizing fixed plant is used.

Costs in the long run. Cost curves appropriate for long-run analysis are more varied in shape than short-run cost curves and fall into three broad classes. In constant-cost industries, average cost is about the same at all levels of output except the very lowest. Constant costs prevail in manufacturing industries in which capacity is expanded by replicating facilities without changing the technique of production, as a cotton mill expands by increasing the number of spindles. In decreasing-cost industries, average cost declines as the rate of output grows, at least until the plant is large enough to supply an appreciable fraction of its market. Decreasing costs are characteristic of manufacturing in which heavy, automated machinery is economical for large volumes of output. Automobile and steel manufacturing are leading examples. Decreasing costs are inconsistent with competitive conditions, since they permit a few large firms to drive all smaller competitors out of business. Finally, in increasing-cost industries average costs rise with the volume of output generally because the firm cannot obtain additional fixed capacity that is as efficient as the plant it already has. The most important examples are agriculture and extractive industries.

CRITICISMS OF THE THEORY

The theory of production has been subject to much criticism. One objection is that the concept of the production function is not derived from observation or practice. Even the most sophisticated firms do not know the direct functional relationship between their basic raw inputs and their ultimate outputs. This objection can be got around by applying the recently developed techniques of linear programming, which employ observable data without recourse to the production function and lead to practically the same conclusions.

On another level the theory has been charged with excessive simplification. It assumes that there are no changes in the rest of the economy while individual firms and industries are making the adjustments described in the theory; it neglects changes in the technique of production; and it pays no attention to the risks and uncertainties that becloud all business decisions. These criticisms are especially damaging to the theory of long-run profit maximization. On still another level, critics of the theory maintain that businessmen are not always concerned with maximizing profits or minimizing costs.

Though all of the criticisms have merit, the simplified theory of production does nevertheless indicate some basic forces and tendencies operating in the economy. The theorems should be understood as conditions that the economy tends toward, rather than conditions that are always and instantaneously achieved. It is rare for them to be attained exactly, but it is just as rare for substantial violations of the theorems to endure.

Only the simplest aspects of the theory were described above. Without much difficulty it could be extended to cover firms that produce more than one product, as almost all firms do. With more difficulty it could be applied to firms whose decisions affect the prices at which they sell and buy (monopoly, monopolistic competition, monopsony). The behaviour of other firms that recognize the possibility that their competitors may retaliate (oligopoly) is still a theory of production subject to controversy and research.

BIBLIOGRAPHY. P.A. SAMUELSON, *Economics,* 8th ed., ch. 23–28 (1970), is an excellent introductory treatment of the subject. Authoritative, intermediate-level discussions may be found in W.J. BAUMOL, *Economic Theory and Operations Analysis,* 2nd ed., ch. 3, 11–13 (1965); and in G.J. STIGLER, *The Theory of Price,* 3rd ed. (1966). V.L. SMITH, *Investment and Production* (1961), emphasizes especially the relationship between long-run costs and investment. Probably the best technical presentation is in P.A. SAMUELSON, *Foundations of Economic Analysis,* ch. 4 (1947). For a discussion of the evolution of the theory, see G.J. STIGLER, *Production and Distribution Theories* (1968); on the relationship between theory and empirical data, P.J.D. WILES, *Price, Cost and Output* (1956); and CONFERENCE ON PRICE RESEARCH, COMMITTEE ON PRICE DETERMINATION, *Cost Behaviour and Price Policy* (1943). J.R. HICKS, *Value and Capital,* ch. *6–8* (1939); and J. VINER, "Cost Curves and Supply Curves," *Zeitschrift für Nutionalokonornie,* 3:23–46 (1931), remain classic works; for an excellent survey of recent work with a full bibliography, see A.A. WALTERS, "Production and Cost Functions," in *Econometric~*,31:1–66 (1963).

(R.D.)

Production and Consumption, Government's Role in

A significant development in the intellectual history of the 20th century has been the explicit recognition by economists, politicians, and the public at large of the importance of government in the operation of the economy. An older view, popular in the 18th and 19th centuries, held that "that government is best which governs least." This usually was interpreted to mean that government should restrict its activities to defense, to fire and police protection, to the performance of various administrative tasks, and to certain statistical and other services that do not lend themselves well to the efforts of firms and private individuals. Indeed, most of these tasks were performed by private armies, volunteer fire departments, vigilantes, etc. A more common view now is that all levels of government (central, regional, local) are, and must be, important participants in the production and consumption decisions of a modern economy.

THE PUBLIC AND PRIVATE SECTORS

The idea that government, especially the central government, must participate in basic economic decisions is not in itself entirely new. Some governments have completely dominated the lives of their people. In the past, this was frequently associated with a marriage between secular and religious power, the outstanding illustration being the civilization of the Incas, in which the emperor was at once the divinity, the lawgiver, and the law in a society planned down to the last detail. Remote from the concerns of modern industrial economies as such societies seem, they do show the possible social costs of excessive centralization. The technical aspects of excessive centralization are, however, more germane to present-day problems, and these will be discussed below.

The modern conception of the economic role of the public (government, as distinct from private) sector is that the various levels of government must be recognized as major links in the economic process. Their contributions to political and economic welfare must, however, be evaluated, not merely in terms of technical efficiency but also in the light of acceptability to a particular society at a particular state of political and economic development. Even in a dictatorship, this principle is formally observed, although the authorities usually destroy the substance by presuming to interpret to the public its collective desires.

The question of efficiency

The relative efficiency of the private and public sectors in allocating economic resources (capital, labour, materials) must be subject to continuous appraisal by an estimate of the comparative costs and benefits of resource-using projects entrusted by society to the public or private sectors. Indirect costs and benefits, which are often crucial to the decision whether a given project should be undertaken by private industry or by government, are difficult to estimate. For example, a new public highway may contribute to the enjoyment of the automobile and may reduce transport costs, but it also may destroy the ecology of a wilderness area. In the private sector, production of a cheap and safe airplane may enhance leisure and increase the mobility of business executives, but it also may add seriously to the noise level. Budgeting, in the broadest sense, then, involves the weighing of alternative costs; and these costs are not merely the obvious, tangible ones that are taken into account in much cost-benefit analysis but include such fundamental, yet intangible, consequences as the impact on the future of decisions made in the present.

Modern societies recognize, therefore, that one of their basic concerns is continuously to weigh alternatives with respect to the optimum allocation of resources between and within the public and private sectors. Once the concept of social welfare that is acceptable to a national ethos has been established, it must be recognized that there is no presumption in favour of either public or private responsibility for economic decisions. The palm is awarded on the basis of comparative efficiency.

Two subjects will occupy the remainder of this article.

The first is a consideration of the logical basis for arriving at the optimal ratio of public to private spending; the second, an examination of the significance of trends in public and private spending for the centralization of economic power.

Public and private goods

A clarification of terms is necessary at the outset. A strictly private good is one that can be consumed by only one purchaser: if X buys and consumes an orange, it is not available to Y. A strictly public good, on the other hand, is equally enjoyable by everyone. A park is accessible to all, even though wealthy taxpayers may contribute a relatively high proportion of its cost. (There are, obviously, mixed cases in between these two extremes.) Two points need to be observed with respect to this distinction. First, although governments usually produce the bulk of public goods, they also produce toll roads, subways, electricity, and air-travel services that are sold in markets just as are goods produced by private firms. The widespread use of subsidies to hold down the prices of these services confuses matters, however, for subsidies involve a transfer of purchasing power from taxpayers to the users of the government-produced output. Conversely. business firms may produce goods that are not sold in private markets. An example is military aircraft. Second, the distinction between public and private goods, though it is a handy one for logical thinking, is not absolutely clear-cut. Many public, or collective, goods could be sold in private markets. Flood control, for example, may involve the creation of artificial lakes that can be enjoyed by all without charge. On the other hand, the government could sell these services in the same way that the owner of a private amusement park does. Again, flood-control installations may lead to a rise in the value of surrounding land, and the government conceivably could charge rent to the beneficiaries.

THE ALLOCATION OF RESOURCES

A principle is needed to determine the amount of resources that should be devoted to the production of public goods. Such a principle exists in the private sector, where the allocation of resources is determined by (1) consumers, when they attempt to derive the most satisfaction in distributing their incomes between consumption and saving and between different types of consumers' goods and services, and *(2)* producers, in maximizing profit plus some combination of other possible business objectives (the firm's desired position in the industry, for example, or its anticipated size at some future date). Clearly, such a principle also exists with respect to public goods, except that here a complex political process aims at interpreting the desires of the public with respect to what public goods should be produced and how they should be financed. (It should be noted that consumer choice in any literal sense is often rather remote from reality in the provision of both private and public goods and services. Just as firms successfully influence consumers by advertising campaigns, so in the public sector a variety of pressures are brought to bear on the voter.) Public discussions of government activity often revolve around the issue of taxation. But it is important not to overestimate the part played by the tax decision in the budgetary process. The taxes that pay for the production and distribution of public goods do, of course, reduce the ability of individuals and firms to purchase private goods. Taxes, along with government borrowing, are one of the financial instruments utilized for transferring resources from the private to the public sector. But the decision to tax usually plays a subsidiary role in the decision to transfer resources to the government. Taxation is especially important when a subordinate level of government elects to restrict its spending to receipts from a given tax system, and there have been many cases in which an inefficient central-government tax structure has discouraged extensive spending programs. It is much more usual, however, for the government to decide first on the program, even when spending and tax proposals are presented simultaneously to the legislature in an integrated budget. In a progressive economy, tax receipts rise automatically with rising national income and spending. To the extent that no tax rate increases are necessary to finance expanded public-spending programs, the tax decision is likely to be subordinate to the spending decision. In an era of sharply rising public demand for collective goods and services, the automatic rise in tax receipts from a given tax structure will be inadequate; and distaste for higher tax rates is very likely to constrain decisions with respect to government resource taking.

The preceding remarks can be summarized as follows: the decision on the proportion of available resources to be devoted over a given period of time to public and private goods is a budgetary matter. But the budgetary decision is not merely a choice between the anticipated benefits of the public goods and the additional taxes required to finance them. (This is, of course, an important consideration in the political implementation of any decision to change the level of public spending, for taxes are likely to be prominent in the methods of financing that have to be considered.) The fundamental decision is, rather, the choice between devoting a certain amount of physical resources to the production of commodities for purchase in private markets and allocating the same resources to the output of public goods.

In a small country with a homogeneous population and a stable political system, this decision is likely to be made rather smoothly. Indeed, the very smoothness may be a source of concern if the favourable effects of a reasonable amount of conflict on economic and social progress are considered. It does not necessarily follow that in a large country, beset by an array of complex issues, there may not be periods during which the weight of public opinion unambiguously favours a rise or a fall in the proportion of public to private goods. Usually, however, there is much division of opinion.

The concept of balance

The answer to what it is that determines whether a nation feels comfortable with a particular distribution of resources between public and private use can be given most broadly by reference to the concept of balance, but it is necessary to know what it is that has to be balanced. The term balance may itself be somewhat misleading; sometimes a country progresses more rapidly with imbalance, in the usual sense of the term, than with balance. There is considerable debate over the relative merits of balanced and unbalanced growth and therefore of balance and imbalance in the constituents of growth, including public and private spending. Imbalance would be justified, for example, if there were reason to believe that public spending would, in the foreseeable future, be more effective than would private investment in opening up new markets. One example is education, which might be expected to have the incidental effect of creating more sophisticated wants on the part of the general public. Another is massive government spending on the conservation of natural resources, pure air and water, and open spaces — necessary ingredients of a viable society in future generations.

It is possible, nevertheless, to accept the view that, with a sufficiently broad horizon, efficiency calls for balance in the use of resources by the public and private sectors. The question then becomes one of whether there are any mechanisms that tend to keep society on the desired path. The idea that such a mechanism exists in the "way of growth" of the social organism is deep-seated and of ancient lineage. Heracleitus thought that deviations from the inherent growth process of the organism are punished. The frequent recurrence of this idea in the history of thought probably owes something to the feeling that man usually manages to "muddle through." With respect to public expenditure, even a persistent tendency for a rise in the ratio of public to private spending is not necessarily inconsistent with the idea of a self-steering mechanism. One might share the view of the 19th-century German economist Adolph Wagner that not only will the state inevitably increase the scope of its activities so tha‘ its share in national output continuously rises but thai this is socially desirable. On this view, balance refers to the change in the ratio of public to private spending, not to the ratio itself.

Wagner couched his argument in terms of per capita government spending and national output. It is not difficult to understand that public expenditures tend to rise proportionately more than the rise in population. So do private expenditures. Rising trends in productivity, due largely to technological progress, imply rising per capita real income. This "social dividend" is at the disposal of society and is hardly likely to be divided between the public and private sectors in such a way that only one of them benefits from it. Thus, in an absolute sense, both public and private resource use can rise, and the "law" of increasing per capita public expenditure is really only a manifestation of economic progress.

Such a tendency does not imply any inevitable increase in governmental functions. Even though there may be no theoretical ceiling on the proportion of public to private spending short of the government's responsibility for all of it, political and economic pressures build up against an indefinite increase in the ratio. Even in national states subject to highly centralized planning, these pressures become important when the proportion of public to total spending enters the range of about 35 to 40 percent.

Economic budgeting

The pressures that ultimately work against an indefinite increase in the ratio of public to total spending may be summed up in the concept of balance, and this, in turn, is the essence of economic budgeting. Economic budgeting is a form of planning wherein the objectives of government spending programs are carefully weighed against the sacrifice entailed to private spending programs if the former are accepted. Part of government spending is allocated to projects that cannot efficiently be carried out by the private sector. In this case, balance must be sought in terms of the contribution of these projects to social welfare if they are accepted. The rest of government spending is on projects that might be carried out by either government or the private sector, and here the choice should be determined by comparative efficiency.

In the absence of formal central planning, society depends on political forces to keep the balance of public and private spending at a point that represents the optimum technical relationship between the two, but it may be difficult—short of a high degree of formal planning—to determine whether this relationship is in fact the criterion accepted in governmental decisions. It is to be noted that the decision is not solely in the hands of the government. When firms and individuals are determined to increase or maintain their resource taking—if necessary by borrowing from the banks—prices may be driven up; and governmental appropriations made in money terms will be found to command fewer real resources than expected. If government then backtracks from its original plans (in the interest of inflation control), the private sector will have succeeded in tilting the balance in resource distribution between it and the public sector.

No distinction has so far been made between investment and consumption spending. With respect to the former, the comparative roles of the public and private sectors will depend on which category of investment is expected to make the greater contribution to economic growth. The ratio between public and private consumption spending is decided by the legislative and executive branches of government, responding to the interaction of group pressures. The special interests include not only private lobbies but also the various government agencies charged with administering programs concerned with public consumption. Their conflicting aims are resolved periodically in each budget. In wartime the criteria are different. Military expenditures, though necessary to achieve national objectives, do not contribute significantly to the accumulation of productive capital and must therefore be treated as public consumption. Within limits imposed by the necessity of feeding and clothing the population, government consumption takes precedence over private consumption in time of war. The public-consumption target is simply taken to be the maximum that is possible without significantly injuring the will or the capacity to fight. The magnitudes involved may be illustrated by the experience of the United States in World War II. In 1944, out of a national income of $183,000,000,000, some $103,000,000,000, or *56.5* percent, was devoted by all levels of government to public spending. In 1940 the percentage had been 22.6. Large as the increase was, it did not represent the maximum possible; to a surprising extent, the United States was able to have both guns and butter in World War II.

HISTORICAL TRENDS

The historical rise in government spending in nearly all countries in the 19th and 20th centuries cannot be taken as a measure of either the relative importance of government as a whole in economic decision making or the comparative roles of the central and lower levels of government. Inflation aside, in most countries the major reasons for the persistent rise in public spending since the middle of the 19th century have been war and the preparation for war, the rise in the cost of pensions for soldiers of former wars, the great increase of the administrative role of government in response to expanded and urbanized populations, and the marked rise in the demand for a varied list of public services as the vote was gradually extended to the lower income classes.

Writing in 1890, the Irish economist Charles Bastable observed that "in nearly all modern States outlay is steadily increasing," and "the older doctrines of economy and frugality have disappeared." He was referring to doctrines that had developed in the latter part of the 18th century, particularly in connection with the Industrial Revolution. He did not mean that there had been a "golden age" in which governments entirely refrained from interfering in the private sector. As Bastable himself pointed out, even the strictures of Anne-Robert-Jacques Turgot and Adam Smith on "excessive" government intervention did not preclude the encouragement of new industries.

The tradition of government action

In western Europe there was a long tradition of government influence on private economic decisions. The interventionist policies in the England of Henry VIII, Elizabeth I, and Oliver Cromwell, the France of Louis XIV and Colbert, and the Russia of Peter the Great are examples of such influence. But the sense of confidence conferred on the industrial class by the industrial and transportation revolutions of the 19th century, especially in Britain and the United States, produced an atmosphere that was unfavourable to government intervention. This did not, however, prevent rising pressure for government spending on economic resources, together with a secular rise in the magnitude and variety of the output of public goods that is still in evidence at the present time.

The complaints of the 19th-century exponents of laissez-faire are echoed today by the 20th-century "neoliberals," who deplore "governmental" interference with the free-market mechanism in the form of subsidies and tax incentives to business firms and even to individuals (for example, incentives to save rather than consume or to invest savings in government securities). Opponents of government intervention are not, however, concerned as much with the increased role of government in economic affairs as they are with the social cost of interference in the market mechanism. This cost takes two forms: (1) decreased efficiency of the market mechanism as an instrument for the efficient allocation of resources and (2) the arrogation of power by the central government.

As long as the ratio of public to private spending is not extremely high and is not rising rapidly, government intervention in the market mechanism carries more of a threat than does the rise in government output; however, the two phenomena are closely related. For example, despite a stated policy aimed at restraining federal expenditures in the U.S. during the first 30 years of the present century, these expenditures nevertheless rose greatly. The reason was a tremendous expansion in services (*i.e.*, public goods) to agriculture, commerce, and industry. On the one hand, this diversion of resources from the private to the public sector was designed to encourage economic growth by adding to the efficiency of the private sector; on the other hand, in providing these services, the federal government enhanced its own role in the economic process.

The tendency is not inevitable. The costs of centralization may become so burdensome that they produce a countertendency toward decentralization. In some industrialized countries, the public goods demanded by an increasingly sophisticated and urbanized public are felt to be more efficiently provided by secondary political units and by localities rather than by the central government; there is also the feeling that conscious efforts ought to be made to avoid excessive concentration of power in a central government that is remote from many local problems. It is not possible to predict how the contest between centralizing and decentralizing forces will be resolved. But it is of interest that national plans are devoting more and more attention to the gains in efficiency to be derived from a measure of decentralization of authority.

BIBLIOGRAPHY. A useful introduction is J.M. BUCHANAN, *The Public Finances* (1965), especially ch. 5, "Reasons for Growth of the Public Sector." On a more theoretical level are L. JOHANSEN, *Public Economics* (Eng. trans. 1965); and RA. MUSGRAVE, *The Theory of Public Finance* (1959). The question of whether the public sector of the economy ought to be expanded is dealt with in F.M. BATOR, *The Question of Government Spending* (1960); and J.K. GALBRAITH, *The Affluent Society* (1958). For historical trends in public expenditure, see C.F. BASTABLE, *Public Finance* (1892); H.F. WILLIAMSON (ed.), *The Growth of the American Economy*, 2nd ed. (1958); and A.T. PEACOCK *et* al., *The Growth of Public Expenditure in the United Kingdom* (1961).

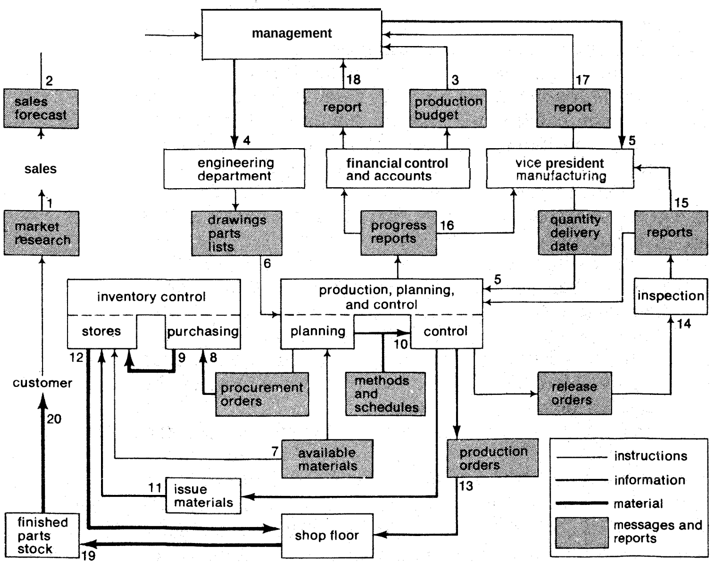
Production Management

Production, though it is often thought of as the processes involved in the operation of a manufacturing plant, is not restricted to the making of material objects; it may also include the performance of services, such as maintenance or transportation. Production management is concerned with planning and controlling the process of production so that it moves smoothly at the required level.

From customer to drawing board

Flow channels. In a large enterprise, a complex managerial system may be needed to do the work of advising, coordinating, controlling, and providing services to the production departments. In the last analysis, production management consists of making choices about the use of men, money, materials, and time. The way this is done in one fairly typical manufacturing firm is shown in the Figure, in which the main flow channels of instructions, information, and materials, are outlined. The sales department (number 1 in the Figure) analyzes the market for the firm's products. It also carries out market research to estimate the selling potential of new products. It makes a sales forecast (2) and submits it to top management. The financial department, in consultation with the production department, draws up a production budget (3). The proposed budget and the sales forecasts are closely scrutinized by management, and decisions as to the annual or semi-annual quantity of a given item to be produced are reached. The engineering department (4) is then instructed to prepare drawings, parts lists, and specifications or to check and modify existing ones. The manufacturing budget is adjusted correspondingly. Instructions are issued to the production planning and control department (5) specifying the quantities to be made and their delivery schedules. The necessary technical information (6) is obtained from the engineering department (including drawings, parts lists, specifications, standards, and so forth) and passed on to the planning section.



Production–consumption cycle.

From drawing board to customer

One of the first functions of the production planning and control department is to be well informed about the availability of materials and the expected delivery dates of materials already ordered (7). Detailed schedules are prepared. Inventory levels are checked to determine the orders that have to be issued (8) for procurement of materials and standard parts. Parts and assemblies that are subcontracted are also ordered by the purchasing department. When these purchased materials arrive, they are inspected and stored (9) until instructions to release them to the shops are received. The production-planning section supplies all the necessary data on methods of production, the loading of machines, and machine utilization, as well as production schedules, to the control section (10) for dispatching. The control section ieleases orders (11) for materials, tools, fixtures, and so on. Supplies (12) are released to the shop. Detailed production orders (13) are dispatched to the shop by the production-control section, specifying what, how, when, and where operations should be performed.

The control functions continue throughout the manufacturing period, and progress is constantly compared with the schedules so that suitable modifications may be considered and made when required. Inspection orders (14) are released. This is the function known as quality control, and its purpose is to ensure that the product conforms to specifications. Final inspection is carried out before the product leaves the shop. Evaluation of the production operations is the main part of the control function and has to be carried on both during and after these operations. Inspection reports (15) are one element of evaluation; they form the basis for corrective changes in the processes or methods of production, and sometimes even for changes in the specifications of raw materials. The production planning and control department reports on the progress of the work (16) to the management official responsible for manufacturing. These reports also go to the financial control department. The control section also evaluates data obtained from the shops about operation times, the idle time of men and machines, the causes and effects of breakdowns, fluctuations in output, and the like. The official responsible for manufacturing in turn reports (17) to management, which also receives a report (18) from the financial department. The finished product is transferred to stock (19). Finally, the product is delivered to the customer (20), who, after comparing the characteristics of the product with those of its competitors and with his expectations, is ready to contribute his views and reactions to market researchers.

This general description of one manufacturing firm's operations is sufficient to indicate the various activities and functions that comprise production management. Some of these may be examined in more detail.

The stages of control

The control function. Much of production management is concerned with control. Control has two purposes: first, to ensure that operations are performed according to plan and, second, to evaluate the production plan and to see whether a better one could not be devised in the light of the experience gained. Production control may be divided into four stages: (1) the observation and recording of progress, (2) the analysis of factual data in relation to plans and objectives, (3) the taking of corrective action to modify plans and redirect activities, and (4) evaluation. In each of these stages the production controller has to take certain steps or perform certain operations. Examples of these, as they relate to the control of processes, to the control of inventory, to inspection, and to cost control, appear in the Table.

Production-control Activities

	processes	inventory	inspection	costs
Observation	measuring rate of output; recording idle time or downtime	recording stock levels	inspecting materials and parts	collecting cost data
Analysis	comparing progress with the plan	analyzing demand for stocks in different uses and at different times	estimating process capabilities	computing costs in relation to estimates
Corrective action	expediting	issuing production and procurement orders	initiating full inspection; adjusting processes	adjusting selling price of product
Evaluation	estimating production capacity and maintenance schedules	drawing up replenishment policies and inventory systems	reassessing specifications; improving processes and procedures	evaluating production economics; improving data

Control of variety

One of the important problems in production management is control of the variety of products, materials, and methods. Variety, from the standpoint of management, is a kind of disorder; it has a tendency to grow, unless a conscious effort is made to limit it. Variety is encouraged by the efforts of salesmen to meet the individual tastes of their customers. From the standpoint of the firm there are advantages in having a variety of products: it can satisfy a wider range of demand, it can hold customers who might be inclined to take their business elsewhere, it can adjust more readily to changes in the market, and it may thus be enabled to expand its business into new lines or to acquire new categories of customers. But there are also advantages in limiting the variety of products: the firm can then operate with smaller stocks of materials and finished goods, and with less plant and equipment; it can simplify production planning and control procedures; it can reduce the range of skills required and simplify its training methods; and it can get higher output per man-hour.

A balance must therefore be sought. There are not many products for which demand is high enough to justify the existence of specialized production lines working on a continuous schedule. The desire to keep production facilities busy, coupled with the pressure from customers who increasingly prefer variations of the basic product instead of the standard model, lead inevitably to a diversification of products. It is not uncommon, among firms with a diversified product range, to find that one-quarter of the products account for three-quarters of the total sales receipts and there have been cases in which 10 or 20 percent of the products were responsible for more than 80 percent of the receipts.

Scheduling. Production scheduling involves sequencing the activities of the plant so that the product will emerge from the assembly line at the time set for it. This task becomes complex when the same facilities are used for several products, or when some jobs can be run concurrently while others must be done in sequence. In some cases the problem is to steer the job through the system, whenever alternative routes exist, and to determine the queuing discipline at each queue—that is, to order the jobs in the sequence in which they are to be processed by each machine. In other cases there is the problem of determining production levels for each product in order to meet various levels of demand.

Project scheduling. When a project consists of numerous individual jobs, only some of which have to be carried out in a particular sequence, it is necessary to draw up a schedule showing which jobs control the completion of the project. An example of such a project is the construction of an office building, in which some operations (for example, the steelwork) are prior to the performance of others, such as brickwork, although both may take place concurrently in different locations. One approach to this is network, or critical-path, analysis. The project plan is drawn up in the form of a network diagram, consisting of arrows which each represent a particular job; the points where the arrows join (called nodes) denote the starting or finishing of jobs. The network will show which jobs are concurrent and which follow a sequence. The diagram makes it possible to determine the "critical path" that consists of all the jobs whose actual duration must not exceed a given minimum if the project is to be completed on schedule. The use of network analysis in project scheduling allows the reallocation of resources and the rearrangement of the sequence of jobs at the planning stage and also provides an effective means of control during the execution of the project.

Job-production scheduling. In some cases several orders have to be processed on common facilities or production centres, each job having its own unique specifications and requirements in terms of production resources. A "job" may be defined as an order consisting of a single item or a batch of identical items. The scheduling problem is to determine the sequence in which jobs should be processed at each centre—that is, the scheduling rules or the "queuing disciplines" that should be adopted.

A distinction can be made between the static case, in which a fixed number of available jobs needs to be scheduled, and the dynamic case, in which jobs arrive in sequence, sometimes at random, and in which scheduling is a continuous activity. Another distinction is usually made between jobs in which processing times are known in advance or at the time of scheduling, and jobs in which processing times may deviate from given estimated times.

The objectives of job scheduling are the minimization of total time for a given number of jobs, the minimization of the average (or the variance or both) of time (or delay time) per job, the meeting of due dates (when jobs are due to leave the production system) or the minimizing of deviations from given due dates. One method of comparing the relative merits of alternative scheduling rules is to use simulation. This consists of generating, with the aid of a computer, simulated jobs with an arrival pattern and work content similar to the situation under stndy, and experimenting with various control procedures.

Batch-production scheduling. In cases in which the rate of production exceeds the rate of demand, an item may be produced in batches in order to avoid excessive stock building. Between batches of one product the manufacturing facilities are available for other products. The scheduler has to determine the batch sizes of the various products and the order in which they should be produced. Two methods have been used to solve this problem. One employs mathematical programming; the other uses a mathematical model that attempts to maximize the ratio of profit to production costs for the whole production cycle (in which all the products are produced at least once in turn) by calculating batch sizes of the products in the ratio of their demand.

Continuous-production scheduling. When the demand for a product is high enough to justify production on a continuous basis, the production level may need to be adjusted from period to period because of fluctuating demand. This is called the production-smoothing problem. When more than one product is involved, it may be treated either as an aggregate-production-smoothing problem

The production-smoothing problem

(in which the production level for the system as a whole is determined and then broken down into schedules for each product), or as a variant of the batch-production problem.

Two principal methods of solving the production-smoothing problem are: (1) the use of linear programming to compare the costs of using alternative production resources (such as regular time, overtime, or subcontracting) in relation to the constraints on the availability of resources and on minimum-demand requirements that must be met; and (2) production-decision rules that take account of future demand in the light of the present level of production (and, when appropriate, employment). Both methods are chiefly concerned with minimizing costs over a given period of time.

Inventory control. Inventories include raw materials, component parts, work in process, finished goods, packing and packaging materials, and general supplies. The control of inventories, vital to the financial strength of the firm, in general involves deciding at what points in the production system stocks shall be held and what their form and size are to be. As some unit costs increase with inventory size—including storage, obsolescence, deterioration, insurance, investment—and other unit costs decrease with inventory size—including setup or preparation costs, delays because of shortages, and so forth—a good part of inventory management consists of determining optimal purchase or production lot sizes and base stock levels that will balance the opposing cost influences. Another part of the general inventory problem is deciding the levels (reorder points) at which orders for replenishment of inventories are to be initiated.

Inventory control is concerned with two questions: when to replenish the store and by how much. There are two main control systems. The two-bin system (sometimes called the min-max system) involves the use of two bins, either physically or on paper. The first bin is intended for supplying current demand and the second for satisfying demand during the replenishment period. When the stock in the first bin is depleted, an order for a given quantity is generated. The reorder-cycle system, or cyclical-review system, consists of ordering at fixed regular intervals. Various combinations of these systems can be used in the construction of an inventory-control procedure. A pure two-bin system, for example, can be modified to require cyclical instead of continuous review of stock, with orders being generated only when the stock falls below a specific level. Similarly, a pure reorder-cycle system can be modified to allow orders to be generated if the stock falls below the reorder level between the cyclical reviews. In yet another variation, the reorder quantity in the reorder-cycle system is made to depend on the stock level at the review period or the need to order other products or materials at the same time or both.

Other aspects of production management. On a broader scale the concerns of production management include the effective use of all resources available to the enterprise. These resources include manpower, materials, machines, money, and methods.

The effective use of manpower has long been the object of work-study techniques first developed by an American industrial engineer, Frederick W. Taylor (1856-1915), who introduced time-and-motion studies, as well as systems of incentive pay for labour. The measurement of repetitive work has come to be widely accepted as a way of increasing labour productivity and reducing labour costs.

The effective use of materials often involves investigations of the causes of scrap and waste, and the study of alternative materials that may be used in the same production process. Likewise, the effectiveness of machines depends on their suitability for specific tasks, the degree of their utilization, the extent to which they are kept in optimum running condition, and the extent to which they can be mechanically or automatically controlled.

The effective use of financiai resources is generally regarded as being outside the responsibility of production management. Rut many problems of production management have a considerable effect on the finances of the enterprise: the selection of processes, the installation and replacement of equipment, and decisions involving inventory and purchasing policies.

Operations research

Production management has always made use of quantitative analysis. Recent developments in the field of operations research or, more broadly, in the management sciences, have increased the mathematical emphasis in production management (see OPERATIONS RESEARCH). Mathematical programming techniques have been applied to a variety of production allocation and scheduling problems. Queuing theory is used in the analysis of production lines and maintenance problems. System simulation, with electronic computers, is used to study the characteristics of complex production systems. From this point of view the production system consists of a sequence of operations that transform a set of physical inputs (raw materials, components, customers) into a specified set of physical outputs (finished products, serviced customers). The transformation takes one or more of the following forms: (1) *disintegration*, transforming a single input into several outputs, as in producing steel bars and sheets from ingots, or a variety of chemical products from crude oil; (2) *integration* or *assembly*, combining many inputs to produce a relatively small number of finished products, as in the manufacture of machines, automobiles, and various chemical products that are made by blending; (3) *service*, performing an operation that changes certain characteristics of an object, as in maintenance, transportation, or the process of aging.

There is even a possibility that production management and other specialized managerial functions may eventually disappear and be replaced by a general science of management. Even if this happens, the actual management of production is not likely to become a mere package of techniques or management by formula. Production decisions are made by people in human organizations existing in a dynamic environment, in which only the fact of change is constant.

BIBLIOGRAPHY. A practical handbook is G B CARSON (ed.), *Production Handbook,* 2nd ed. (1958). An analytical approach to production control is S. EILON, *Elements of Production Planning and Control* (1962). The use of operational-research models ıs covered in E H BOWMAN and R.B. FETTER, *Analysis for Productron and Operations Management,* 3rd ed. (1967); E S. BUFFA, *Production-inventory Systems* (1968); and M K. STARR, *Pi oduction Management: Systems and Synthesis* (1964). (S.E.)

Productivity, Economic

Productivity in economics is the ratio of what is produced to what is required to produce it. Usually this ratio is in the form of an average, expressing the total output of some category of goods divided by the total input of, say, labour or raw materials. In principle, any input can be used in the denominator of the productivity ratio. Thus, one can speak of the productivity of land, labour, capital, or subcategories of any of these factors of production. One may also speak of the productivity of a certain type of fuel or raw material or may combine inputs to determine the productivity of labour and capital together or of all factors combined.

The productivity of labour, land, and capital

Labour is by far the commonest of the factors used in measuring productivity. One reason for this is, of course. the relatively large share of labour costs in the value of most products. A second reason is that labour inputs are measured more easily than certain others, such as capital. This is especially true if by measurement one means simply counting heads and neglecting differences among workers in levels of skill and intensity of work. In addition, statistics of employment and man-hours are often readily available, while information on other productive factors may be difficult to obtain. Not least important in explaining the emphasis on labour as an input is the fact that, historically, technological advance has made itself felt through the displacement of labour—that is, through increases in labour productivity—rather than through the displacement of other factors. Some kinds of labour productivity measures are thus valuable as indicators of this process and of the resulting improvements in man's material well-being.

The productivity of land, though it receives considerably less attention than the productivity of labour, has been of historical interest. In ancient and preindustrial times the products of the soil comprised the bulk of total output, and land productivity thus constituted the major ingredient in a people's standard of living. Soil of low productivity could, and over much of the Earth still does, mean poverty for a region's inhabitants. It is, however, no longer generally believed, as it was in past centuries, that a country's economic well-being is inevitably tied to the productive powers of the land, and the productive potential of the land itself has proved to be not fixed but greatly expandable through the use of modern agricultural methods. Moreover, industrialization, where it has taken place, has greatly reduced man's dependence on agriculture. These circumstances, together with expanding opportunities for trade, have enabled some countries to overcome in substantial degree the handicaps of a meagre agricultural endowment.

Attempts to measure the productivity of capital

The productivity of capital—plant, equipment, tools, and other physical aids—is a subject of long-standing interest to economists, though concern with its empirical aspects is of more recent origin. Improved statistical reporting and the availability of data in a few industrially advanced countries, notably since World War II, have encouraged systematic efforts to measure the productivity of this factor. Compared with achievements in measuring labour productivity, however, the progress realized has been quite limited. There are considerable theoretical and practical difficulties to be overcome.

USES OF PRODUCTIVITY MEASUREMENT

As an index of growth. A nation or an industry advances by using less to make more. Labour productivity is an especially sensitive indicator of this economizing process and is one of the major measures used to chart a nation's or an industry's economic advance. An overall rise in a nation's labour productivity signifies the potential availability of a larger quantity of goods and services per worker than before and, accordingly, a potential for higher real income per worker. Countries with high real wages are usually also those with high labour productivity, while those with low real wages are generally low in productivity. If, for the moment, other productive factors are neglected, one can see that the wage level will then be equal to the total national product divided by the number of workers; that is, it will be equal to the level of labour productivity.

The change in a nation's overall labour productivity during any given interval represents the sum of changes in the major economic sectors and industries. Some sectors and industries move ahead more rapidly than the overall average while others may gain more slowly or even decline. In the movement of a country from a level of low productivity and low income to one of high productivity and high income a strategic role is played by the industrial, rather than by the agricultural and other sectors. In the late 18th and early 19th centuries the effect of the Industrial Revolution was felt first in the manufacture of woollen and cotton textiles, power generation, the metal trades, and machine-making industries. Along with the development of new processes came the development of new products and services that formed the basis for new industries. An outstanding feature of these changes was an increased labour productivity that in turn laid the foundations for an enormous expansion of output. Technological change exerted its influence irregularly and unevenly and continues to do so.

In the compilation of overall averages this diversity is concealed because high rates in some industries offset low rates in others. Thus, the rate of increase of productivity for the economy as a whole varies within narrower limits than the spread of rates among individual industries would suggest. Aside from erratic short-term movements, the rate of growth of productivity may appear to be fairly stable over extended periods. A surge of labour-saving innovations would cause the overall average rate to move higher, while a technological lull would depress the average rate. History suggests that the surges tend to be associated with basic technological changes such as, for example, the steam engine, the gasoline engine, the electric motor, and the concept of the standardization of parts. Once introduced, such inventions or developments are used in many different industries. These surges tend also to be associated with such developments as, for instance, employment of the open-hearth furnace in steel manufacture or the introduction of the steam railroad.

Productivity is valuable also as an indicator of comparative rates of change among industries and products. Growth in general can be better understood if the relative contributions of individual industries and the circumstances underlying productivity changes in each of these industries are understood.

As a measure of efficiency. Productivity is also used to measure efficiency, as an aid in economic planning and forecasting, and as a means of assessing the uses to which resources are being put. As to the first of these, the efficiency of industrial operations, for instance, may be evaluated by the yardstick of output per man or machine, and such a yardstick may also provide the basis for supplemental or premium payments for workers. When pay is based on piecework alone, labour productivity becomes the sole determinant. Productivity may also serve as a standard for grading and evaluating any group of workers performing common tasks, distinguishing the more from the less productive. And applied to equipment, productivity standards can indicate when a machine is performing poorly and is in need of service. In forecasting, productivity estimates are useful when it is necessary to be able to project the performance of the economy at some future date, given the probable size of the working force. A variant of this is common in planning for underdeveloped countries that want to increase their productivity; information about target levels of productivity, together with expectations as to the growth of the labour force and some undeistanding of the relation between capital per worker and output per worker, helps in estimating the amount of capital investment needed to reach the target. Again, estimates of the probable annual gain in labour productivity together with estimates of the probable annual increase in output allow one to estimate how many jobs will become available at some time in the future. Finally, productivity is a helpful analytical tool in studying the possible allocation of resources among different uses. The extent to which resources flow to various uses depends, among other things, on their productivity in each of those uses. Changes in productivity in the course of time alter the pattern of use and cause the quantities of resources required in particular uses to change. The resulting trends depend on several things. On the one hand, an increase in the productivity of, for instance, labour, since it means a decrease in labour requirements per unit of output, will tend to reduce the demand for labour. But it will also imply a cheapening of labour relative to the cost of other competing factors of production. Hence there will be a tendency to substitute labour for other factors. When labour cost represents a large fraction of total cost, a productivity increase will contribute toward a reduction in the price of the product, thereby expanding sales and with them the demand for labour. The net result will depend upon the sum total of all of these separate effects. It is by no means uncommon to find that the expansionary effects predominate, and many economists consider this to be the normal outcome. In any event, the productivity concept and data on productivity trends can contribute to an understanding of resource and output flows.

As an economic standard. Productivity is an important factor in determining prices and wages. Economists are far from a full understanding of the relations among the variables, but there is substantial agreement on the following points:

Variables in price and wage standards

1. The large increases in real wages that have come about over the long term in many countries are closely associated with large increases in labour productivity in these countries.

2. In the absence of increases in labour productivity, a stable price level is inconsistent with persistent increases in money wages.

3. An increase in labour productivity or in the productivity of other factors usually brings with it a reduction in costs and hence tends to result in price reductions, wage increases, or both.

4. In industries in which sales of products are comparatively insensitive to price changes, increases in labour productivity will tend to reduce employment and possibly also reduce wages.

5. Wage increases in individual plants and industries may induce productivity increases by encouraging the substitution of capital and other factors for labour.

This last statement forms the basis for one explanation of the apparently high rate of mechanization in the United States: abundant economic opportunities for labour on the land and in the frontier west, it is said, resulted in a scarcity of labour in industry, and hence in high wages and intensive mechanization. The same logic, with a reverse twist, is sometimes used to account for low labour productivity in underdeveloped countries. In this instance, the argument is that very low wage rates make it economical to rely heavily on labour and to use little capital. While these explanations leave many things out of account, they appear to be valid within limits.

FACTORS THAT DETERMINE PRODUCTIVITY LEVELS

The level of productivity in a country, industry, or enterprise is determined by a number of factors. These include the available supplies of labour, land, raw materials, capital facilities, and mechanical aids of various kinds. Included also are the education and skills of the labour force; the level of technology; methods of organizing production; the energy and enterprise of managers and workers; and a range of social, psychological, and cultural factors that underlie and condition economic attitudes and behaviour.

These variables interact and mutually condition one another in determining productivity levels and their changes. Thus, in any country one expects the level of technology, the skills of the work force, the quantity of capital, and the capacity for rational economic organization to be positively correlated. A country with low productivity is likely to have deficiencies on all counts; a country with high productivity is likely to score high on all. To put it differently, the numerous productivity-determining factors behave as variables in a system of simultaneous equations, with all acting concurrently to shape the outcome. Within this system, there are no grounds for assigning causal priority to one or a few variables. All interact mutually to determine the outcome. Within certain problem frameworks, however, it may be entirely appropriate and indeed essential for explanatory purposes to emphasize certain variables over others.

Two broad problem frameworks may be distinguished, both of them of perennial concern to students of productivity and growth. One of these involves changes in productivity over time, the other involves differences in productivity levels among enterprises, industries, and countries at a given time. Within these frameworks are countless problems and subproblems, each of which may lead to a somewhat different selection and emphasis of variables.

Changes in long-term productivity

Explanations of long-term productivity changes in a country, region, or industry usually stress technological change and, as an adjunct, changes in the quality and quantity of capital. Other variables, though not ignored, are regarded as playing a passive role and are thus given a subordinate position. The justification for this is that change in technological knowledge and the capital embodying it is not only essential to substantial gains in productivity but is the factor most immediately associated with those gains. It ordinarily is perceived as the leading and moving force in the process. When technological change occurs, the quaiiry of capital improves and the amount available to aid each worker usually increases. The kinds of raw materials used may change, with better grades being required or the use of lower grades becoming possible. Changes occur in the way productive factors are organized and production is carried on. Although in some periods and in some circumstances work may have become harder and more tedious following technological advance and although the transition from land to factory has often entailed special hardships, the dominant trend has been toward shorter hours and a diminution of the arduousness of labour,

Emphasis on technological change and capital accumulation as primary forces arises also from a recognition that they are essential and unique to large and systematic advances in productivity. Those gains that can be obtained solely through a reorganization of work or the use of better raw materials or the breakdown of restraining attitudes or practices may occasionally be dramatic, but they are always limited. By contrast, very substantial gains can follow in the wake of growing technological knowledge and increasing supplies of capital. If allowance is made simply for adaptive changes in other factors, the prospects for advance become almost unlimited. Only these two factors can fairly be singled out as constituting the engines of productivity growth.

It has been noted that both the quantity of capital and its quality change as productivity increases, and it is not possible adequately to separate the two in terms of their effects. Increases in capital per worker through the accumulation of more and more of the same kinds of equipment and tools would not lead continuously to proportionate or more than proportionate increases in output per worker. They would, after a point, ·lead to diminishing increases and eventually even to a decline in output per worker. The onset of a decline would be far distant in an industry or economy possessed of a high level of technical knowledge but starting near the bottom of the accumulation ladder and affected by an acute scarcity of capital instruments. But an ultimate decline would be expected.

Qualitative changes in capital, reflecting advances in knowledge and skill and leading to the design and construction of improved capital instruments, offer an escape from this principle. If capital can be steadily improved over time, its expansion need not entail diminishing returns. In countries for which data from broad sectors and many individual industries are available, there is a rough correlation between growth in the quantity of capital per worker and increases in labour productivity.

HISTORICAL TRENDS

Man's use of capital as an aid in production is, strictly speaking, as old as his use of primitive tools of wood and stone. But the introduction of power-driven machinery, its systematic improvement, and its progressive substitution for labour are a set of much more recent phenomena.

Growth of industry. The influences of technological change and industrial development have touched virtually all regions of the world, though in different ways in widely differing degrees. Some areas were involved only through trade, receiving manufactured goods in exchange for raw-material exports. Others developed industry to a limited extent that served principally as an adjunct to foreign trade and did not penetrate deeply into the domestic economy. Still other countries, like Great Britain and the United States, were fundamentally affected as their economies underwent progressive advance and transformation. At the close of the 19th century, France, Italy, Germany, Russia, Japan and Canada, among others, also possessed substantial manufacturing capability. The transition was most evident in western and northern Europe and in North America and least evident in the Middle East, Africa, Asia, and South America.

The countries that stood in the industrial forefront by the first decade of the 20th century remained there up to World War II, though their relative positions shifted. Most conspicuous was the forward surge of the Soviet Union, following the inauguration of the five-year plans in 1928. After World War II large strides were made by other countries, particularly those of eastern and southern Europe. China and India also moved ahead, as did several South American countries. Japan's advance in the decades since 1950 has been outstanding.

The changes that accompany increasing productivity

The consequences for labour productivity of the changes under discussion — industrialization, mechanization, and capital accumulation — are summarized in Table 1 for the United States, Great Britain, Germany, and Japan. Because of the difficulties inhering in productivity measurement, the figures are only rough approximations. Nonetheless, they suffice to distinguish the rates of change among the four countries. It should be noted that in 1890 each of the countries occupied a different rung on the ladder of industrial development. By certain yardsticks, Britain was already a mature country; the United States and Germany were less advanced, while Japan stood in a comparatively early stage of industrialization. Equally important, each country was differently endowed in terms of skills and resources, possessed different social and economic institutions, and was differently situated geographically. As a result, the potentials for further growth differed among the four countries.

Table 1: Long-Term Trends in National Output per Worker
(index numbers, 1890 = 100)

year	country			
	United States	Great Britain	Germany*	Japan
1890	100	100	100	100
1900	122	107	100	144
1910	138	110	107	166
1920	142	100	—	228
1929	172	116	90	366
1938	182	132	127	547
1948	223	132	—	314
1960	295	161	166	747

*For 1948 and later, German Federal Republic (West Germany) only.
Sources: Figures adapted and assembled by the author from data in numerous sources, including the following: Solomon Fabricant, ***Basic Facts on Productivity Change,*** National Bureau of Economic Research, Occasional Paper **63,** Table **A** (1959); Joint Economic Committee, 85th Congress, 1st session, ***Productivity, Prices, and Incomes,*** Tables 1 and 2; Colin Clark, ***The Conditions of Economic Progress,*** 3rd ed., ch. 3 (1957); Kazushi Ohkawa, ***The Growth Rate of the Japanese Economy Since 1878,*** Appendix Table ***6*** (1957); M. Frankel, "Some Implications of International Postwar Productivity Trends," ***The*** 1958 ***Proceedings of the Business and Economic Statistics Section of the American Statistical Association,*** Table ***2*** (1959).

The figures show great unevenness in the rate of gain for each country from period to period; differences among the countries are marked, both for individual subperiods and for the entire 70-year span. These differences reflect the variety of forces that contribute to productivity change, their varying importance at different times and in different places, and the complex ways in which they interact. Britain experienced no perceptible gain from 1890 to 1920 but moved ahead significantly during the next 18 years. The United States gained during the 1938–60 interval at a rate much above those that had prevailed during the preceding 50 years. Japan's rate during the 18 years following 1920 was about 80 percent higher than its rate for the preceding 30 years. The very high rate in Japan between 1948 and 1960 was the result of recovery and restoration following World War II. A similar phenomenon is observable in a number of other countries, including Germany, though the figures in Table 1 do not show it. Britain and Germany are noteworthy for their low average rates over the long term. Japan, in contrast, is unique for the high average rate attained over a very long period.

Changes in labour input. An index of output per worker, like any other single productivity index, provides only limited information on the process of productivity change. Long-term increases in labour productivity have usually been accompanied by reductions in the number of hours worked per day and per week. In Britain or the United States, for example, a 60-hour week was not uncommon in 1850, but a century later 40 hours was a familiar figure. Hence, if the data in Table 1 were put on a man-hour basis, the rates of increase would, in general, be much higher.

A reduction in hours worked is simply one of the ways in which a people may benefit from productivity increases. Such reductions as have taken place probably have not entailed proportionate sacrifices in the quantities of goods and services that, with constant hours, might otherwise have been obtained. For when hours of work are very long, worker efficiency tends to be low, and within limits, as hours are reduced efficiency rises. There is substantial evidence that the decline of the working day from very high levels has brought compensatory gains of this kind.

Systematic long-term increases in labour productivity have also been accompanied by changes in the quality of labour and in the quality and quantity of other inputs. Generalizations about these other changes are, however, difficult to make. In many fields of production and for many classes of work, the introduction of machines has entailed a downgrading of skills. The loss of many traditional handicraft skills during the early stages of mechanization is a case in point. This type of loss has been repetitive throughout the history of mechanization. A machine replaces one class of skills and at the same time generates requirements for other skills, usually of a lower order.

But the sequence is by no means one-directional. Machines are complex, and over the decades their complexity has increased. This growing complexity has created a need for skills of a high order for machine development and for the installation, servicing, and operation of machines. Organizational requirements for the effective use of machines have also become more complex, thereby increasing the need for a large array of highly trained specialists. As a result, the downgrading and displacement of some skills have been accompanied by the upgrading of others and the emergence of new ones. There is little doubt that the latter tendency has predominated over the long term. The general educational and technical qualifications of an industrial, highly productive labour force are very much higher than those of a low productivity labour force engaged largely in agricultural and handicraft pursuits.

Increases in the productivity of capital

Land and capital. Changes in the productivity of other factors have accompanied the increases in labour productivity. Unfortunately the record as to the nature of these changes is far less comprehensive and in some respects less clear than in the case of labour productivity. By introducing constant improvements in farming methods, farm machinery, and fertilizers, technology led to large increases in the productivity of land as measured by the output of foods and fibres per acre. But it should be noted that, unlike output per worker, output per acre does not correlate well with living standards because of the varying intensity with which cultivation is carried on in individual countries. This circumstance accounts, for example, for the fact that output per acre for a particular commodity may sometimes be higher in a poor country than in a rich one. Technology has also made it possible to economize in the use of some raw materials in production and thus raise output per unit of raw material consumed. But in practice, higher productivity, while possible, may not result, since with a cheapening of this factor it often proves economical to use it more liberally than before. Sometimes, also, more mechanized methods of production are inherently more wasteful of raw materials than less mechanized ones.

In some countries, at least for some periods, the productivity of capital has risen. In the United States, from 1900 to 1960, output per unit of tangible capital increased about 80 percent, or at an average annual rate of just over 1 percent, with the bulk of the increase occurring after 1929. On the other hand, it had barely changed between 1890 and 1920. As between the two factors, labour and capital, it is clear that over the long term the major savings have been in labour. Both theoretical considerations and statistical data suggest that continued technological change will bring further large gains in labour productivity, but the probable trend with respect to capital is uncertain.

From the standpoint of the individual enterprise, any reduction per unit in inputs of labour and capital is important. The economic benefit is the same whether a given net reduction in cost results from the saving of labour or of capital or of raw material. But from a worldwide or economy-wide point of view, labour savings occupy a unique place because labour, interpreted in the broadest sense, is not only an input in the productivity process but also represents the goal of that process. Ultimately, goods and services are consumed by people. An increase in output per worker or per capita signals the availability or potential availability of increased quantities of goods and services for each individual. An increase in output per unit of capital or raw material does not necessarily carry this connotation. If the objective is to attain ever-rising living standards, then it is labour productivity that, over the long term, must be increased.

THE COMPARISON OF PRODUCTIVITY TRENDS

Trends in overall productivity are composites of trends in the several sectors and subsectors of the economy and, in the last analysis, of trends in individual industries and enterprises. At these subordinate levels trends often differ widely, both from one another and from the broader economy-wide averages.

Farm and **nonfarm.** Some of this diversity may be seen by comparing the trend in output per man-hour in the total United States private economy with similar trends in farm and nonfarm subsectors. For the entire period from 1909 to 1956 production per man-hour in both subsectors moved ahead by about the same amount and roughly in line with the overall movement. Between 1909 and 1929, however, the increase in the farm sector was far below that in the nonfarm sector, while for the period from 1938 to 1948 the reverse was true. The periods of 1929 to 1938 and 1948 to 1956 show a higher trend in the farm sector than in the nonfarm sector.

The figures serve to qualify the popular impression that agriculture is a persistent laggard in the technological march. In the United States, during the 19th and early 20th centuries, the nonfarm sectors—including mining, manufacturing, communications, and utilities—were in the vanguard. But in later decades, productivity in agriculture rose. The farm surpluses of the 1950s and 1960s were the result.

These productivity movements do not exhibit a close relation to movements in output. For all periods, increases in farm output, though relatively low, averaged close to 1 percent per year. At the same time productivity increases varied widely, ranging from under .5 percent to over 3 percent. For the nonfarm sector an annual 2 percent productivity increase was registered between 1929 and 1938, a period when output declined by 1 percent a year. By contrast, much the same productivity increase occurred from 1938 to 1948 when output advanced at 6 percent per year. This outcome is perhaps not surprising in view of the fact that the sources of output and productivity increases are not identical. Productivity increases will result in output increases provided that the quantity of inputs does not decline. But output increases may also result independently of productivity increases, from an expansion of inputs or from an increase in the intensity with which resources are used.

To gauge the contribution of any sector to the production total it is necessary to consider the size of the sector and its productivity level. Because agriculture in the United States contributes less than 5 percent of the national product and employs less than 9 percent of the labour force, even a large change in output per worker would have but a nominal effect on the total. The outcome may be very different if the sector is large and if its productivity level, measured by value of output per worker, is high relative to other sectors. In that case and depending on the method of measurement, a redistribution of labour in favour of the high productivity sector can produce large productivity changes in the total, even though sector productivity changes little. This source of productivity gain, while important for all dynamic economies, is especially so for one that is in the early stages of industrialization. In such economies, low-productivity agricultural pursuits absorb the bulk of the labour force, and hence the potential gain from their transfer to more productive occupations is very large.

Among countries. Changes in productivity and changes in total output do not always move in pace. When they do, it means that the gains in output have come exclusively from increased productivity and not from changes in the working force. (Strictly speaking, this is true only if the productivity figures relate to output per man-hour; if they represent output per man-year, for example, they may reflect an increase in the working force.) By contrast, an increase in output accompanied by no change in productivity would indicate that thc advance was attributable solely to the use of greater manpower or other resources. The data for the years following World War II show that both rising productivity and greater manpower contributed to the advances in output in all countries but that the influence of the former was generally greater. In Japan, Italy, France, and Austria, for example, productivity was more important, while in Poland, West Germany, the Soviet Union, and Canada manpower increases played a larger role.

Long-run and short-run growth rates

It is ordinarily preferable that increases in output be obtained through productivity growth rather than through a larger labour force, for this implies not only more product but also more leisure, or at least a potential for more leisure. A tacit assumption here is that the leisure is voluntary. If it is nor, then the problem of unemployment must be reckoned in the balance. Italy is a case in point. Between 1948 and 1957 industrial productivity in Italy rose at a rapid rate and accounted for almost the whole increase in output, but industrial employment expanded only slightly and did not relieve serious unemployment.

If average rates of growth over a long period, say 1938–60 for example, are examined, it is found that the figures differ considerably from those for the shorter postwar intervals. Indeed, one is left by the long-term data with a quite conservative impression of the progress made by some countries, both separately and as a group.

The contrast between growth rates over the long term and the short term reflects the impact of war and the efforts to recover from it. Japan and Austria are excellent illustrations. The high rates of increase in productivity realized by Japan and Austria in the postwar period did little more, by 1960, than restore those economies to their prewar levels. Much the same could be said of West Germany and of Britain, though in the latter case the gap between long-term and short-term growth rates is more modest. Other west European countries—France and Italy, for example—had by 1960 surpassed their 1938 levels by more substantial margins, though these economies also were obliged to devote a major fraction of their energies to overcoming wartime arrears. This also applies to the east European countries, the Soviet Union, Poland, and Czechoslovakia. The U.S. registered an average advance in excess of 2 percent from 1938 to 1960. A notable feature of the U.S. trend, in contrast with trends for most other countries, was its stability. Gains in the 1948–60 period were appreciably greater than those for the longer interval, but, comparatively speaking, the gap was small. The comparative closeness of long-term and short-term rates for the U.S. reflects its good fortune in escaping the physical destruction and economic disorganization of war suffered by other countries.

NATIONAL LEVELS OF PRODUCTIVITY

It is sometimes useful to compare the levels of productivity of different countries at the same period of time. Table 2 makes such a comparison, based on estimates of output per worker and per capita for 16 countries. The fact that some of the figures are for 1950 rather than a more recent year is of minor importance because overall data of the kind given tend to change only slowly. Neglecting small intercountry differences, the basic impressions conveyed by the table were doubtless still valid in the early 1960s. Yet it must be stressed that the figures are to be treated as only rough approximations.

Various countries compared

The general level of productivity in the United States is by a wide margin the highest of those shown, and a more comprehensive listing of countries would not alter its position. New Zealand and Canada are not far behind the United States, but the gap between them and the others is fairly wide. Australia, Sweden, and Denmark bracket the high side of what might be called a middle productivity

Table 2: Comparison **of Levels** of Output, About 1960*
(in both columns the figure 100 represents U.S. output)

country	real output per worker	real output per capita
Argentina	35†	27
Australia	62†	72
Brazil	21†	20
Canada	92†	74
Chile	29†	24
Denmark	62	62
France	52	52
Germany, West	46	51
Great Britain	50	58
Ireland	36	39
Italy	37	29
Japan	31	27
New Zealand	88†	90†
Soviet Union	25†	25†
Sweden	57†	65
United States	100	100

*A country's output per capita, relative to that in the U.S., exceeds its output per worker, relative to that in the U.S., if the fraction of its population in the employed labour force is greater than the corresponding fraction in the U.S. † About 1950 rather than 1960.

Sources: Data developed from Colin Clark, ***The Conditions of Economic Progress,*** 3rd ed. (1957); ***Statistical Yearbook*** (United Nations); ***Yearbook of Labour Statistics***, International Labour Organization; ***Economic Survey of Denmark,*** Secretariat of the Government of Denmark; ***Survey of Current Business,*** United States Department of Commerce; ***United States Income and Output***, United States Department of Commerce.

range, while Britain, France, and—with allowance for incomplete postwar recovery—West Germany fall on the lower half of this range. The remaining countries, with productivity levels of between one-third and one-fifth that in the U.S., are located still lower on the scale. A large group of excluded countries, belonging in the underdeveloped class, would occupy still lower positions. This group would embrace the bulk of the peoples in Africa, Asia, the Middle East, and South America. It is well to keep in mind that these people comprise a majority of the world's total population and, accordingly, that the average productivity level for the world as a whole is, by Western standards, very low.

Differences among countries in the relation between the output per worker and output per capita figures are attributable to differences among countries in the percentage of the total population at work. If the proportion of those seeking and finding gainful employment was the same in all countries, the relation between each pair of figures in Table 2 would be the same. One might expect that with higher output and income levels there would be a tendency for the percentage of the population seeking work to decline. Entrance into the labour force would be delayed by longer schooling, and fewer family members would be obliged to work in order to maintain any given income level. Table 2 suggests a relationship of this sort, though it is not a strong one. It may be that the tendency in this direction is stronger than appears but that it is offset by the more abundant and attractive occupational opportunities existing in countries with high incomes. In any case, the differences that exist between the two series are not large and do not alter the overall intercountry pattern. The close correspondence between them affirms the overriding importance of productivity levels for living standards.

The reasons for differences. At least two broad approaches can be taken in seeking to explain such productivity differences as are found in Table 2. One of these may be termed cross-sectional. It seeks to identify the chief factors associated with the observed differences and to ascertain their relative importance. Measurement and analysis of the degree of association between intercountry differences in output per worker and corresponding differences in, say, size of plant is an example of this approach. It does not of itself tell the direction of cause and effect between two variables nor even that a causal relationship is present. Neither does it say anything about the time trend of the relationship—whether it has always existed, whether its form has changed over the years, or why it may have changed. Nonetheless, the approach is helpful in suggesting which factors may contribute significantly to productivity differences.

The other approach might be called developmental, since it involves an assessment of the process of economic change as it affects productivity levels. It goes beyond the cross-sectional approach in that it endeavours to explain how certain causal factors came to be important and how they have interacted with other factors to cause shifts in labour productivity over time. Necessarily in this approach there arises a question as to where and how to apportion responsibility for change. The answers supplied by economists have varied. The English economist T.R. Malthus (1803) selected population growth as his key variable. The Austrian J.A. Schumpeter (1912) emphasized the role of entrepreneurship in a country's development. In much contemporary literature, whether concerned with industrialized or underdeveloped countries, the process of capital accumulation is regarded as of overriding importance. Despite their differences, all of these treatments may be characterized as developmental since they give attention to the movement and influence of particular factors over time.

The two approaches are complementary. While useful hypotheses might be built wholly from one or the other, the value of each is enhanced by their joint use. The cross-sectional approach, in identifying factors of probable significance, facilitates the application of the developmental or historical approach. At the same time, the latter helps to amplify the meaning and significance of the factors found to be associated with productivity differences.

Needless to say, each country's current circumstances and development, as these bear on productivity levels, possess unique characteristics. For this reason no single, simple hypothesis, whether rooted in one approach or in a combination of approaches, is likely to go very far in accounting for the wide range of differences in Table 2. One probably valid generalization does however seem worth making. Differences in growth rates are essential to an understanding of most large productivity differences among countries. Almost without exception, the countries with high productivity are those that have succeeded in mastering improved technology; with the aid of capital accumulation they have diffused this mastery through the several sectors of the economy and have continuously improved it. Only by continued productivity advances over a fairly long period is it possible for a country to achieve such levels as prevail among the high-income countries.

PROBLEMS OF PRODUCTIVITY MEASUREMENT

Complexi of the dat:

Many difficulties, both theoretical and practical, attend the development of productivity statistics.

Heterogeneity. A wide variety of inputs and outputs go to make up the productivity ratio. Ordinarily such ratios are computed not for a single, homogeneous type of output but for product categories that embrace a host of subproducts. Thus the output of the steel industry consists of sheets, wire, rods, structural shapes of various kinds, and a great many other items. Computation of satisfactory productivity data for an industry usually requires, therefore, that account be taken of the diversity of output and its changing composition. This can and often is done by weighing the subproducts in accord with their relative values and then adding them together. Unfortunately, however, relative values change over time, raising the question of what weights to use. Should they be initial year weights or terminal year weights or some combination of the two? The question is not academic, since different weights sometimes produce significantly different amounts of change between the initial and the terminal years. A parallel problem arises on the input side. Strictly speaking, the labour force is not homogeneous. It is made up of a range of skills and specialties that embody varying amounts of education and training, and it is reasonable to suppose that their contributions to the production process vary accordingly.

Incommensurability. Labour inputs are relatively easy to measure, particularly if one is content simply to count heads. But if one wishes to take account of differences in the quality and intensity of labour inputs, the question of measurement immediately arises. At what rate should one type of labour be converted into another? Wage rates often are used for the purpose, not because of a belief that they are correct but because they are the most readily available yardstick.

Measurement problems are equally difficult in connection with capital inputs. Plant and equipment lose their value gradually over time, and in any one year contribute but a part of this value in production. There is no universally acceptable procedure for measuring this contribution. There exist a few recognized accounting practices, but no one of them is recognized as superior to the others. It probably is true that no one procedure is best in all situations but that each has unique advantages for certain applications. Measurement is further complicated by the diverse composition of capital that rules out the sort of headcounting that can be done with labour inputs.

Moreover, the composition of capital changes over time with the result that the kinds of machines and facilities used in one year may differ markedly from those employed a generation earlier. Any one of these circumstances would alone suffice to make measurement difficult.

For some factors of production, such as organization or managerial ability, there seems to be no acceptable method of measurement. The quality and very likely the quantity of each has changed greatly over the years, and their importance relative to other inputs has changed. But no reasonably rigorous means for evaluating these changes is available.

On the output side, measurement difficulties are especially apparent with regard to services. In contrast to commodity outputs, which are tangible and divisible into identifiable units, some service outputs are very difficult to define and measure satisfactorily. In concrete terms, what is the output of an enterprise engaged in business consulting? Of an organization dispensing banking services? Of a government agency exercising regulatory functions? More is involved here than the fact that each of these activities embraces a mixture of distinguishable services. The main trouble is the lack of any acceptable standard by which to measure such outputs.

This problem is not unique to service outputs, but it shows itself most clearly in that sphere. Lacking a suitable direct measure of service outputs the student will often use inputs (numbers of workers) as a substitute measure, the assumption being that inputs and outputs are equal or will move together over time. Whatever its merits for gauging output, this method is unsuited to measuring productivity. For the validity of a measure of productivity depends on a clear separation of outputs from inputs. Considering the nature of the problems, it is not surprising that the bulk of available productivity information relates to commodity production.

Lack of information. Censuses of production and population, national income statistics and their components; series regularly published on industrial and farm output, on wages, hours, and the labour force; and data provided by regulatory and other government agencies are among the basic source materials. The scope and quality of these materials vary widely among countries and tend to be more comprehensive and reliable in the more advanced, industrialized countries. With few exceptions, unfortunately, such data are not collected for the purpose of providing information on productivity. Special studies often must be undertaken either to supplement what information is available or, for certain input–output areas, to obtain any data at all. Even where information for recent periods of time is extensive the researcher may find it difficult to prepare productivity tables that extend back very many years, and for no country can knowledge of productivity trends in the 19th century be described as better than meagre. The situation for many underdeveloped countries is even less satisfactory.

A miscellany of other difficulties affect productivity measurement. One is the problem of choosing a time period over which to measure changes in productivity. Another involves the inputs of the productivity ratio. If the input is labour, should it cover all employees or only production workers? Should it be on a man-hour or a man-year basis? Yet another problem is the content of the output category and the breadth or narrowness with which it is defined. Decisions on these problems, which are both theoretically sound and practical, are often very hard to reach.

BIBLIOGRAPHY. General works dealing with productivity and its measurement include: SOLOMON FABRICANT, ***Basic Facts on Productivity Change*** (1959); JEAN FOURASTIE, ***La Producfivith,*** 5th ed. (1962); GERHART E. REUSS, ***Produktivitatsanalyse: Ökonomische Grundlagen und statistische Methodik (1960);*** UNITED STATES BUREAU OF LABOR STATISTICS, ***Productivity: A Bibliography*** (1966); and the UNITED STATES CONGRESS, JOINT ECONOMIC COMMITTEE, ***Productivity, Prices, and Incomes*** (1967). Some of the earliest work in the measurement of productivity was done in the United States. A pioneering study was SOLOMON FABRICANT, ***Employment*** in ***Manufacturing, 1899–1939: An Analysis of Its Relation to the Volzime of Production*** (1942). Other studies using U.S. data are EDWARD F. DENISON, ***The Sources of Economic Growth in the United States and the Alternatives Before Us*** (1962); and JOHN W. KENDRICK, ***Productivity Trends in the United States*** (1961). For productivity trends in various countries, see ABRAM BERGSON and SIMON KUZNETS (eds.), ***Economic Trends in the Soviet Union*** (1963); COLIN CLARK, The ***Conditions of Economic Progress,*** 3rd ed. (1957); EVSEY D. DOMAR ***et al.,*** "Economic Growth and Productivity in the United States, Canada, United Kingdom, Germany and Japan in the Post-War Period," ***Review of Economics and Statistics,*** 46:33–40 (1964); ANGUS MADDISON, ***Economic Growth in the West: Comparative Experience in Europe and North America*** (1964). The relation of productivity to technoloey is examined in W.E.G. SALTER, ***Productivity and Technical Change,*** 2nd ed. (1969).

(Ma.F.)

Prokofiev, Sergey

The range and imagination of the huge musical legacy of the Russian composer Sergey Prokofiev make clear his central role in enriching the structure and the expressiveness of Western music in the first half of the 20th century. His more than 135 works include works of almost every musical genre, from children's songs to oratorios, with contributions that were especially important in the development of opera and ballet, in which he was an audacious reformer, and nearly as important in symphonic and piano music. These works reflect not only the distinct musical traditions of the 19th-century Russian masters and of the innovators of 20th-century music but also the social upheavals of a half-century that embraced cataclysmic revolutions and two world wars.

Sovfoto

Prokofiev.

Pre-Revolutionary period. Sergey Sergeyevich Prokofiev (Prokofjev in the transliteration system of the Akademiya Nauk of the Soviet Union) was born on April 23, 1891, in the village of Sontsovka in Ekaterinoslav province (now Donets region) into a family of agriculturalists. Village life, with its peasant songs, left a permanent imprint on him. His mother, a good pianist, became the highly gifted child's first mentor in music; and at the age of five he composed his first little piece for piano, "Indian Gallop," which was carefully written down by his mother. Later, there appeared a whole series of "little pieces" for piano and the first naïve attempts at composing an opera, under the influence of those he had seen on a trip to Moscow. A high evaluation was put upon the boy's talent by a Moscow composer and teacher, Sergey Taneyev, on whose recommendation the Russian composer Reinhold Glier twice went to Sontsovka in the summer months to become young Sergey's first teacher in theory and composition and to prepare him for entrance into the conservatory at St. Petersburg (later Petrograd, now Leningrad), Russia's foremost conservatory. The years Prokofiev spent there—1904 to 1914—were a period of swift creative growth. His teachers, who were struck by the originality of his musical thinking, included such composers as Nikolay Rimski-Korsakov, Anatoly Lyadov, and Nikolay Tcherepnin. When he graduated in 1914 he was awarded the Anton Rubinstein Prize in piano for a brilliant performance of his own first large-scale work—the *Piano Concerto No. I in D Flat Major,* Opus 10.

The conservatory gave Prokofiev a firm foundation in the academic fundamentals of music, but he avidly sought musical novelty, studying the works of such innovative confemporaries as the French composers Claude Debussy and Maurice Ravel, the Germans Richard Strauss and Max Reger, and a fellow Russian, Aleksandr Scriabin. His enthusiasms were supported by progressive circles advocating musical renewal. Prokofiev's first public appearance as a pianist took place before such a group in St. Petersburg in 1908. A little later he met with friendly sympathy in a similar circle in Moscow, which helped him make his first appearances as a composer, at the Moscow summer symphony seasons of 1911 and 1912. The Moscow journal *Muzyka* expressed immediate enthusiasm for his work.

Debuts as pianist and composer

Prokofiev's talent developed rapidly as he applied many new musical ideas. Unlike others who were similarly disenchanted with late Romanticism and Russian academicism, he did not become a follower of either the ecstatic symbolism of Scriabin or the Impressionism of Debussy. Instead, he studied the compositions of Igor Stravinsky, particularly the early ballets, but maintained a critical attitude toward his countryman's brilliant innovations.

Contacts with the then new currents in theatre, poetry, and painting also played an important role in Prokofiev's development. He was attracted by the work of modernist Russian poets; by the painting of the Russian followers of Cézanne and Picasso; and by the theatrical ideas of Vsevolod Meyerhold, whose experimental productions were directed against an obsolescent naturalism. In 1914 Prokofiev became acquainted with the great ballet impressario Sergey Diaghilev, who commissioned a ballet from him and became one of his most influential advisors for the next decade and a half.

After the death of his father in 1910, Prokofiev lived under more straitened material conditions, though his mother provided for his continuing studies. On the eve of World War I, he visited London and Paris to acquaint himself with the newest in art. The tense pre-storm atmosphere that pervaded Russia sharpened in him a feeling of skepticism, of disbelief in romantic ideals, but did not shake his essentially healthy outlook on life. Exempt from war mobilization as the only son of a widow, Prokofiev continued to perfect his musicianship on the organ and appeared in concerts in the capital and elsewhere. His youthful and mischievous music disturbed academicians and aesthetes but won the support of his most perspicacious contemporaries, including the authors Maksim Gorky and Vladimir Mayakovsky. Concert agencies began to organize his sensational composer's recitals. The pre-Revolutionary period of Prokofiev's work was marked by intense exploration. The harmonic thought and design of his work grew more and more complicated. Prokofiev wrote the ballet *Ala and Lolli* (1914), on themes of ancient Slav mythology, for Diaghilev, who rejected it. Thereupon, Prokofiev reworked the music into the *Scytlzian Suite,* Opus 20, for orchestra. Its premiere in 1916 caused a scandal but was the culmination of his career in Petrograd. The ballet *The Tale of the Buffoon Who Outjested Seven Buffoons* (1915; *The Buffoon,* 1915), also commissioned by Diaghilev, was based on a folktale; it served as a stimulus for Prokofiev's searching experiments in the renewal of Russian music. Despite Diaghilev's assertion of the priority of ballet over opera, which he considered a dying genre, Prokofiev was active in the field of opera. Following the immature *Maddalena,* which he wrote in 1911–13, he composed in 1915–16 *The Gambler,* a brilliant and dynamic adaptation of the story by Dostoyevsky. Continuing the operatic tradition of Mussorgsky, Prokofiev skillfully combined subtle lyricism, satiric malice, narrative precision, and dramatic impact. During this period, Prokofiev achieved great recognition for his first two piano concertos—the first the one-movement *Concerto in D Flat Major* (1911), and the second the dramatic four-movement *Concerto in G Minor* (1913).

Ballets for Diaghilev

The year 1917—the year of two Russian revolutions—was astonishingly productive for Prokofiev. When the Tsar was overthrown in February 1917 he was in the streets of Petrograd, expressing the joy of victory. Perhaps as if inspired by feelings of social renewal, he wrote within one year an immense quantity of new music: two sonatas, the *Violin Concerto No. I in D Major,* the *Classical Symphony,* and the choral work *Seven, They are Seven;* he began the magnificent *Piano Concerto No. 3 in C Major,* Opus 26, and planned a new opera—*The Love for Three Oranges,* after a comedy tale by the Italian dramatist Carlo Gozzi. In the summer of 1917 Prokofiev was included in the Council of Workers in the Arts, which led Russia's left wing of artistic activity; but for almost nine months he was stranded in the Caucasus, cut off from Petrograd by the civil war. Only in the spring of 1918 did he succeed in returning there. In the difficult circumstances of these years, however, he concluded that music had no place and decided to leave Russia temporarily to undertake a concert tour abroad. Prokofiev travelled, with official sanction, over the difficult route through Siberia, where civil strife was raging.

Effects of the 1917 revolutions

Foreign period. The next decade and a half are commonly called the "foreign period" of Prokofiev's work. For a number of reasons, chiefly the continued blockade of the Soviet Union, he could not return at once to his homeland. Nevertheless, he did not lose touch with Russia.

The first five years of Prokofiev's life abroad are usually characterized as the "years of wandering." On the way from Vladivostok to San Francisco, in the summer of 1918, he gave several concerts in Tokyo and Yokohama. In New York City the sensational piano recitals of the "Bolshevik Pianist" evoked both delight and denunciation. The composer had entrée to the Chicago Opera Association, where he was given a commission for a comic opera. The conductor and the producer of the opera, both Italian, gladly backed the idea of an opera on the Gozzi plot. Accordingly, *The Love for Three Oranges* was completed in 1919, though it was not produced until 1921. Within a few years the opera was also produced with immense success on the stages of the U.S.S.R. as well as in western Europe.

In America, Prokofiev met a young singer of Spanish extraction, Lina Llubera, who eventually became his first wife and the mother of two of his sons, Svyatoslav and Oleg.

Not meeting with continuing support in the United States, the composer set out in the spring of 1920 for Paris for meetings with Diaghilev and the conductor Serge Koussevitzky. They soon secured for him wide recognition in the most important west European musical centres. The production of *The Buffoon* by Diaghilev's ballet troupe in Paris and London in 1921 and the Paris premiere of the *Scythian Suite* in 1921 and that of *Seven, They Are Seven* in 1924 evoked enormous interest, consolidating his reputation as a brilliant innovator. The successful performance of the *Third Piano Concerto* (1921), completed in France, also marked one of the peaks of Prokofiev's dynamic national style.

Triumph in Paris

Prokofiev spent more than a year and a half in 1922–23 in southern Germany, in the town of Ettal in 'the

Bavarian Alps. Resting after fatiguing premieres and reviewing the course of his creative path, he also prepared many of his compositions for the printer. The attention of the composer at this period turned to the basic conception of the opera *The Flaming Angel,* after a story by the contemporary Russian author Valery Bryusov, depicting the savage "witch trials" of 16th-century Germany. In complete contrast to the witty eccentricity of the Gozzi story, he now selected a story of great human passions expressed in realistic drama. The opera, which required many years of work (1919–27), did not find a producer within Prokofiev's lifetime.

Meanwhile, Prokofiev, finding himself not interested in the musical activity in Germany, settled in Paris in the autumn of 1923. There he was in close touch with progressive French musical figures, such as the composers Francis Poulenc and Arthur Honegger, while continuing his own intensive creative activity. Vexed by criticisms of his melodically lucid *First Violin Concerto,* which had its premiere in Paris in 1923, he addressed himself to a search for more avant-garde style. These tendencies appeared in such compositions of the early 1920s as the epic *Symphony No. 2 in D Minor,* Opus 40, commissioned by Koussevitzky. Its intense dramatic quality and its striking sense of proportion are also found in the *Symphony No. 3 in C Minor* (1928), based on thematic material from the opera *The Flaming Angel,* reworked by the composer. In close collaboration with Diaghilev, Prokofiev created new one-act ballets, *Le Pas d'acier* (performed in 1927) and *The Prodigal Son* (performed in 1929). *Le Pas d'acier* had a sensational success in Paris and London, thanks to its original staging and bold evocation of images of Soviet Russia at the beginning of the 1920s—with its economic dislocation and the beginnings of industrialization. *The Prodigal Son* had a lofty biblical theme and music that was exquisitely lyrical. It reflects a striving toward emotional relaxation and toward clarification of style that are also seen in the *String Quartet No. I in B Minor,* Opus 50, in the *Sonata for Two Violins in C Major,* Opus 56 (1932), and in the ballet *On the Dnieper.*

In 1927 Prokofiev toured the U.S.S.R. and was rapturously received bv the Soviet public as a world-renowned Russian musician-revolutionary. While there, he strengthened his old associations with the innovative theatrical producer Vsevolod Meyerhold, who helped him in a basic revision of the opera *The Gambler,* produced in 1929 in Brussels.

During the 1920s and early 1930s, Prokofiev toured with immense success as a pianist in the great musical centres of western Europe and the United States. His U.S. tours in 1925, 1930, and 1933 were attended with tumultuous success and brought him new commissions, such as the *Symphony No.* 4 *in C Major,* Opus 47 (1930), incorporating musical material of *The Prodigal* Son, for the 50th anniversary of the Boston Symphony, and the *First String Quartet,* commissioned for the Library of Congress. His new piano concertos—No. 4, Opus 53 (1931), for the left hand, and *No.* 5 *in* G *Major,* Opus 55 (1932)—demonstrated anew his bent for impulsiveness and virtuoso brilliance.

Soviet period. Although he enjoyed material well-being, success with the public, and contact with outstanding figures of Western culture, such as Stravinsky, Chaplin, and Picasso, Prokofiev increasingly missed his homeland. Visits to the U.S.S.R. in 1927, 1929, and 1932 led him to the decision to conclude his foreign obligations and return to Moscow once and for all. From 1933 to 1935 the composer gradually accustomed himself to the new conditions and became one of the leading figures of Soviet culture. He established close connections with theatres and cinema studios and received interesting commissions, while not abandoning concert tours abroad until 1938. He valued the opportunity for contact and collaboration with eminent figures in Soviet art—the film maker Sergey Eisenstein, the ballerina Galina Ulanova, the pianist Svyatoslav Richter, the writers Ilya Ehrenburg and Aleksey Tolstoy, and others.

In the two decades constituting the "Soviet period" of Prokofiev's work—1933 to 1953—the realistic and epical traits of his art became more clearly defined. The synthesis of traditional tonal and melodic means with the stylistic innovations of 20th-century music was more fully worked out.

In the years preceding World War II, Prokofiev created a number of classical masterpieces. These included his *Violin Concerto No. 2 in* G *Minor,* Opus 63 (1935), the ballet *Romeo and Juliet* (1935–36), and the music for Eisenstein's film *Alexander Nevsky* (1938). His work in theatre and the cinema gave rise to a number of charming programmatic suites, such as the *Lieutenant Kije* suite (1934), the *Egyptian Nights* suite (1934), and the symphonic children's tale *Peter and the Wolf* (1936). Turning to opera, he cast in the form of a contemporary drama of folk life his *Semyon Kotko,* depicting events of the civil war in the Ukraine (1939). The basis of the brilliantly modernized opéra bouffe the *Betrothal in a Monastery* (composed in 1940, produced in 1946) was the play *The Duenna,* by the 18th-century British dramatist Richard Brinsley Sheridan. Testing his powers in other genres, he composed the monumental *Cantata for the 20th Anniversary of the October Revolution* (1937), on texts by Lenin, and the epic cantata *The Toast* (1939).

On his last trip abroad, Prokofiev visited Hollywood, where he studied the technical problems of the sound film; the experience thus gained he applied brilliantly in the striking national music for Eisenstein's film *Alexander Nevsky* (1938), depicting the heroic Russian struggle against the Teutonic Knights of the 13th century. The cantata *Alexander Nevsky* was based on the music of the film. One of the summits of Prokofiev's art was the production of his ballet *Romeo and Juliet* in Leningrad, with Ulanova in the leading role. Throughout the 1930s Prokofiev took part in the organizational work of the Composers' Union, made appearances as conductor and as pianist, and travelled much throughout the country.

The war
years

On the eve of World War II, a change occurred in his personal life: leaving his first family, he linked his destiny with that of the poet Mira Mendelssohn, who became his second wife.

The war sharpened Prokofiev's national and patriotic feelings. Regardless of the difficulties of the war years, he composed with remarkable assiduity, even when the evacuation of Moscow in 1941 made it necessary for him and his wife to move from one place to another until they were able to return in 1944.

From the first days of the war, the composer's attention was centred on a very large-scale operatic project: an opera based on Tolstoy's novel *War and Peace.* He was fascinated by the parallels between 1812, when Russia crushed Napoleon's invasion, and the then current situation. The first version of the opera was completed by the summer of 1942, but subsequently the work was fundamentally revised, a task that occupied more than ten years of intensive work. Those who heard it were struck both by the immense scale of the opera (13 scenes, more than 60 characters) and by its unique blend of epic narrative with lyrical scenes depicting the personal destinies of the major characters. An increasing predilection for national-epical imagery is manifested in the heroic majesty of the *Symphony No.* 5 *in B Flat Major,* Opus 100 (1944), and in the music (composed, 1942–45) for Eisenstein's two-part film *Ivan the Terrible* (Part I, 1944; Part II, 1948). Living in the Caucasus, in Central Asia, in the Urals, the composer was everywhere interested in the folklore, an interest reflected in the *String Quartet No. 2 in F Major,* Opus 92, on Kabardinian and Balkarian themes (1941); and in the comic opera *Khan Buzai,* on themes of Kazakh folktales. Documents of those troubled days are three piano sonatas, *No. 6,* Opus 82 (1940), *No.* 7, Opus 83 (1942), and *No.* 8, Opus 84 (1944), which are striking in the dramatic conflict of their images and their irrepressible dynamism. Critics saw in the intense climaxes of the *Seventh Sonata* and the *Fifth Symphony* the spirit of Russia courageously repelling the Nazi assault. Prokofiev spent the summers of 1944 and 1945 near Ivanovo, at a former state poultry farm placed at the disposal of composers during the war; there he worked in close association with Nikolay Myaskovsky, Dmitry Shostakovich, Aram Khachaturian, Dmitry Kabalevsky, and others.

Illness and reproach

Overwork was fatal to the composer's health: in 1945 he became afflicted with a severe form of high blood pressure. In the following years, the illness continually worsened. His doctors strictly limited his work schedule. They even forbade him his favourite diversions—playing chess and driving a car. Nevertheless, the last eight years of his life were, like the preceding ones, filled with work, which continued despite the strong criticism that was directed at some of his compositions in the late 1940s. Unfounded accusations appeared in the press against Prokofiev's work; they were instigated by supporters of formalism and decadent complexity. A decade later, however, these charges were officially repudiated by the Central Committee of the Communist Party.

During the last years of his life, Prokofiev seldom left his villa in a suburb of Moscow. His propensity for innovation, however, is still evident in such important works as the *Symphony No. 6 in E Flat Minor,* Opus 111 (1945–47), which is laden with reminiscence of the tragedies of the war just past; the *Sinfonia Concerto for Cello and Orchestra in E Minor,* Opus 125 (1950–52), composed with consultation from Mstislav Rostropovich; and the *Violin Sonata in F Minor,* Opus 80 (1938–46), dedicated to David Oistrakh, which is in Russian folk imagery. Just as in earlier years, the composer devoted the lion's share of his energy to musical theatre: cases in point were the opera *The Story of a Real Man* (1947–48), the ballet *The Stone Flower* (1948–50), and the oratorio *On Guard for Peace* (1950), which was performed by a mixed chorus and soloists. In these years Prokofiev reworked some of his earlier compositions and created fundamentally new versions of the *Fourth Symphony* (1947) and the *Piano Sonata No. 5 in C Major,* Opus 135 (1952–53). The lyrical *Symphony No. 7 in C Sharp Minor,* Opus 131 (1951–52) was the composer's swan song.

Works left incomplete

On March 5, 1953, Prokofiev died suddenly of cerebral hemorrhage. On his worktable there remained a pile of unfinished compositions, including sketches for a 6th concerto for two pianos, a 10th and an 11th piano sonata, a Kazakh comic opera, and a solo violoncello sonata. The subsequent years saw a rapid growth of his popularity in the Soviet Union and abroad. In 1957 he was posthumously awarded the Soviet Union's highest honour, the Lenin Prize, for the *Seventh Symphony.*

MAJOR WORKS

Orchestral music

SYMPHONIES: *No. 1 in D Major (Classical Symphony),* op. 25 (1916–17); *No. 2 in D Minor,* op. 40 (1924); *No. 3 in C Minor,* op. 44 (1928); *No. 4 in C Major,* op. 47 (1930); *No. 4 in C Major,* op. 112 (1947, revision); *No. 5 in B Flat Major,* op. 100 (1944); *No. 6 in E Flat Minor,* op. 111 (1945–47); *No. 7 in C Sharp Minor,* op. 131 (1951–52).

CONCERTOS: Nine concertos, including *First Piano Concerto in D Flat Major,* op. 10 (1911); *Third Piano Concerto in C Major,* op. 26 (1917–21); *First Violin Concerto in D Major,* op. 19 (1916–17); *Second Violin Concerto in G Minor,* op. 63 (1935); *Cello Concerto in E Minor,* op. 58 (1935–38); *Sinfonia Concerto for Cello and Orchestra in E Minor,* op. 125 (1950–52).

BALLETS: *The Buffoon,*op. 21 (1915, ballet; 1922, symphonic suite); *Le Pas d'acier,* op. 41 (1925); *The Prodigal Son,* op. 46 (1928, ballet; 1929, symphonic suite); *Romeo and Juliet,* op. 64 (1935–36, ballet and suites); *Cinderella,* op. 87 (1940–44); *The Stone Flower* (1948–50, ballet and suites).

OTHER ORCHESTRAL WORKS: *Scythian Suite,* op. 20 (1914–15); *Lieutenant Kije,* op. 60 (1934, suite); *Egyptian Nights,* op. 61 (1934, suite); *Russian Overture,* op. 72 (1936).

Chamber music

Two quartets, a quintet for wind instruments, an Overture-sextet on Jewish themes, a violin sonata, and two sonatas for violin and piano.

Piano works

Numerous compositions for piano, including ten sonatas; *Ten Pieces for Piano,* op. 12 (1906–13); *Sarcasms,* op. 17 (1912–14, five pieces for piano); *Visions Fugitive,* op. 22 (1915–17, 20 pieces for piano); *Tales of the Old Grandmother,* op. 31 (1918, four pieces for piano).

Vocal works

OPERAS: *The Gambler,* op. 24 (1915–16, rev. 1927); *The Love for Three Oranges,* op. 33 (1919); *The Flaming Angel,* op. 37 (1919–27); *Semyon Kotko,* op. 81 (1939); *War and Peace,* op. 91 (1941–52); *Betrothal in a Monastery (The Duenna),* op. 86 (1940); *The Story of a Real Man* (1947–48).

CANTATAS: *Seven, They Are Seven,* op. 30 (1917–18); *Cantata for the 20th Anniversary of the October Revolution,* op. 74 (1937); *Alexander Nevsky,* op. 78 (1938–39); *Zdravitsa* (earlier called *Toast*), op. 85 (1939).

OTHER WORKS FOR VOICE AND ORCHESTRA: *Peter and the Wolf,* op. 67 (1936, symphonic tale); *Winter Bonfire,* op. 122 (1949, suite for narrator, children's choir, and orchestra): *On Guard for Peace,* op. 124 (1950, oratorio).

SONGS: About 60 songs and romances, including "The Ugly Duckling," op. 18 (1914); 12 arrangements of Russian folk songs for voice and piano, 2 vol., op. 104 (1944).

BIBLIOGRAPHY. Two of the most important sources of information are the documentary collections S. *Prokofiev: Autobiography, Articles, Reminiscences,* ed. by S. SHLIFSTEIN (1960; orig. pub. in Russian, 1956; 2nd ed., 1961), and a larger collection of the composer's memoirs, *Prokofiev by Prokofiev* (1979; edited by David H. Appel from the original compilation edited by M. Kozlova). Although in the years since the death of the composer an extensive musicological literature concerning him has appeared, very little has been published in English. ISRAEL NESTYEV, *Prokofiev* (1960; orig. pub, in Russian, 1957; new ed., 1973), is the first serious work to systematically study the man and his music. A popular biographical and critical study is R. HOFMANN. *Serge Prokofiev: l'homme et son oeuvre* (1964).

In Russian, the following analytical studies are recommended: СЕРГЕЙ М. СЛОНИМСКИЙ, *Симфонии Прокофьева. Опыт 'исследования* (1964), on the symphonies; МАРИНА Д. САБИНИНА, *«Семен Котко» и проблемы оперной драматургии Прокофьева* (1963), on the dramaturgy of the operas; and В.Н. ХОЛОПОВА and Ю.Н. ХОЛОПОВ, *Фортепьянные сонаты С.С. Прокофьева* (1961), on the contemporary characteristics of Prokofiev's harmony.

(I.V.N.)

Propaganda

Propaganda is the more or less systematic effort to manipulate other people's beliefs, attitudes, or actions by means of symbols (words, gestures, banners, monuments, music, clothing, insignia, hairstyles, designs on coins and postage stamps, and so forth). Deliberateness and a relatively heavy emphasis on manipulation distinguish propaganda from casual conversation or the free and easy exchange of ideas. The propagandist has a specified goal or set of goals. To achieve these he deliberately selects facts, arguments, and displays of symbols and presents them in ways he thinks will have the most effect. To maximize effect, he may omit pertinent facts, and he may try to divert the attention of the reactors (the people whom he is trying to sway) from everything but his own propaganda.

Propaganda distinguished from education

Comparatively deliberate selectivity and manipulation also distinguish propaganda from education. The educator tries to present various sides of an issue—the grounds for doubting as well as the grounds for believing the statements he makes, and the disadvantages as well as the advantages of every conceivable course of action. Education aims to induce the reactor to collect and evaluate evidence for himself and assists him in learning the techniques for doing so. It must be noted, however, that a given propagandist may look upon himself as an educator, may believe that he is uttering the purest truth, that he is emphasizing or distorting certain aspects of the truth only to make a valid message more persuasive, and that the courses of action that he recommends are in fact the best actions that the reactor could take. By the same token, the reactor who regards the propagandist's message as self-evident truth may think of it as educational; this often seems to be the case with "true believers"—dogmatic reactors to dogmatic religious or social propaganda. "Education" for one person may be "propaganda" for another.

PROPAGANDA AND RELATED CONCEPTS

Connotations of the term propaganda. The word propaganda itself, as used in recent centuries, apparently derives from the title and work of the Congregatio de Propaganda Fide (Congregation for Propagation of the Faith), an organization of Roman Catholic cardinals founded in 1622 to carry on missionary work. To many Roman Catholics the word may therefore have, at least in missionary or ecclesiastical terms, a highly respectable connotation. But even to these persons. and certainly to many others. the term is often a dirty one tending to connote such things as the discredited atrocity stories and deceptively stated war aims of World Wars I and II, the operations of the Nazis' Ministry of Public Enlightenment and Propaganda, and the broken campaign promises of a thousand politicians. Also, it is reminiscent of countless instances of false and misleading advertising (especially in countries using Latin languages, in which *piopagande commerciale* or some equivalent is a common term for commercial advertising).

Agitprop: agitation and propaganda

To informed students of Communism, the term propaganda has yet another connotation, associated with the term agitation. The two terms were first used by the Marxist Ceotgy Plekhanov and later elaborated upon by Lenin in a pamphlet *What* Is *To Be Done?* (1902), in which he defined "propaganda" as the reasoned use of historical and scientific arguments to indoctrinate the educated and enlightened (the attentive and informed publics, in the language of today's social sciences); he defined "agitation" as the use of slogans, parables, and half-truths to exploit the grievances of the uneducated and the unreasonable. Since he regarded both strategies as absolutely essential to political victory, he twinned them in the term agitprop. Today every unit of a Communist party must have an agitprop section, and to the Communist, the use of propaganda in Lenin's sense is commendable and honest. Thus, a standard Soviet manual for teachers of social sciences is entitled *Propagandistu politekonoinii (For the Propagandist of Political Economy)*, and a pocket-sized booklet issued weekly to suggest timely slogans and brief arguments to be used in speeches and conversations among the masses is called *Bloknot agitatora* (*The Agitator's Notebook).*

Related terms. Related to the word propaganda, as it is more generally used, is the concept of "propaganda of the deed." This denotes taking nonsymbolic action (such as economic or coercive action), not for its economic or coercive effects but for its possible propagandistic effects. Examples of propaganda of the deed would include staging an atomic "test" or the public torture of a criminal for its presumable deterrent effect on others, or giving foreign "economic aid" primarily to influence the recipient's opinions or actions and without much intention of building up the recipient's economy.

Distinctions are sometimes made between overt propaganda, in which the propagandist and perhaps his backers are made known to the reactor, and covert propaganda, in which the source is secret or disguised—a "hidden persuader." Covert propaganda might include such things as unsigned political advertisements, clandestine radio stations using false names, and statements by editors, politicians, or others who have been secretly bribed by governments, political backers, or business firms. Sophisticated diplomatic negotiation, legal argument, collective bargaining, commercial advertising, and political campaigns are of course quite likely to include considerable amounts of both overt and covert propaganda and to be accompanied by propaganda of the deed.

Another term related to propaganda is psychological warfare (sometimes abbreviated to "psychwar"), which is the prewar or wartime use of propaganda directed primarily at confusing or demoralizing enemy populations or troops, putting them off guard in the face of coming attacks, or inducing them to surrender.

Still another related concept is that of brainwashing. This term usually means intensive political indoctrination. It may involve long political lectures or discussions, long compulsory reading assignments, and so forth, sometimes in conjunction with efforts to reduce the reactor's resistance by exhausting him either physically through torture, overwork, or denial of sleep or psychologically through solitary confinement, threats, emotionally disturbing confrontations with interrogators or defected comrades, humiliation in front of fellow citizens, and the like. The term brainwashing has been widely used in sensational journalism to refer to Such activities (and to many other activities) when they have allegedly been conducted by Maoists in China and elsewhere.

Another related word, advertising, has mainly commercial connotations, though it need not be restricted to this; political candidates, party programs, and positions on political issues may be "packaged" and "marketed" by advertising firms. The words promotion and public relations have wider, vaguer connotations and are often used to avoid the implications of "advertising" or "propaganda." "Publicity" and "publicism" often imply merely making a subject known to a public, without educational, propagandistic, or commercial intent.

Signs, symbols, and media used in contemporary propaganda. The 20th-century propagandist with money and imagination can use a very wide range of signs, symbols, and media to convey his message. Signs are simply stimuli—"information bits" capable of stimulating, in some way, the human organism. These include sounds, such as words. music, or a 21-gun salvo; gestures (a military salute, a thumbed nose); postures (a weary slump, folded arms, a sit-down, an aristocratic bearing); structures (a monument, a building); items of clothing (a uniform, a civilian suit); visual signs (a poster, a flag, a picket sign, a badge, a printed page, a commemorative postage stamp, a swastika scrawled on a wall); and so on and on.

The nature of symbols

A symbol is a sign having a particular meaning for a given reactor. Two or more reactors may of course attach quite different meanings to the same symbol. Thus, to Nazis the swastika was a symbol of racial superiority and the crushing military might of the German folk; to some

The cover of Time, August 31, 1962, exemplifies propaganda against the construction of the Berlin wall by East Germany.

Asiatic and North American peoples it is a symbol of universal peace and happiness. Some Christians who find a cross reassuring may find a hammer and sickle displeasing and may derive no religious satisfaction at all from a Muslim crescent, a Hindu cow, or a Buddhist lotus.

The contemporary propagandist can employ elaborate social-scientific research facilities, unknown in previous epochs, to conduct opinion surveys and psychological interviews in efforts to learn the symbolic meanings of given signs for given reactors around the world and to discover what signs leave given reactors indifferent because, to them, these signs are without meaning.

Media are the means—the channels—used to convey signs and symbols to the intended reactor or reactors. A comprehensive inventory of media used in 20th-century propaganda could cover many pages. Written media include letters, handbills, posters, billboards, newspapers, magazines, books, and handwriting on walls and streets. Among audiovisual media, television may be the most powerful for many purposes. Television can convey a great many types of signs simultaneously; it can gain heavy impact from mutually reinforcing gestures, words, postures, and sounds and a background of symbolically significant leaders, celebrities, historic settings, architectures, flags, music, placards, maps, uniforms, insignia, cheering or jeering mobs or studio audiences, and staged assemblies of prestigious or powerful people. Other audiovisual media include public speakers, motion pictures, theatres, marching bands, mass demonstrations, picketing, face-to-face conversations between individuals, and "talking" exhibits at fairs, expositions, and art shows.

The nature of organizational media

The larger the propaganda enterprise, the more important are such mass media as television and the press and also the organizational media—that is, pressure groups set up under leaders and technicians who are skilled in using many sorts of signs and media to convey messages to particular reactors. Vast systems of diverse organizations can be established in the hope of reaching leaders and followers of all groups (organized and unorganized) in a given area, such as a city, region, nation or coalition of nations, or the entire world. Pressure organizations are especially necessary, for example, in closely fought sales campaigns or political elections, especially in socially heterogeneous areas that have extremely divergent regional traditions, ethnic and linguistic backgrounds, and educational levels and very unequal income distributions. Diversities of these sorts make it necessary for products to be marketed in local terms and for political candidates to appear to be friends of each of perhaps a dozen or more mutually hostile ethnic groups, of the educated and the uneducated, and of the very wealthy as well as the poverty-stricken.

EVOLUTION OF THE THEORY OF PROPAGANDA

Early commentators and theories. The archaeological remains of ancient civilizations indicate that dazzling clothing and palaces, impressive statues and temples, magic tokens and insignia, and elaborate legal and religious arguments have been used for thousands of years, presumably to convince the common people of the purported greatness and supernatural prowess of kings and priests. Instructive legends and parables, easily memorized proverbs and lists of commandments (such as the Analects of Confucius, the Judaic Ten Commandments, the Hindu Laws of Manu, the Buddhists' Eightfold Noble Path), and highly selective chronicles of rulers' achievements have been used to enlist mass support for particular social and religious systems. Very probably, much of what was said in antiquity was sincere, in the sense that the underlying religious and social assumptions were so fully accepted that the warlords' spokesmen, the pharaohs' priests, and their audiences believed all or most of what was communicated and hence did not deliberate or theorize very much about alternative arguments or means of persuasion.

The systematic, detached, and deliberate analysis of propaganda, in the West, at least, may have begun in Athens about 500 BC, as the study of rhetoric (Greek: "the technique of orators"). The tricks of using sonorous and solemn language, carefully gauged humour, artful congeniality, appropriate mixtures of logical and illogical argument, and flattery of a jury or a mob were formulated from the actual practices of successful lawyers, demagogues, and politicians. Relatively ethical teachers such as Isocrates, Plato, and Aristotle compiled rules of rhetoric (1) to make their own arguments and those of their students more persuasive and (2) to design counterpropaganda against opponents and also (3) to teach their students how to detect the logical fallacies and emotional appeals of demagogues.

The Greco-Roman tradition of rhetoric

Early students of rhetoric also examined what today's analysts would call the problem of source credibility—what a speaker can say or do to convince his hearers that he is telling the truth, is well intentioned, is public-spirited, and so forth. For example, an Athenian lawyer defending an undersized man on trial for murder might instruct him to say to a jury: "Is it likely that an undersized man like me, so often ridiculed for being clumsy with a sword, would have attacked and killed this very tall war veteran who is famous everywhere for his swordsmanship?" But a tall and strong defendant might be told to invert the plea: "Would any man of my unusual height, who is rather well known to have slain 300 Persians in sword fights, have allowed himself to be drawn into a quarrel with this puny man—knowing full well that a jury of reasonable Athenians would be inclined from the start to hold me guilty if someone killed him?" So well did Greek rhetoricians analyze the arts of legal sophistry and political demagoguery that their efforts were imitated and further developed in Rome by such figures as Cicero and Quintilian. Aristotle's Rhetoric and similar works by others have, indeed, served as model texts for Western scholars and students until this day.

Hindu and Chinese traditions

There have been similar lines of thought in other major civilizations. In ancient India, the Buddha, and in ancient China, Confucius, both advocated, much as Plato had, the use of truthfulness, "good" rhetoric, and "proper" forms of speech and writing as means of persuading men, by both precept and example, to live the good life. Toward 400 BC in India, Kauṭilya, a Brahmin believed to have been chief minister to the emperor Candragupta Maurya, reputedly wrote the *Arthaśāstra* (Principles of Politics), a book of advice for rulers that has often been cempared with Plato's Republic and Machiavelli's much later work The Prince. Kauṭilya discussed, in some detail, the use of psychological warfare, both overt and clandestine, in efforts to disrupt an enemy's army and capture his capital. Overtly, he said, the propagandists of a king should proclaim that he can do magic, that God and the wisest men are on his side, and that all who support his war aims will reap benefits. Covertly, his agents should infiltrate his enemies' and potential enemies' kingdoms, spreading defeatism and misleading news among their people, especially in capital cities, among leaders, and among the armed forces. In particular, a king should employ only Brahmins, unquestionably the holiest and wisest of men, as propagandists and diplomatic negotiators. These morally irreproachable experts should cultivate the goodwill of their king's friends, and of friends of his friends, and also should woo the enemies of his enemies. A king should not hesitate, however, to break any friendships or alliances that are later found to be disadvantageous.

Similar advice is found in The Art of War by the Chinese theorist Sun Tzu, who wrote at about the same time. "All warfare," he said, "is based on deception. Hence, when able to attack, we must seem unable; when using our forces, we must seem inactive; when we are near, we must make the enemy believe that we are far away; when far away, we must make him believe we are near. Hold out baits to entice the enemy. Feign disorder, and crush him."

The spread of all complex political systems and religions probably has been due very largely to a combination of earnest conviction and the deliberate use of propaganda. This mixture can be detected in the recasting in various times and places of the legends of the Judaeo-Christian messiah, of heroes of the Hindu Mahdbhdrata.

of the Buddha, of the ancestral Japanese Sun Goddess, of the lives of Muhammad and his relatives, of the Christian saints, of such Marxist heroes as Marx, Engels, Lenin, and Stalin, and even in the story of George Washington and the cherry tree.

Scattered and sometimes enlightening comment on political and religious propaganda has occurred in all major civilizations. In ancient Greece and Rome there was much writing on election tactics. In 16th-century Italy, Machiavelli discussed, very much like Kauṭilya and Sun Tzu, the uses of calculated piety and duplicity in peace and war. In Shakespeare's plays, Mark Antony and the Duke of Buckingham display the principles of propaganda and discuss them in words and concepts that anticipate the present-day behavioral scientist (see *Julius Caesar*, Act III and *Richard III*, Act III). They refer to such propaganda stratagems as the seizure and monopolization of propaganda initiatives, the displacement of guilt onto others (scapegoating), the presentation of oneself as morally superior, and the coordination of propaganda with violence and bribery.

Modern research and the evolution of current theories. After the decline of the ancient world, no elaborate systematic study of propaganda appeared for centuries—not until the Industrial Revolution had brought about mass production and raised hopes of immensely high profits through mass marketing. Toward the beginning of the 20th century, researchers began to undertake studies of the motivations of many types of consumers and of their responses to various kinds of salesmanship, advertising, and other marketing techniques. From the early 1930s on, there have been "consumer surveys" much in the manner of public-opinion surveys. Almost every conceivable variable affecting consumers' opinions, beliefs, suggestibilities, and behaviour has been investigated for every kind of group, subgroup, and culture in the major capitalist nations. Consumers' wants and habits are beginning to be studied in the same ways in the socialist countries—partly to promote economic efficiency and partly to prevent political unrest. Data on the wants and habits of voters as well as consumers are now being gathered in the same elaborate ways in many parts of the world.

Sample surveys and market research

Large quantities of such information on consumers and voters are stored and statistically processed by computers and are drawn upon for nationwide and international advertising campaigns costing billions of dollars annually. Such advertising—including political advertising—occupies a very high percentage of radio and television time and of newspaper, magazine, and billboard space in countries where it is permitted. By conservative estimates $140,000,000 was spent in the U.S. presidential election of 1952, $155,000,000 in that of 1956, $175,000,000 in 1960, and $200,000,000 in 1964. On radio and television alone the Republican Party was estimated to have spent more than $12,000,000 and the Democratic Party over $7,100,000, for their presidential and vice presidential candidates in 1968. Critics have argued that advertising expenditures on such a scale, whether for deodorants or presidents, tend to waste society's resources and also to preclude effective competition by rival producers or politicians who cannot raise equally large amounts of money. A rising tide of consumer resistance and voter skepticism is leading to various attempts at consumer education, voter education, counterpropaganda, and proposals for regulatory legislation.

As far back as the early 1920s, there developed an awareness among many social critics that the extension of the vote and of enlarged purchasing power to more and more of the ignorant or ill-educated meant larger and larger opportunities for both demagogic and public-spirited propagandists to make headway by using fictions and myths, utopian appeals, and "the noble lie." Interest was aroused not only by the lingering horror of World War I and of the postwar settlements but also by publication of Ivan Pavlov's experiments on conditioned reflexes and of analyses of human motivations by various psychoanalysts. Freud's *Group Psychology and the Analysis of the Ego* (1922) was particularly relevant to the study of leaders, propagandists, and followers, as were Walter Lippmann's *Public Opinion* (1922) and *The Phantom Public* (1925).

In 1927, an American political scientist, Harold D. Lasswell, published a now-famous book, *Propaganda Technique in the World War*, a dispassionate description and analysis of the massive propaganda campaigns conducted by all the major belligerents in World War I. This he followed with studies of Communist propaganda and of many other forms of communication. Within a few years, a great many other social scientists, along with historians, journalists, and psychologists, were producing a wide variety of publications purporting to analyze military, political, and commercial propaganda of many types. During the Nazi period and the period of World War II and the subsequent cold war between the U.S. and the Soviet Union, a great many researchers and writers, both skilled and unskilled, scholarly and unscholarly, were employed by governments, political movements, and business firms to conduct propaganda. Some of those who had scientific training designed very carefully controlled experiments or Intelligence operations, attempting to quantify data on appeals of various types of propaganda to given reactors.

In the course of this theory building and research, the study of propaganda advanced a long way on the road from lore to science. Today several hundred more or less scholarly books and thousands of articles shed substantial light on the psychology, techniques, and effects of propaganda campaigns, major and minor.

Propaganda specialists

In recent decades, nearly every significant government, political party, special-interest group, social movement, and big business firm in the advanced countries has developed its own corps of specialized researchers, propagandists, or "opinion managers" (sometimes referred to as information specialists, lobbyists, legislative representatives, or vice presidents in charge of public relations). Some have become members of parliaments, cabinets, and corporate boards of directors. The most expert among them sometimes are highly skilled or trained, or both, in history, psychiatry, politics, social psychology, survey research, and statistical inference.

Many of the bigger and wealthier propaganda agencies conduct (overtly and covertly) elaborate observations and opinion surveys, among samples of the leaders, the middle strata, and the rank and file of all social groups, big and little, whom they hope to influence. They tabulate many kinds of data concerning those contents of the press, films, television, and organizational media that reach given groups. They chart the responses of reactors, through time, by statistical formulas. They conduct "symbol campaigns" and "image-building" operations with mathematical calculation, using quantities of data that can be processed only by computers. To the ancient art of rhetoric, the "technique of orators," have been added the techniques of the psychopolitical analyst and the media man and the know-how of the administrators of giant advertising agencies, public relations firms, and governmental ministries of information that employ armies of analytic specialists and "symbol-handlers."

It is a commonplace among the highly educated that men in the mass—and even men on high educational and social levels—often react more favourably to utopian myths, wishful thinking, and nonrational residues of earlier experiences than they do to the sober analysis of facts. The average citizen who may be aware of being duped is not likely to have enough education, time, or economic means to defend himself against the massive organizations of opinion managers and hidden persuaders. Indeed, to affect them he would have to act through large organizations himself and to use, to some extent, the very means used by those he seeks to control. The still greater "curse of bigness" that may evolve in the future is viewed with increasing concern by many politically conscious people.

THE ANALYSIS OF CONTEMPORARY PROPAGANDA

The components of propaganda. The contemporary propagandist employing behavioral theory tends to analyze his problem in terms of at least ten questions:

1. What are the goals of the propaganda? (What

changes are to be brought about? In whom? And when?)

2. What are the present and expected conditions in the world social system?

3. What are the present and expected conditions in each of the subsystems of the world social system (such as international regions, nations, lesser territories, interest groups)?

4. Who should distribute the propaganda—the propagandist or his agents?

5. What symbols should be used?

6. What media should be used?

7. Which reactors should the propaganda be aimed at?

8. How can the effects of the propaganda be measured?

9. By what countermeasures can opponents neutralize or suppress the propaganda?

10. How can such countermeasures be measured and dealt with?

In the present state of social science, this ten-part problem can be solved with only moderate confidence with respect to any really major propaganda campaign, even if one has a great deal of money for research. Yet if the propagandist is to proceed as rationally as possible, he needs the best answers that are available.

Goals. Goals are fairly easy to define if the propagandist simply wants to sell a relatively safe, useful, and simple good or service. When the propagandist aims to convert great numbers of people to a religion or a new social order or to induce extremely dangerous collective action like a waɪ or revolution, however, the definition of goals becomes highly complex. It is complicated further by problems about "means–goals" or intermediate goals: probably the campaign will have to go on for a long time and will have to be planned in stages, phases, or waves. The propagandist may find it hard to specify, even to himself, exactly what beliefs, values, or actions he wants to bring about, by what points in time, among different sorts of people. Very large and firmly held complexes of values are involved, such as prestige, peace of mind, income, and even life itself or the military security of entire nations or regions––even, in modern times, the annihilation of all mankind. In such a situation, a mass of intricate and thorny value dilemmas arises: Is military or revolutionary victory worth the price of economic ruin? Can a desired degree of individual liberty be achieved without too much loss of social equality? Is a much quicker achievement of goals worth a much greater amount of human suffering? Are war crimes to be committed in order to win a battle? In short: What is the propagandist willing to risk, for what, across what periods of time?

Particularism versus universalism

Present and expected conditions in the world social system. Under modern conditions, each act of propaganda is apt to have effects in several parts of the world. Some of these may boomerang unexpectedly against the propagandist himself unless he can visualize the global system and its components and anticipate the problems that may arise. The global system, moreover, is inexorably changing. As population, trade, travel, education, and technology evolve, new centres of political, cultural, and economic power emerge. This social evolution, extremely rapid in current times, tends on balance to limit the use of more simplistic and parochial kinds of propaganda and increases the need for more sophisticated, scientifically formulated, and univeisalistic (world-oriented) types. If, for example, there is, as some theorists argue, an evolution everywhere from less rationality and scientism toward more and from the primacy of particularistic loyalties toward the primacy of a universalistic loyalty, is the propagandist to use appeals that resist such trends or accept them? If he resists, what is the cost? If his appeals are far ahead of his time, again what is the cost?

Present and expected conditions in subsystems. In many times and places in the past, the propagandist could profit handsomely by ignoring the welfare of a nation or the world and appealing to extremes of religious, racial, political, or economic fanaticism. This paid off very well, in the short run at least, within many subsystems. Today, however, this kind of propaganda can prove to be useless and even dangerous. The prudent propagandist has therefore to decide what mix of universalistic and particularistic symbolism will best serve his purposes at given times in given places. The choice is never an easy one: parochial or class-conscious or national groups may be aroused to the highest passions; and they are numerous and diverse and often highly incompatible with one another and with the imperatives of the nation or the world.

Propaganda "fronts"

The propagandist and his agents. The use of seemingly reputable, selfless, or neutral agents or so-called front organizations, while the propagandist himself remains behind the scenes, may greatly improve his prospects. If the authorities are after the propagandist, seeking to suppress his activities, he ***must*** stay underground and work through agents. But even in freer circumstances, he may wish someone else to speak for him. The propagandist, for instance, may not speak the reactors' language or idiom fluently. He may not know what they associate with given symbols. Or their cultural, racial, or religious feelings may bias them against him and thus tend to deny him a favourable hearing. In such cases the use of agents is inescapable. Thus, subsidizing a native news commentator or lecturer in a foreign country or furnishing propagandistic music for use by a foreign broadcasting station may be more effective than conducting one's own broadcasts. (There are exceptions, however. Many surveys have shown, for example, that news broadcasts by the British Broadcasting Corporation are considered by various foreign audiences to be more truthful than broadcasts originating in their own countries.) Furthermore, if the propaganda fails or is exposed for what it is, the agent can be publicly scapegoated while the real propagandist continues to operate and develop new stratagems. The prince, said Machiavelli, may openly and conspicuously bestow awards and honours and public offices; but he should have his agents carry out all actions that make a man unpopular, such as punishments, denunciations, dismissals, and assassinations.

A complicated modem campaign on a major scale is likely to be planned most successfully by a collective leadelship—a team of broadly educated and skilled people who have had both practical experience in public affairs and extensive training in history, psychology, and the social sciences. The detachment, skepticism, and secularism of such persons may, however, cause them to be viewed with great suspicion by many reactors. It may be important, therefore, to keep the planners behind the scenes and to select intermediaries, front men, Trojan horses, and "dummy leaders" whom the reactors are more likely to listen to or appreciate.

Image makers

Contemporary social-psychological research, dating from Freud's ***Group Psychology and the Analysis of the Ego,*** makes clear the wisdom of traditional insights concerning the supreme importance of leadership in any group, be it the family, the nation, or the world social system. The rank and file of any group, especially a big one, have been shown to be remarkably passive until aroused by quasi-parental leaders whom they admire and trust. It is hard to imagine the Gallic wars without Caesar, the psychoanalytic movement without Freud, the Nazis without Hitler, or the major Communist revolutions without Lenin and Mao Tse-tung and their politburos. These leaders were real, not dummies invented and packaged by image makers from an advertising agency or public relations firm. In the age of massive opinion researches, however, and with the aid of speech coaches and makeup artists and the magic impact of television, it has become increasingly possible for image makers to create front men who can affect the votes and other behaviour of very large percentages of a national audience. As one knowledgeable participant phrased it in 1970:

> There are now four essential ingredients to a professionally managed political campaign: political polls, data processing, imagery, and money. The polls discover what the voter already believes, and data processing interprets and analyzes the depth of voters' attitudes. After that, an image of the candidate is tailored to meet the voters' demands and desires, and the whole package is then sold by massive expenditures of money in the advertising media, particularly television.
>
> The candidate has become relatively unimportant as long as he can be properly managed. The candidate must be

> bright enough to handle the material furnished to him, but not too intelligent, because there is always the danger that an intelligent candidate may come up with unpopular or controversial ideas of his own, and thereby destroy a carefully contrived campaign strategy. [Excerpt from a public address by Zolton Ferency, chairman and gubernatorial candidate of the Democratic Party of Michigan, June 1970.1

Probably this is an overstatement, but it conveys the flavour of a great deal of contemporary political propaganda. Yet a dummy leader invented by an image maker may not always be invulnerable to counterpropaganda by a real leader, if one should turn up. Even a giant, expensive television campaign may not be able to conceal from all reactors the differences between a dummy and a bona fide leader with high political skills—a Franklin D. Roosevelt, for example, or a Jawaharlal Nehru—whose voice and gestures express a genuine and spontaneous concern for public policy and a determination to "wear no man's collar," and who goes in for great numbers of face-to-face appearances that demonstrate that he has no need for a voice coach and a makeup artist.

Predispositions and inducements

Selection and presentation of symbols. The propagandist must realize that neither rational arguments nor catchy slogans can, by themselves, do much to influence human behaviour. A reactor's behaviour is also affected by at least four other variables. The first is the reactor's predispositions—that is, his stored memories of, and his past associations with, related symbols. These often cause the reactor to ignore the current inflow of symbols, to perceive them very selectively, or to rationalize them away. The second is the set of economic inducements (gifts, bribery, pay raises, threats of job loss, and so forth) which the propagandist or others may apply in conjunction with the symbols. The third is the set of physical inducements (love, violence, protection from violence) used by the propagandist or others. The fourth is the array of social pressures that may either encourage or inhibit the reactor in thinking or doing what the propagandist advocates. Even one who is well led and is predisposed to do what the propagandist wants may be prevented from acting by counterpressures within the surrounding social systems or groups of which he is a part.

In view of these predispositions and pressures, the skilled propagandist is careful to advocate chiefly those acts that he believes the reactor already wants to perform and is in fact able to perform. It is fruitless to call upon most people to perform acts that may involve a total loss of income or terrible physical danger—for example, to act openly upon Communist leanings in a totalitarian fascist country. To call upon reactors to do something extremely dangerous or hard is to risk having the propaganda branded as unrealistic. In such cases, it may be better to point to actions that the reactor can *avoid* taking—that is, to encourage him in acts of passive resistance. The propagandist will thereby both *seem* and *be* realistic in his demands upon the reactor, and the reactor will not be left with the feeling, "I agree with this message, but just what am I supposed to do about it?"

For maximum effect, the symbolic content of propaganda must be active, not passive, in tone. It must explicitly or implicitly recommend fairly specific actions to be performed by the reactor ("buy this," "boycott that," "vote for X," "join Group Y," "withdraw from Group Z"). Furthermore, because the ability of the human organism to receive and process symbols is strictly limited, the skillful propagandist attempts to substitute quality for quantity in his choice of symbols. A brief slogan or a picture or a pithy comment on some symbol that is emotion laden for the reactors may be worth ten thousand other words and cost much less. In efforts to economize symbol inputs, the propagandist attempts to make full use of the findings of all the behavioral sciences. He draws upon the psychoanalysts' studies of the bottled-up impulses in the unconscious mind; he consults the elaborate vocabulary counts produced by professors of education; he follows the headline news to determine what events and symbols probably are salient in reactors' minds at the moment; and he analyzes the information polls and attitude studies conducted by survey researchers.

There is substantial agreement among psychoanalysts that the psychological power of propaganda increases with use of what Lasswell termed the triple-appeal principle. This principle states that a set of symbols is apt to be most persuasive if it appeals simultaneously to three elements of an individual's personality—elements that Freud labelled the ego, id, and superego. To appeal to the ego, the skilled propagandist will present the acts and thoughts that he desires to induce as if they were rational, advisable, wise, prudent, and expedient; in the same breath he says or implies that they are sure to produce pleasure and a sense of strength (an appeal to the id); concurrently he suggests that they are moral, righteous, and—if not altogether legal---decidedly more justifiable and humane than the law itself (an appeal to the superego, or conscience). Within any social system, the optimal blend of these components varies from individual to individual and from subgroup to subgroup: some individuals and subgroups love pleasure intensely and show few traces of guilt; others are quite pained by guilt; few are continuously eager to be rational or to take the trouble to become well informed. Some cautious individuals and subgroups like to believe that they never make a move without preanalyzing it; others enjoy throwing prudence to the winds. There are also changes in these blends through time: personalities change, as do the morals and customs of groups. In large collectivities like social classes, ethnic groups, or nations, the particular blends of these predispositions may vary greatly from stratum to stratum and subculture to subculture. Only the study of history and behavioral research can give the propagandist much guidance about such variations.

Role models and parental symbols

A propagandist is wise if, in addition to reiterating his support of ideas and policies that he knows the reactors already believe in, he includes among his images a variety of symbols associated with parents and parent surrogates. The child lives on in every adult, eternally seeking a loving father and mother. Hence the appeal of such familistic symbolisms as "the fatherland," "the mother country," "the Mother Church," "the Holy Father," "Mother Russia," and the large number of statesmen who are known as the "fathers of their countries." Also valuable are reassuring maternal figures like Queen Victoria of England, the Virgin Mary, and the Japanese Sun Goddess. In addition to parent symbols, it is usually well to associate one's propaganda with symbols of parent substitutes, who in some cases exert a more profound effect on children than do disappointing or nondescript parents: affectionate or amiable uncles (Uncle Sam, Uncle Ho Chi Minh); lively aunts (*la belle France,* Britannia, the Spanish Communist leader La Pasionaria, and Kuan-yin, the Chinese Goddess of Mercy); admired scholars and physicians (Karl Marx, Dr. Sun Yat-sen); politico-military heroes and role models (Abraham Lincoln, Winston Churchill, Mao Tse-tung, "the wise, mighty, and fatherly Stalin"); and, of course, saints (Joan of Arc, Mahatma Gandhi, Martin Luther King, the Buddha). A talented and well-symbolized leader or role model may achieve a parental or even godlike ascendancy (charisma) and magnify the impact of a message many times.

Media of propaganda. There are literally thousands of written, audiovisual, and organizational media that a 20th-century propagandist might use. All human groupings are potential organizational media, from the family and other small organizations through advertising and public relations firms, trade unions, churches and temples, theatres, readers of novels and poetry, special-interest groups, political parties and front organizations to the governmental structures of nations, international coalitions, and universal organizations like the United Nations and its agencies. From all this variety of media, the propagandist must choose those few media (especially leaders, role models, and organizations) to whose messages he thinks the intended reactors are especially attentive and receptive.

In recent years the communications revolution has brought about a massive, worldwide proliferation of school systems and of facilities for news gathering, publishing, broadcasting, holding meetings, and speechmaking. At present, almost everyone's mind is bombarded daily by far more media, symbols, and messages than the human organism can possibly pay attention to. The mind reels under noisy assortments of information bits about rival politicians, rival political programs and doctrines, new technical discoveries, insistently advertised commercial products, and new views on morality, ecological horrors, and military nightmares. This sort of communication overload already has resulted in the alienation of millions of people from much of modern life. Overload and alienation can be expected to reach even higher levels in coming generations as still higher densities of population, intercultural contacts, and communication facilities cause economic, political, doctrinal, and commercial rivalries to become still more intense.

Communication overload

Research has demonstrated repeatedly that most reactors attempt, consciously or unconsciously, to cope with severe communication overload by developing three mechanisms: selective attention, selective perception, and selective recall. That is, they pay attention to only a few media; they fail (often unconsciously) to perceive therein any large proportion of the messages that they find uncongenial; and, having perceived, even after this screening, a certain number of unpleasing messages, they repress these in whole or in part (*i.e.*, cannot readily remember them). The contemporary propagandist therefore tries to find out: (1) what formative experiences and styles of education have predisposed his intended audiences to their current "media preferences"; (2) which of all the publications, television shows, leaders, and role models in the world they do in fact pay attention to; and (3) by which of these they are most influenced. These topics have thus become the subjects of vast amounts of commercial and academic research.

In most cases, reactors are found to pay the most attention to the publications, shows, leaders, and role models with whose views they already agree. People as a rule attend to communications not because they want to learn something new or reconsider their own philosophies of life but because they seek psychological reassurance about their existing beliefs and prejudices. When the propagandist does get their attention by putting his message into the few media they heed, he may discover that, to hold their attention, he must draft a message that does not depart very far from what they already want to believe. Despite the popular stereotypes about geniuses of politics, religion, or advertising whose brilliant propaganda converts the multitudes overnight, the plain fact is that even the most skilled propagandist must usually content himself with a very modest goal: packaging a message in such a way that much of it is familiar and reassuring to the intended reactors and only a little is so novel or true as to threaten them psychologically. Thus, revivalists have an a priori advantage over spokesmen of a modernized ethic, and conservative politicians an advantage over progressives. Propaganda that aims to induce major changes is certain to take great amounts of time, resources, patience, and indirection, except in times of revolutionary crisis when old beliefs have been shattered and new ones have not yet been provided. In ordinary periods (intercrisis periods), propaganda for changes, however worthy, is likely to be, in the words of the German sociologist Max Weber, "a slow boring of hard boards."

Use of reference groups

For reasons just indicated, the most effective media as a rule (for messages other than the simplest of commercial advertising) are not the impersonal mass media like newspapers and television but rather those few associations or organizations (reference groups) with which the individual feels identified or to which he aspires to relate his identity. Quite often the ordinary man not only avoids but actively distrusts the mass media or fails to understand their messages; but in the warmth of his reference groups he feels at home, assumes that he understands what is going on, and feels that he is sure to receive a certain degree of emotional response and personal protection. The foremost reference group, of course, is the family. But many other groups perform analogous functions—for instance, the group of sports fans, the church, the trade union, the alumni group, the clique or gang, the Communist cell. By influencing the key members of such a group, the propagandist may establish a "social relay" channel that can amplify his message. By concentrating thus on the few, he increases his chances of reaching the many—often far more effectively than he could through a plethora of mass meetings, paid broadcasts, handbills, or billboards and at much lower cost. Therefore, one important stratagem involves the combined use of mass media and reference-group channels—writing up materials for such media as news releases or broadcasts in ways designed specifically to reach specified groups (and especially their elites and leaders): who can then relay the messages to other sets of reactors.

The reactors (audiences). The audiences for the propagandist can be classified into: (1) those who are initially predisposed to react as the propagandist wishes, (2) those who are neutral or indifferent, and (3) those who are in opposition or perhaps even hostile.

As already indicated, propaganda is most apt to evoke the desired responses among those already in agreement with the propagandist's message. Neutrals or opponents are not apt to be much affected even by an intensive barrage of propaganda unless it is reinforced by nonpropagandistic inducements (economic or coercive acts) or by favourable social pressures. These facts, of course, are recognized by advocates of civil disobedience; their propagandists would contend that sloganeering and reasoned persuasion must be accompanied by sit-ins and other overt acts of passive resistance; they aim for a new climate of social pressure. These facts are also significantly recognized by Communist regimes; by controlling all means of production, they can offer great economic inducements or threaten a man's livelihood, thus making him a very attentive audience for propaganda. If these copressures are applied too strongly, however, they may become so distasteful to reactors that the associated propaganda will backfire.

Measurement of the effects of *propaganda*. The modern world is overrun with all kinds of competing propaganda and counterpropaganda and a vast variety of other symbolic activities, such as education, publishing, newscasting, and patriotic and religious observances. The problem of distinguishing between the effects of one's own propaganda and the effects of these other activities is often extremely difficult.

Use of experiments

The ideal scientific method of measurement is the controlled experiment. Carefully selected samples of members of the intended audiences can be subjected to the propaganda while equivalent samples are not. Or the same message, clothed in different symbols—different mixes of sober argument and "casual" humour, different proportions of patriotic, ethnic, and religious rationalizations, different mixes of truth and the "noble lie," different proportions of propaganda and coercion—can be tested on comparable samples. Also, different media can be tested to determine, for example, whether results are better when reactors read the message in a newspaper, observe it in a spot commercial on television, or hear it wrapped snugly in a sermon. Obviously the number of possible variables and permutations in symbolism, media use, subgrouping of the audience, and so forth is extremely great in any complicated or long-drawn-out campaign. Therefore, the costs for the research experts and the fieldwork that are needed for thorough experimental pretests are often very high. Such pretests, however, may well save money in the end.

An alternative to controlled experimentation in the field is controlled experimentation in the laboratory. But it may be impossible to induce reactors who are truly representative of the intended audience to come to the laboratory at all. Moreover, in such an artificial environment their reactions may differ widely from the reactions that they would have to the same propaganda if reacting unself-consciously in their customary environment. For these and many other obvious reasons, the validity of laboratory pretests of propaganda must be viewed with the greatest caution.

Whether in the field or the laboratory, the value of all controlled experiments is seriously limited by the problem of "sleeper effects." These are long-delayed reactions that may not become visible until the propaganda has penetrated resistances and insinuated itself deep down into the reactor's mind—by which time the experiment may have been over for a long time. Another problem is that most people acutely dislike being guinea pigs and also dislike the word propaganda. If they find out that they are subjects of a propagandistic experiment, the entire research program, and possibly the entire campaign of propaganda of which it is a part, may backfire.

Use of interviews and observation techniques

Another research device is the panel interview—repeated interviewing, over a considerable period of time, of small sets of individuals considered more or less representative of the intended audiences. The object is to obtain (if possible, without their knowing it) a great deal of information about their life-styles, belief systems, value systems, media habits, opinion changes, heroes, role models, reference groups, and so forth. The propagandist hopes to use this information in planning ways to influence a much larger audience. Panel interviewing, if kept up long enough, may help in discovering sleeper effects and other delayed reactions. The very process of being "panel interviewed," however, produces an artificial environment that may induce defensiveness, suspiciousness, and even attempts to deceive the interviewer.

For many practical purposes, the best means of measuring—or perhaps one had better say estimating—the effects of propaganda is apt to be the method of extensive observation, guided of course by well-reasoned theory and inference. "Participant observers" can be stationed unobtrusively among the reactors. Voting statistics, market statistics, press reports, police reports, editorials, and the speeches or other activities of affected or potentially affected leaders can also give clues. Evidence on the size, composition, and behaviour of the intermediate audiences (such as elites) and the ultimate audiences (such as their followers) can be obtained from these various sources and from sample surveys. The statistics of readership or listenership for printed and telecommunications media may be available. If the media include public meetings, the number of people attending and the noise level and symbolic contents of cheering (and jeering) can be measured. Observers may also report their impressions of the moods of the audience and record comments overheard after the meeting. To some extent, symbols and leaders can be varied, and the different results compared.

Use of "content analysis"

Using methods known in recent years as content analysis, the propagandist can at least make reasonably dependable quantitative measurements of the symbolic contents of his own propaganda and of communications put out by others. He can count the numbers of column inches of printed space or seconds of radio or television time that were given to the propaganda. He can categorize and tabulate the symbols and themes in the propaganda. To estimate the implications of the propaganda for social policy, he can tabulate the relative numbers of expressed or implied demands for actions or attitude changes of various kinds. The 1970 edition of volume 1 of the *Big Soviet Encyclopedia,* for example, had no pictures of Stalin; in the previous edition, volume 1 had four pictures. Did this mean that a new father figure and role model was being created by the Soviet propagandists? Or did it indicate a return to the cult of older father figures such as Marx and Lenin? If so, what were the respective father figures' traits, considered psychoanalytically, and what are the political, economic, and military implications for Soviet policy?

By quantifying his data about contents, the propagandist can bring a high degree of precision into experiments using different propaganda contents aimed at the same results. He can also increase the accuracy of his research on the relative acceptability of information, advice, and opinion attributed to different sources. (Will given reactors be more impressed if they hear 50, 100, or 200 times that a given policy is endorsed--or denounced—by the president of the U.S., the premier of the U.S.S.R., or the pope?)

Very elaborate means of coding and of statistical analysis have been developed by various content analysts. Some count symbols, some count headlines, some count themes (sentences, propositions), some tabulate the frequencies with which various categories of "events data" (newspaper accounts of actual happenings) appear in some or all of the leading newspapers ("prestige papers") or television programs of the world. Some of these events data can be counted as supporting or reinforcing the propaganda, some as opposing or counteracting it. Whatever the methodology, content analysis in its more refined forms is an expensive process, demanding long and rigorous training of well-educated and extremely patient coders and analysts. And there remains the intricate problem of developing relevant measurements of the effects of different contents upon different reactors.

Countermeasures by opponents. Some countermeasures against propaganda include simply suppressing it by eliminating or jailing the propagandist, burning down his premises, intimidating his employees, buying him off, depriving him of his use of the media or the money that he needs for the media or for necessary research, and applying countless other coercive or economic pressures. It is also possible to use counterpropaganda, hoping that the truth (or at least some artfnl bit of counterpropaganda) will prevail.

One special type of counterpropaganda is "source exposure"-informing the audience that the propagandist is ill informed, is a criminal, or belongs to some group that is sure to be regarded by the audience as subversive, thereby undermining his credibility and perhaps his economic support. In the 1930s there was in the U.S. an Institute for Propaganda Analysis that tried to expose such propaganda techniques as "glittering generalities" or "name-calling" that certain propagandists were using. This countermeasure may have failed, however, because it was too intellectual and abstract and because it offered the audience no alternative leaders to follow or ideas to believe.

In many cases opponents of certain propagandists have succeeded in getting laws passed that have censored or suppressed propaganda or required registration and disclosure of the propagandists and of those who have paid them.

Measures against countermeasures. It is clear, then, that opponents may try to offset propaganda by taking direct action or by invoking covert pressures or community sanctions to bring it under control. The propagandist must therefore try to estimate in advance his opponents' intentions and capabilities and invent measures against their countermeasures. If he thinks that they will rely only on counterpropaganda, he can try to outwit them. If he thinks that they will withdraw advertising from his newspaper or radio station, he may try to get alternative supporters. If he expects vigilantes or police persecution, he can go underground and rely, as the Russian Communists did before 1917 and the Chinese before 1949, primarily on agitation through organizational media.

SOCIAL CONTROL OF PROPAGANDA

The democratic ideal and propaganda

Democratic control of propaganda. Different sorts of polities, ranging from the democratic to the authoritarian, have attempted a variety of social controls over propaganda. In an ideal democracy, everyone would be free to make propaganda and free to oppose propaganda habitually through peaceful counterpropaganda. The democratic ideal assumes that, if a variety of propagandists are free to compete continuously and publicly, the ideas best for society will win out in the long run. This outcome would require that a majority of the general populace be reasonably well-educated, intelligent, public-spirited, and patient, and that they not be greatly confused or alienated by an excess of communication. A democratic system also presupposes that large quantities of dependable and relevant information will be inexpensively disseminated by relatively well-financed, public-spirited, and uncensored news gathering and educational agencies. The extent to which any existing national society actually conforms to this model is decidedly an open question. That the world social system does not is self-evident.

In efforts ***to*** guard against "pernicious" propaganda by hidden persuaders, modern democracies sometimes require that such propagandists as lobbyists and publishers register with public authorities and that propaganda and advertising be clearly labelled as such. The success of such measures, however, is only partial. In the U.S., for instance, publishers of journals using the second-class mails are required to issue periodic statements of ownership, circulation, and other information; thereby, at least the nominal owners and publishers become known—but those who subsidize or otherwise control them may not. In many places, paid political advertisements in newspapers or on television are required to include the name of a sponsor—but the declared sponsor may be a "dummy" individual or organization whose actual backers remain undisclosed. Furthermore, agents of foreign governments or organizations engaged in propaganda in the U.S. are required to file forms with the U.S. Department of Justice, naming their principals and listing their own activities and finances—but it is impossible to know whether the data so filed are correct, complete, or significant. In many Western industrial nations, similar registrations and disclosures are required of those who circulate brochures inviting investors to buy stocks and bonds. This principle of disclosure, which appears so useful with respect to foreign agents and securities salesmen, is not often applied, however, to other media of propaganda. (In the U.S. the disclosure of certain types of political campaign advertisements and contributions is required, but the requirement is easily circumvented.) In many countries, claims made in propaganda (including advertising) about the contents or characteristics of foods and drugs and some other products are also subject to registration and to requirements of "plain labelling." In some places, consumer research organizations, privately or publicly supported, examine these claims rigorously and sometimes publish scientifically based counterpropaganda. Finally, there has been an increase in laws and customs requiring that equal space or time or a right of reply be rendered all major contenders in political campaigns or even major spokesmen differing on major issues of the day. In view of the apparently massive effects and the certainly massive expenses of political propaganda on television, there are many movements afoot in democracies to limit expenditures on campaign propaganda and to require networks to give time free of charge for even the minor parties, especially in the weeks immediately preceding elections. There have also been movements to require that political propaganda be halted for a specified number of days before the holding of an election—the idea being that a cooling-off period would allow voters to rest and reflect after the communication overload of the campaign period and would prevent politicians and their backers from using last-minute slander and sensationalism.

Equal time
and equal
space

Authoritarian control of propaganda. In a highly authoritarian polity, the regime tries to monopolize for itself all opportunities to engage in propaganda, and often it will stop at nothing to crush any kind of counterpropaganda. How long and how completely such a policy can be implemented depends, among other things, on the amount of force that the regime can muster, on the thoroughness of its police work, and, perhaps most of all, on the level, type, and distribution of secular higher education. Secular higher education invariably promotes skepticism about claims that sound dogmatic or are made without evidence; and if such education is of a type that emphasizes humane and universalistic values, an ignorant or unreasonable authoritarian regime is not likely to please the educated for very long. If the educated engage in discreet counterpropaganda, they may in the end modify the regime.

World-level control of propaganda. One of the most serious and least understood problems of social control is above the national level, at the level of the world social system. At the world level there is an extremely dangerous lack of means of restraining or counteracting propaganda that fans the flames of international, interracial, and interreligious wars. The global system consists at present of a highly chaotic mixture of democratic, semidemocratic, and authoritarian subsystems. Many of these are controlled by leaders who are ill educated, ultranationalistic, and religiously, racially, or doctrinally fanatical. At present, every national regime asserts that its national sovereignty gives it the right to conduct any propaganda it cares to, however untrue such propaganda may be and however contradictory to the requirements of the world system. The most inflammatory of such propaganda usually takes the form of statements by prominent national leaders, often sensationalized and amplified by their own international broadcasts and sensationalized and amplified still further by media in the receiving countries. The only major remedy would lie, of course, in the slow spread of education for universalist humanism. A first step toward this might be taken through the fostering of an energetic and highly enlightened press corps and educational establishment, doing all it can to provide the world's broadcasters, newspapers, and schools with factual information and illuminating editorials that could increase awareness of the world system as a whole. Informed leaders in world affairs are therefore becoming increasingly interested in the creation of world-level media and multinational bodies of reporters, researchers, editors, teachers, and other intellectuals committed to the unity of mankind.

BIRLIOGRAPHY. Annotated listings of books and articles of all times, countries, and languages, with respect to public opinion and the theory and practice of communication (including propaganda) appear in H.D. LASSWELL, R.D. CASEY, and B.L. SMITH (eds.), *Propaganda and Promotional Activities: An Annotated Bibliography* (1935, reprinted 1969); and in B.L. SMITH, H.D. LASSWELL, and R.D. CASEY, *Propaganda, Communication and Public Opinion: A Comprehensive Reference Guide* (1946). Further listings on general and international propaganda are in B.L. and C.M. SMITH, *International Communication and Political Opinion: A Guide to the Literature* (1956). For more recent periodical literature, see *International Political Science Abstracts* (quarterly); *Psychological Abstracts* (monthly); and *Sociological Abstracts* (8/yr.).

(B.L.S.)

Propertius, Sextus

The most forceful of the Latin elegiac poets, Sextus Propertius emerges from his poetry as a man with a wonderful capacity for living, eager to embrace every aspect of life and experience. Although best known for its sensuousness, his work also reveals a deep understanding of life's tragic underside: that there is sometimes only a step between happiness and misery. He is often self-absorbed and self-pitying, and his poetry can suffer from an overdose of pathos, but these defects are largely neutralized by his welcome sense of humour and, especially, by his poetic power and range of imagination. Technically a very competent poet, his handling of the elegiac couplet is unmistakable for its vigorous, masculine rhythm.

Sextus Propertius was born in or near Assisi, in Umbria, between 55 and 43 BC (most probably *c.* 50 BC). Very few details of his life are known. His father died when Propertius was still a boy, but he was given a good education by his mother. Part of the family estate was confiscated (*c.* 40 BC) to satisfy the resettlement needs of the veteran troops of Octavian, later the emperor Augustus, after the civil wars. Propertius' income was thus severely diminished, though he was never really poor. With his mother, he left Umbria for Rome, and there (c. 34 BC) he assumed the dress of manhood. Some of his friends were poets (including Ovid and Bassus), and he had no interest in politics, the law, or army life. His first love affair was with an older woman, Lycinna, but this was only a passing fancy when set beside his subsequent serious attachment to the famous "Cynthia" of his poems.

The first of Propertius' four books of elegies (the second of which is divided by some editors into two) was published in 29 BC, the year in which he first met "Cynthia," its heroine. It was known as the *Cynthia* and also as the *Monobiblos* because it was for a long time afterward sold separately from his other three books. Complete editions of all four books were also available. *Cynthia* seems to have had an immediate success, for the influential literary patron Maecenas invited Propertius to his house, where he doubtless met the other prominent literary figures who formed Maecenas' circle. These included the poets Virgil (whom Propertius admired) and Horace (whom he never mentions). The influence of both, especially that of Horace in Book III, is manifest in his work.

Meeting with Virgil and Horace

Cynthia's real name, according to the 2nd-century writer Apuleius, was Hostia. It is often said that she was a courtesan, but elegy 16 in Book I seems to suggest that she belonged to a distinguished family. It is likely that she was married, though Propertius only mentions her other lovers, never her husband. From the poems she emerges as beautiful, passionate, and uninhibited. She was intensely jealous of Propertius' own infidelities and is painted as a woman terrible in her fury, irresistible in her gentler moods. Propertius makes it clear that, even when seeking pleasures apart from his mistress, he still loved her deeply, returning to her full of remorse, and happy when she reasserted her dominion over him.

After many violent scenes, it appears that Propertius finally broke off his tempestuous affair with her in 24 BC, though inferring dates from the poems' internal evidence cannot be undertaken with real confidence, as this kind of personal poetry often interweaves fact with fancy. He was to look back on his liaison with her as a period of disgrace and humiliation. This may be more than a mere literary pose, although after Cynthia's death (she does not seem to have lived for long after their break) he regretted the brusqueness of their separation and was ashamed that he had not even attended her funeral. In a most beautiful and moving elegy (IV:7), he conjures up her ghost and with it recreates the whole glamour and shabbiness of the affair. While he makes no attempt to brush over the disagreeable side of her nature, he also makes it clear that he loves her beyond the grave.

Propertius' poetic powers matured with experience. The poetry of Book II is far more ambitious in scope than that of Book I and shows a richer orchestration. His reputation grew, and the emperor Augustus himself seems to have taken notice of him, for, in Books III and IV, the poet laments the premature death of Marcellus, Augustus' nephew and heir apparent (III:18), and he composed a magnificent funeral elegy (IV:11) in praise of Cornelia, Scribonia's daughter by her first marriage—the "Queen of Elegies" as it is sometimes called.

Content of the poetry

As his poetic powers developed, so also did Propertius' character and interests. In his earliest elegies, love is not only his main theme but is almost his religion and philosophy. It is still the principal theme of Book II, but he now seems a little embarrassed by the popular success of Book I and is anxious not to be thought of simply as a gifted scoundrel who is constantly in love and can write of nothing else. In Book II he considers writing an epic, is preoccupied with the thought of death, and attacks (in the manner of later satirists, such as Juvenal) the coarse materialism of his time. He still loves to go to parties and feels perfectly at ease in the big city with its crowded streets, its temples, theatres, porticoes, and its disreputable quarters. In a way he is a conservative snob, in general sympathy with Roman imperialism and Augustan rule; but he is open to the beauties of nature and is genuinely interested in works of art; though he disapproves of ostentatious luxury, he also appreciates contemporary fashions.

Some of his contemporaries accused him of leading a life of idleness and complained that he contributed nothing to society. But Propertius felt it his duty to support the right of the artist to lead his own life, and he demanded that poetry, and art in general, should not be regarded simply as a civilized way of passing the time. In elegy 3 of Book III he gives deep meaning to the process of artistic creation and emphasizes the importance of the creative artist.

Influence of Alexandrian poets on Propertius

In Books III and IV Propertius demonstrates his command over various literary forms, including the diatribe and the hymn. Many of his poems show the influence of such Alexandrian poets as Callimachus and Philetas. Propertius acknowledges this debt, and his claim to be the "Roman Callimachus," treating Italian themes in the baroque Alexandrian manner, is perhaps best shown in a series of elegies in Book IV that deal with aspects of Roman mythology and history, and were to inspire Ovid to write his *Fasti,* a calendar of the Roman religious year. These poems are a compromise between the elegy and the epic. Book IV also contains some grotesque, realistic pieces, two unusual funeral elegies, and a poetic letter.

Two of the lasting merits of Propertius seem to have impressed the ancients themselves. The first they called *blanditia,* a vague but expressive word by which they meant softness of outline, warmth of colouring, a fine and almost voluptuous feeling for beauty of every kind and a pleading and melancholy tenderness: this is most obvious in his descriptive passages and in his portrayal of emotion. His second and even more remarkable quality is poetic *facundia,* or command of striking and appropriate language. Not only is his vocabulary extensive but his employment of it is extraordinarily bold and unconventional: poetic and colloquial latinity alternate abruptly, and in his quest for the striking expression he frequently seems to strain the language to the breaking point.

Propertius' handling of the elegiac couplet, and particularly of the pentameter, deserves especial recognition. It is vigorous, varied, and picturesque. In the matter of the rhythms, caesuras, and elisions that it allows, the metrical treatment is more severe than that of Catullus, but noticeably freer than that of Ovid, to whose stricter usage, however, Propertius increasingly tended (particularly in his preference for a disyllabic word at the end of the pentameter). An elaborate symmetry is observable in the construction of many of his elegies, and this has tempted critics to divide a number of them into strophes.

As Propertius had borrowed from his predecessors, so his successors, Ovid above all, borrowed from him; and *graffiti* on the walls of Pompeii attest his popularity in the 1st century AD. In the Middle Ages he was virtually forgotten; and since the Renaissance he has been studied by professional scholars more than he has been enjoyed by the general public. To the modern reader, acquainted with the psychological discoveries of the 20th century, the self-revelations of his passionate, fitful, brooding spirit are of peculiar interest.

Almost nothing is known about Propertius' life after his love affair with Cynthia was over. It is possible that he married her successor in his affections (perhaps in order to qualify for the financial benefits offered to married men by the *leges Juliae* of 18 BC) and had a child, for an inscription in Assisi and two passages in the letters of the younger Pliny (AD 61/62–*c.* 113) indicate that Propertius had a descendant called Gaius Passennus Paulus Propertius, who was also a poet. During his later years he lived in an elegant residential area in Rome on the Esquiline Hill. The date of his death is not certain, though he was still alive in 16 BC, for two events of that year are mentioned in his fourth book, which was perhaps edited posthumously.

Sextus Propertius is generally thought of as a difficult poet, partly because of the uncertainty of many manuscript readings, partly because of the often obscure mythological allusions in which his work abounds. But such allusions are not there for ornament; they are a kind of emotional shorthand by which Propertius expresses his deep insight into human nature. The mellifluous Greek names, moreover, are skillfully woven into the rich verbal pattern that, along with his sincerity, is one of his outstanding characteristics.

MAJOR WORKS

Four Books of Elegies: Book I, known in antiquity as the *Cynthia Monobiblos* (*c.* 33–c. 28 BC); Book II (*c.* 28–c. 25 BC); Book III (c. 24–c. 22 BC); and Book IV (*c.* 21–c. 16 BC). Special mention may be made of Elegy 1, Book I, which introduces Cynthia; of Elegy 28 (both parts), Book II, a prayer for her recovery from illness; of Elegy 10, Book III, on Cynthia's birthday; of Elegy 24, Book III, on their final parting after a quarrel; and of Elegy 7, Book III, on Cynthia's death.

BIBLIOGRAPHY

Important editions and textual criticism: JOSEPHUS SCALIGER (1577) contains many textual conjectures and transpositions of lines that were accepted by most subsequent editors before CARL LACHMANN (1816), who restored essentially the text of the best manuscripts. E.A. BARBER (1953) is the most commonly used critical edition today. D.R. SHACKLETON BAILEY, ***Propertiana*** (1956), gives valuable critical and exegetical discussions of difficult passages.

Commentaries: JANUS BROUKHUSIUS (1727), still recommended for its elegance and learning; W.A. CAMPS, 4 vol. (1961–67), original 'and penetrating.

Translation: A.E. WATTS, ***The Poems of Sextus Propertius,*** rev. ed. (1966), in rhymed couplets—often refreshing but makes Propertius sound too harmless.

Literary criticism: G. LUCK, ***The Latin Love Elegy,*** 2nd ed. (1969), has two chapters on Propertius, the man and the artist, and a bibliographical survey of recent research.

(G.Lu.)

Property, Law of

Property may be defined as an exclusive right to control an economic good; it is the name for a concept that refers to the rights and obligations, privileges and restrictions that govern the relations of men with respect to things of value. People everywhere and at all times desire the possession of things that are necessary for survival or valuable by cultural definition and that, as the result of the demand placed upon them, become scarce. Customs as well as legislation enforced by organized society control the competition for, and guarantee the enjoyment of, these desired things. What is guaranteed to be one's own is, in a broad sense, property.

The word property is frequently used indiscriminately to denote not only ***objects*** of rights that have a pecuniary content but also ***rights*** that persons have with respect to things. Thus, lands and chattels are said to be property, and rights, such as ownership, life estates, and easements, are likewise said to be property. Accurate legal terminology, however, usually reserves the use of the word property for the designation of rights that persons have with respect to ***things.***

The concept of things

Not every thing is controlled by property rights, nor are these rights themselves always governed by the law of property. Legislation, doctrine, or jurisprudence in various legal systems defines the things that can become objects of property rights. In most legal systems. including common law jurisdictions and systems of the French family, the word things applies to both physical objects and intangibles. In legal systems following the model of the German Civil Code, such as the Japanese system, the word things applies only to corporeal objects that are susceptible to appropriation. In these systems, intangibles, such as rights and obligations, are not things nor are they, technically, objects of property rights. Accurate definition of the word things is indispensable because only things in the legal sense can be objects of property rights.

With respect to things, persons may have a variety of rights, some of which confer a direct and immediate authority over a thing whereas others merely confer the possibility of enjoyment through the intervention of another person. An owner and a lessee, according to appearances, for example, seem to have the use and enjoyment of a house in much the same way. But technically the owner has a direct and immediate authority over the house; the lessee has a right against the owner of a house to let him enjoy the house. All rights with respect to things, if they are susceptible to monetary evaluation, are property in the sense that they are guaranteed by the legal order and form part of a person's patrimony. But only rights that confer a direct and immediate authority over a thing are governed by the law of property.

For the purposes of this article, the law of property may thus be defined as a branch of private law that deals with rights conferring a direct and immediate authority over things. This definition of the domain of property law distinguishes it from other branches of private law, namely, from the law of persons, the law of contracts or conventional obligations, the law of torts, the law of family, and the law of successions. These branches deal with relations that may, and frequently do, give rise to property rights. Because of their origin and purpose, however, these property rights are often subject to special rules outside the law of property.

The article contains the following sections:

I. Historical development of property rights

Property rights have developed along with the social organization of mankind. As a legal institution, private property has been known in ancient and even primitive legal systems; as a social fact, private property has been observed in the most primitive societies, tribes, clans, or other groups. Of course, definitions of what constitutes property, and attitudes toward property rights, vary with different cultures and different historical periods.

PROPERTY RIGHTS IN DIFFERENT TYPES OF SOCIETIES

Primitive and nomadic societies. From a partial study of primitive groups and cultures, the German philosopher Friedrich Engels (1820–95) advanced his political rather than scientific thesis that the most primitive form of social and economic organization was that of communism, and this thesis is still expounded today. Modern research has shown, however, that such simple labels as communistic or individualistic are not adequate for the complex scheme of privileges and duties that characterize the relations between individuals and the primitive community with respect to things. It is true, of course, that the institutions of primitive societies often show a much closer relationship between the individual and his group than they do in Western cultures, and they show a greater readiness to yield to the claims of the group. Among hunting or fishing tribes, the community may have the cverlordship of hunting grounds, of fishing vessels, and even of dwellings or of any domesticated animals, although individual claims and privileges are not excluded. At the same time, private property is clearly recognized in weapons, articles of clothing, and ornaments, Individual claims and privileges to other things, such as hunting grounds, are often accompanied by specified duties and responsibilities toward the things and the community. Nowhere has there been discovered an irrational or undifferentiated absorption of the individual into the group.

Community control

In nomadic societies, property rights are distributed among the tribe, clans or families, and the individual members. Individual property rights are largely confined to chattels, especially weapons, utensils, and ornaments. Domesticated animals, ceremonial items, and medicine bundles manifesting the possession of supernatural powers may be the objects of either tribal, family, or individual property rights, depending on the economic conditions and social structure of each community. When land is plentiful and when the whole system of husbandry is based on roaming about large tracts of land, there is no reason to carve out individual plots for permanent occupation and use. Even with the appearance of agriculture, territorial rights remain for some time vested in the community or in clans and families.

Agricultural societies. In developed agricultural societies, in addition to property rights in chattels, there are well-defined property rights in land, which, by virtue of cultivation, become a most important economic good. Rights in land, at any historical stage, may be vested in the community, in clans or families, and in individual members with a varying degree of intensity. It would be dangerous to generalize from a number of observed types of social and economic organization and to project conclusions as to the most prevalent form of property rights in land, namely, as to the communal, family, or individual ownership of the soil. Vestiges of communal tenure have been observed in various parts of the world, ranging from exclusive control to mere supervision of the use of lands by families or individuals. Clan, family, and individual rights to the exclusive use of parcels of land, subject to a variety of obligations and responsibilities, have also been observed. The intensity of individual claims to the exclusive use and enjoyment of lands, and of attending duties and responsibilities, may vary with each society, but one may assert with a degree of certainty that the phenomenon of individual property rights in lands appeared for the first time in the framework of agricultural societies.

Urban societies. In urban and commercial societies, as exemplified by ancient Greek and Roman communities, family and individual property rights in lands and chattels tend to become the rule. Vestiges of communal tenure within the tribe are scarce in the case of Greek and Roman communities, because the culture of these peoples developed in connection with towns surrounded by small plots of intensive cultivation. Individual ownership of lands and chattels achieved the status of an exclusive right in ancient Greek communities and that of dominium, an absolute right of ownership, in Rome.

In the long history of property law in Western civilization, simple and unencumbered ownership was known almost exclusively at the beginning and end of the Roman period and. again, after the French Revolution. In the Middle Ages, lands in western Europe were subjected to feudal tenures, namely, to a regime of division of ownership into perpetual interests of landlords and tenants. Landowners retained the ownership of lands, but they did not have possession. Originally land reverted to the landowner on the death of the tenant, to be redistributed at the landowner's will, but by the 9th and 10th centuries tenants began to hold lands by virtue of a perpetual and heritable right of enjoyment even though they did not have ownership. At the end of the feudal period (12th and 13th centuries), the nature of the tenant's interest came to be identified as true ownership, although it remained subject to a tax or relief in favour of the former landlord at the time of inheritance. Although feudalism in the strict sense ceased to exist, some perpetual tenures and land reliefs continued to exist in France until the beginning of the Revolution, and in Prussia until almost the same time. Since that time, the only right of ownership recognized in the legal systems belonging to the French family has been full ownership corresponding to the *dominium* of the early Roman law. Analogous developments took place in most parts of continental Europe where feudalism had prevailed. In the United States, tenures have been largely abolished by statutes declaring all land to be allodial (freely held, without obligation to another); and in American jurisdictions in which tenures may be said to have survived, the only incident of tenure is escheat (property that reverts to the state if there is no one competent to inherit it). In England, reform legislation designed to suppress the few remaining vestiges of feudal law was enacted in 1925.

Feudal development

Modern reforms

Neither codification of the law of property in civil law jurisdictions nor reform legislation in common law jurisdictions has hindered further evolution. Modern legislation and judicial practice in the Western world and countries with comparable or derivative systems exhibit a tendency toward a limitation of the intensity of ownership in the interest of all and, at the same time, toward extension of ownership to new forms of wealth. These developments in contemporary systems tend to indicate that ownership is not an absolute right but involves, rather, social as well as individual responsibilities. The right of ownership does not confer today, as it did in the feudal period, political, social, and economic privileges. Yet the possession of wealth still exerts much de facto power in society. In spite of limitations, ownership allows considerable freedom for the satisfaction of purely private interests and endows the owner with a type of limited sovereignty.

In Socialist countries, the institutions of property underwent drastic changes. Traditional concepts were suppressed, and new kinds of property rights emerged in conformity with Marxist philosophy. Property in Socialist countries is fundamentally divided into goods of production and goods of consumption and into personal property, cooperative property, and Socialist property. Superficial comparison between these divisions and property institutions in the Western sense, without reference to underlying basic economic, political, and social philosophy, would be both misleading and inaccurate.

ACQUISITION OF PROPERTY RIGHTS

Property rights may be acquired in a variety of ways: by the occupancy of things that belong to no one, by transfer from a previous owner or even by a nonowner, by operation of law, by the effect of judgments, and by acts of public authorities. For systematic purposes, distinction may be made between *original* and *derivative* acquisition of property rights. An original acquisition involves the creation of new property right; it is independent of any pre-existing rights over the same thing. A derivative acquisition involves a transfer of a pre-existing right from one person to another.

The distinction between the two modes of acquisition of property rights is important in the light of the maxim, prevailing in most legal systems, that no one can transfer a greater right than one has. This means that, ordinarily, the transferor must be owner and must transfer the property as it may be burdened with rights of third persons. In a number of contemporary legal systems, the scope of the maxim has been narrowed by exceptions. Thus, under the laws of France and Germany, property rights in movables that are neither lost nor stolen may be transferred by a nonowner to a good-faith purchaser for value. In American jurisdictions, analogous results have been reached by a so-called bona fide (good-faith) purchaser doctrine. Lands, as a rule, must be transferred by the true owner; yet, by way of exception, a good-faith purchaser may be protected in several legal systems if he has relied on entries in land registers or other public records. These problems do not arise in cases of original acquisition of property rights.

Original acquisition. There is a variety of original modes of acquisition of property rights. For the purposes of this article, attention may be focussed on occupancy, finding, accession, acquisitive prescription, expropriation, and the establishment of property rights by acts of public authorities.

Occupancy. Occupancy—namely, the taking of possession of things that belong to no one—is perhaps universally recognized. In Roman law things without owner became the property of the first possessor. In contemporary legal systems, this mode of acquisition of property rights is largely limited to movable things, such as wild animals, birds, fish, and abandoned chattels. In times past, lands could also be acquired by mere occupancy or cultivation in various parts of the world; today, however, as a rule, the acquisition of property rights in lands is subject to license or grant by the state, which is supposed to hold title to all unclaimed lands. Akin to occupancy is the finding of lost things and the trove of a treasure. Lost things have an owner, but laws in various jurisdictions ordinarily attribute ownership to the finder after the lapse of a certain period of time or upon the completion of certain formalities, such as advertisements or reports to the authorities. Likewise, laws provide for the apportionment of a treasure trove between the finder and the owner of the property in which the treasure was hidden.

Owner's right to fruits of earth

Accession. Accession is another broadly recognized mode of acquisition of property rights. It is based on the principle that the ownership of a thing, either movable or immovable, carries with it the right to whatever the thing produces and to certain other things that are united with it, whether naturally or artificially. Thus, the fruits of the earth, whether spontaneous or cultivated, and the increase of animals belong to the owner by right of accession. The ownership of the land carries with it the ownership of all that is directly above and under it, unless the contrary is established by provision of law or contract; therefore, buildings and other constructions erected by trespassers on the land of another become the property of the landowner. Detailed provisions in various legal systems deal with accession to movables, which, apart from the increase of animals, ordinarily takes place in cases of joining materials belonging to different owners; mixing grains or fluids; and, in cases of production of new things, bestowing labour on the materials of another person.

Acquisitive prescription. Acquisitive prescription, a civil law method of acquisition, is predicated on the possession of a thing over a designated period of time with the intention to own it. Acquisition of property rights in immovables ordinarily requires a longer period of possession than the acquisition of property rights in movables. The required period of time may also vary with the nature of possession: a good-faith possessor ordinarily acquires property rights in a shorter period of time than a bad-faith possessor. In common law jurisdictions, the institution of "adverse possession" performs the same function as acquisitive prescription. Technically, adverse possession extinguishes the right of the previous owner and bars his remedy against the possessor; it does not confer title upon the adverse possessor. In all legal systems today, however, those in adverse possession are equally well protected and are able to transfer their rights to their heirs or administrators and such.

Power of eminent domain

Expropriation. Expropriation of property for purposes of public utility, with or without compensation, is known in all contemporary legal systems. Even when made without compensation, expropriation is distinguished from confiscation, the taking of property by the authorities arbitrarily or as a penalty for the violation of law. Ordinarily, constitutional provisions and other legislative texts insist upon notice and the payment of an adequate, fair, or just compensation to the owner for the expropriation to be valid. In effect, expropriation is made in favour of the state, its political subdivisions, or private utilities enjoying the so-called power of eminent domain because of the services they render to the general public. The possibility of expropriation in all legal systems indicates that property rights are not absolute.

Privileges conferred by public authorities. Finally, an original acquisition of property rights occurs when public authorities confer upon certain persons entirely new economic privileges or recognize privileges that had existed in fact but not in law. Examples are grants of property rights to lands of the public domain, including ownership and rights for the exploitation of mineral resources; grants for the exploitation of natural resources, such as hydroelectric energy or radio waves; and patents, registered designs, trademarks, trade names, and copyright, which form so-called industrial or intellectual property. (Material on these subjects can be found in the following articles: COPYRIGHT LAW; TRADEMARK LAW; PATENT LAW.)

Derivative acquisition. All legal systems establish methods for the acquisition of property rights by transfer from a previous owner. The transfer may be voluntary, as in the case of a last will and testament or an agreement between the previous owner and the transferee; it may be involuntary, as in the case of a judicial sale; or it may take place by operation of law, as in the case of intestate succession.

Sale. One of the most prevalent modes of acquisition of property rights is by the contract of sale. A sale involves the transfer of a thing for a sum of money or the promise of a sum of money; if the transfer is for something other than money, the transaction is technically designated as exchange. In legal systems of the French family and in common law jurisdictions, the contract of sale transfers the ownership of the things sold. Insofar as third persons are concerned, however, transfer of ownership may depend on delivery of movables or the recording of the title of immovables. In Roman law and in systems following the German Civil Code, however, the contract of sale merely involves a promise to transfer the peaceable possession of the thing sold; the actual transfer of property rights may depend on delivery or on compliance with certain formalities. In most legal systems, contracts of sale are free of any formalities and may be based on verbal agreement, but the rules of evidence may exclude the proof of certain verbal contracts if the object exceeds a specified value. Moreover, in most contemporary systems, the sale of immovable property must be recorded, either for its validity against third persons or for the actual transfer of rights.

Acquisition through wills and testaments

Donation. Another prevalent mode of acquisition of property rights is by donation. Donations may be *inter vivos,* intended to take effect while the donor and the donee are living, or *mortis* causa—that is, in contemplation of death. Donations of all sorts are ordinarily subject to strict requirements of form intended to ensure that their execution and the intent of the donor are genuine. *Moıtis causa* donations are ordinarily contained in last wills and testaments, which must be executed everywhere in strict compliance with the requisite formalities. Formal requirements are usually dispensed with in cases in which the possession of tangible movables is transferred to the donee. As in the case of sales, the transfer of property rights may be effective as between the donor and the donee upon completion of a donation or it may require for its effect the delivery of movables and the recording of necessary documents.

Judicial Sale. Anothei prevalent mode of acquisition of property rights is by judicial sale. Judicial sales take place in a variety of circumstances, such as in cases when the property of an insolvent debtor is seized and sold for the satisfaction of his creditors, when property is sold by the state or by its political subdivisions for the payment of tax claims, when property is judicially partitioned among co-owners, or when inherited property or that of a minor is sold by an administrator or tutor. Provisions of law ordinarily establish the requisite formalities and rules of substance for the validity of a judicial sale. As a derivative mode of acquisition, the judicial sale transfers to the acquirer only the property rights that the previous owner had.

Intestate succession. Finally, derivative acquisition of property rights takes place by operation of law in cases of intestate succession; that is, when a person dies without leaving a will. Rules of law in developed as well as primitive legal systems determine which rights are heritable and specify the order of succession, which varies with the culture and the structure of society. In Socialist legal systems, the devolution of property by inheritance tends to be restricted. In most other modern legal systems, death taxes have, to some extent, restricted the devolution of large fortunes, but the right of inheritance remains one of the fundamental precepts of law. In civil law systems, the legal heirs of a deceased person are supposed to continue the "personality" of the deceased and to succeed to all of his rights and obligations that are considered to be heritable. Moreover, certain close relatives—whether descendants, ascendants, or a surviving spouse—are entitled to a forced share of the estate, even against the will of the deceased. In common law systems, the property of an intestate is placed under the authority of an administrator who pays all debts and charges and who puts the legal heirs into possession upon completion of the administration. Although the concept of a forced share is foreign to common law, the children and surviving spouse share the estate·of one who dies intestate. Modern legislation in a number of common law jurisdictions has also granted the spouse a right to elect what the law would allow her in the case of intestacy rather than accept the provisions of an unfavourable will.

Forced share in civil law countries

II. Types of property rights

OWNERSHIP

The rights of individuals, groups of individuals, or other entities, for the exclusive enjoyment of economic goods may be designated as rights of ownership. The word ownership has a precise technical meaning in most legal systems and, especially, in civil law countries. It is seldom used in the professional literature of English law and most common law jurisdictions, though in the United States ownership is frequently used synonymously with property. In this article the word ownership will be used in a broad sense to designate rights for the exclusive enjoyment of economic goods.

Rights of ownership may be classified according to a variety of criteria. From the viewpoint of the *subjects* of these rights—that is, the persons or entities that hold them—rights of ownership may be distinguished according to whether they are held by individuals, by tribes and clans, by family groups, by collectives and cooperatives, by unincorporated associations, by corporations, or by the state and public corporations. Each right of ownership in this respect may have peculiar characteristics of its own.

Varieties of owners. *Ownership by individuals.* Ownership by individuals has been recognized by all societies and at all times, although the scope, extent, and incidents of individual claims have varied with the culture and structure of each society. Moreover, variations have been common with respect to the objects that may be owned by individuals. For example, individual ownership of lands or of other means of production may be excluded, but individual ownership of chattels may be allowed.

In developed legal systems, ownership may be vested in a single individual, in which case one speaks of individual ownership purely and simply; or it may be vested in a number of individuals, in which case one speaks of individual co-ownership. Co-ownership has been recognized from early times, and, in a sense, the ownership of lands and chattels by tribes, clans, or other groups, may be regarded as a form of co-ownership. But it was in ancient Rome that the institution of co-ownership by individuals assumed certain typical characteristics that survive in contemporary lega! systems.

Co-ownership

In civil law systems, the share of each individual co-owner is a distinct right of property; it gives rise to a claim for the proportional use or enjoyment of the thing held in common; it is freely disposable unless there is an agreement to the contrary; and the share of each owner devolves to his legal heirs or legatees at death. The rights and obligations of the co-owners are ordinarily determined by directly applicable provisions in civil codes. If one co-owner wishes to sell his part of a thing held in common, as distinguished from selling individual shares, consent of all the co-owners is ordinarily required, unless, of course, the law or contractual provisions establish a different rule. Co-ownership is essentially voluntary; thus, ordinarily co-owners have the right to demand partition of the thing held in common, whether in kind or by judicial sale.

In common law jurisdictions, the institution of co-ownership may assume either the form of an *ownership in common*, corresponding to the civil law notion of co-ownership, or the form of *joint ownership*, which is an original common law institution. The difference between the two forms of co-ownership depends upon the manner in which an individual interest devolves upon the death of a co-owner. If an owner in common dies, his share passes to his successors, whether by will or on an intestacy; but if a joint owner dies, his interest accrues to the remaining owners, so that when all owners but one are dead the survivor becomes the sole owner.

Ownership by tribes and clans. In tribal societies, ownership by individuals tends to be limited to certain chattels only. Apart from cultural, geographical, and historical variations, the exclusive control of lands and of .most chattels is vested in the tribal community. Tribes on the move and tribes engaged in agriculture as an occasional pursuit have been known to assign lands to clans or kindreds for temporary occupation. In a more settled state of society, portions of the tribal territory may be assigned for permanent occupation, but occasional redistributions of land indicate that the overlordship remains vested in the tribe. Once a tribe is fully settled, there is frequently a gradual transition from tribal communalism to clan or kindred communalism; that is, transfer of the ownership of lands from the tribe to the clans or kindreds.

Vestiges of tribal and of clan ownership persisted in most European countries in the form of the open-field system, until enclosures put an end to it in relatively modern times. This system was based on the idea that the ownership of land was vested in the collective body, which was charged with the duty to see that every individual or household would have the means and opportunity for profitable labour. Survival of tribal custom may still be observed in isolated parts of the continent in the form of village ownership of pastures and forests.

Effect of the enclosures

Ownership by family groups. Ownership by family groups is predicated on the existence of an "extended" family—a family of many blood relatives—that tends to curtail individual interests in order to preserve the unity of the household. Extended family arrangements have been prevalent in India, where they continue to exist today; extended-family arrangements were known to exist among the southern Slavs in the Balkan Peninsula up to the first part of this century, and comparable institutions have been observed in the early history of the Germans, the eastern Slavs, and certain Romance nations.

Since Indian family ownership contains features that distinguish it from property institutions of the Western world, mention of these features is appropriate here. Ordinarily the property of an extended family in India is owned by the body of the members. The head of the family has merely the management of the propeity rather than title to it. When the head of the family dies, the members may not be said to be heirs, because they do not take property that did not already belong to them. The only change is that the family is reduced in size, a result that would also follow the death or departure of a junior member. According to some local customs, the head of the family may be regarded as nominal owner of the property, but even in this case the ownership of the head of the family is subject to stringent collective controls that exclude the idea of individual ownership in the Western sense.

Therights of individual members

The rights of individual members may be described as undivided shares in the whole of the family property. In principle, shares are assigned to members in the light of their relative seniority and are given to branches of the family rather than to individuals. Members of junior generations may not get their shares until the death of their parents, who, as long as they live, represent the whole branch.

Since ordinarily the head of the family is manager rather than owner of the family property, his acts are supervised and at times overruled by the body of members. As a rule, alienation or encumbrances such as sales or mortgages require the consent of all members.

The purpose of the institution of family ownership is to secure the means of subsistence for all of the members of the extended family. As a consequence, the members have a right of maintenance that is quite alien to Western views: weaker members of the family are given the means of support without regard to their contribution of labour; spinsters are provided with a dowry; and children are given the means of education. To achieve these ends, the family sets aside a certain amount of the property or its income and does not allow such funds to be used for other purposes. The beneficiaries, however, have no direct property interest in the funds; their position, in effect, is similar to that of beneficiaries of charitable institutions.

Family ownership does not preclude individual ownership. In certain circumstances, family ownership may be converted into individual ownership by dividing the assets among the individual members. Moreover, in the framework of any extended family, there may be a distinction among objects belonging to individual members (as a result of their personal labours) and objects belonging to the family community as a whole.

Ownership by collectives and cooperatives. Property owned by collectives and cooperatives is found in primitive as well as in developed legal systems and in capitalistic as well as in socialistic countries. Since the beginning of the 19th century, this type of property has proliferated as a result of pronounced movements toward collectivism and cooperation.

In capitalist countries, collectives and cooperatives are associations of individuals, such as farmers, labourers, consumers, home owners, or small entrepreneurs, formed for the pursuit of some productive enterprise, the benefits of which are to be shared in accordance with the capital or labour contributed by each member. The rights and obligations of members may be specified in contractual provisions or in legislation. Although these associations are ordinarily formed voluntarily, there are instances in certain countries where they may be formed under legal compulsion. In the United States during the 20th century, the most common type of cooperatives have been formed for the production and distribution of electricity in rural areas and for the building and enjoyment of apartment units in metropolitan areas.

In Socialist countries, collectives and cooperatives of a variety of sorts flourish as realizations of Marxist theory under the protection or under the compulsion of law. In Socialist countries, the property of cooperatives exists alongside personal property and property belonging to the state. The prime example of cooperative property in the U.S.S.R. is that of the kolkhozes, or collective farms, which have the perpetual right of enjoyment of state lands. The kolkhozes must be organized and administered in strict compliance with legislation; they are bound to cultivate or exploit the lands assigned to them in certain designated ways and to give certain payment to the state; and in this respect they differ from corresponding institutions in capitalistic countries.

Rights of kolkhozes

Ownership by unincorporated associations. According to the Roman law tradition, rights of ownership, as indeed any rights and obligations, may exist only in those entities possessing legal personality. Such entities are living human beings (natural persons), associations of human beings, and foundations established for the realization of a general interest (juristic persons). The state and its political subdivisions, profit and nonprofit corporations, and partnerships are examples of associations capable of possessing legal personality and of owning property. Hospitals and charitable institutions are examples of foundations likewise capable of possessing legal personality and of owning property.

Unincorporated associations formed for the pursuit of vocational, artistic, scientific, or religious purposes may or may not possess legal personality depending on applicable laws and on compliance with required formalities. If they do not possess legal personality, they cannot hold property in their own name; their property belongs directly to the members of the association and is usually held in undivided shares. If they possess legal personality, they have property of their own that is distinct and distinguishable from the individual property of the members.

Ownership by corporations. Corporations are juristic persons—that is, artificial entities formed by human beings to which the law attributes legal personality for the pursuit of social and economic purposes. They have no physical existence, but, as persons, they participate in legal life and are capable of holding property in their own name. There are various sorts of corporations: private and public, secular and religious, and profit and nonprofit corporations.

The proliferation of corporations since the 19th century has been said to reflect, throughout the world, a movement from the individual ownership of capital to the collective ownership of capital. This movement has been observed in capitalist countries, in which wealth tends to be concentrated in the hands of private corporations, as well as in Socialist countries, in which wealth is concentrated in the hands of the state and other public corporations.

Distinction between property of corporation and shareholder

The corporate device allows for a clear distinction between the property of the corporation and the property of a shareholder. Technically, no one owns the corporation, which has an independent existence of its own. A share merely represents a fractional interest in the property of the corporation and confers a corresponding interest in its administration, and even when all shares are concentrated in the hands of a single person, there is still a clear distinction between the property of the corporation and the property of the sole owner of its shares. When incorporation is completed, the individual property of a shareholder is completely insulated from the risks of the corporate enterprise. Creditors of the corporation may not take the property of a shareholder for the satisfaction of their claims, nor may creditors of the shareholder take the corporate assets. The only risk that a shareholder assumes is that represented by the amount of his investment in the corporation, and it is only his own shares that constitute property that may be seized by his own creditors.

Ownership by state and state corporations. In all legal systems, the state and its political subdivisions are political corporations that have the capacity to own property. This property may be of two sorts: public property (such as navigable waterways, national parks, and monuments), which is ordinarily inalienable and is held in trust for the benefit of all citizens, and private property (such as state-owned enterprises and buildings housing various agencies), which does not differ in essence from property held by private persons.

In modern times, states have asserted ownership over a variety of things that previously were considered to be without owner, such as running waters and wild animals. This form of state ownership, asserted in an effort at conservation of natural resources, confers mainly administrative advantages and prevents the private appropriation or ownership of certain assets of society except under regulations that protect the social interest.

In socialist countries, lands, industrial capital, and vari-

Public corporations

ous service fields are ordinarily owned by the state and its political subdivisions to the exclusion of private interests. In capitalist countries, the state and its political subdivisions may enjoy certain economic monopolies and may directly own a variety of enterprises whether in competition or in cooperation with private interests. Moreover, the state and its political subdivisions may undertake economic activities through a variety of public corporations. Thus, for example, postal services, telecommunications, and the exploitation of hydraulic energy may be in the hands of public corporations. In recent times, there has been much experimentation toward the development of public corporations with the cooperation of private capital; the state may preserve the control and administration of a public corporation in a service field, but the profits of the enterprise may be shared by private shareholders.

Legal distinctions between movable (personal) and immovable (real) properly. In civil law systems, in mixed jurisdictions, and in Scandinavian countries, things are divided into movables and immovables, a division that was also known in ancient legal systems. In common law jurisdictions, property (rather than things) is divided into personal property and rea! property (realty), but these terms may be taken as roughly equivalent to the civil law notions of movables and immovables. In socialist legal systems, the traditional divisions of things into movables and immovables tends to be suppressed. In the U.S.S.R., this division has been expressly discarded and replaced by new classifications reflecting prevailing economic and political theory. The significance of the division of things into movables and immovables lies primarily in the fact that special rules of property law apply to the various categories of things classified as immovables. Almost universally, the acquisition, possession, transfer, or encumbrance of immovables is subject to rules of property law that are materially different from those governing movables. Moreover, immovables may be subject to special rules in the fields of obligations and contracts, family law, successions, civil procedure, taxation, criminal law, and conflict of laws.

Special position of land

The rules of property law applicable to immovables tend, on the one hand, to delimit narrowly individual rights in this type of wealth and, on the other hand, to enhance security of title. In modern times, there has been more emphasis on security of title, but, even today, rights in immovables may be subject to special limitations concerning acquisition, alienation, seizure, testamentary disposition, and partition. The modem trend toward security of title has led to an increased emphasis on public records. In central European countries and in part's of the British Commonwealth the very existence of interests in immovables depends, ordinarily, on the recording of formal acts in land registers. Moreover, all entries in the land registers are accorded full faith and credit (that is, are accepted in other states or countries) so that innocent third parties may rely upon them. In the United States, in legal systems of the French family, in Scandinavian countries, and in other parts of the world in which a land register system has not as yet been established, the transfer or encumbrance of immovable property is ordinarily effective toward third persons from the time pertinent documents are placed in public records. The degree of faith and credit accorded to entries in these records varies from country to country.

Since ancient times and up to the era of the Industrial Revolution, land (an immovable) was regarded as the most important type of wealth; hence, particular rules were developed to safeguard interests connected with the possession, use, and enjoyment of land. In modern times, however, economic emphasis has shifted to values other than land, and the law tends to accord to these values the type of protection traditionally reserved for land.

Ancient divisions of property. In ancient Roman law, emphasis on the relative significance of the elements of wealth led to the division of things into res mancipi and res nec mancipi. Land subject to Roman ownership, cattle, beasts of draft and burden, and rural servitudes attached to land subject to Roman ownership were classified, in the light of their importance for the realization of economic, political, and social interests, as res mancipi; all other elements of wealth were res nec mancipi. This division of things was kept alive by classical jurists in spite of profound changes in the economy and society. The Emperor Justinian formally abolished it in the 6th century and replaced it with the distinction between movables and immovables, a distinction that had been known but was relatively insignificant under earlier law.

Roman law scholars elaborating on Justinian's *Corpus juris civilis* during the era of reception of Roman law in continental Europe (14th to 16th centuries) paid little attention to the old division of things and quite naturally focussed attention on the distinction between movables and immovables. This distinction was elaborated further in the following centuries and found its way into the developing legal systems of various continental countries.

Modern variations. In legal systems of the French family, the distinction between movables and immovables rests, in principle, on physical notions of mobility and on inherent characteristics of things. An immovable is defined as a thing having a fixed place in space, and a movable as one that can either move itself or be removed in space. For reasons of policy, however, the law may treat as movables things that according to lay notions could be regarded as part of an immovable, such as standing crops. On the other hand, the law may qualify as immovable things broadly considered to be movables, such as farm implements and animals. Rights that attach to an immovable object are also immovables.

In Germany, and in legal systems following the model of the German Civil Code, immovables are tracts of land and their essential component parts; things that are neither tracts of land nor essential component parts of tracts of land are movables. Since things in these legal systems are defined as tangible objects, rights are neither movables nor immovables; nevertheless, for certain practical purposes, rights closely connected with immovables may be subject to the rules governing immovable property.

In England, the distinction of property into personal and real was considered as late as 1925 to be the keystone of property law. The distinction arose in the formative era of the common law and corresponds roughly to the distinction between feudal and nonfeudal property. Because land was the foundation of feudalism, the distinction between real property and personal property corresponds roughly to that between land and chattels. The distinction between the two kinds of property was originally procedural; lawyers distinguished between real actions, tending to secure the recovery of property in kind, and personal actions, tending to secure the payment of damages for unlawful interference with one's possessions. Because feudal relations were largely determined by the manner in which particular tracts of land were held, it was necessary for an ousted landholder to recover his own particular tract. Hence, real actions were largely available for the protection of interests in land, whereas personal actions were available for the protection of interests in chattels; in time, the terms real and personal property came to denote the objects of property rights protected by these actions.

Real property

Real property (realty) may thus be defined as interests in land other than leasehold interests (held for a definite duration); personal property (personalty) includes interests in movables and leasehold interests in land. Each type of property was, in effect, governed by a distinct set of rules. With the exception of certain technical rules of minor significance, however, the differences between real and personal property were swept away in England as a result of statutes enacted after 1925. The differences between the notions of movables and immovables in civil law and real and personal property in English common law have thus been minimized. In spite of differences in methodology and conceptual technique, the law of real property in England today performs a function essentially similar to that performed by the law of immovable property in civil law jurisdictions.

Similarly, legislation in the United States and in other common law jurisdictions has simplified the law of real property and has transformed it into a law applicable to land. The distinction between real and personal property is still drawn in the United States in the light of the historical past, but it has lost most of its original significance. In contemporary American practice, distinction is made between land and movables, and modern treatises of property law include consideration of both elements of wealth.

In the U.S.S.R., the distinction between movables and immovables was expressly abolished by the Russian Civil Code of 1922, which was largely reproduced in the various civil codes of the constituent republics. Since all land had been nationalized and, therefore, removed from commerce, it was thought that the distinction between movables and immovables had lost its reason of existence. Today, property in the U.S.S.R. and other Socialist countries is divided into goods of production and goods of consumption and into personal property, cooperative property, and socialist property. As such, these distinctions reflect Marxist philosophy. Land, which can no longer be privately owned, is subject to special rules. Buildings and other constructions may be personal property, cooperative property, or socialist property, depending on their function. In each case, they are subject to appropriate legislation rather than a common set of rules, although it is true that residential homes, which may be privately owned, are subject to a number of special rules that are inapplicable to other types of personal property. The transfer of a residential home, for example, is subject to the requirements of notarial act and registration in public records, whereas the alienation of other things is effected by informal agreement and delivery.

Choice of law. The laws of a state or country apply, in principle, to all persons, acts, and things within its geographical limits. This principle of the territoriality of laws, however, is not absolute. In cases involving foreign elements, courts must decide whether they have jurisdiction to pass upon the controversy before them and whether the controversy is governed by the court's own law or by some foreign law. These questions form part of the discipline known as conflict of laws (*q.v.*) or private international law.

Law of the situs

The division of things into movables and immovables has legal consequences in the field of conflicts of laws. According to a universally recognized rule of choice of law, the determination of whether a particular thing is movable or immovable and the determination of most disputes concerning rights in immovable property are made by application of the law of the place in which the property is situated—the law of the situs. In common law jurisdictions, almost all claims with respect to iinmovable property, whether they arise from contractual transactions or from inheritance, are said to be governed by the law of the situs. Because common law courts refuse to exercise jurisdiction when immovable property is situated in a foreign state or country, this law is ordinarily the court's own law. In civil law countries the law of the situs ordinarily governs claims arising from transactions among living persons only; succession rights in immovable property are governed, as a rule, by the law of the nationality of the deceased. In contrast with common law courts, courts in civil law countries exercise jurisdiction quite freely when immovable property involved in litigation is situated on foreign soil, applying the law of the situs.

Choice of law in civil law countries

There is a variety of law rules in existence for movable property. The traditional common law rule is that movables, having no fixed location, are governed by the law of the domicile of their owner. In modern times, however, the courts tend to pay lip service to the traditional rule while they actually fashion new rules; movables are now governed by such criteria as their original or current placement or the place where the parties involved carried out their transactions, depending on particular facts and circumstances. In civil law countries, as a rule, the creation, modification, or termination of rights in individual corporeal movables is determined by application of the law of the situs. Succession rights in movable property, however, are ordinarily determined by application of the law of the nationality of the deceased. In these countries, the division of things into movables and immovables tends to lose much of its significance in conflicts law, since, as a rule, all types of property are governed either by the law of the situs or by the law of the nationality of the deceased. In all jurisdictions, rights in industrial property are governed either by the law of the place in which these rights were created or by directly applicable international conventions.

Legal **distinctions** between tangible **and** intangible property. The Romans classified objects of property rights as either corporeal or incorporeal. Physical objects that could be felt or touched were given as illustrations of corporeals. Incorporeals were abstract conceptions, objects having no physical existence but having monetary value; the illustrations given were rights of various kinds, among them inheritance, obligations, and all proprietary interests in things with the exception of the right of ownership, which was considered as corporeal because its object was corporeal.

In legal systems of the French family, which follow the Roman tradition, things are divided into corporeals and incorporeals. A thing is corporeal if it is perceivable by any of the senses; incorporeals are rights that are conceived by the intellect. Under the German Civil Code, however, and those modelled after it, ownership and other proprietary interests may exist for corporeal objects only. Incorporeal objects, such as rights having monetary value, though part of a person's patrimony, are not governed by the law of property.

Types of intangible property

In common law jurisdictions, a distinction is made between tangible and intangible property that corresponds roughly to the Roman division of things into corporeals and incorporeals but does not coincide with it. Tangible property includes lands and certain chattels known as choses in possession; that is, rights in definite tangible things over which possession may be taken. Intangible property is largely one of two types: (1) choses in action, namely, rights of property that can only be claimed or enforced by legal action and not by taking physical possession, such as bank accounts; debts generally; stocks and shares; and industrial property, including patents, registered designs, trademarks and trade names, and copyright and (2) *incorporeal hereditamenis,* namely, heritable rights, or rights passed by way of descent to heirs, such as those relating to lands, buildings, minerals, trees, and all other things that are part or affixed to land and also easements, profits, and rents.

Servitudes and easements. From among the various species of incorporeal things or intangible property, attention may be focussed at this point on servitudes in civil law jurisdictions and on easements and profits in common law jurisdictions. A servitude is a proprietary interest, which amounts to a real right on the property of another person. It may be a charge laid on one estate in favour of another estate, such as a right of passage, or a right of diverting water or drainage through the other estate. Or it may be a charge laid on an estate in favour of a person, such as a right of usufruct, use, or habitation. An easement may be defined roughly as a property right in a person or a group of persons to use the land of another for special purposes, such as rights of way, rights of diverting the course of a stream for irrigation purposes, and rights for the support of buildings—that is, any right not inconsistent with the general property right of the owner of the land.

Profits. A profit, technically known as *profit-d-prendre,* is the right to use another's land by removing a portion of the soil or its products; it includes the right to take fish or game; to pasture one's animals on the land of another; and to take wood, sand, coal, and other mineral substances. At least in American jurisdictions, easements as well as profits may be established in favour of an estate or in favour of a designated person.

Rights of way. Rights of passage or rights of way are some of the most frequently encountered servitudes and easements. These are rights to pass over the land of another. They are not natural rights and must be created by application of one of the methods that are available for the acquisition of property rights. Rights of passage or of way may be either public, for all persons to enjoy, or

Water rights

private, for the benefit of a designated person or a class of persons. Rights with respect to the use of waters are likewise some of the most frequently encountered servitudes or easements. According to civil law conceptions, which have been broadly adopted in Anglo-American jurisdictions, landowners have certain well-defined rights with respect to surface waters; underground waters; and natural watercourses, such as rivers, streams, and lakes traversing or bordering their lands. Modifications of these well-defined rights may take the form of servitudes or easements. Thus, the owner of an estate situated above may acquire, from the owner of an estate situated below, the right to pollute a natural stream traversing both estates or the right to obstruct the flow of the stream or the flow of surface waters; the owner of the upper estate may acquire the right to use an unreasonably great amount of water for his own purposes or to discharge drain and refuse waters upon the lower estate; and any landowner may acquire the right to divert the flow of natural water courses and to maintain on another estate an aqueduct for his needs.

Mineral rights

Finally, mineral rights, especially rights for the exploitation of oil and gas, may take the form of servitudes in civil law jurisdictions and of profits in common law jurisdictions. In most parts of the world, however, mineral exploration depends on prior license, concession, franchise, or grant by the state that has asserted its ownership of valuable natural resources. Only seldom are oil and gas rights profits in American jurisdictions; ordinarily, persons undertaking such operations acquire from the owner of the land the ownership of the minerals in place.

TEMPORAL DIVISION OF OWNERSHIP

In all legal systems, the right of ownership is susceptible to division among co-owners holding undivided interests over the same thing. In common law juridictions, however, ownership is capable of being divided in a great variety of ways from the viewpoint of time as well as from the viewpoint of space. The law governing temporal division was worked out in the first instance for land and later applied to funds comprising both land and certain chattel interests of a permanent nature, such as stocks and shares.

Common law: estates. The historical basis of common law property is that only the Crown can own land. A landowner, strictly speaking, does not own land but a ***time*** in the land, an interest called an ***estate.*** Lawyers manipulated this concept of time in the land and devised an intricate system of estates, which may be either successive in time or concurrent, in the sense that two or more persons may own property jointly or they may have separate rights of ownership in the same property at the same time. Ownership is not attached to the land itself but to an abstract entity, the estate, that is interposed between the tenant and the land. The estate is purely conceptual, yet it is treated by the law as if it were a real thing.

Three simple classifications of estates may be mentioned at this point. The first is into estates in ***possession*** and estates in ***expectancy.*** If a person's estate gives him a right to the immediate possession of the land, it is said to be an estate in possession; if, on the other hand, he must wait for his right to possession to take effect, he has only an estate in expectancy. The second classification concerns only estates in expectancy, which are divided into ***remainders*** and ***reversions.*** A remainder is an estate that becomes effective when the estate of a previous owner expires. A reversion is similar to a remainder in that the right to enjoy the land is postponed to a future date; when there is a reversion, however, the land eventually returns to the grantor, whereas with a remainder the land goes to some other person. The third classification is into ***freehold*** and ***leasehold*** estates, the former having an indefinite and the latter a definite duration.

Fee simple, fee tail, and life estate

Freehold estates. The simplest examples of freehold estates are the estate in fee simple, the estate tail, and the estate for life. The estate in fee simple is, in the ordinary course of events, the nearest thing to full ownership of land found in common law jurisdictions. It confers full rights of possession, enjoyment, and disposition during life and by will. If the owner of the estate in fee simple dies intestate, the land passes to the relatives entitled under statute in that event. Only in the event of the owner dying intestate and without relatives will the estate come to an end and will the land pass to the Crown in England or to the state in other common law jurisdictions. The estate tail or fee tail is an estate less than a fee simple in the sense that it is limited to the person and the heirs of his body. The tenant in tail has full rights of possession and enjoyment, and the estate does not come to an end at his death; it passes to his heirs but only a limited class of heirs, his descendants. The line of descent may be further limited by allowing the estate to descend only through males or through females. If the tenant dies without leaving descendants, the estate may revert to the grantor, or it may go to someone enjoying a remainder. A life estate is one whose duration may be measured by the lifetime of the tenant or of another person. It may also be cut off by the occurrence of a specified contingency, as, for example, the remarriage of the life tenant. The life tenant has the right to obtain the profits of the property, the right to possession, and the right to dispose of his interest. When a life estate is created, there is always a corresponding estate in expectancy that will come into existence when the life estate is terminated. The owner of this estate may have rights of reversion or of remainder.

Leaseholds. Leaseholds or estates less than freehold are those that have a definite duration or a duration that may be made definite a the will of one of the parties concerned. Not all leaseholds arise from leases in the strict sense of the word; some arise from other arrangements and are more properly called ***tenancies.*** The most important and the most frequent are the so-called periodical tenancies, for example, from week to week, from month to month, or from year to year; they may be terminated by notice given by the landlord or by the tenant only on the anniversary of the original grant. When the proper day for notice passes without notice being given, the tenancy is renewed for an additional definite term. Other possible tenancies are those at will and at sufferance. A tenancy at will may terminate at any moment by notice given either by the landlord or by the tenant; a tenancy by sufferance is one held by a person whose lawful term has ended and who continues to possess without right.

Rights of reversion

Whenever a person holds a terminable estate, such as a life estate, questions arise as to his duties toward persons holding rights of reversion or remainder. Ordinarily, a life tenant is entitled only to the income of the property, including the physical use of tangible things; he may not touch the capital that must be transmitted intact at the termination of his interest. Of course, it is frequently difficult to draw a clear line of distinction between capital and income, and the problem is even more complicated when the enjoyment of land is divided among several persons successively. To resolve this difficulty in a practical manner, and in order to afford a measure of protection to the interests of successive holders of land, courts developed remedies for waste. The ever-present temptation of a temporary holder of land to exhaust the soil or to let buildings fall into disrepair may be checked by an action for damages or, even more important, by an injunction restraining the commission of waste.

Statutes enacted in various jurisdictions since the 19th century have worked out substantial modifications of the common law governing estates over land. In most American jurisdictions, the estate in fee tail has been practically abolished, and landholdings have been declared to be allodial (owned and heritable without obligation). In England, the Law of Property Act of 1925 reduced the number of legal estates that can exist over land to two, namely, (1) a fee simple absolute in possession, and *(2)* possession for an unlimited period of time; the number of legal interests or charges was also reduced to five years. All other estates, interests. and charges must exist in trusts (see below ***Ownership for the benefit of others: trusts as property),*** the trustees having the legal estate in fee simple.

Civil law. Compared with the common law doctrine of estates, the institution of ownership in civil law systems is the essence of simplicity. No such abstraction as an estate is interposed between the owner and his property, nor is ownership built on ownership as in the case of a trust. Thus, there is no temporal division of ownership; a person either owns a thing or he does not; it is as simple as that. The content of ownership may be limited, as when burdens on the land such as servitudes are created, but these burdens are regarded as restrictions on the use of the land rather than as rights of separate or concurrent ownership.

Dominium: absolute ownership. The idea of absolute or at least exclusive ownership has been inherited from Roman law. One of the most striking institutions of that legal system was dominium, upon which all the civil law systems have modelled their treatment of ownership. Dominium was, in the final form that it received in the Justinian legislation, as near to being absolute as any institution of private law can be. The owner had an almost absolute right to use, enjoy, and dispose of a thing as he saw fit, subject to exceedingly few restrictions imposed by the state. The kinds of encumbrances (servitudes, mortgages) with which a thing could be burdened were kept to the lowest possible number, and when created they were carefully distinguished from ownership; upon the disappearance of an encumbrance, ownership resumed its original plenitude, leaving no room for the concept of a remainder or a reversionary interest. In contemporary civil law systems, ownership is ordinarily defined as an exclusive right that exhausts the utility of a thing. This right may be either perfect or imperfect. Perfect or full ownership implies that the owner has the prerogatives of use, enjoyment, and disposition of a thing. Imperfect or naked ownership exists when the power of disposing of the property rests with the owner hut when the use or enjoyment is vested in whole or in part in another person. The right of ownership may be dismembered in a number of ways specified by law. Among the permissible dismemberments of ownership in any civil law jurisdiction are included servitudes and real security rights, such as pawn, pledge, and mortgage. All dismemberments of ownership are proprietary interests, which, by their nature, confer direct and immediate authority over a thing belonging to another person.

Perfect and imperfect ownership

Usufruct. Prominent among the personal servitudes in any civil law jurisdiction is the right of perfect usufruct, which corresponds roughly with the concept of a life estate in common law jurisdictions. A perfect usufruct is a real right of enjoyment of limited duration that is exercised on a thing belonging to another person. The usufructuary has a right to draw from the thing all the advantages and utility that it may produce, as if he were owner, but he must restore the thing to the owner or his successors at the end of the usufruct. The creation of a usufruct does not deprive the owner of his ownership; it merely deprives him of the prerogatives of exclusive use and enjoyment.

The difference between usufruct and life estate relates to theory and structure rather than to function. In spite of historical, theoretical, and structural differences, civil law and common law tend to give in most instances strikingly similar solutions to problems of everyday life. A comparison of the function of the life estate with usufruct furnishes an illustration: the two systems, though starting with different basic premises have arrived at substantially the same position.

Obligations to owner or successive heir

Although technically there are neither remainders nor reversions in civil law systems, there are persons whose positions correspond roughly with those who enjoy remainder or reversion. When the proprietary interest of a person in a piece of property is certain to terminate, as in the case of a usufruct, the property eventually is restored to the owner or to another person. Further, cases of terminable ownership are not rare in civil law jurisdictions: any ownership acquired by juridical act may be stipulated to terminate upon the lapse of a term or upon the occurrence of a condition. The duties of the temporary owner toward his successor are ordinarily governed by contractual stipulations rather than by rules of property law, but there is a notable exception concerning the duties of an heir instituted by a will toward the person (successive heir) designated by the will to receive the property after the death of the instituted heir. His obligations to preserve and transmit the inheritance to the persons entitled to take it after him are governed by the rules of succession.

The usufructuary is under obligation to ensure that the property will be restored intact to the owner at the cessation of his interest. He must not destroy or alter the character of the buildings or of the land, and, if the land is agricultural, he may not even change the type of farming practiced. Further, the usufructuary is under obligation to keep the property in a good state of repair, though in this respect there are some variations in detail from country to country. The instituted heir is entitled to use and enjoy the property as owner, but, like the usufructuary, he is under duty to manage the property with a certain degree of care.

OWNERSHIP FOR THE BENEFIT OF OTHERS: TRUSTS AS PROPERTY

In all legal systems, the ownership of a thing normally carries with it the power to enjoy the thing and to manage it; but, since not all persons are capable or willing to manage their property, the law allows management to be detached from the enjoyment of the property. This may be accomplished everywhere by vesting property in an artificial person, such as a corporation or a foundation. There is no necessity, however, to interpose an artificial person between human beings and a fund; property may be vested in human beings for the benefit of other human beings or indeed for themselves. This is accomplished in common law jurisdictions by means of a trust.

A trust is a legal relationship whereby a person called *trustee* undertakes the obligation to deal with property over which he has control (called the *trust property)* for the benefit of persons called *beneficiaries,* of whom he may himself be one. Generally speaking, all kinds of property, real or personal and tangible or intangible, may be held in trust; but the property most frequently so held includes land, stocks, and shares. A trust generally involves separation of the management from the beneficial enjoyment of property. although in civil law jurisdictions this can occur only when a person is incompetent to manage his own affairs because of absence, age, or unsound mind.

The separation of management and beneficial enjoyment. In all cases in which management and beneficial enjoyment are separated, the question arises as to the nature of the respective interests of the manager and of the person having the beneficial enjoyment. It might be possible to say that the manager owns the property but that he is under duty to manage it for the benefit of another who has nothing more than a personal right to take action against the manager. It might also be possible to say that the beneficiary owns the property, but the manager has full powers of administration without any proprietary interest in the property. This second possibility exists in civil law jurisdictions, where the property administered by the tutor of a minor or by the curator of a person of unsound mind belongs to the incompetent. Neither possibility exists in common law jurisdictions. In these jurisdictions, in effect, both the trustees and the beneficiaries own the property in different ways; or, more accurately, neither owns the property in the sense of the Roman dominium, but each owns an interest in it, called, respectively, the legal estate and the equitable interest.

For historical reasons as well as functional purposes, it became necessary to treat the right of the beneficiary as a separate equitable estate comparable to the legal estate; the desire to make a temporal division that had led to the development of the doctrine of estates was also found in the area of trust property. Thus there is not one object of ownership, a physical thing, but two separate abstract things, the legal estate owned by the trustee for the purpose of managing the property and the equitable interest owned by the beneficiary for the purpose of enjoying the same. The legal estate is a way of explaining that the trustees may act commercially as owners of the property, enjoying wide powers of alienating it in the market; the equitable estate means that the beneficiaries have the beneficial ownership, which implies that they can enjoy the use and possession of it and draw an income from it.

Obligations of trustees. Property may be given to trustees for the benefit of persons or for the accomplishment of certain purposes, usually charitable. In either case, the trustees may not take any benefit themselves in their character as trustees, unless they are entitled to charge for their services under the instrument creating the trust. They must obey the terms of the trust and are under personal duty toward the beneficiaries for the proper management of the trust property. If the trustees do not carry out their duties toward the beneficiaries, the beneficiaries may bring proceedings in a court of equity to have the trust enforced.

Rights of beneficiaries

The fragmentation of ownership into a legal estate and an equitable interest is an original common law institution that serves a variety of functions. There is no equivalent institution in civil law jurisdictions, unless one may regard as equivalent a substitution or fideicommissum, whereby an instituted heir or legatee is bound to restore the inheritance to another person. Yet it ought to be noted that the instituted heir, though temporary owner of property, has both management and bexeficial enjoyment as long as his right lasts. In recent years, because of economic considerations, the institution of trusts has been introduced by legislation in a limited number of civil law jurisdictions having close ties with the United States or with countries of the British Commonwealth (*e.g.*, Mexico and Liechtenstein). As a single device to accomplish a variety of purposes, the trust has no equal, but nearly everything that the trust can accomplish may actually be achieved within the framework of a civil law system, the policies of the law permitting. When something achievable with the trust is not achievable in civil law jurisdictions, it is usually because the result is forbidden for reasons of social policy.

Vesting of titles. The law does not tolerate a high degree of uncertainty as to who is entitled to the enjoyment of material goods, and it develops devices tending to prevent goods from being kept out of the market for long periods of time. These devices relate to the *vesting* of titles. In civil law jurisdictions and in Socialist countries, the rules governing the vesting of property rights are very simple. Property at any given moment must be owned either by a natural person or by an artificial person; contingent ownerships, likely to arise upon the lapse of a term or upon the occurrence of a condition, are ordinarily based on transactions among living persons. As a rule, property must be transmitted by contract, by will, or by operation of law to a person that is living or that at least is conceived in the womb.

In common law jurisdictions, the word vesting has different meanings, and the rules concerning the vesting of property rights are more complicated than in civil law jurisdictions. All interests in property are divided into vested interests and contingent interests. For an interest to be vested, the person entitled to it need not have a right to the immediate possession of land or to draw an income immediately from a fund; all that is required is that the nature and amount of the interest and the identity of the person entitled to it should be known. If the identity of the person or the amount of his interest is not yet known and will be known only upon the happening of a contingency, the interest is qualified as contingent.

RESTRICTIONS ON THE OWNERSHIP OF PROPERTY

In all legal systems, the scope, incidents, and content of ownership are subject to restrictions made in the general interest of society in the enjoyment of its material goods. It is in the light of these restrictions that ownership is ordinarily qualified as an exclusive rather than an absolute right. Some of these restrictions are imposed by rules of public law, others by rules of private law, and still others by the effect of lawfully executed private covenants.

Limitations on what may be owned. In the first place, there are limitations everywhere as to the kinds of things that may become objects of property rights. In almost all modern civilized legal systems (the exceptions being such aberrations as Nazi Germany), human beings may not be owned by other human beings. According to modern conceptions, a living human body and any member or part thereof are regarded as incidents of a comprehensive "right of personality" rather than objects of property rights, other than that one may have an ownership right in his own body. Contemporary legislation, jurisprudence, and doctrine indicate that transactions concerning parts or members of human bodies, such as donations of blood or legacies of eyes, are valid, unless, of course, they conflict with social mores. With regard to dead bodies, the possibility of private ownership is broadly admitted, although such bodies are ordinarily subject to compulsory disposal by burial or cremation. Apart from human bodies and members or parts thereof, there are things that may not become objects of property rights either because of a physical impossibility of appropriation or because the law so provides. Running waters, the atmospheric air, and the open sea, for example, may not be appropriated in their entirety by an individual or artificial person. According to traditional civilian ideas, these are common things and insusceptible of any ownership.

Rights of states to property. Second, the state may, and frequently does, assert primary rights to property, thns excluding from the sphere of private ownership a wide variety of elements of wealth. In civil law as well as in common law jurisdictions, the state usually asserts its ownership of the seashore, the continental shelf, and inland navigable waters and bottoms. These are ordinarily designated as public things or public property held by the state in trust for the benefit of all. Further, the state may assert its ownership of a variety of mineral substances (including, in some jurisdictions, oil and gas), unclaimed lands, and such natural resources as hydroelectric energy and radio waves; and it may monopolize a growing number of service fields, such as telecommunications. These are ordinarily designated as the private property of the state or of public corporations. In recent years, statutes have been enacted in various capitalist countries asserting state ownership over running waters and wildlife—things that have been traditionally regarded as belonging to no one in particular. This form of state ownership is a new conception, giving expression to the demand for conservation of natural resources, which are assets of society and capable of appropriation only under regulations that protect the general interest.

State ownership of certain minerals

The state's assertion of primary rights to property is much more intense in Socialist countries, where the bulk of the wealth constitutes Socialist property. Land, productive capital, and most service fields belong, as a rule, to the state, its political subdivision, or to public corporations. The kinds of objects that may become personal property of individuals are thus severely limited in comparison with capitalist countries, and there are even limitations as to the quantity of things that a citizen may own. In the U.S.S.R., for example, a citizen may own only one dwelling, be it a house or an apartment. In no circumstances may personal property be used to derive nonlabour income, such as rents, dividends, or interests.

Limitations on uses of property. Finally, in all legal systems there are limitations pertaining to the use of lands by private landowners. Until the era of the Industrial Revolution, lands constituted the bulk of wealth and the foundation of the social order; hence, there was a need for limitations that would safeguard the general interest. In spite of changed economic conditions, most of these limitations are still relevant and continue to prevail. They may derive from rules of public law, such as zoning regulations and provisions concerning the expropriation of lands for purposes of public utility; from rules of private law, such as provisions prohibiting excessive emissions of smoke, noise, vibrations, and odours; and from protective covenants entered into among landowners under the protection of the law. The matter of excessive emissions is dealt with in civil law jurisdictions under the heading of neighbourhood rights, because the restrictions are imposed in favour of adjoining owners. In common law jurisdictions, the same matter forms the object of the law of nuisance, a topic of tort law. Protective covenants (covenants that are attached to a property deed and go with

Protective covenants

the property when sold, usually containing restrictions on maintenance or sale to specific parties) are rare in civil law jurisdictions, because the field is adequately covered by directly applicable legislation; moreover, the scarcity of protective covenants may be attributed to the fact that restrictions on the use of lands by juridical act necessarily must take the form of a servitude, namely, of a charge laid on an estate in favour of another estate. In common law jurisdictions, however, protective covenants are quite common in subdivision developments. They are ordinarily established by a subdivider or by a group of landowners for the purpose of preserving and enhancing real property values by the maintenance of certain building standards and uniformity in the use of lands. Protective covenants also were once used in the United States to perpetuate racial discrimination in housing, but the United States Supreme Court ordered an end to this practice on constitutional grounds.

SOCIAL CONSEQUENCES OF PROPERTY RIGHTS

The issue of the social consequences of property rights, inextricably connected with the questions of the nature, origin, and justification of private property, has given rise to interminable discussions throughout the ages. A deep analysis of this issue properly belongs to the domains of the philosophy of law, sociology, economics, and political theory. At this point, it suffices to discuss a few social effects of property rights.

Political effects. The political organization of society often determines the kinds, scope, and content of property rights that may be enjoyed by individuals; in turn, it is inevitable that the distribution of wealth should exert influence on the structure and the evolution of the political organization. The fact that property rights exercise political power has not escaped the attention of philosophers since the time of Plato and Aristotle. Plato attacked private property because he thought that, without its abolition, his philosopher kings, the future guardians of his ideal state, would become enemies and tyrants instead of allies of the people. Aristotle criticized his contemporaries' proposals to equalize individual fortunes in order to prevent revolution, but he fully concurred in the view that all civic dissensions arise from inequality of wealth. Consequently, he suggested that all gifts of property should be outlawed and that severe restrictions should be imposed upon the right of inheritance, the means by which an oligarchy preserves itself. The idea that private property was at the root of political and economic evils was carried into modem times by several theorists and philosophers, including, of course, Karl Mam.

Economic effects. The effect of property rights on the economic system is as profound as that on the political organization of society, and the two are frequently inseparable and indistinguishable. Certainly, whether a political and economic system qualifies as capitalistic or socialistic depends on the kinds, scope, and extent of property rights available to individuals. And both capitalistic and Socialist countries control economic activities in terms of their philosophies regarding property rights. Antitrust legislation enacted in the United States, for example, is intended to encourage competition and to prevent the concentration of wealth in the hands of a few powerful individuals or corporations. In the Soviet Union, however, legislation consistent with Marxist philosophy narrowly delimits individual property rights and secures the concentration of wealth in the hands of the state; as a result, the influence of private property on social and economic organization is minimized.

Effects on social stability. The effect of property rights on social stability and, conversely, the effect of internal security on economic development have been discussed extensively by economic theorists, political scientists, and social philosophers. Classical economists, for instance, believed that social stability was possible only if individuals might control, for purposes beneficial to themselves, what they have discovered and appropriated to their use, what they have created by their own labour, and what they have acquired under the existing social and economic order. Private property was deemed to be the cement of society. Socialists, of course, have often had arguments precisely to the contrary.

Effects on initiative and production. Economists and political thinkers have for many years debated the effect of property rights on individual initiative and productivity. Classical economists, for instance, believed that the right of property was the most powerful of all encouragements to the increase of wealth. This view has been consistently challenged by theoretical socialists who have postulated the existence of altruistic motives in the production of goods. Pragmatic considerations, however, seem to have led some Socialist countries, including the Soviet Union, to recognize that, at least to some degree, profit taking does provide incentives. Individual motives for the acquisition of personal property thus help to make the wheels of industry go round in Socialist as well as in capitalist countries.

(A.N.Y.)

Property Tax

A property tax is a tax levied upon land and buildings. In some countries, including the United States, the tax is also levied upon business and farm equipment and inventories. Sometimes the tax extends to automobiles, jewelry, furniture, and even to such intangibles as bonds, mortgages, and shares of stock that represent claims on, or ownership of, tangible wealth.

National differences in taxable property

In most countries, property taxes are used by local or state rather than national governments. Property-tax receipts in 1970 supplied about 55 percent of the revenue raised by local governments in the United States. Throughout much of Europe and Latin America and parts of Africa and Asia, one finds taxes that may be broadly classified as property taxes in their functioning and that supply significant proportions of total tax revenue.

In several countries the property tax applies in fact primarily to urban real property. The intensity of use varies widely—revenues total about 4 percent of national income in Canada, Ireland, the United Kingdom, and the United States; about 2 percent in Australia, Denmark, and New Zealand; somewhat more than 1 percent in Belgium, Japan, South Africa, and Taiwan; and lesser but still significant amounts in a dozen or more other countries.

In some countries, property-tax revenues have lagged far behind the growth of national income because the tax has been based on measures that have not responded to changes in the general level of prices. The original land surveys were designed to serve for long periods, and the taxes were based on surface area or presumed income at rates that might have served moderately well in a world of stable economies. War, inflation, and other forces, however, have made them obsolete; and popular resistance and lack of administrative capacity have generally prevented their modernization.

Levies not ordinarily included in property taxes are those on transfer of property (by sale, gift, or death), on net wealth, and on capital; special charges for some public service or improvement (such as special assessments in the United States); certain types of agricultural imposts; and portions of income taxes that apply to presumed or actual yield of farm or urban land.

THE DEVELOPMENT OF PROPERTY TAXATION

The tax base

One of the most difficult problems in taxing property is to find a reasonable basis of assessment. The problem has grown more difficult as the complexities of economic life have increased. The taxes of the ancient world, of parts of medieval Europe, and of the American colonies were originally land taxes based on area rather than on value. Eventually gross output came to serve as the base. At a later stage, attempts were made to find a measure of what would now be called the individual "ability to pay"; thus, other forms of wealth, such as farmhouses, animals, and implements, were included. At various times, governments have tried to make the tax base one of general property value rather than of specific amounts of different types of particular properties. Yet to reach movable property effectively for taxation has always been difficult; and taxing intangible forms of wealth has proved even harder.

The New England colonies developed taxes that sought to reach all of the "visible estate," real and personal. The "general property tax," applying to all property, was on the statute books of some states by 1800. During the colonial period, the southern and middle colonies made relatively little use of property taxation, but by the middle of the 19th century it had become the principal source of revenue in all the states. The base of the general property tax was defined to include intangible wealth. Yet the value of mortgages and other intangibles consisted largely of claims to rights in real estate and tangible personal property, which were also taxed. Since the double burden seemed excessive, and since concealment was easy, enforcement of the tax on intangibles became difficult and ultimately almost impossible. Disintegration of the property tax as a general tax began early and continued into the 20th century as more and more property escaped, legally and nonlegally. Today the tax in most U.S. states applies to real property; to machinery and inventory of businesses; to relatively small amounts of furniture and jewelry and somewhat more to the value of autos; and in a small degree to bank balances, securities, and other intangible personal property. A national census in 1966 found that real estate accounted for 85 percent of the property-tax base.

The property tax is ultimately a tax upon persons; property serves only as the basis of assessment. The amount payable is based not on a person's or a company's total net wealth but on gross value without regard to debts. The tax will ordinarily be paid from income (either from the property or from other sources).

The property tax in the United States is the chief source of revenue for local government. State governments once used the tax as an important source of revenue, but only a dozen now get as much as 2 percent of their revenue from this source. Forty state governments, however, assess some or all of the operating property of railroads and other utilities. For many years, few if any states took serious interest in the way in which local governments administered the tax; but active efforts to improve it expanded after World War II, and by 1969 significant leadership was found in half or more of the states. Some authorities favour a state takeover of the tax, partly because they believe that states would administer it better and partly in order to remove inequalities in taxing capacity among local governments (especially for financing schools).

The scope of the tax in different countries varies greatly, depending upon legal factors, administrative realities, tradition, availability of other sources of revenue, the organization of government—especially the relative role of local government, for which this levy is of key significance—and the public services provided. The attempt to extend the tax to other than real property (land and buildings) is almost unique to the United States. There is a strong argument in principle for broad coverage of tangible property, since otherwise the tax discriminates (is not neutral) among types of consumption and investment. Administrative difficulties limit what is possible in practice. Classification of property by different types has served as a basis for varying the effective burdens, sometimes by providing for the exclusion of a fraction of the value of some kinds of property (machinery, forests, mines, securities, furniture, etc.), sometimes by adjusting the rates of tax.

ADMINISTRATION

Problems of tax administration

Responsibility for the various phases of administration rests almost entirely upon government officials. Administration involves the discovery or identification of the property to be taxed, its valuation, the application of the appropriate tax rate, and collection. Where the amount of tax is measured by income, as in Great Britain and some of the British Commonwealth countries, income rather than capital value must be determined. The methods of self-assessment or withholding by a third party (an employer or seller) that are used in other forms of taxation are seldom applied in this area. Important aspects, especially valuation, are a matter of judgment rather than of fact. The determination of value for tax purposes is not an incidental result, or an automatic by-product, of a transaction entered into for other purposes, such as a wage payment or a retail sale.

Difficult administrative problems arise in determining (1) what actually exists in a physical sense (the location, topography, and area of a piece of land; the size, materials, and condition of buildings; the number and types of machines or items of inventory) and (2) the value of the property. To do this well requires skilled professional personnel, access to information of various types, and appropriate facilities. The quality of most property-tax administration is far below satisfactory levels. Valuation procedures in Australia, New Zealand, and Great Britain appear superior to those often accepted in the United States, although some states and communities in the United States have shown considerable improvement.

Better administration involves a number of things. One is better mapping and the improvement of other means of getting accurate property descriptions. Another is more sources of data about values and more sophisticated approaches to valuation. For some types of properties, such as single-family residences, sales of generally similar properties provide a good basis for valuation. Some properties, such as office and apartment buildings, can be valued on the basis of the income they yield. For unique and highly specialized properties, including factory and other buildings that are integral parts of a business operation, the value for tax purposes must rest on estimates of reproduction cost less depreciation. Business inventories may be valued on the basis of company records and so may machinery and equipment.

Assessing the tax

Good assessment requires the skills of a permanent professional staff, selected and promoted on a merit basis, working full time at pay comparable to that in private industry and free from political pressures. The United States assessor has typically been a part-time official, usually elected, poorly paid, and without the special training now recognized as essential. Rarely has he had the basic information and other facilities needed. Incompetence has sometimes been compounded by favouritism and corruption. The area under the responsibility of one assessment staff needs to be large enough to permit specialization and the development of expertise. Rarely are staffs large enough to make reasonably complete coverage oftener than every four or five years. Yet the pace of change and the amount of new constiuction are so great as to make many assessments significantly obsolete before a new cycle can correct them. Keeping maps and records up-to-date calls for more continuing work than most governments will support, though modern data-processing techniques offer hope of reducing the burden.

Practice in most countries has been to assess at only a small fraction of the full, current market value even when the governing law specifies that assessment shall be at 100 percent. Low valuations mean that tax rates must be higher. This tends to make inequities in the tax burden greater because a large rate difference magnifies any inequity growing out of poor valuation. As a practical matter, it is more difficult to compare the assessments of different properties when all are far from market levels; and it is more difficult to criticize an assessment as being unfairly high when it is, say, one-fourth of market price while others are one-fifth or less.

Tax review

Because the tax base, and hence the amount of tax payable, depends upon an official's estimate of value rather than on a free-market test (as with a sales tax) or on the taxpayer's report (as with an income tax), the taxpayer will not have participated in the determination of the assessment. The law usually provides facilities for appeal before the tax becomes final, but these are often of little worth. Such review often is farcical. The taxpayer may be ignorant of procedure, or he may not consider the possible saving worth the trouble. Occasionally an owner comes armed with legal talent, piles of evidence that the board cannot check, and perhaps political influence. The elements of unchecked discretion, in both the original assessment and in its later review, provide opportunities for abuse. A owner who hires the right attorney may get a reduction easily, especially if the assessor has deliberately overestimated the value.

TAX RATES

Generally in the United States, but rarely in other countries, the tax rate consists of two or more superimposed elements accruing to separate jurisdictions—to city or town, school district, county, perhaps the state, and to one or more special districts (sewer, drainage, etc.). Each unit of government determines the tax rate it will apply, ordinarily expressed as a percentage of the assessed value. Since assessments are usually much below market values, nominal tax rates give a misleading impression of the burden. For example, 20 U.S. cities in 1966 had nominal rates averaging 9.33 percent, but assessments averaged 15 to 20 percent of market values; consequently, the true rates were 1.6 to 2.1 percent. In eight cities with average tax rates of 5.23 percent, the property was generally assessed at 50 to 60 percent of market prices; effective rates, then, ranged from 2.6 to 3.1 percent of full value.

When government functions were narrow and the property tax the sole source of local revenue, tax rates were determined simply by dividing the figure for estimated expenditure by that for assessed valuation. If spending was to be $400,000 and assessments were $40,000,000, a rate of 1 percent would suffice. Political attitudes have changed. 'Today officials are more likely to estimate the amount that will be available if the existing tax rate is maintained and then try to judge whether taxpayers will consider additional spending to be worth a higher rate of tax. U.S. state governments formerly used the property tax as a flexible element, relying for the most part on other taxes. According to whether these were inadequate or in surplus, the state would raise or lower its property-tax rate. Many states still have constitutional power to do so. When a strong demand for some particular service appears but officials prefer not to raise their "general fund" rates, the legislature may vote to mandate a "special" rate.

Rate limitations are common, imposed sometimes by the state constitution, often by statute. For each class of government—counties, cities, school districts—a maximum ceiling rate will be set. Sometimes the limit may be changed upon referendum or by special legislative action. It is difficult to judge whether such limitations have been effective in restraining the growth of spending. One result, however, has been the establishment of special districts that have independent taxing power and thus lie outside the limitations.

THEORY OF PROPERTY TAXATION

Shifting and incidence

Most taxes can be shifted in some degree from the taxpayer to other persons. As a rule, the higher the tax on land, the lower the price. But if land is in great demand, the buyer may absorb some or all of the tax. The actual amount a buyer will pay for a plot of land depends upon the net income he can expect from it in relation to the yields available from other investments. If the net income from a plot of land is expected to be $1,200 a year indefinitely, and if the prevailing yield on long-term assets is 6 percent, then the land will be worth $20,000. If the tax then rises by $200, the net yield drops to $1,000 and the worth of the land falls to $16,667. The tax increase is said to have been capitalized. To the buyer of the land, the tax in effect at the time of purchase will not be a burden thereafter because he has already discounted it in the purchase price. Since land prices generally have gone up over time, the property tax has not so much lowered land prices as retarded their rise. In the United States, in the ten years up to 1966, land prices are estimated to have risen on the average by 6.9 percent a year.

The extent to which taxes on buildings and other improvements can be shifted involves quite different factors. The construction of buildings depends upon the willingness of investors to make capital available for them, and taxes affect that willingness. A property tax will be treated as a cost of doing business. It must generally be recovered in higher prices from consumers (or in lower prices paid to suppliers or workers). Firms that do not succeed in passing the tax on to customers will suffer a lower rate of return on invested capital. Companies in competition with others located where rates are lower may be unable to shift the tax fully to consumers. New investment will go where net earnings after tax are greatest. The supply of capital, and thus of goods and services, grows when investment yields are promising; it lags when profits are low. As output and prices adjust to changes in tax rates, the taxes will tend to be shifted to consumers. The length of time it takes for a change in a property tax on buildings to be reflected in prices paid by consumers varies from a few months to a number of years. For regulated public utilities, the shifting of a change in tax will usually require some time because new rates will have to be authorized by an official agency. The regulatory process typically requires many months. In some cases, notably United States railroads, after-tax returns have been markedly lower than those in the economy generally; the taxes have been heavier than on business generally, and they have fallen largely on owners (and on suppliers of debt capital) rather than on customers.

The homeowner cannot shift the tax on his dwelling. The price he paid for the land, of course, will have been adjusted to the tax that was in effect when he purchased the property; this tax is no burden on the owner after his purchase (though few homeowners realize that if the tax had been lower, the price paid for the land would have been higher). The tax on the house closely resembles a tax on other items of consumption, although it tends in the United States to be higher than the burdens on most other consumer goods: Deduction of the tax in computing income for the individual income tax helps reduce the net burden for the homeowner.

Burden of the property tax

The amounts of property tax borne by persons at different levels of income cannot be determined accurately. There is almost no way to take account adequately of the element represented by capitalized land tax in the price of land. The portion of property tax falling on businesses (often more than **40** percent) is presumably shifted to consumers according to their purchases, including those of telephone, electric, and other utility services.

In general, the property tax seems to be either roughly proportional to income or slightly regressive (in that the increases in amounts of tax paid do not rise as rapidly, in percentage terms, as income). Regressive taxes are widely believed to be inequitable. While property taxes burden persons with low incomes more than may seem wise, their ultimate benefits have a "pro-low-income" bias. This means that their total redistributive effect from higher to lower income groups is substantial when account is taken of the degree to which property taxes pay for schools and other services for low-income groups. There is also widespread "horizontal inequity" in property taxes because of unequal assessments upon owners. The tax falls more heavily on some kinds of business (*e.g.*, railroads and other utilities) and some types of consumption (*e.g.*, housing) than on others. In the United States, property taxes on farming as a business tend generally to be low relative to the value of property but high in relation to income. Because property taxation is of such long standing that its many elements have worked themselves into the economy, some portions being capitalized and others variously adjusted to, the inequities have to some extent been reduced.

Exemptions in the United States

The property tax has been increasingly weakened by exemptions. In the United States exemptions apparently remove about **30** percent of the land area in the average locality. Most of this, however, consists of streets, schools, parks, and other property of local government; therefore, to apply the tax would merely transfer funds from one government account to another. In some localities, state- or federal-government real estate is important, although these bodies sometimes make payments in lieu of local taxes. Property owned and used for religious, educational, charitable, and some other purposes is generally exempt.

Some exemptions are made in order to attract new businesses or to encourage low-income housing. Some states grant exemptions for part of the value of a "homestead," perhaps with a limitation based on income of the owner-occupant; several give some exemption to persons over age *65* or to veterans.

Economic effects. Property taxation finances local government, not fully but enough to make the independence of local government meaningful. This permits decentralization of government, which may be considered a good because it enables a community to exercise a degree of choice.

The property tax may have substantial nonrevenue effects. Where it is heavy enough to bring large revenues, it leads to changes in behaviour, not just because taxpayers have less to spend and save but also because individuals and businesses conduct their affairs differently because of it. Although property-tax rates expressed as percentages are usually small, in the United States they apply to capital values and are effectiveiy much higher: if a property that yields 9 percent gross is taxed at **3** percent, the tax is equal to **33** percent of the pretax income—and *50* percent of the 6 percent remaining after tax. A tax of 20 cents for each 80 cents paid for the costs of housing—not as high as actually prevails in many urban areas—is *25* percent when expressed on the same basis as a retail sales tax.

A community with high tax rates on buildings will be at a disadvantage in the national (and international) competition for capital unless it can offer compensatory advantages. The supply of capital for the economy as a whole comes from saving. Whether the property tax affects it materially is not clear. Methods of production requiring relatively large amounts of capital will be discouraged if they are subject to tax.

The effect on new building

The tax on buildings and property other than land distorts resource allocation where older property exists. New, high-quality buildings are taxed more heavily per unit of space than are old ones, including slums. There is no justification for this in the costs that the two types of property and their occupants impose on local government in terms of police, fire protection, etc. Thus the user's payment for the services of local government goes down, relatively, as the building he occupies gets worse, even though public expenses attributable to the property are unchanged or may even increase. Likewise, residents who shift from poorer to better quality housing or business property must pay more toward the costs of government even though they will not ordinarily receive more government services. Cities that urgently need to replace obsolete buildings paradoxically base much of their financing upon a tax that encourages owners to hold on to deteriorated structures and penalizes owners of new ones.

Every increase in the property-tax rates on structures (not land) reduces the desirability of putting capital funds into new buildings, creates an incentive against upgrading quality by new construction, and discourages maintenance. It also leads to the construction of rooms, apartments, and buildings somewhat smaller than would be the case in the absence of tax.

Differences in effective tax rates among localities may have the effect of creating islands of relatively low tax rates. Some communities may have tax bases above average in relation to governmental obligations and can get by with lower tax rates. They attract capital. Some communities, perhaps by the use of zoning, exclude types of property associated with high governmental expense such as high-density housing, which brings many children and requires more schools. Tax rates elsewhere must then be higher. The existence of such enclaves will add to the fiscal imbalance of neighbouring localities and accentuate the difficulties of older areas.

Lower tax rates on the fringes of an urban area encourage suburbanization. Property nearer the centre will be subject to high tax rates, aggravating the troubles of central-city business properties. High taxes on structures also favour horizontal over vertical growth of metropolitan areas.

Where, as in Great Britain, the property tax rests on income, land held idle or far below its best use will yield little revenue. In such cases, the tax incentive for efficient use is notably lacking. The rates at which timber is cut and minerals extracted can be influenced materially by property taxation.

Taxing the "unearned increment"

Site-value taxation. The use of a land tax as the chief source of revenue has often been proposed. It was favoured by the Physiocrats in 18th-century France. Probably the best known exponent was a 19th-century American, Henry George. His Progress and Poverty (1879) drew upon economic analysis in the tradition of Ricardo and Mill to argue persuasively for a single tax on land and the abolition of other taxes (then predominantly levied on other property). More recently, proposals for heavier taxation of land—site-value taxation—have found increasing support. One argument is that much of what is paid for the use of land reflects socially created demand and is not a payment to bring land into existence. The community can capture in land taxes some of the values it has createci—including ihose resulting from streets, schools, and other facilities. This, it is maintained, would be a more equitable way of financing local government. Another argument is that the revenue from a tax on land would permit *a* reduction of taxes on buildings, which tend to deter new construction. A third argument is that higher land taxes would make for more efficient use of land.

There is a great deal to be said in favour of increasing taxes on land and thus lowering land prices. Economically, of course, a "high" price for some land is essential in order to encourage the best employment of it. The user of land ought to pay the amount of its worth in its best use; but the owner, facing no cost of production, need not receive all that is paid. Government can reasonably take much of the total paid by the user.

A heavier land tax would change the conditions of ownership. The total collected from users would not change, but private owners of land would retain less, the public treasury getting more. The price system would still allocate land use. Taxes on improvements could then be reduced greatly. The tax relief for deteriorated buildings would be slight, but for those of high quality the reduction could be large in relation to net return on investment. More buildings, new and better ones, would be supplied. Modernization and maintenance of existing buildings would become more profitable.

Over the longer run, landowners would get less of the increments in land values and the public would get more. Socially created values would be channelled into governmental rather than private uses.

The use of elements other than value as the tax base would offer the possibility of more rational and efficient taxation. Taxes could be related more closely to the cost of governmental services. If land area, the distance from some base point, and perhaps such factors as the floor space or volume of a building were used as criteria—and perhaps related to the specific services of local government—considerable revenue could be collected with much less administrative expense.

The opponents of site-value taxation point out that the unearned increment in land value has been capitalized and question the fairness of imposing a heavy tax on present land values for which owners have paid in good faith. They doubt the ability of assessors to make fair enough appraisals to support much heavier rates on land. They also doubt whether land alone, excluding buildings, would be an adequate tax base.

Moves in the direction of site-value taxation have been made in Australia and New Zealand, South Africa, and parts of western Canada. The case for site-value taxation being a strong one, other areas will probably adopt it. (C.L.Ha.)

PROPERTY TAXATION IN EUROPEAN COUNTRIES

The most common forms of property taxation in Europe are general net-wealth (net-worth) taxes and taxes on specific types of property, such as real estate. Some European countries, however, leave property itself untaxed—although the extent of an individual's property holdings may be used as an index of taxable capacity for personal and corporation income-tax purposes.

The property-tax figures chiefly in the revenues of local governments. For central and federal governments it is not an important source of revenue. In 1969, for example, taxes on net worth and on real estate supplied only 4.5 percent of the revenues of the federal government of West Germany and 4 percent of the revenues of the national government of France. On the other hand, these taxes supplied from 20 to 30 percent of local-tax revenues in Belgium, Denmark, France, and Germany.

Methods of assessment

The three principal approaches to the assessment of property are rental value, capital value, and market value. Swiss cantons assess a property tax on agricultural land based on the income from the land, which is treated as rent. Denmark has to a certain extent adopted the rental-value concept for assessing agricultural land subject to the estate tax and seagoing vessels subject to the net-wealth tax. A modified rental-value concept is used in Spain to assess urban real estate by cadastral income (contribucidn territorial *urbana*), which is assumed to reflect expected rents.

A more common approach to the assessment of real property in European countries is that of capital value. The traditional idea is that capital value can be estimated on the basis of rental values, treating them as earnings on capital. The capital-value concept (Einheitswert) prevails in real-property and net-wealth taxation in West Germany and Luxembourg, in the net-wealth taxation of Austria, and in the taxation of real estate by the net-worth tax of Sweden (*förmögenhetsskatt*).

Most European countries endeavour to assess property according to its market value. Applications of the principle differ. In Swiss cantons, for example, market value is used in net-worth and real-estate taxation of land and buildings, while The Netherlands makes use of market value in net-wealth taxation only for agricultural and other open land. Still another way has been adopted in Austria, where a legally defined "fair-market value" (*gemeiner* Wert) is applied in an effort to come close to the actual selling value of real property.

In Europe as elsewhere, the chief problem in the administration of property taxes is to keep assessed valuations up-to-date. This is especially true for real estate, in which the principal assessments were made decades ago (in The Netherlands at the end of the 19th century, in Germany in 1935, in Spain in 1929, in France in 1925 and 1939). Although new and supplementary assessments have been made since, the relation between the assessed values has remained unchanged and does not reflect current realities.

Efforts to reform the system of property taxation have repercussions upon the rest of the fiscal system and touch the interests of all economic and social groups. Future changes will be concerned with three sets of problems: (1) the need to adapt tax bases to changing property values; (2) the requirement that different kinds of property be treated equally, so as not to discriminate among them; and (3) the need to harmonize taxes among the countries of the Common Market. In the early 1970s various proposals were being considered in European legislative bodies, but there was a lack of unanimity among groups whose interests were directly involved. (H.Fec.)

PROPERTY TAXATION IN ASIAN COUNTRIES

Property taxation has long been a feature of the tax systems of some Asian countries. Its significance as a revenue source has been growing in recent decades.

The tax is imposed mostly at the local government level, although in a few countries, such as Indonesia, Laos, and Singapore, it is levied by the central government. In the Philippines the property tax is imposed by the national government but is collected by, and the entire proceeds distributed among, local units.

Generally, property taxes in Asian countries are paid in cash. In the Republic of China on Taiwan, however, the niral land tax on rice land is payable in kind.

Importance of property taxation in Asia

The ratio of property taxes collected to total local revenues is indicative of the importance of this tax. India, which first imposed the property tax in 1793, drew an average of 57 percent of local revenues from it in the years 1966–68; it is the principal source of revenue of about 2,000 autonomous local bodies. Collections in Japan averaged 15.6 percent of the total revenue of local governments from 1968 to 1970. In the Philippines the property tax brought in about 15 percent of local-government revenues from 1967 to 1969. In Pakistan the ratio averaged 14.3 percent in 1966–69; in South Korea, 9.2 percent in 1967–69; in Thailand in 1968, only 5 percent. In countries where the tax is levied nationally, the ratio of collections to total national revenue is insignificant.

While the property tax serves as a major source of income for local government, other revenue sources are more productive. In Thailand, for example, local governments draw twice as much revenue from the business tax. In Japan they derive more revenue from the municipal inhabitant tax. In Pakistan the yield from the property tax was exceeded by that from the sales tax and income tax in 1966–69. In South Korea the acquisition tax, entertainment and restaurant tax, and automobile tax were more productive in 1967–69.

In Asian countries the property tax applies to land, buildings, and other improvements. In the Philippines, machinery is also included. In general, personal property, including intangibles, is not subject to the tax. There are exceptions to this, as in Indonesia, where net wealth exceeding 2,000,000 rupiahs is taxed, and in Japan, where certain types of personal assets are taxable.

Bases of assessment

The bases used by Asian countries in the assessment of the property tax include market value (in Japan and the Philippines), annual rental value (in India, Singapore, South Vietnam, Malaysia, South Korea, and Laos), and capital value (in Thailand and some states in India).

As a rule, the bases of assessment in Japan are "normal" market value for land, replacement cost less depreciation in the case of buildings, and purchase price less normal depreciation for depreciable assets. In the Philippines the assessment law stipulates fair market value as the basis of assessment, but in practice the basis is far below the market value because assessments have not been carried out periodically.

Most Asian countries use annual rental value as the basis of assessment. Under this principle, the tax is based on the average gross-rental income the property is expected to generate under prevailing market conditions.

In Indonesia the basis of the property tax is the net wealth owned by the taxpayer at the beginning of the calendar year. Net wealth is defined as the value of all property less debt.

Other Asian countries collect a fixed amount based on a particular unit of land measurement. Laos collects a specific amount per square metre of land. In West Malaysia the annual tax on land is a certain amount per 1,000 square feet.

Problems of administration. A number of difficulties have been encountered in the administration of property taxes. In general, these relate to the valuation of property, collection of taxes, and the application of exemptions.

Valuation and collection

In Japan it was noted in a 1959 survey that the methods of land valuation used by different municipalities resulted in an unequal tax burden among landowners. Thus, the assessed value of land averaged 16 percent of the market price for urban land and 25 percent for rural land. To correct this, a new method of valuation was introduced in 1964, but it led to 600–700 percent increase in the tax on urban land. New adjustments had to be made, scaling down the urban land tax to a more equitable level.

Real property in the Philippines is assessed at fair market value, but only about 45 percent of the value is taxed. In many localities, the existing assessment schedules are based on values of a number of years ago. Moreover, many taxable properties have not been included in the assessment rolls because of the absence of tax maps and other basic assessment tools. The need for these tools has long been felt, but funds for their purchase and for the employment of more assessment personnel have been lacking. Another problem in the Philippines is under-collection, resulting from inadequate collection techniques, the low pay levels of collecting officials, and a failure to apply sanctions for noncompliance.

A study of the property tax in South Korea in 1966 disclosed that the assessment base was very low in relation to market value. The actual property-tax rate had continuously decreased until it was lower than its legal rate. Buildings were found to be more heavily assessed than land. The report recommended fundamental reforms in assessment procedures that would lead to the adoption of a system based on market value.

In India the main problem of property taxation is basically that of assessment. Judicial decisions have required the standard rent fixed under the Rent Control Act to be considered the reasonable rent for the purpose of valuation of the property. As a result, the annual rental value of almost all urban property has remained frozen. There is also a lack of proper machinery for correcting and updating the assessment lists in most local bodies, which have also been backward in collecting the tax. There is also a lack of competent personnel. Various study committees set up in India from 1951 to 1966 have recommended: (1) imposition of a minimum statutory rate to be uniformly applied; (2) abolition of the method of assessment based on the Rent Control Act; (3) establishment of an impartial and independent machinery for assessment; and (4) the vesting of independent agencies with powers to recover arrears.

Prominent among the problems besetting the administration of the property tax in many Asian countries is the lacklustre performance of assessors and collectors. Many of the personnel are untrained, and many assessment and collecting units are undermanned. Sometimes considerations other than merit play a decisive role in the appointment of assessors and collectors.

Exemptions in Asian countries

Another problem area of property taxation is that of exemptions. Asian countries allow exemption for a wide range of properties and assets. These can be generally classified as follows: (1) those belonging to the government—state, central, or local—and used for administrative purposes; *(2)* those used for religious, charitable, scientific, and educational purposes; (3) those with values below a certain limit; (4) cemeteries or burial grounds; and (5) property used by international organizations, embassies, and consulates.

The first category is common to almost all Asian countries. Belonging to the second category are pagodas in Laos and places used for sacrificial rites in South Korea. In Japan exemption from the tax is accorded to assets owned by organizations operated for public benefit; *e.g.*, the Japan Red Cross Society and the National Health Insurance Association. Lands held by homesteaders in the Philippines, and reclaimed lands in South Korea, are also exempt.

Preferential tax treatment is also used to encourage building construction and land development. In Singapore, property-tax rates are lower on buildings and vacant land in the less developed areas. In Japan, partial exemptions are given to new fireproof residential buildings having apartments of less than a certain size.

The future of property taxation. While in Europe and the United States the property tax has long been a stable and productive source of revenue, in Asia its full revenue potential is still to be tapped. There are serious deficiencies in the legislation and administration of property taxes. One barrier to reform is a dearth of statistical information that would enable a systematic assessment of the system's effectiveness. Any thoroughgoing reform will also require resolute steps to rid the tax-collection machinery of the inept and the corrupt. Specific changes are needed in the following areas: rate structure, classification of property, exemptions, administration, and technical expertise. (A.Q.Y.)

BIBLIOGRAPHY. A general introduction to the subject of property taxation in the United States and Europe is DICK NETZER, *Economics of the Property Tax* (1966). Descriptions of property taxation in various countries may be found in the "World Tax Series" published in recent years by the Harvard Law School. A summary of current economic theory is contained in C. LOWELL HARRISS, *Property Taxation: Economic Aspects* (1968). Works on specific countries include: GEORGE C.S. BENSON *et al., The American Property Tax: Its History, Administration, and Economic Impact* (1965); FREDERICK L. BIRD, *The General Property Tax: Findings of the 1957 Census of Governments* (1960), on the problems of property-tax administration in the United States; GEORGE F. BREAK and RALPH TURVEY, *Studies in Greek Taxation* (1964); HENRY J. GUMPEL and CARL BOETTCHER, *Taxation in the Federal Republic of Germany*, 2nd ed. (1968); JAMES HEILBRUN, *Real Estate Taxes and Urban Housing* (1966), an analysis of the economic aspects of alternative possible methods of taxing urban housing in the United States; RICHARD W. LINDHOLM (ed.), *Property Taxation, U.S.A.* (1968); ANNEMARIE MENNEL, *Die Steuersysteme in den EWG-Staaten, EFTA-Staaten und den USA* (1971), dealing with the countries of the European Economic Community and the European Free Trade Association, and with the United States; J.F.N. MURRAY, *Valuation and the National Economy* (1967), covering the history of assessing practices in various countries since biblical times; MARTIN NORR and PIERRE KERLAN, *Taxation in France* (1966); and H.P. WALD, *Taxation of Agricultural Land in Underdeveloped Economies* (1959). ARTHUR D. LYNN, JR. (ed.), *The Property Tax and Its Administration* (1969), contains the proceedings of a symposium sponsored by the Committee on Taxation, Resources, and Economic Development (TRED), held at the University of Wisconsin in 1967.

(C.L.Ha./H.Fec./A.Q.Y.)

Prophecy

Prophecy, a religious phenomenon generally associated with Judaism and Christianity, is found throughout the religions of the world, both ancient and modern. In its narrower sense, the term prophet (Greek *prophētēs,* "forthteller") refers to an inspired person who believes that he has been sent by his god with a message to tell. He is, in this sense, the mouthpiece of his god. In a broader sense, the word can refer to anybody who utters the will of a deity, often ascertained through visions, dreams, or the casting of lots; the will of the deity also might be spoken in a liturgical setting. The prophet, thus, is often associated with the priest, the shaman (a religious figure in primitive societies who functions as a healer, diviner, and possessor of psychic powers), the diviner (foreteller), and the mystic.

In a much broader sense, the term prophet has been used in connection with social and religio-political reformers and leaders.

GENERAL CHARACTERISTICS OF PROPHECY

Nature and significance. A primary characteristic of prophetic self-consciousness is an awareness of a call, which is regarded as the prophet's legitimization. This call is viewed as ultimately coming from a deity and by means of a dream, a vision, an audition, or through the mediation of another prophet. The Old Testament prophet Jeremiah's call was in the form of a vision, in which Yahweh (the God of Israel) told him that he had already been chosen to be a prophet before he was born (Jer. 1:5). When the call of the deity is mediated through a prophet who is the master of a prophetic group or an individual follower, such a call can be seen as a mandate. Furthermore, such mediation means that the spirit of the prophet master has been transferred simultaneously to the disciple. In the case of cult prophets, such as the prophets of the gods Baal and Yahweh in ancient Canaan, the call may be regarded as a mandate of the cult.

Prophets were often organized into guilds in which they received their training. The guilds were led by a prophet master, and their members could be distinguished from other members of their society by their garb (such as a special mantle) or by physical marks or grooming (such as baldness, a mark on the forehead, or scars of self-laceration).

The nature of prophecy is twofold: either inspired (by visions or revelatory auditions), or acquired (by learning certain techniques). In many cases both aspects are present. The goal of learning certain prophetic techniques is to reach an ecstatic state in which revelations can be received. That state might be reached through the use of music, dancing, drums, violent bodily movement, and self-laceration. The ecstatic prophet is regarded as being filled with the divine spirit, and in this state the deity speaks through him. Ecstatic oracles, therefore, are generally delivered by the prophet in the first-person singular pronoun and are spoken in a short, rhythmic style.

Prophetic ecstasy

That prophets employing ecstatic techniques have been called madmen is accounted for by descriptions of their loss of control over themselves when they are "possessed" by the deity. Prophets in ecstatic trances often have experienced sensations of corporeal transmigration (such as the 6th-century-BC Old Testament prophet Ezekiel and the 6th–7th-century-AD founder of Islām, Muhammad). Such prophets are believed to have a predisposition for such unusual sensations.

The functions of the prophet and priest occasionally overlap, for priests sometimes fulfill a prophetic function by uttering an oracle of a deity. Such an oracle often serves as part of a liturgy, as when ministers or priests in modern Christian churches read scriptural texts that begin with the proclamation: "Thus says the Lord." The priest, in this instance, fulfills the prophetic function of the cult. Not only do the role, of the prophet and priest overlap but so do the roles of the prophet and shaman. A shaman seldom remembers the message he has delivered when possessed, whereas the prophet always remembers what has happened to him and what he "heard."

The diviner, sometimes compared with the prophet, performs the priestly art of foretelling. His art is to augur the future on the basis of hidden knowledge discerned almost anywhere, as in the constellations (astrology), the flight of birds (auspices), in the entrails of sacrificial animals (haruspicy), in hands (chiromancy), in casting lots (cleromancy), in the flames of burning sacrifices (pyromancy), and other such areas of special knowledge (see also DIVINATION; SHAMANISM).

Mystics and prophets are similar in nature in that they both claim a special intimacy with the deity. The mystic, however, strives for a union with the deity, who usurps control of his ego, whereas the prophet never loses control of his ego. On occasion mystics have delivered messages from the deity, thus acting in the role of a prophet, and have been known to use ecstatic trances to reach the divine or sacred world; *e.g.*, many Roman Catholic saints and Muslim Siifis (see also MYSTICISM; SAINT).

Uniqueness of Israelite prophecy

In the Western world, Israelite prophecy is regarded as unique, for not only did it oppose institutionalized religion but it is understood as having propagated an ethical religion emphasizing individual freedom, a religion not dependent on mechanical ritual and legalism.

The term prophecy also has been used in a strictly predictive sense, not necessarily dealing with religious themes. In this sense, *The Communist Manifesto,* by Karl Marx and Friedrich Engels, was viewed as a "prophecy" of things to come; a new approach that goes against the traditional in literature, art, politics, and other areas may —in this wider sense—be termed "prophetic."

Types of prophecy. *The divinatory prophet.* Types of prophecy can be classified on the basis of inspiration, behaviour, and office. Divinatory prophets include seers, oracle givers, soothsayers, and mantics (diviners), all of whom predict the future or tell the divine will in oracular statements by means of instruments, dreams, telepathy, clairvoyance, or visions received in the frenzied state of ecstasy. Predictions and foretellings, however, may also be the result of inspiration, or of common sense by the intelligent observation of situations and events, albeit interpreted from a religious point of view.

The cult prophet. Of broad importance to the religious community is the cult prophet, or priest-prophet. Under the mandate of the cult, the priest-prophet (who may be an ordinary priest) is part of the priestly staff of a sanctuary, and his duty is to pronounce the divine oracular word at the appropriate point in a liturgy. As such, he is an "institutional" prophet. The difference between a cult prophet and a prophet in the classical sense is that the latter has always experienced a divine call, whereas the cult prophet, pronouncing the word of the deity under cultic mandate, repeats his messages at a special moment in the ritual. Because of the timeless character of cultic activity, however, every time he prophesies, his message is regarded as new.

The role of prophecy in the founding of new religions

The missionary prophet. Missionary (or apostolic) prophets are those who maintain that the religious truth revealed to them is unique to themselves alone. Such prophets acquire a following of disciples who accept that their teachings reveal the true religion. The result of this kind of prophetic action may lead to a new religion; *e.g.*, Zoroaster, Jesus, and Muhammad. The founders of many modern religious sects also should be included in this type.

The reformative prophet. Another type of prophet is of the reformative or revolutionary kind (looking to the past and the future), closely related to the restorative or purificatory type (looking to the past as the ideal). The best examples are the Old Testament classical prophets; *e.g.*, Amos and Jeremiah. Many of these so-called literary prophets were working to reform the religion of Yahweh, attempting to free it from its Canaanite heritage and accretions. In the Arab world Muhammad is included in this category. The social sympathy found among such prophets is rooted in their religious conscience, What may have been preached as religious reform, therefore, often took on the form of social reform. This kind of prophecy is also found in India and Africa, where prophets in modern times have arisen to restore or purify the old tribal religious forms, as well as the customs and laws that had their sources in the older precolonial religious life. Many of these movements became revolutionary not only by force of logic but also by force of social and political pressure (see also MESSIAH AND MESSIANIC MOVEMENTS).

Though there may be several categories of prophecy according to scholars, no sharp line of demarcation differentiates among these different types. Any given prophet may be both predictive and missionary, ecstatic as well as reformative.

PROPHECY IN THE ANCIENT NEAR EAST AND ISRAEL

The ancient Near East. In ancient Egypt, charismatic prophecy apparently was not commonplace, if it occurred at all, though institutional prophecy was of the greatest importance because life was regarded as depending upon what the gods said. Some ancient texts contain what has sometimes been regarded as prophetic utterances, but these more often are considered to be the product of wise men who were well acquainted with Egyptian traditions and history. Among Egyptian sages, historical events were thought to follow a pattern, which could be observed and the laws of which could be discerned. Thus, times of hardship were always thought to be followed by times of prosperity, and predictions were made accordingly.

Egyptian texts

In Egyptian mantic (divinatory) texts there are prophetic sayings, but the particular concerns of these texts are more political than religious. Some are fictitious, and many are considered to have been prophesied after the event has already taken place. The papyrus text "The Protests of the Eloquent Peasant" is considered by some authorities as a prophecy, since the peasant is forced to deliver speeches, saying: "Not shall the one be silent whom thou hast forced to speak." This compulsion to speak in the name of the divine is called by some scholars the "prophetical condition."

In a Hittite text King Mursilis II (reigned 1339–06 BC) mentions the presence of prophets, but there is no information about the type of prophecy. More informative are texts from Mari (Tall al-Ḥarírí, 18th century BC) in northwest Mesopotamia, where some striking parallels to Hebrew prophecy have been discovered. The Mari prophets—believed to be inspired—spoke the word of the god Dagon just as Israelite prophets spoke the word of Yahweh.

In Mari, the two key words for prophet are *muḫḫum* (an ecstatic, a frenzied one) and *āpilum* (the one who responds). Both may be connected with the cult, but there are incidents indicating that the *muḫḫum* was not bound to the cultic setting but received his message in a direct revelation from his god. The *āpilum* usually acted within a group of fellow prophets. Many of their sayings are political in nature, but there are also oracles that deal with the king's duty to protect the poor and needy, indicating that an ethical dimension was present among the Mari prophets. The messages could also contain admonitions, threats, reproofs, accusations, and predictions of either disaster or good fortune.

The Mari texts are important in the history of prophecy because they reveal that inspired prophecy in the ancient Near East dates back 1,000 years before Amos and Hosea (8th century BC) in Israel. From Mesopotamia there is evidence of the *maḫḫu*, the frenzied one, known in Sumerian texts as the *lú-gub-ba*. Mention also is made of some prophets who spoke to Assyrian kings, and their message is sometimes introduced with the clause: "Do not fear." Omina (omens) texts containing promises or predictions are also known. In one of the *maqlu* ("oath") texts, in which an *āšipu* priest is being sent forth by his god, the deity first asks "Whom shall I send?"

The *baru* (a divinatory or astrological priest) declared the divine will through signs and omens, and thus by some is considered to have been a prophet. Though he might possibly have had visions, he was not in actuality an ecstatic. The art of divination became very elaborate in the course of time and required a long period of training.

Zoroaster, the 7th–6th-century-BC Iranian founder of the religion that bears his name, is one of the least well-known founders of a religion because of the character of the existing textual materials and because some scholars have advocated that Zoroaster is a mythical figure. He may have been, however, an ecstatic priest-singer, or *zaotar*, who used special techniques (especially intoxication) to achieve a trance. Zoroaster found the priests and cult of his day offensive, and opposed them. He preached the coming of the kingdom of the god Ahura Mazdā (Ormazd), who is claimed to have revealed to Zoroaster the sacred writings, the Avesta. In the *Yasna* (a section of the Avesta), Zoroaster refers to himself as a Saoshyans, a saviour. Messianic prophecies of the end of the world are found in Zoroastrian literature, but these are more a literary product than actual prophetic utterance (see also ZOROASTRIANISM AND PARSIISM).

Prophets were a common phenomenon in Syria-Palestine. In an Egyptian text (11th century BC), Wen-Amon (a temple official at Karnak) was sent by the pharaoh to Gebal (Byblos) to procure timber. While there, a young noble of that city was seized by his god and in frenzy gave a message to the king of Gebal that the request of Wen-Amon should be honoured. In another instance, an Aramaic inscription from Syria records that the god Ba'al-shemain told King Zakir (8th century BC) through seers and diviners that he would save the king from his enemies. These chapters reveal the close connection between sacrificial rites and divine inspiration. In the Old Testament book of Numbers, chapters 22-24, the Mesopotamian prophet Balaam (who may have been a *maḫḫu*) from Pethor, whom the Moabite king Balak had asked to curse the invading Israelites, is mentioned. In chapter 27, verse 9, of Jeremiah, another Old Testament book, it is said that prophets, diviners, and soothsayers were in the neighbouring countries of Judah: in Edom, Moab, Ammon, Tyre, and Sidon. Since so little is known about these prophets, the question of the uniqueness of Hebrew prophecy is difficult to assess (see also NEAR EASTERN RELIGIONS, ANCIENT).

Origins and development of Hebrew prophecy. The Hebrew word for prophet is *navi'*, usually considered to bc a loan word from Akkadian *nabū, nabāʾum*, "to proclaim, mention, call, summon." Also occurring in Hebrew are *ḥoze* and *ro'e*, both meaning "seer," and *neviʾa* ("prophetess").

Though the origins of Israelite prophecy have been much discussed, the textual evidence gives no information upon which to build a reconstruction. When the Israelites settled in Canaan, they became acquainted with Canaanite forms of prophecy. The structure of the prophetic and priestly function was very much the same in Israel and Canaan. Traditionally, the Israelite seer is considered to have originated in Israel's nomadic roots, and the *nnvi'* is considered to have originated in Canaan, though such judgments are virtually impossible to substantiate. In early Israelite history, the seer usually appears alone, but the *navi'* appears in the context of a prophetic circle. According to I Samuel, there was no difference between the two categories in that early time; the terms *navi'* and *roʾe* seem to be synonymous. In Amos, *ḥoze* and *navi'* are used for one and the same person. In Israel, prophets were connected with the sanctuaries. Among the Temple prophets officiating in liturgies were the Levitical guilds and singers: the "sons" of Asaph, Heman, Jeduthun, who are said to "prophesy with lyres, with harps, and with cymbals" (I Chronicles). Other prophetic guilds are also mentioned. Members of these guilds generally prophesied for money or gifts and were associated with such sanctuaries as Gibeah, Samaria, Bethel, Gilgal, Jericho, Jerusalem, and Ramah. Jeremiah mentions that the chief priest of Jerusalem was the supervisor of both priests and prophets, and that these prophets had rooms in the Temple buildings. In pre-exilic Israel (before 587/586 BC), prophetic guilds were a social group as important as the priests. Isaiah includes the *navi'* and the *qosem* ("diviner," "soothsayer") among the leaders of Israelite society. Divination in the pre-exilic period was not considered to be foreign to Israelite religion.

Prophets connected with sanctuaries

In reconstructing the history of Israelite prophecy, the prophets Samuel, Gad, Nathan, and Elijah (11th to 9th centuries BC) have been viewed as representing a transitional stage from the so-called vulgar prophetism to the literary prophetism, which some scholars believed represented a more ethical and therefore a "higher" form of prophecy. The literary prophets also have been viewed as being antagonistic toward the cultus. Modern scholars recognized, however, that such an analysis is an oversimplification of an intricate problem. It is impossible to prove that the *nevi'im* did not emphasize ethics simply because few of their utterances are recorded. What is more, none of the so-called "transitional" prophets was a reformer or was said to have inspired reforms. Samuel was not only a prophet but also a priest, seer, and ruler ("judge") who lived at a sanctuary that was the location of a prophetic guild and furthermore was the leader of that *navi'* guild. In the cases of Nathan and Gad there are no indications that they represented some new development in prophecy. Nathan's association with the priest Zadok, however, has led some scholars to suspect that Nathan was a Jebusite (an inhabitant of the Canaanite city of Jebus).

Elijah was a "prophet father" (or prophet master) and a prophet priest. Much of his prophetic career was directed against the Tyrian Baal cult, which had become popular in the northern kingdom (Israel) during the reign (mid-9th century BC) of King Ahab and his Tyrian queen, Jezebel. Elijah's struggle against this cult indicated a religio-political awareness, on his part, of the danger to Yahweh worship in Israel; namely, that Baal of Tyre might replace Yahweh as the main god of Israel.

Classical prophecy in Israel and Judah

The emergence of classical prophecy in Israel (the northern kingdom) and Judah (the southern kingdom) begins with Amos and Hosea (8th century BC). What is new in classical prophecy is its hostile attitude toward Canaanite influences in religion and culture, combined with an old nationalistic conception of Yahweh and his people. The reaction of these classical prophets against Canaanite influences in the worship of Yahweh is a means by which scholars distinguish Israel's classical prophets from other prophetic movements of their time. Essentially, the classical prophets wanted a renovation of the Yahweh cult, freeing it from all taint of worship of Baal and Asherah (Baal's female counterpart). Though not all aspects of the Baal-Asherah cult were completely eradicated, ideas and rituals from that cult were rethought, evaluated, and purified according to those prophets' concept of true Yahwism. Included in such ideas was the view that Yahweh was a jealous God who, according to the theology of the psalms, was greater than any other god. Yahweh had chosen Israel to be his own people and, therefore, did not wish to share his people with any other god. When the prophets condemned cultic phenomena, such condemnation reflected a rejection of certain kinds of cult and sacrifice—namely, those sacrifices and festivals not exclusively directed to Yahweh but rather to other gods. The prophets likewise rejected liturgies incorrectly performed. The classical prophets did not reject all cults, per se; rather, they wanted a cultus ritually correct, dedicated solely to Yahweh, and productive of ethical conduct. Another important concept, accepted by the classical prophets, was that of Yahweh's choice of Zion (Jerusalem) as his cult site. Thus, every cult site of the northern kingdom of Israel and all the sanctuaries and *bamot* ("high places") were roundly condemned, whether in Israel or Judah.

Amos, whose oracles against the northern kingdom of Israel have been misunderstood as reflecting a negative attitude toward cultus per se, simply did not consider the royal cult of the northern kingdom at Bethel to be a legitimate Yahweh cult. Rather, like the prophet Hosea after him. Amos considered the Bethel cult to be Canaanite.

Prophets of the ancient Near East generally interjected their opinions and advice into the political arena of their countries, but in this regard the classical Hebrew prophets were perhaps more advanced than other prophetic movements. They interpreted the will of God within the context of their particular interpretation of Israel's history, and on the basis of this interpretation often arrived at a word of judgment. Important to that interpretation of history was the view that Israel was an apostate people—having rejected a faith once confessed—from the very earliest times, and the view that Yahweh's acts on behalf of his chosen people had been answered by their worship of other gods. In this situation, the prophets preached doom and judgment, and even the complete destruction of Israel. The source of prophetic insight into these matters is the cultic background of liturgical judgment and salvation, wherein Yahweh judged and destroyed his enemies, and in so doing created the "ideal" future. What is totally unexpected is that the prophets would go so far as to include Israel itself as among Yahweh's enemies, thus using these ideas against their own people. Usually, however. the prophets allowed some basis for hope in that a remnant would be left. The future of this remnant (Israel) lay in the reign of an ideal king (as described in Isaiah), indicating that the prophets were not antiroyalists. Though they could and did oppose individual kings, the prophets could not make a separation between Yahweh and the reign of his chosen king or dynasty. Their messianic ideology, referring to the messiah, or anointed one, is based on old royal ideology, and the ideal king is not an eschatological figure (one who appears at the end of history). In this respect, the prophets were nationalistic; they believed that the ideal kingdom would he in the promised land, and its centre would be Jerusalem.

Concepts of the remnant and of the messiah

With the Exile of the Judaeans to Babylon of 586 BC, prophecy entered a new era. The prophecies of what is called Deutero-Isaiah (Isaiah 40–45), for instance, were aimed at preserving Yahwism in Babylonia. His vision of the future went beyond the pre-exilic concept of a remnant and extended the concept into a paradisiacal future wherein Yahweh's new creation would be a new Israel. This tone of optimism is continued in the prophetic activity (late 6th century BC) of Haggai and Zechariah, prophets who announced that Yahweh would restore the kingdom and the messianic vision would come to pass. Prerequisite to this messianic age was the rebuilding of the Temple (which was viewed as heaven on earth). When, however, the Temple had been rebuilt and long years had passed with neither the kingdom being restored nor the messianic age initiated, Israelite prophecy declined.

There is a tendency in prophetic preaching to spiritualize those aspects of religion that remain unfulfilled; herein lie the roots of eschatology, which is concerned with the last times, and apocalyptic literature, which describes the intervention of God in history to the accompaniment of dramatic, cataclysmic events. Since the predictions of the classical prophets were not fulfilled in a messianic age within history, these visions were translated into a historical apocalypse, such as Daniel. Why prophecy died out in Israel is difficult to determine, but Zechariah offers as good an answer as any in saying that the prophets "in those days" told lies. Prophets did appear, but after Malachi none gained the status of the classical prophets. Another reason may be found in Ezra's reform of the cult in the 5th century BC, in which Yahwism was so firmly established that there was no longer any need for the old polemics against Canaanite religion.

Reinterpretation of the prophetic heritage

Prophecy and apocalyptic literature. With the advent of postexilic Judaism (Ezra and after), including its emphasis on law and cult, there was not much room left for prophecy. The prophetic heritage was channelled through the teaching of their words. What remained of prophetic activity was expressed in various literary works that claimed esoteric knowledge of the divine purpose. The apocalyptic writers saw themselves as taking over and carrying on the prophetic task, but they went beyond the prophets in their use of old mythological motifs. The events they described had usually occurred long ago, but their recounting of these events was for the purpose of hinting and even predicting the events of the future. There was a far greater emphasis upon predictive speculation about the future than on the prophetic analysis and insight into history. The apocalyptic authors wrote pseudonymously, using the names of ancient worthies (such as Adam, Enoch, Abraham, Daniel, and Ezra). The literature is predominantly prose, but that of the classical prophets was predominantly poetry. Apocalyptic language is lavish in its use of fantastic imagery, frequently using riddles and numerical speculations. In apocalyptic literature angelology came into full blossom, with accounts of fallen angels (fallen stars) caught up in the forces opposed to God, frequently pictured in the old mythological motif of the struggle between darkness and light. Wild beasts symbolized peoples and nations, and there were esoteric calculations and speculations about the different eras through which history was passing as the world approached the eschaton (the consummation of history).

Dominant in apocalyptic literature is the theme of God's sovereignty and ultimate rule over all the universe. The message of the apocalyptic writers is one of both warning of the doom to come at the end of history, and hope in the new age beyond history under the rule of God, when the righteous will be vindicated.

Prophecy and prophetic religion in postbiblical Judaism. Though prophecy did not cease functioning in early Judaism, rabbinical Judaism—that influenced by rabbis, scholars, and commentators of the Bible—sought to limit it by advocating the pre-exilic era as the classical time of prophecy. Prophecy was not suppressed, but it came to be encircled by the law (Torah) in that all prophecy had to be in harmony with Torah, which was the definitive revelation of God's will. Thus, rabbinical Judaism gave prophecy its place of importance, but only as a phenomenon of the past. Such a theological stricture could not restrain the charismatic, eschatologically oriented patriots who arose during the time of Roman hegemony (mid-1st century BC–4th century AD). One rabbi, Akiba ben Joseph, joined with a messianic pretender, Simeon bar Kokhba (ber Kochba), in a revolt (132–135) and functioned as a prophet within that movement.

Eschatologically oriented prophets

Some prophets are known from the period of Hellenistic Judaism. I Maccabees, chapter 14, relates that Simon Maccabeus, who finally secured political independence for Judaea in 142 BC, was chosen as "leader and high priest forever, until a trustworthy prophet should arise." The same notion of a prophet soon to appear is expressed in chapter 1 of I Maccabees. The Hasmonean (Maccabean) prince John Hyrcanus (reigned 135–104 BC) was regarded as fulfilling these expectations and was called a prophet by the 1st-century AD Jewish historian Josephus (Jewish *War).* Josephus also mentions some Zealots (Jewish revolutionaries) as prophets and also one Jesus, son of Ananias, who in AD 62 predicted the destruction of the Temple and the defeat of the Jews. Josephus also mentions the seer Simon, a prophet leader (Antiquities), and Menahem, who prophesied in the 1st century BC. Among the followers of Judas Maccabeus, the leader of the 2nd-century-BC revolt, there apparently were persons who divined knowledge of the future. These and other notations indicate that seers and prophets played an important role in the intertestamental and postbiblical periods.

Jewish theology in Alexandria (Egypt) took up early rabbinical ideas and postulated that the will of God was to be discerned in the Torah and affirmed that the interpretation of law succeeded both the prophetic office and the role of sages. The law was thus considered to be superior to prophetic teaching. The Jewish philosopher Philo of Alexandria (*c.* 30 BC–after AD 40) affirmed that the Jews are a people of prophets. He also asserted that when a prophet has reached the fourth and final stage of ecstasy he is ready to become an instrument of divine power. Though Philo was influenced by Hellenistic concepts of prophecy, his basic foundation was still the Old Testament. Later rabbis believed that prophecy, though it was a gift from the world beyond, still required some knowledge. In rabbinic discussions of the nature of truth, it was generally held that reason alone was necessary but insufficient; prophecy could supply what was missing.

Superiority of law in relation to prophecy

The medieval Jewish philosopher Maimonides understood prophecy as an emanation from God to the intellect of man. Thus, prophecy could not be acquired by human effort. The divine gift of prophecy was bestowed upon those with both mental and moral perfection, combined with the presence of superior imagination. Opponents of this view advocated that Maimonides' concept of prophecy was not Jewish because Jewish prophecy always showed itself to be miraculous (see also JUDAISM; JUDAISM, HISTORY OF).

PROPHECY IN CHRISTIANITY

Divination and prophecy in the Hellenistic world. The problem of false prophets that occurred in Old Testament times also occurred in the early Christian communities. Prophets and diviners were widespread throughout the Hellenistic world. The Greek *prophētēs* was not only a forthteller but also an interpreter of divine messages. In addition, there were mantics (from the Greek mantis)—*i.e.*, visionary seers—whose visions were interpreted by prophets, soothsayers, diviners of all kinds, and especially astrologers. The impetus for much of this activity came from Babylonia. The influx of new religions from the East brought a profusion of astrologers and prophets. Many schools of astrology were founded throughout the Hellenistic world, and old schools of philosophy became very much occupied with astrology.

New Testament and early Christianity. Prophecy in the New Testament is seen as both a continuation of Old Testament prophecy as well as its fulfillment. For New Testament authors, the correct interpretation of Old Testament prophecy is that it speaks in *toto* of Christ. To prove their point, they often cite passages of Old Testament prophecy that are then elucidated as the words of God about Christ. New Testament writers follow Jesus himself in this matter, and Jesus is taken to be the prophet that was promised in Deuteronomy (see John 1:45, cf. 5:39, 6:14; Acts 3:22 *ff.*). Jesus regarded himself as a prophet, and so did some of his contemporaries. One special aspect of the prophetic image, however, is missing in Jesus: he was not an ecstatic, although supernatural revelations are found in connection with him; *e.g.*, the transfiguration of Jesus as witnessed by some of his Apostles on Mt. Tabor. In these New Testament descriptions of the transfiguration, Jesus is proclaimed to be the Son of God in words borrowed directly from Old Testament enthronement ritual. As a prophet, Jesus predicted his own death, his return as the Son of man at the end of the world, and the destruction of the Jerusalem Temple. At many points, Jesus is compared with and interpreted by the classical prophets in New Testament writings: his death—seen as the martyrdom of a prophet, his sufferings, and even his identity.

Though the New Testament describes Jesus as a prophet, he is at the same time believed to be more than a prophet: he is the expected Messiah (Greek *christos*, "anointed one"), predicted by prophets of old, who should reign as the Son of David and the Son of God. The royal ideology of the Old Testament was most important to early Christianity, for herein lay the seeds of its doctrines of Christ (see also MESSIAH AND MESSIANIC MOVEMENTS).

Several prophets are mentioned in the New Testament. One, Zechariah, is said to have perished "between the altar and the sanctuary" (Luke). Reference to his death is included by the Gospel writers because he was the last prophet before Jesus to have been killed by the Jews. Zechariah, the father of John the Baptist, uttered the Benedictus ("Blessed," the initial Latin word of the prophetic song) under the inspiration of the spirit. His wife, Elizabeth, also was described as being inspired by the spirit.

Others are Simeon, the prophetess Anna, and John the Baptist. These prophets are conceived by the New Testament writers as the termination of Old Testament prophecy, a concept also expressed by Jesus with reference to John the Baptist.

New Testament prophetic figures

The New Testament mentions several prophetic figures in the early church. Among them are Agabus of Jerusalem; Judas Barsabbas and Silas, who also were elders of the Jerusalem Church; the four prophesying daughters of

Philip the evangelist; and John, the author of Revelation. The term prophet is used with reference to an office in the early church along with evangelists and teachers, and the recipient of the letter bearing his name, Timothy, is called both a minister and a prophet. The prophet's role in the early church was to reveal divine mysteries and God's plan of salvation. Paul instructed his followers in the correct use of prophecy, and evaluated it as more beneficial to the life of congregations than ecstatic glossolalia (speaking in tongues). He considered prophecy to be the greatest spiritual gift from God, and in his view a prophet therefore ranks ahead of evangelists and teachers. With all this prophetic activity, the problem of false prophecy was crucial, and warnings against it abound in the New Testament. The most dangerous of the false prophets is predicted in the book of Revelation to John as yet to come. Many of these prophets, viewed as magicians and exorcists, are condemned for inducing chaos and for leading people astray. Therefore all prophetic activity had to be examined.

In the period immediately after the Apostles, prophets continued to play an important leadership role in the church, sometimes being called high priests. They were the only ones permitted to speak freely in the liturgy because of their inspiration by the Holy Spirit. Gradually, however, the liturgy became more and more fixed, and less freedom and innovation was permitted; this change, combined with the threat of false prophecy, eliminated these charismatic personalities. Among the heretical sects that advocated a return to prophetic activity, Montanism (2nd century), led by the prophet Montanus, advocated that the spirit of truth had come through Montanus. The freedom of doctrinal innovation that Montanus advocated could well have led to doctrinal anarchy, and the result of the struggle against this heresy was the suppression of charismatic prophecy, wherein ecstatic inspiration came to be viewed by the church as demonic.

Montanism

Another prophet who created a problem in the early church was Mani—the 3rd-century founder of a dualistic religion that was to bear his name (Manichaeism)—who considered himself to be the final messenger of God, after whom there was to be no other.

Prophetic and millenarian movements in later Christianity. In Western medieval church doctrines and rituals, active prophecy had no place. Prophetic activity was carried on, however, through holy orders. Mystically oriented holy men would sometimes appear as prophets with a special message, and even ecstatics found their places within the monasteries. In Eastern Christianity, monastic life stressed training in mystical experience.

Throughout Christian history there have been millenarian movements, usually led by prophetic-type personalities and based on the New Testament belief in Christ's return. Their basic doctrine is chiliasm (from Greek *chilioi,* "thousand"), which affirms that Christ will come to earth in a visible form and set up a theocratic kingdom over all the world and thus usher in the millennium, or the 1,000-year reign of Christ and his elect.

The early and medieval church hierarchy generally opposed chiliasm because such movements often became associated with nationalistic aspirations. Though the key leaders of the Protestant Reformation opposed chiliasm. and therefore minimized its effects upon the emergent denominations (*e.g.,* Lutheran, Calvinist, and Anglican), chiliasm did influence Anabaptist circles (radical reformation groups), and through them chiliastic ideas influenced Protestant Reformed theology and have appeared in reform movements, such as Pietism in Lutheran churches, and various revivalistic movements.

PROPHECY IN ISLAM

The centrality of prophecy in Islām. Pre-Islāmic prophecy in Arabia was no different in character from other Semitic prophecy. Pre-Islāmic terms for prophet are *ʿarrāf* and *kāhin* ("seer," cognate to Hebrew ***cohen,*** "priest"). The *kāhin* could often be a priest, and as a diviner he was an ecstatic. The *kāhin* was considered to be possessed by a *jinnī* ("spirit"), by means of whose power miracles could be performed. Also, poets were considered to be possessed by a *jinnī* through whose inspiration they composed their verses. The importance of the seers and diviners was noted in all aspects of life. Any problem might be submitted to such men, and their oracular answers were given with divine authority. It is not surprising, therefore, to find that a *kāhin* often became a sheikh, a temporal leader, and there were instances in which the position of *kāhin* was hereditary.

The role of the *kāhin*

It was against this background that the founder of Islām, Muhammad, appeared. During his early career in Mecca (in Arabia) he was considered by his tribesmen, the Quraysh, to be only another jinni-possessed *kāhin.* His utterances during this time were delivered in the same rhymed style as that used by other Arab prophets and were mostly the products of ecstatic trances. At about 40 years of age Muhammad experienced the promptings of the one god, Allāh, and retreated into the solitude of the mountains. These retreats served psychologically as preparations for his later revelations. The central religious problem of Muhammad was the fact that Jews had their sacred scriptures in Hebrew, and Christians had theirs in Greek, but there was no written divine knowledge in Arabic. Muhammad's preoccupation with this concern, along with a sense of the coming Day of Judgment, became the seeds of his new religion. Contemplation had matured Muhammad, and biographers point out that, as one may conclude from the Qur'Bn, Muhammad received the divine call in a vision. His ecstatic revelations were in the form of auditions, usually involving the angel Gabriel reading the divine message from a book. The illiterate Muhammad had his wife Khadijah, who was 15 years his senior, record them, and they are preserved in the Qur'Bn. Because this is believed to be a verbatim copy of the Heavenly Book, literally the words of Allāh himself, it cannot be questioned.

Muhammad considered himself to be more than a mere prophet (*nābi*); he thought of himself as the messenger (*rasūl*) of Allāh, the final messenger in a long chain that had begun with Noah and run through Jesus. As Allāh's *rasūl,* Muhammad saw his first mission to be that of warning the Arab peoples of the impending doomsday. No doubt Muhammad was influenced by the Judeo-Christian tradition in his concept of the Day of Judgment, as well as in his concept of himself as a prophet. Muhammad, who had felt at one time that Arabs were religiously inferior to Jews and Christians, became the medium of revelations that created Islām, and raised the Arabs in Muhammad's own evaluation to a status equal with that of the other two religions.

After AD 622, when Muhammad left Mecca and found refuge in Medina, ecstatic revelations began to play a secondary role in his prophecy—due to his political concerns—and not only does the rhymed prose of his message give way to more conventional prose but the content is more obviously the product of reasoned reflection on all aspects of life.

The Qur'ānic doctrines of prophecy. An official Islāmic view, and also that of Muhammad himself, was that Muhammad was the final Prophet. The Qur'Bn mentions those men who are considered to have imparted divine knowledge: Adam, Noah, Abraham, Isaac, Jacob, Moses, David, and Jesus. None of these revealed Allāh's message in full, since they were sent only to one nation. Muhammad, on the other hand, was sent to all nations and also to the *jinn.* The messages of the prophets before Muhammad were believed to have been either forgotten or distorted, but Islām claims that the Qur'Bn both corrects and confirms the sayings of the earlier prophets; Muhammad is the "seal of the prophets"; *i.e.,* the end of prophecy. All prophecy before Muhammad is incomplete and points to the coming of the final revelation.

The final Prophet

The prophetic activity of Muhammad serves as the foundation of Islām and Muslim society. The incomparable revelations of Muhammad are believed to have brought true monotheism into the world, to which nothing can be added or taken away. Thus, there is no more need of prophets or revelations (see also QUR'AN).

Later theological and philosophical doctrines. After the death of Muhammad, the expansion of Islām brought it into contact with the world at large, and a Muslim culture (involving science, philosophy, and literature) emerged, partially as a result of the Muslim acquisition of Byzantine culture. Christians and Jews became advisers and officials in Muslim courts. Christian philosophers introduced Muslim students to the works of the 4th-century-BC Greek philosopher Aristotle and to Neoplatonism (a philosophical system concerning the complex levels of reality), to theories about the nature of man, to theology, to the nature of existence, and to cosmology. Philosophical discussions about God, however, leave little or no room for prophets, and the savant displaced the prophet as the one proclaiming the will of God. As religious leaders, the savants were the keepers of sunnah (the life and habits of the prophet) and hadith (traditions about Muhammad's utterances and actions), which are supplements to the Qur'ān. Study of *ḥadīth* and *sunnah* contributed to the beginning of scholarly and scholastic activities in Islām, from which study emerged the Muslim system of duties and obligations (*fiqh*). Muslim theology began in the formulation of the doctrine of the general consensus (*ijmāʿ*), which was used to determine what was genuine sunnah. None ventured to question that Allāh was the only God, that Muhammad was his prophetic messenger, or that the Qur'ān was Allāh's word; to have done so would have been tantamount to admitting that one was not a Muslim.

Displacement of prophets

Scholastic philosophy was first introduced openly into Muslim theology by al-Ash'ari (10th century) who was the first to give Islām a systematic exposition. Another theologian, Ibn Sina (Avicenna), considered prophecy still to be a fundamental aspect of Islām, but for him, a prophet was not the spirit-possessed spokesman of God but rather an intelligent, intuitive man whose insight results in a place of leadership in society. Another philosopher, Ibn Rushd (Averroes), denied the belief that man's knowledge could ever be the same as God's knowledge; he also denied doctrines of predestination and corporeal resurrection, both of which were aspects of Muhammad's message.

Prophetic figures after Muḥammad. The fact that Muhammad was considered to be the final prophet did not end prophecy in Islām. After Muhammad's death, several seers proclaimed themselves his successors. Muhammad had designated no one to succeed himself, and left no sons. Abū Bakr, the father of Muhammad's wife ʿA'ishah, was chosen caliph (Arabic khalifah, "substitute, deputy"), but this did not discourage others from claiming that they were called of Allāh and thus trying to lead their own tribes as Muhammad had led his. Such movements were crushed by force, which contributed to the rapid expansion of Islām.

The *mahdī*

Some prophets claimed that they were long-awaited saviour-deliverers (mahdi, "restorer of the faith") and even gained some following beyond their own local tribes. Muhammad Aḥmad ibn as-Sayyid 'Abd Allāh of the Sudan preached a holy war against Egypt (1881) and fought and defeated the British governor-general C.G. Gordon at Khartoum in 1885. In India (Punjab), Mirza Ghulan Aḥmad claimed that he had received the spirit of Jesus and that he was a prophet-messiah. He recorded his revelations from Allāh in a book. Considering himself to be the Christ to his generation, he set out to reform Islām by liberalizing strict orthodoxy, yet avoiding the extremes of the pro-western movements of his time. He gained a large following among middle-class Muslims, but was soon disowned by orthodox Islām. His sect (Ahmadiyah), though small in numbers, has through its missionary activities spread over much of the world. Its socio-political stance is similar to that of the Black Muslims of the United States (see also ISLAM).

PROPHECY IN OTHER RELIGIONS

Pronhetic movements and figures in the Eastern religions. Buddhist literature contains predictions of a certain Buddha Maitreya, who will come as a kind of saviour-messiah to inaugurate a paradisaical age on earth. Gautama the Buddha himself, the 6th-century-BC founder of Buddhism, mentioned this prediction. Among the Hindus, the *Purāṇa* literature ("old history") contains prophetic passages, but these are to be understood as predictions after the event has occurred. Hindu religion has had many prophetic reformers, and the tribes of India, in their struggle for freedom, have produced prophets who combined the ideas of religious freedom with the hope of political and social freedom. The Oraons, a tribe in Chota Nāgpur, saw several prophets (bhagats) appear around the turn of the 20th century. Their intent was to free their people from foreign culture and political rule, returning to the older Hindu culture and religion. Such efforts often led to armed rebellion and ended in disaster.

In ancient China, divination was commonplace. One Confucian book involving divination, the "Classic of Changes," may have been connected with pre-Han Confucianism (before the 3rd century BC). Classical Confucian religion, however, emphasized the importance of rational process over inspiration and divination. Autocratic governments eliminated any such revolutionary, prophet-led movements as occurred in India, and any prophecy against the establishment was regarded as heretical. Inspired prophecy found little place in the official state religion. This situation did not rule out prophecy in folk religion, in which prophets appeared and promised their followers the good life in this world and in the next. In modern times, some of these movements became religio-political movements, as when Hung Hsiu-Ch'üan, an ecstatic epileptic noble of the middle 19th century, started a movement called the Taiping ("Great Peace"), a sect claiming that it was establishing the correct political order anew. Hung's movement—perhaps under the impact of Protestant missions—was quite austere, and it opposed magic, idols, and belief in spirits. He considered the New Testament to be authoritative for his new sect, and its rapid growth—aided by connections with other revolutionary movements—soon resulted in a genuine danger to the Manchu ruler of China. The Taiping Rebellion was crushed by Gordon in 1864.

Folk religion prophets

Diviners and shamans (male and female) are well represented in old Japanese Shintb. Japanese shamanism, which was closely related to Korean shamanism, often played a role in political disturbances and still does. Among old Japanese Buddhist sects is that founded by Nichiren (13th century AD), a prophetic enthusiast, religious revivalist, and zealous nationalist who taught that the Japanese people were the chosen people of God. In the Shintō revival movements of the 18th and 19th centuries, inspired persons with eschatological concepts founded movements that became messianic in character, and drew many of their followers from among the farmers, many of whom had practiced a Buddhist folk piety.

Prophetic movements and figures in the primitive religions. In many primitive religions, especially those of Africa, shamans, seers, and prophets are quite common. The same distinction between technical divination and charismatic prophecy is to be found in these cultures as in the ancient Near East. When it is possible to trace the history of prophetic activity in Africa, scholars usually find that it arises in times of confrontations with foreign cultures and with the advent of new religions. A sharp distinction between the diviner and the prophet cannot always be maintained, for diviners sometimes appear as prophets. A diviner may hear the voice of a god or spirit in his dreams and visions (in Zulu he is called a "dreamhouse") and receive a message. Some prophets, avowing a call, deny any training in prophecy. There are many parallels with the "rebel" prophets of India. Ecstatic prophets have played an important role not only in chiliastic and messianic movements but also in those movements opposing imperialism and European colonization of Africa. Their goal was and is a return to the old African culture and religion. Eschatological motifs have often been used in the prophetic preaching of tribal and national movements aspiring for freedom. Many of these prophets took up Christian ideas. Nxele, a 19th-century prophet of the South African Xhosas, preached the return of the dead on a certain day, and his successor, Mlandsheni, claimed to be the reincarnation of Nxele. He and others like him were healers and miracle workers.

Some of the prophetic founders of reform movements, which often were more political than religious, became messianic figures. Other prophets started out as Christian converts but came to a strong awareness that God had destined them to separate from their churches and lead syncretistic movements (fusions of various sources), all of which incorporate aspects of old African religion and, often, allow polygamy. In all these movements, syncretistic or not, there are also many prophetesses.

Prophets also have been found among American Indians. In 1675, a medicine man, Popé, arose as a prophetic leader among the Pueblo Indians. He preached the end of Spanish tyranny and a restoration of Indian sovereignty. At the height of the movement, several massacres took place, along with the burning of various church buildings (see also NATIVISTIC RELIGIOUS MOVEMENTS).

Prosody

As it has come to be defined in modern criticism, the term prosody encompasses the study of all of the elements of language that contribute toward acoustic and rhythmic effects, chiefly in poetry but also in prose. The term derived from an ancient Greek word that originally meant a song accompanied by music or the particular tone or accent given to an individual syllable. Greek and Latin literary critics generally regarded prosody as part of grammar; it concerned itself with the rules determining the length or shortness of a syllable, with syllabic quantity, and with how the various combinations of short and long syllables formed the metres (*i.e.*, the rhythmic patterns) of Greek and Latin poetry. Prosody was the study of metre and its uses in lyric, epic, and dramatic verse. In sophisticated modern criticism, however, the scope of prosodic study has been expanded until it now concerns itself with what the 20th-century poet Ezra Pound called "the articulation of the total sound of a poem."

Prosody and prose rhythm

Prose as well as verse reveals the use of rhythm and sound effects; however, critics do not speak of "the prosody of prose" but of prose rhythm. The English critic George Saintsbury wrote *A History of English Prosody from the Twelfth Century to the Present* (3 vol., 1906–10), which treats English poetry from its origins to the end of the 19th century; but he dealt with prose rhythm in an entirely separate work, *A History of English Prose Rhythm* (1912). Many prosodic elements such as the rhythmic repetition of consonants (alliteration) or of vowel sounds (assonance) occur in prose; the repetition of syntactical and grammatical patterns also generates rhythmic effect. Traditional rhetoric, the study of how words work, dealt with acoustic and rhythmic techniques in Classical oratory and literary prose. But although prosody and rhetoric intersected, rhetoric dealt more exactly with verbal meaning than with verbal surface. Rhetoric dealt with grammatical and syntactical manipulations and with figures of speech; it categorized the kinds of metaphor. Modern critics, especially those who practice the New Criticism, might be considered rhetoricians in their detailed concern with such devices as irony, paradox, and ambiguity. These subjects are discussed at greater length in the articles RHETORIC; LITERARY CRITICISM.

This article will discuss prosody chiefly in terms of the English language—the only language that all of the readers of this article may be assumed to know. Some examples are given in other languages to illustrate particular points about the development of prosody in those languages; because these examples are pertinent only for their rhythm and sound, and not at all for their meaning, no translations are given. A further general discussion of the development of prosodic elements will be found in the article POETRY; prosodic development in specific literatures is discussed in articles on the history of literature, such as LITERATURE, WESTERN; LITERATURE, EAST ASIAN; and in the literature sections of articles on the arts of various peoples, such as AFRICAN PEOPLES, ARTS OF; AMERICAN INDIAN PEOPLES, ARTS OF; etc.

ELEMENTS OF PROSODY

As a part of modem literary criticism, prosody is concerned with the study of rhythm and sound effects as they occur in verse and with the various descriptive, historical, and theoretical approaches to the study of these structures.

Scansion. The various elements of prosody may be examined in the aesthetic structure of prose. The celebrated opening passage of Charles Dickens' novel *Bleak House* (1853) affords a compelling example of prose made vivid through the devices of rhythm and sound:

> Fog everywhere. Fog up the river, where it flows among green aits and meadows; fog down the river, where it rolls defiled among the tiers of shipping, and the waterside pollutions of a great (and dirty) city. Fog on the Essex Marshes, fog on the Kentish heights. Fog creeping into the cabooses of collier-brigs; fog lying out on the yards, and hovering in the rigging of great ships; fog drooping on the gunwales of barges and small boats. Fog in the

eyes and throatc of ancient Greenwich pensioners, wheezing by the firesides of their wards; fog in the stem and bowl of the afternoon pipe of the wrathful skipper. . . .

Two phrases of five syllables each ("Fog everywhere"; "Fog up the river") establish a powerful rhythmic expectation that is clinched in repetition:

. . . fog down the river . . . . Fog on the Essex . . . , fog on the Kentish . . . . Fog creeping into . . . ; . . . fog drooping on the . . . .

This phrase pattern can be scanned; that is, its structure of stressed and unstressed syllables might be translated into visual symbols:

´ ˘ ˘ ´ ˘
Fog down the ri ver.

(This scansion notation uses the following symbols: the acute accent [´] to mark metrically stressed syllables; the breve [˘] to mark metrically weak syllables; a single line [|] to mark the divisions between feet [*i.e.*, basic combinations of stressed and unstressed syllables]; a double line [‖] to mark the caesura, or pause in the line; a rest [A] to mark a syllable metrically expected but not actually occurring.) Such a grouping constitutes a rhythmic constant, or cadence, a pattern binding together the separate sentences and sentence fragments into a long surge of feeling. At one point in the passage, the rhythm sharpens into metre; a pattern of stressed and unstressed syllables falls into a regular sequence:

Cadence and metre

´ ˘ ˘ ´ ˘ ´ ˘ ´ ˘ ˘
Fog on the|Es sex|mar shes, ‖ fog on the|

´ ˘ ´
Ken tish|heights.

The line is a hexameter (*i.e.*, it comprises six feet), and each foot is either a dactyl (´ ˘ ˘) or a trochee (´ ˘).

The passage from Dickens is strongly characterized by alliteration, the repetition of stressed consonantal sounds:

Fog creeping into the cabooses of collier-brigs;

and by assonance, the patterned repetition of vowel sounds:

. . . fog down the river, where it rolls defiled among . . . .

Here the vowel sounds are symmetrically distributed: short, long and long, short. Thus, it is clear that Dickens uses loosely structured rhythms, or cadences, an occasional lapse into metre, and both alliteration and assonance.

The rhythm and sound of all prose are subject to analysis; but compared with even the simplest verse, the "prosodic" structure of prose seems haphazard, unconsidered. The poet organizes his structures of sound and rhythm into rhyme, stanzaic form, and, most importantly, metre. Indeed, the largest part of prosodical study is concerned with the varieties of metre, the nature and function of rhyme, and the ways in which lines of verse fall into regular patterns or stanzas. An analysis of "Vertue" by the 17th-century English poet George Herbert reveals how the elements of prosody combine into a complex organism, a life sustained by the technical means available to the poet. When the metre is scanned with the symbols, it can be seen (and heard) how metre in this poem consists of the regular recurrence of feet, how each foot is a pattern of phonetically stressed and unstressed syllables.

Scansion

˘ ´ ˘ ´ ˘ ´ ˘ ´
1 Sweet day,|so cool,|so calm,|so bright,
˘ ´ ˘ ´ ˘ ´ ˘ ´
2 The bri|dall of|the earth|and skie:
˘ ´ ˘ ´ ˘ ´ ˘ ´
3 The dew|shall weep|thy fall|to-night;
˘ ´ ˘ ´
4 For thou|must die.

˘ ´ ˘ ´ ´ ˘ ˘ ´
5 Sweet rose,|whose hue|an grie|and brave
´ ˘ ˘ ´ ˘ ´ ˘ ´
6 Bids the|rash ga|zer wipe|his eye:
˘ ´ ˘ ´ ˘ ´ ˘ ´
7 Thy root|is ev|er in|its grave,
˘ ´ ˘ ´
8 And thou (must die.

˘ ´ ´ ˘ ˘ ´ ˘ ´ ˘
9 Sweet spring,|full of|sweet dayes|and ro|ses,
˘ ´ ˘ ´ ˘ ´ ˘ ´
10 A box|where sweets|com pac|ted lie;
˘ ´ ˘ ´ ˘ ´ ˘ ´ ˘
11 My mu|sick shows|ye have|your clo|ses,
˘ ´ ˘ ´
12 And ail|must die.

´ ˘ ˘ ´ ˘ ´ ˘ ´
13 Onely|a sweet|and ver|tuous soul,
˘ ´ ˘ ´ ˘ ´ ˘ ´
14 Like sea|son'd tim|ber, ne|ver gives;
˘ ´ ˘ ´ ˘ ´ ˘ ´
15 But though|the whole|world turn|to coal,
˘ ´ ˘ ´
16 Then chief|ly lives.

The basic prosodic units are the foot, the line, and the stanza. The recurrence of similar feet in a line determines the metre; here there are three lines consisting of four iambic feet (*i.e.*, of four units in which the common pattern is the iamb—an unstressed syllable followed by a stressed syllable), which are followed by a line consisting of two iambic feet. Thus the stanza or recurring set of lines consists of three iambic tetrameters followed by one iambic dimeter. The stanzaic form is clinched by the use of rhyme; in "Vertue" the first and third and second and fourth lines end with the same sequence of vowels and consonants: bright/night, skie/die, brave/grave, eye/die, etc. It should be observed that the iambic pattern (˘´) is not invariable; the third foot of line 5, the first foot of line 6, the second foot of line 9, and the first foot of line **13** are reversals of the iambic foot or trochees (´˘). These reversals are called substitutions; they provide tension between metrical pattern and meaning, as they do in these celebrated examples from Shakespeare:

˘ ´ ˘ ´ ˘ ´ ´ ˘ ˘ ´ ˘
To be,|or not|to be, ‖ that is|the ques tion . . . .

Hamlet

˘ ´ ˘ ´ ´ ˘ ˘ ´ ˘ ´
His sil|ver skin|laced with|his gol|den blood . . .

Macbeth

Meaning, pace, and sound. Scansion reveals the basic metrical pattern of the poem; it does not, however, tell everything about its prosody. The metre combines with other elements, notably propositional sense or meaning, pace or tempo, and such sound effects as alliteration, assonance, and rhyme. In the fifth line of "Vertue," the reversed third foot occurring at "angry" brings that word into particular prominence; the disturbance of the metre combines with semantic re-enforcement to generate a powerful surge of feeling. Thus, the metre here is expressive. The pace of the lines is controlled by the length of vowel sounds; although lines 5 and 6 contain the same number of syllables and feet, line 5 obviously takes longer to read or recite. The line contains more long vowel sounds:

Sweet rose, whose hue angrie and brave. . .

Quantity

Vowel length is called quantity. In English verse, quantity cannot by itself form metre although a number of English poets have experimented with quantitative verse. Generally speaking, quantity is a rhythmical but not a metrical feature of English poetry; it can be felt but it cannot be precisely determined. The vowel sounds in "Sweet rose" may be lengthened or shortened at will. No such options are available, however, with the stress patterns of words; the word ´˘ an-gry cannot be read ˘´ an-gry.

Assonance takes into account the length and distribution of vowel sounds. A variety of vowel sounds can be noted in this line:

Sweet day, so cool, so calm, so bright . . .

To borrow a term from music, the line modulates from ēē, through ā, 66, ă, to i. Alliteration takes into account the recurrence and distribution of consonants:

so cool, so calm.. .
Sweet spring . . .

Rhyme normally occurs at the ends of lines; "Virtue" reveals, however, a notable example of interior rhyme, or rhyme within the line:

> My musick *shows* ye have your *closes*. . .

Types of metre. *Syllable-stress metres.* It has been shown that the metre of "Virtue" is determined by a pattern of stressed and unstressed syllables arranged into feet and that a precise number of feet determines the measure of the line. Such verse is called syllable-stress verse (in some terminologies accentual-syllabic) and was the norm for English poetry from the beginning of the 16th century to the end of the 19th century. A line of syllable-stress verse is made up of either two-syllable (disyllabic) or three-syllable (trisyllabic) feet. The disyllabic feet are the iamb and the trochee (noted in the scansion of "Virtue"); the trisyllabic feet are the dactyl (´∪∪) and anapest (∪∪´).

Following are illustrations of the four principal feet found in English verse:

iambic	be hold
trochaic	ti ger
dactylic	des per ate
anapestic	un der stand

Some theorists also admit the spondaic foot (´´) and pyrrhic foot (∪∪) into their scansions; however, spondees and pyrrhics occur only as substitutions for other feet, never as determinants of a metrical pattern:

> When to | the ses | sions of | sweet si | lent thought . . .

It has been noted that four iambic feet make up a line of tetrameter verse; a line consisting of one iambic foot is called monometer, of two dimeter, of three trimeter, of five pentameter, of six hexameter, and of seven heptameter. Lines containing more than seven feet rarely occur in English poetry.

The following examples illustrate the principal varieties of syllable-stress metres and their scansions:

Iambic (pentameter)

Then say | not Man's | im per | fect, ‖ Heaven | in fault;
Say ra | ther, ‖ Man's | as per | fect as | he ought:
His know | ledge meas | ured ‖ to | his state | and place,
His time | a mo | ment, ‖ and | a point | his space.

Alexander Pope, *An Essay on Man* (1733–34)

Trochaic (dimeter)

Could I | catch that
Nim ble | trai tor
Scorn ful | Lau ra,
Swift-foot | Lau ra,
Soon then | would I
Seek a | venge ment.

Thomas Campion (1602)

Dactylic (tetrameter)

Af ter the | pangs of a | des per ate | Lover, ^
When day and | night I have | sigh'd all in | vain, ^ ^
Ah what a | pleas ure it | is to dis | co ver ^
In her eyes | pi ty, who | cau ses my | pain! ^ ^

John Dryden, *An Evening's Love* (1671)

Anapestic (tetrameter)

The As syr | ian came down | like a wolf | on the fold,
And his co | horts were gleam | ing in pur | ple and gold;
And the sheen / of their spears | was like stars | on the sea,
When the blue | wave rolls night | ly on deep | Ga li lee.

Lord Byron, "The Destruction of Sennacherib" (1815)

Syllable stress became more or less established in the poetry of Geoffrey Chaucer (c. 1340–1400). In the century that intervened between Chaucer and the early Tudor poets, syllable-stress metres were either ignored or misconstrued. By the end of the 16th century, however, the now-familiar iambic, trochaic, dactylic, and anapestic metres became the traditional prosody for English verse.

Challenges to traditional prosody in the 19th century

Strong-stress metres. In the middle of the 19th century, with Walt Whitman's free verse and Gerard Manley Hopkins' extensive metrical innovations, the traditional prosody was challenged. Antecedent to the syllable-stress metres was the strong-stress metre of Old English and Middle English poetry. Strong-stress verse is measured by count of stresses alone; the strong stresses are usually constant, but the number of unstressed syllables may vary considerably.

Strong-stress verse survives in nursery rhymes and children's counting songs:

> One, two, ‖ buckle my shoe;
>
> Three, four, ‖ knock at the door;
>
> Five, six, ‖ pick up sticks . . .

The systematic employment of strong-stress metre can be observed in the Old English epic poem *Beowulf* (c. 1000) and in William Langland's vision-poem, *Piers Plowman* ('A' Text, *c.* 1362):

> In a somer sesun ‖ whon softe was the sonne,
>
> I schop me in-to a schroud ‖ a scheep as I were;
>
> In habite of an hermite ‖ un-holy of werkes,
>
> Wende I wydene in this world ‖ wondres to here.

These lines illustrate the structural pattern of strong-stress metre. Each line divides sharply at the caesura (‖), or medial pause; on each side of the caesura are two stressed syllables strongly marked by alliteration.

Strong-stress verse is indigenous to the Germanic languages with their wide-ranging levels of stressed syllables and opportunities for alliteration. Strong-stress metre was normative to Old English and Old Germanic heroic poetry, as well as to Old English lyric poetry. With the rising influence of French literature in the 12th and 13th centuries, rhyme replaced alliteration and stanzaic forms replaced the four-stress lines. But the strong-stress rhythm persisted; it can be felt in the anonymous love lyrics of the 14th century and in the popular ballads of the 15th century.

"Lord Randal" can be comfortably scanned to show a line of mixed iambic and anapestic feet; it clearly reveals, however, a four-stress structure:

> 'O where ha' you been, ‖ Lord Randal, my son?
>
> And where ha' you been, ‖ my handsome young man?'
>
> 'I ha' been at the greenwood ; ‖ mother, mak my bed soon,
>
> For I'm wearied wi' huntin', ‖ and fain wad lie down.'

A number of 20th-century poets, including Ezra Pound, T.S. Eliot, and W.H. Auden, have revived strong-stress metre. The versification of Pound's *Cantos* and Eliot's *Four Quartets* (1943) shows the vitality of the strong-stress, or, as they are often called, "native," metres.

Syllabic metres. The greatest part of English poetry is carried by the strong-stress and syllable-stress metres.

The dominant alexandrine

Two other kinds of metres must be mentioned: the purely syllabic metres and the quantitative metres. The count of syllables determines the metres of French, Italian, and Spanish verse. In French poetry (both dramatic and lyric) the alexandrine, or 12-syllabled line, is a dominant metrical form:

> O toi, qui vois la honte oh je suis descendue,
> Implacable Vbnus, suis-je assez confondue?
> Tu ne saurais plus loin pousser ta cruautb.
> Ton triomphe est parfait; tous tes traits ont porté.
> Racine, *Phèdre* (1677)

Stress and pause in these lines are variable; only the count of syllables is fixed. English poets have experimented with syllabic metres; the Tudor poet Thomas Wyat's translations from Petrarch's Italian poems of the 14th century attempted to establish a metrical form based on a decasyllabic or ten-syllabled line:

> The long love that in my thought doth harbor,
> And in my heart doth keep his residence,
> Into my face presseth with bold pretense
> And there encampeth, spreading his banner.
> "The Lover for Shamefastness Hideth . . ." **(1557)**

Most ears can detect that these lines waver between syllabic and syllable-stress metre; the second line falls into a pattern of iambic feet. Most ears also discover that the count of syllables alone does not produce any pronounced rhythmic interest; syllabic metres in English generate a prosody more interesting to the eye than to the ear.

Quantitative metres. Quantitative metres determine the prosody of Greek and Latin verse. Renaissance theorists and critics initiated a confused and complicated argument that tried to explain European poetry by the rules of Classical prosody and to draft laws of quantity by which European verse might move in the hexameters of the ancient Roman poets Virgil or Horace. Confusion was compounded because both poets and theorists used the traditional terminology of Greek and Latin prosody to describe the elements of the already existing syllable-stress metres; iambic, trochaic, dactylic, and anapestic originally named the strictly quantitative feet of Greek and Latin poetry. Poets themselves adapted the metres and stanzas of Classical poetry to their own languages; whereas it is not possible here to trace the history of Classical metres in European poetry, it is instructive to analyze some attempts to make English and German syllables move to Greek and Latin music. Because neither English nor German has fixed rules of quantity, the poets were forced to revise the formal schemes of the Classical paradigms in accordance with the phonetic structure of their own language.

A metrical paradigm much used by both Greek and Latin poets was the so-called Sapphic stanza. It consisted of three quantitative lines that scanned

-u---uu-u-u,

followed by a shorter line, called an Adonic,

–◡◡––.

Sapphics in English and German

"Sapphics" by the 19th-century English poet Algernon Charles Swinburne shows the Sapphic metre and stanza in English:

> **All** the night sleep came not upon my eyelids,
> Shed not dew, nor shook nor unclosed a feather,
> Yet with lips shut close and with eyes of iron
>   Stood and beheld me.. .
> Saw the white implacable Aphrodite,
> Saw the hair unbound and the feet unsandalled
> Shine as fire of sunset on western waters;
>   Saw the reluctant. . . .

The same metre and stanza in German are found in "Sapphische Ode," by the 19th-century poet Hans Schmidt, which was beautifully set to music by Johannes Brahms (Opus 94, No. 4):

> Rosen brach ich nachts mu am dunklen Hage;
> süsser hauchten Duft sie, als je am Tage;
> doch verstreuten reich die bewegten Äste
>   Tau den mich nasste.
> Auch der Küsse Duft mich wie nie beriickte,
> die ich nachts vom Strauch deiner Lippen pfluckte:
> doch auch dir, bewegt im Gernut gleich jenem,
>   tauten die Tranen.

Quantitative metres originated in Greek, a language in which the parts of speech appear in a variety of inflected forms (*i.e.*, changes of form to indicate distinctions in case, tense, mood, number, voice, and others). Complicated metrical patterns and long, slow-paced lines developed because the language was hospitable to polysyllabic metrical feet and to the alternation of the longer vowels characterizing the root syllables and the shorter vowels characterizing the inflected case-endings. The Classical metres can be more successfully adapted to German than to English because English lost most of its inflected forms in the 15th century, while German is still a highly inflected language. Thus Swinburne's "Sapphics" does not move as gracefully, as "naturally" as Schmidt's. A number of German poets, notably Goethe and Friedrich Holderlin, both of the early 19th century, made highly successful use of the Classical metres. English poets, however, have never been able to make English syllables move in the ancient metres with any degree of comfort or with any sense of vital rhythmic force.

The American poet Henry Wadsworth Longfellow adapted the Classical hexameter for his Evangeline (1847):

´ ◡ ◡ ´ ◡ ◡ ´ ◡ ◡ ´ ◡ ◡ ´ ◡
This is the | for est pri | me val. The | mur mu ring | pines and
◡ ´ ◡
the | hem locks . . .

In Virgil's Aeneid, Longfellow's Classical model, the opening line scans:

– ◡ ◡ – u u - – – ◡ – u u - -
Ar ma vi rum que ca no, Troj ae qui pri mus ab or is

The rules determining length of syllable in Classical Greek and Latin poetry are numerous and complicated; they were established by precise grammatical and phonetic conventions. No such rules and conventions obtain in English; Robert Bridges, the British poet laureate and an authority on prosody, remarked in his Poetical Works (1912) that the difficulty of adapting English syllables to the Greek rules is "very great, and even deterrent." Longfellow's hexameter is in reality a syllable-stress line of five dactyis and a final trochee; syllabic quantity plays no part in determining the metre.

PROSODIC STYLE

The analysis of prosodic style begins with recognizing the metrical form the poet uses. Is he writing syllable-stress, strong-stress, syllabic, or quantitative metre? Or is he using a nonmetrical prosody? Again, some theorists would not allow that poetry can be written without metre; the examples of Whitman and many 20th-century innovators, however, have convinced most modern critics that a nonmetrical prosody is not a contradiction in terms but an obvious feature of modern poetry. Metre has not disappeared as an important element of prosody; indeed, some of the greatest poets of the modern period—William Butler Yeats, T.S. Eliot, Ezra Pound, Wallace Stevens—revealed themselves as masters of the traditional metres. They also experimented with newer prosodies based on prose cadences, on expansions of the blank-verse line, and revivals of old forms—such as strong-stress and ballad metres. Also noteworthy are the "visual" prosodies fostered by the poets of the Imagist movement and by such experimenters as E.E. Cummings. Cummings revived the practice of certain 17th-century poets (notably George Herbert) of "shaping" the poem by typographic arrangements.

Non-metrical prosody

The prosodic practice of poets has varied enormously with the historical period, the poetic genre, and the poet's individual style. In English poetry, for example, during the Old English period (to 1100), the strong-stress metres carried both lyric and narrative verse. In the Middle English period (from *c.* 1100 to *c.* 1500), stanzaic forms developed for both lyric and narrative verse. The influence of French syllable counting pushed the older stress lines into newer rhythms; Chaucer developed for The Canterbury Tales a line of ten syllables with alternating accent and regular end rhyme—an ancestor of the heroic couplet. The period of the English Renaissance (from c. 1500 to 1660) marks the fixing of syllable-stress metre as normative for English poetry. Iambic metre carried three major prosodic forms: the sonnet, the rhyming couplet, and blank verse. The sonnet was the most important of the fixed stanzaic forms. The iambic pentameter rhyming couplet (later known as the heroic couplet) was used by Christopher Marlowe for his narrative poem *Hero* and Leander (1598); by John Donne in the early 17th century for his satires, his elegies, and his longer meditative poems. Blank verse (unrhymed iambic pentameter), first introduced into English in a translation by Henry Howard, earl of Surrey, published in 1557, became the metrical norm for Elizabethan drama. The period of the Renaissance also saw the refinement of a host of lyric and song forms; the rapid development of English music during the second half of the 16th century had a salutary effect on the expressive capabilities of poetic rhythms.

The personal element. A poet's choice of a prosody obviously depends on what his language and tradition afford; these are primary considerations. The anonymous author of the Old English poem *Deor* used the conventional four-stress metric available to him; but he punctuated groups of lines with a refrain:

þaes ofereode: þisses swa maeg!
(that passed away: this also may!)

The refrain adds something to the prosodic conventions of regulated stress, alliteration, and medial pause: a sense of a smaller and sharper rhythmic unit within the larger rhythms of the given metre. While the poet accepts from history his language and from poetic convention the structure of his metre, he shapes his own style through individual modifications of the carrying rhythms. When critics speak of a poet's "voice," his personal tone, they are also speaking of his prosodic style.

Style through tension

Prosodic style must be achieved through a sense of tension; it is no accident that the great masters of poetic rhythm work against the discipline of a given metrical form. In his sonnets, Shakespeare may proceed in solemn iambic regularity, creating an effect of measured progression through time and its legacy of suffering and despair:

No longer mourn for me when I am dead
Than you shall hear the surly sullen bell
Give warning to the world that I am fled. . . .
"Sonnet 71"

Or he may wrench the metre and allow the reader to feel the sudden violence of his feelings, the power of a conviction raised to a command:

´ ∪ ´ ∪ ∪ ´ ∪ ∪ ´
Let me|not to|the mar|riage of|true minds
∪ ´ ∪ ´ ∪ ´ • ∪ ∪ ´
Ad mit|im pe|di ments.|Love is|not love . . . .
"Sonnet 116"

The first two feet of the first line are trochaic reversals; the last two feet comprise a characteristic pyrrhic-spondaic formation. A trochaic substitution is auite normal in the first foot of an iambic pentameter line–a trochaic substitution in the second foot, however, creates a marked disturbance in the rhythm. There is only one "normal" iambic foot in the first line; this line runs over (or is enjambed) to the second line with its three consecutive iambic feet followed by a strong caesura and reversed fourth foot. These lines are, in Gerard Manley Hopkins' term, metrically "counter-pointed"; trochees, spondees, and pyrrhics are heard against a ground rhythm of regular iambics. Without the ground rhythm, Shakespeare's expressive departures would not be possible.

Whitman's innovations

A poet's prosodic style may show all of the earmarks of revolt against prevailing metrical practice. Whitman's celebrated "free verse" marks a dramatic break with the syllable-stress tradition; he normally does not count syllables, stresses, or feet in his long sweeping lines. Much of his prosody is rhetorical; that is, Whitman urges his language into rhythm by such means as anaphora (*i.e.*, repetition at the beginning of successive verses) and the repetition of syntactical units. He derives many of his techniques from the example of biblical verses, with their line of various types of parallelism. But he often moves toward traditional rhythms; lines fall into conventional parameters:

O past! O happy life! O songs of joy!
"Out of the Cradle Endlessly Rocking" (1859)

Or they fall more often into dissyllabic hexameters:

Borne through the smoke of the battles and pierc'd
with missiles I saw them . . . .
"When Lilacs Last in the Door-Yard Bloom'd" (1865–66)

Despite the frequent appearance of regular metrical sequences, Whitman's lines cannot be scanned by the usual graphic method of marking syllables and feet; his prosody, however, is fully available to analysis. The shape on the page of the lines below (they comprise a single strophe or verse unit) should be noted, specifically the gradual elongation and diminution of line length. Equally noteworthy are the repetition of the key word *carols*, the alliteration of the *s* sounds, and the use of words in falling (trochaic) rhythm, "lagging," "yellow," "waning":

Shake out carols!
Solitary here, the night's carols!
Carols of lonesome love! death's carols!
Carols under that lagging, yellow, waning moon!
O under that moon where she droops almost down into the sea!
O reckless despairing carols.
"Out of the Cradle"

No regular metre moves these lines; but a clearly articulated rhythm—produced by shape, thematic repetitions, sound effects, and patterns of stress and pause—defines a prosody.

Whitman's prosody marks a clear break with previous metrical practices. Often a new prosody modifies an existing metrical form or revives an obsolete one. In "Gerontion" (1920), T.S. Eliot adjusted the blank-verse line to the emotionally charged, prophetic utterance of his persona, a spiritually arid old man:

After such knowledge, what forgiveness? Think now
History has many cunning passages, contrived corridors
And issues, deceives with whispering ambitions,
Guides us by vanities. Think now. . .
(From T.S. Eliot, Collected Poems *1909–1962*,
Harcourt Brace Jovanovich, Inc.)

The stress prosodies of Pound and Eliot

The first three lines expand the pentameter line beyond its normal complement of stressed and unstressed syllables; the fourth line contracts, intensifying the arc of feeling. Both Pound and Eliot used stress prosodies. Pound counted out four strong beats and used alliteration in his brilliant adaptation of the old English poem "The Seafarer" (1912):

Chill its chains are; chafing sighs
Hew my heart round and hunger begot
Mere-weary mood. Lest man know not
That he on dry land loveliest liveth . . .
(From Ezra Pound, Personae, Copyright 1926 by Ezra Pound. Reprinted by permission of New Directions Publishing Corporation.)

He uses a similar metric for the energetic opening of his "Canto I." Eliot mutes the obvious elements of the form in the celebrated opening of The *Waste Land* (1922) :

April is the cruellest month, breeding
Lilacs out of the dead land, mixing
Memory and desire, stirring
Dull roots with spring rain.
(From T.S. Eliot, Collected Poems *1909–1962*,
Harcourt Brace Jovanovich, Inc.)

Here is the "native metre" with its falling rhythm, elegiac tone, strong pauses, and variably placed stresses. If this is free verse, its freedoms are most carefully controlled. "No verse is free," said Eliot, "for the man who wants to do a good job."

The prosodic styles of Whitman, Pound, and Eliot—though clearly linked to various historical antecedents—are innovative expressions of their individual talents. In a sense, the prosody of every poet of genius is unique; rhythm is perhaps the most personal element of the poet's expressive equipment. Alfred Lord Tennyson and Robert Browning, English poets who shared the intellectual and spiritual concerns of the Victorian age, are miles apart in their prosodies. Both used blank verse for their dramatic lyrics, poems that purport to render the accents of real men speaking. The blank verse of Tennyson's "Ulysses"

The prosody of Tennyson and Browning

(1842) offers smoothly modulated vowel music, carefully spaced spondaic substitutions, and unambiguous pentameter regularity:

The long day wanes; the slow moon climbs; the deep
Moans round with many voices. Come, my friends,
'Tis not too late to seek a newer world.

Browning's blank verse aims at colloquial vigour; its "irregularity" is a function not of any gross metrical violation—it always obeys the letter of the metrical law—but of the adjustment of abstract metrical pattern to the rhythms of dramatic speech. If Tennyson's ultimate model is Milton's Baroque prosody with its oratorical rhythms, Browning's model was the quick and nervous blank verse of the later Elizabethan dramatists. Characteristic of Browning's blank verse are the strong accents, involuted syntax, pregnant caesuras, and headlong energy in "The Bishop Orders His Tomb at St. Praxed's Church" (1845):

Vanity, saith the preacher, vanity!
Draw round my bed: is Anselm keeping back?
Nephews—sons mine . . . ah God, I know not! Well—
She, men would have to be your mother once,
Old Gandolf envied me, so fair she was!

Influence of period and genre. In the lyric genres, the rhythms of the individual poet—or, in the words of the 20th-century American poet Robert Lowell, "the person himself"—can be heard in the prosody. In the long poem, the dramatic, narrative, and didactic genres, a period style is more likely to be heard in prosody. The blank-verse tragedy of the Elizabethan and Jacobean dramatists, the blank verse of Milton's Paradise Lost (1667) and its imitators in the 18th century (James Thomson and William Cowper), and the heroic couplet of Neoclassical satiric and didactic verse, each, in different ways, defines the age in which these prosodies flourished. The flexibility and energy of the dramatic verse of Marlowe, Shakespeare, and John Webster reflect the later Renaissance with its nervous open-mindedness, its obsessions with power and domination, and its lapses into despair. Miltonic blank verse, based on Latin syntax and adaptations of the rules of Latin prosody, moved away from the looseness of the Elizabethans and Jacobeans toward a more ceremonial style. It is a Baroque style in that it exploits the musical qualities of sounds for their ornamental values. The heroic couplet, dominating the poetry of the entire 18th century, was unequivocally a prosodic period style; its elegance and epigrammatic precision entirely suited an age that valued critical judgment, satiric wit, and the powers of rationality.

Prosody in dramatic verse

It is in dramatic verse, perhaps, that a prosody shows its greatest vitality and clarity. Dramatic verse must make a direct impression not on an individual reader able to reconsider and meditate on what he has read but on an audience that must immediately respond to a declaiming actor or a singing chorus. The ancient Greek dramatists developed two distinct kinds of metres: "stichic" forms (*i.e.*, consisting of "stichs," or lines, as metrical units) such as the iambic trimeter for the spoken dialogues; and lyric, or strophic, forms (*i.e.*, consisting of stanzas), of great metrical intricacy, for the singing and chanting of choruses. Certain of the Greek metres developed a particular ethos; characters of low social standing never were assigned metres of the lyric variety. Similar distinctions obtained in Elizabethan-drama. Shakespeare's kings and noblemen speak blank verse: comic characters, servants, and country bumpkins discburse in prose; clowns, romantic heroines, and supernatural creatures sing songs. In the early tragedy Romeo and Juliet, the chorus speaks in "excellent conceited" sonnets: in what was one of the most popular and easily recognized lyric forms of the period.

The metrical forms used by ancient and Renaissance dramatists were determined by principles of decorum. The use or non-use of a metrical form (or the use of prose) was a matter of propriety: was the metre suitable to the social status and ethos of the individual character; was the metre suitable to the emotional intensity of the particular situation? Decorum, in turn, was a function of the dominant Classical and Neoclassical theories of imitation.

THEORIES OF PROSODY

Ancient critics like Aristotle and Horace insisted that certain metres were natural to the specific poetic genres; thus, Aristotle (in the Poetics) noted that "Nature herself, as we have said, teaches the choice of the proper measure." In epic verse the poet should use the heroic measure (dactylic hexameter) because this metre most effectively represents or imitates such qualities as grandeur, dignity, and high passion. Horace narrowed the theory of metrical decorum, making the choice of metre prescriptive; only an ill-bred and ignorant poet would treat comic material in metres appropriate to tragedy. Horace prepared the way for the legalisms of the Renaissance theorists who were quite willing to inform practicing poets that they used "feete without joyntes," in the words of Roger Ascham, Queen Elizabeth's tutor, and should use the quantitative metres of Classical prosody.

Middle Ages. During the Middle Ages little of importance was added to actual prosodic theory; in poetic practice, however, crucial developments were to have important ramifications for later theorists. From about the second half of the 6th century to the end of the 8th century, Latin verse was written that no longer observed the rules of quantity but was clearly structured on accentual and syllabic bases. This change was aided by the invention of the musical sequence; it became necessary to fit a musical phrase to a fixed number of syllables, and the older, highly complex system of quantitative prosody could not be adapted to simple melodies that must be sung in sequential patterns. In the musical sequence lies the origin of the modem lyric form.

The musical sequence

The 9th-century hymn "Ave maris stella" is a striking instance of the change from quantitative to accentual-syllabic prosody; each line contains three trochaic feet determined not by length of syllable but by syllabic intensity or stress:

Ave maris stella
Dei mater alma
atque semper virgo,
felix caeli porta.

Sumens illud Ave
Gabrielis ore,
funda nos in pace,
mutans nomen Evae

The rules of quantity have been disregarded or forgotten; rhyme and stanza and a strongly felt stress rhythm have taken their place. In the subsequent emergence of the European vernacular literatures, poetic forms follow the example of the later Latin hymns. The earliest art lyrics, those of the Provençal troubadours of the 12th and 13th centuries, show the most intricate and ingenious stanzaic forms. Similarly, the Goliardic songs of the Carmina Burana (13th century) reveal a rich variety of prosodic techniques; this "Spring-song" embodies varying lines of trochees and iambs and an ababcdccd rhyme scheme:

Ver redit optatum
  Cum gaudio,
Flore decoratum
  Purpureo;
Aves edunt cantus
  Quam dulciter!
Revirescit nemus,
Cantus est amoenus
  Totaliter.

Renaissance. Renaissance prosodic theory had to face the fact of an accomplished poetry in the vernacular that was not written in metres determined by "rules" handed down from the practice of Homer and Virgil. Nevertheless, the classicizing theorists of the 16th century made a determined attempt to explain existing poetry by the rules of short and long and to draft "laws" by which modem verse might move in Classical metres. Roger Ascham, in *The* Scholemaster (1570), attacked "the Gothic . . . barbarous and rude Ryming" of the early Tudor poets. He admitted that Henry Howard, earl of Surrey, did passably well as a poet but complained that Surrey did not understand "perfite and trewe versifying"; that is, Surrey did not compose his English verses according to the principles of Latin and Greek quantitative prosody.

Rules of "trewe versifying"

Ascham instigated a lengthy argument, continued by succeeding theorists and poets, on the nature of English prosody. Sir Philip Sidney, Gabriel Harvey, Edmund Spenser, and Thomas Campion all (to use Saintsbury's phrase) committed whoredom with the enchantress of quantitative metric. While this hanky-panky had no adverse effect on poetry itself (English poets went on writing verses in syllable-stress, the prosody most suitable to the language), it produced misbegotten twins of confusion and discord, whose heirs, however named, are still apparent today. Thus, those who still talk about "long and short" (instead of stressed and unstressed), those who perpetuate a punitive prosodic legalism, and those who regard prosody as an account of what poets should have done and did not, trace their ancestry back to Elizabethan dalliance and illicit classicizing.

Although Renaissance prosodic theory produced scarcely anything of value to either literary criticism or poetic technique—indeed, it did not even develop a rational scheme for scanning existing poetry—it raised a number of important questions. What were the structural principles animating the metres of English verse? What were the aesthetic nature of prosody and the functions of metre? What were the connections between poetry and music? Was poetry an art of imitation (as Aristotle and all of the Neoclassical theorists had maintained), and was its sister art painting; or was poetry (as Romantic theory maintained) an art of expression, and prosody the element that produced (in Coleridge's words) the sense of musical delight originating (in T.S. Eliot's words) in the auditory imagination?

Pope's doctrine of imitation

The 18th century. Early in the 18th century, Pope affirmed, in his ***Essay on Criticism*** (1711), the classic doctrine of imitation. Prosody was to be more nearly onomatopoetic; the movement of sound and metre should represent the actions they carry:

> 'Tis not enough no harshness gives offence,
> The sound must seem an Echo to the sense:
> Soft is the strain when Zephyr gently blows,
> And the smooth stream in smoother numbers flows;
> But when loud surges lash the sounding shoar,
> The hoarse, rough verse should like the torrent roar.
> When Ajax strives some rock's vast weight to throw,
> The line too labours, and the words move slow;
> Not so, when swift Camilla scours the plain,
> Flies o'er th' unbending corn, and skims along the main.

In 18th-century theory the doctrine of imitation was joined to numerous strictures on "smoothness," or metrical regularity. Theorists advocated a rigid regularity; minor poets composed in a strictly regular syllable-stress verse devoid of expressive variations. This regularity itself expressed the rationalism of the period. The prevailing dogmas on regularity made it impossible for Samuel Johnson to hear the beauties of Milton's versification; he characterized the metrically subtle lines of "Lycidas" as "harsh" and without concern for "numbers." Certain crosscurrents of metrical opinion in the 18th century, however, moved toward new theoretical stances. Joshua Steele's ***Prosodia Rationalis*** (1779) is an early attempt to scan English verse by means of musical notation. (A later attempt was made by the American poet Sidney Lanier in his ***Science of English Verse,*** 1880.) Steele's method is highly personal, depending on an idiosyncratic assigning of such musical qualities as pitch and duration to syllabic values; but he recognized that a prosodic theory must take into account not merely metre but "all properties or accidents belonging to language." His work foreshadows the current concerns of the structural linguists who attempt an analysis of the entire range of acoustic elements contributing to prosodic effect. Steele is also the first "timer" among metrists; that is, he bases his scansions on musical pulse and claims that English verse moves in either common or triple time. Modern critics of musical scanners have pointed out that musical scansion constitutes a performance, not an analysis of the metre, that it allows arbitrary readings, and that it levels out distinctions between poets and schools of poetry.

The 19th century. With the Romantic movement and its revolutionary shift in literary sensibility, prosodic theory became deeply influenced by early 19th-century speculation on the nature of imagination, on poetry as expression—"the spontaneous overflow of powerful feelings," in Wordsworth's famous phrase—and on the concept of the poem as organic form. The discussion between Wordsworth and Coleridge on the nature and function of metre illuminates the crucial transition from Neoclassical to modern theories. Wordsworth (in his "Preface" to the ***Lyrical Ballads,*** 1800) followed 18th-century theory and saw metre as "superadded" to poetry; its function is more nearly ornamental, a grace of style and not an essential quality. Coleridge saw metre as being organic; it functions together with all of the other parts of a poem and is not merely an echo to the sense or an artifice of style. Coleridge also examined the psychologic effects of metre, the way it sets up patterns of expectation that are either fulfilled or disappointed:

The poem as organic form

> As far as metre acts in and for itself, it tends to increase the vivacity and susceptibility both of the general feelings and of the attention. This effect it produces by the continued excitement of surprize, and by the quick reciprocations of curiosity still gratified and still re-excited, which are too slight indeed to be at any one moment objects of distinct consciousness, yet become considerable in their aggregate influence. As a medicated atmosphere, or as wine during animated conversation; they act powerfully, though themselves unnoticed. Where, therefore, correspondent food and appropriate matter are not provided for the attention and feelings thus roused, there must needs be a disappointment felt; like that of leaping in the dark from the last step of a staircase, when we had prepared our muscles for a leap of three or four.
>
> ***Biographia Literaria, XVIII (1817)***

Romantic literary theory, although vastly influential in poetic practice, had little to say about actual metrical structure. Coleridge described the subtle relationships between metre and meaning and the effects of metre on the reader's unconscious mind; he devoted little attention to metrical analysis. Two developments in 19th-century poetic techniques, however, had greater impact than any prosodic theory formulated during the period. Walt Whitman's nonmetrical prosody and Gerard Manley Hopkins' far-ranging metrical experiments mounted an assault on the traditional syllable-stress metric. Both Whitman and Hopkins were at first bitterly denounced, but, as is often the case, the heresies of a previous age become the orthodoxies of the next. Hopkins' "sprung rhythm"—a rhythm imitating natural speech, using mixed types of feet and counterpointed verse-emerged as viable techniques in the poetry of Dylan Thomas and W.H. Auden. It is virtually impossible to assess Whitman's influence on the various prosodies of modem poetry. Such American poets as Hart Crane, William Carlos Williams, and Theodore Roethke all have used Whitman's long line, extended rhythms, and "shaped" strophes.

The 20th century. Since 1900 the study of prosody has emerged as an important and respectable part of literary study. George Saintsbury published his great ***History of English Prosody*** during the years 1906–10. Sometime later, a number of linguists and aestheticians turned their attention to prosodic structure and the nature of poetic rhythm. Graphic prosody (the traditional syllable and foot scansion of syllable-stress metre) was placed on a securer theoretical footing. A number of prosodists, taking their lead from the work of Joshua Steele and Sidney Lanier, have recently attempted to use musical notation to scan English verse. For the convenience of synoptic discussion, modern prosodic theorists may be divided into four groups: the linguists who examine verse rhythm as a function of phonetic structures; the aestheticians who examine the psychologic effects, the formal properties, and the phenomenology of rhythm; the musical scanners, or "timers," who try to adapt the procedures of musical notation to metrical analysis; and the traditionalists who rely on the graphic description of syllable and stress to uncover metrical paradigms. It is necessary to point out that only the traditionalists concern themselves specifically with metrical form; aestheticians, linguists, and timers all examine prosody in its larger dimensions.

Linguists, aestheticians, timers, and traditionalists

Modern structural linguistics has placed the study of language on a scientific basis. Linguists have measured the varied intensities of syllabic stress and pitch and the durations of junctures or the pauses between syllables. These techniques of objective measurement have been applied to prosodic study. The Danish philologist Otto Jespersen's early essay "Notes on Metre" (1900) made a number of significant discoveries. He established the principles of English metre on a demonstrably accurate structural basis; he recognized metre as a gestalt phenomenon (*i.e.*, with emphasis on the configurational whole); he saw metrics as descriptive science rather than proscriptive regulation. Jespersen's essay was written before the burgeoning interest in linguistics; since World War II numerous attempts have been made to formulate a descriptive science of metrics.

It has been noted that Coleridge defined metrical form as a pattern of expectation, fulfillment, and surprise. Taking his cue from Coleridge, the British aesthetician I.A. Richards in *Principles of Literary Criticism* (1924) developed a closely reasoned theory of the mind's response to rhythm and metre. His theory is organic and contextual; the sound effects of prosody have little psychologic effect by themselves. It is prosody in conjunction with "its contemporaneous other effects^x—chiefly meaning or propositional sense—that produces its characteristic impact on our neural structures. Richards insists that everything that happens in a poem depends on the organic environment; in his *Practical Criticism* (1929) he constructed a celebrated "metrical dummy" to "support [an] argument against anyone who affirms that the mere sound of verse has *independently* any considerable aesthetic virtue." For Richards the most important function of metre is to provide aesthetic framing and control; metre makes possible, by its stimulation and release of tensions, "the most difficult and delicate utterances."

Rhythmic structure as a symbolic form

Other critics, following the Neo-Kantian theories of the philosophers Ernst Cassirer and Susanne Langer, have suggested that rhythmic structure is a species of symbolic form. Harvey Gross in *Sound and Form in Modern Poetry* (1964) saw rhythmic structure as a symbolic form, signifying ways of experiencing organic processes and the phenomena of nature. The function of prosody, in his view, is to image life in a rich and complex way. Gross's theory is also expressive; prosody articulates the movement of feeling in a poem. The unproved assumption behind Gross's expressive and symbolic theory is that rhythm is in some way iconic to human feeling: that a particular rhythm or metre symbolizes, as a map locates the features of an actual terrain, a particular kind of feeling.

The most sophisticated argument for musical scansion is given by Northrop Frye in his influential *Anatomy of Criticism* (1957). He differentiates between verse that shows unmistakable musical quality and verse written according to the imitative doctrines current in the Renaissance and Neoclassic periods. All of the poetry written in the older strong-stress metric, or poetry showing its basic structure, i3 musical poetry, and its structure resembles the music contemporary with it.

The most convincing case for traditional "graphic prosody" has been made by the American critics W.K. Wimsatt and Monroe C. Beardsley. Their essay "The Concept of Meter" (1965) argues that both the linguists and musical scanners do not analyze the abstract metrical pattern of poems but only interpret an individual performance of the poem. Poetic metre is not generated by any combination of stresses and pauses capable of precise scientific measurement; rather, metre is generated by an abstract pattern of syllables standing in positions of relative stress to each other. In a line of iambic pentameter

Preserved in Milton's or in Shakespeare's name

the "or" of the third foot is only slightly stronger than the preceding syllable "-ton's," but this very slight difference makes the line recognizable as iambic metre. Wimsatt and Beardsley underline the paradigmatic nature of metre; as an element in poetic structure, it is capable of exact abstraction.

Non-Western theories of prosody. The metres of the verse of ancient India were constructed on a quantitative basis. A system of long and short syllables, as in Greek, determined the variety of complicated metrical forms that are found in poetry of post-Vedic times—that is, after the 5th century BC.

Chinese prosody is based on the intricate tonal system of the language. In the T'ang dynasty (AD 618–907) the metrical system for classical verse was fixed. The various tones of the language were subsumed under two large groups, even tones and oblique tones. Patterned arrangements of tones and the use of pauses, or caesuras, along with rhyme determine the Chinese prosodic forms.

Japanese prosody

Japanese poetry is without rhyme or marked metrical structure; it is purely syllabic. The two main forms of syllabic verses are the tanka and the haiku. Tanka is written in a stanza of 31 syllables divided into alternating lines of five and seven syllables. Haiku is an extremely concentrated form of only 17 syllables. Longer poems of 40 to 50 lines are also written; however, alternate lines must contain either five or seven syllables. The haiku form has been adapted to English verse and has become in recent years a popular form. Other experimenters in English syllabic verse show the influence of Japanese prosody. Syllabic metre in English, however, is limited in its rhythmic effects; it is incapable of expressing the range of feeling available in the traditional stress and syllable-stress metres.

Prostitution

Prostitution is described most precisely by emphasizing two essential elements: (1) the exchange of money or valuable materials in return for sexual activity and (2) the relatively indiscriminate availability of such a transaction to individuals other than spouses or friends. This description specifically limits the exchange to money or valuable materials; sexual activity to earn good will or subsequent favours is not properly construed as prostitution. Acceptance of money or gifts in exchange for sexual activity may be found among mistresses, gigolos, friends, and spouses; the economic criterion alone does not suffice. Similarly, sexual activity with strangers or with persons for whom there is no affectional feeling does not in itself constitute prostitution if the economic element is absent. Lastly, sexual activity denotes some physical contact. Sexual gratification solely from visual or auditory stimuli cannot ordinarily be included as prostitution; if it could, a substantial part of the entertainment world would be inadvertently included under the term.

Distinctions between prostitutes and other sexual partners

It is most expedient to adopt an operational definition: a prostitute is a person who for immediate payment in money or valuables will engage in sexual activity with any other person, known or unknown, who meets minimal requirements as to gender, age, cleanliness, sobriety, ethnic group, and health.

Even this definition does not wholly suffice, for the concept of prostitution is based on culturally determined values that differ in various societies in the world. Such a definition represents only one end of a continuum ranging from the socially accepted arrangement of marriage, wherein one male is morally and legally entitled to sexual gratification in exchange for support, to the other extreme where the arrangement is of very brief duration and involves numerous males. Borderline cases are not uncommon. A female who makes herself sexually available only to suitors who bestow gifts is a case in point: how many suitors in what span of time suffice to change her status from that of girl friend to mistress to prostitute? The opinion varies according to the attitudes and values of the culture or subculture in which the individuals live. In modern Western society the fact that a sexual relationship frequently involves an important economic element is often not faced up to: in many cases a female would not continue with a male who did not periodically give her gifts of at least some monetary value, which are most often understood as symbolic of affection or esteem rather than as payment.

CROSS-CULTURE COMPARISONS

Cross-species comparisons. Some primates use sexual behaviour for nonsexual purposes: female chimpanzees and baboons will sometimes present themselves sexually to a male in order to avoid attack or to distract the male while the female purloins his food. It is a small step from such primate behaviour to accepting coitus in exchange for food. Consequently it seems likely that the exchanging of food for coitus began in the transitional period between man and ape; and that with the subsequent development of more elaborate rules of social behaviour, the sexual restrictions of marriage, and the concept of parenthood, prostitution was eventually defined in some form and set apart as an entity to be accepted or condemned.

Historical comparisons. Prostitution has not, insofar as is known, been a cultural universal. In sexually permissive societies it is often rare because it is unnecessary, whereas in other societies it has been largely suppressed. Complete suppression seems virtually impossible in large urban centres where anonymity is easily achieved and where many persons are transients. But in a small community where secrecy is difficult and where life depends on communal cooperation, social sanctions—chiefly in the forms of ridicule, economic retribution, pressure from relatives, and ostracism—are extremely effective. In such small groups prostitution can be and has been prevented. Human societies are so labile and diverse that virtually every form of sexual behaviour, even those that are generally assumed to be socially disruptive, has somewhere at some time been regarded as either normal or, under special circumstances, permissible. This is true of prostitution. In addition to the societies in which it is absent, there are many (possibly the majority) in which it is tolerated, accepted, or encouraged. Toleration with some degree of stigma seems a common societal posture; in such societies prostitution is often the resort of disadvantaged females: slaves, captives, divorcees, widows, outcasts, and the unmarriageable. In brief it is, in part, the solution to the economic problem faced by females without husbands.

Motivations for prostitution

Acceptance or encouragement of prostitution under special conditions seems chiefly a matter of economics or religion. In a number of societies girls earn their dowries through prostitution, chiefly away from home, and return enriched and eminently marriageable. This custom occurred in some, but not many, preliterate groups in the New World, among certain ancient Mediterranean cultures such as the Lydians and Cyprians, and, within modern times, among the *ouled-naïl* of Algeria. Sometimes, in societies that ordinarily denigrate prostitution and even make some effort to preserve female virginity, it is encouraged when the economic reward is sufficiently great. Thus Marquesan parents may encourage daughters to barter coitus for valuable goods brought by sailors.

Religions have sometimes incorporated prostitution as a transitory rite to be done once or, more commonly, as a continuing religious obligation of a particular class of priestesses. An example of the former is the "Myletta" rite of ancient Babylonia, wherein every female was required to sit in the temple of the goddess Ishtar and accept coitus from the first male who threw a silver coin in her lap. Similar rites involving other goddesses are known to have existed elsewhere in the Middle East. Obligatory prostitution by certain priestesses was also a custom in this area but rare elsewhere, although examples are known in India and western Africa.

In societies of sufficient technological achievement and urbanization to warrant the label "civilizations," there has usually been an attempt to make secular prostitutes identifiable by requiring them to dress in some distinctive manner or live in a restricted area or both. Efforts of this kind were made in ancient Israel, Greece, and Rome and continued through medieval times into the 20th century. In other areas distinctive garb and locale were typical of prostitutes, but it seems that this was generally a voluntary pattern of behaviour to facilitate the clients' search rather than a regulation imposed by society. It should be noted, however, that informal social pressures have always served the same purpose as codified laws and ordinances; even in modern times prostitutes tolerated in one section of a city find it difficult to establish residence in a "decent" neighbourhood.

Early attempts at government control

Attempts to confine a group as inherently mobile as prostitutes have met with only temporary success. Prostitution always tends to fan out beyond the demarcated borders. The Oriental civilizations were no more successful than those of the West. During the T'ang dynasty in China, prostitutes (as well as merchants) were required to operate in specified areas; but in the following Sung Dynasty (AD 960–1126), cafes employing prostitutes infiltrated other districts, and combination entertainment places and brothels known as *wa-tzu* proliferated; there were over a score in the city of Hangchow alone. It should not surprise readers of modern Western newspapers to learn that prostitutes have been discovered operating from residences in upper middle class neighbourhoods.

Nevertheless, sufficient identification and localization were often obtained to make prostitutes liable to the inevitable by-products of civilization, licensing and taxation, which were imposed as early as Roman times. The degree of governmental control of prostitution has varied from nation to nation. Localization of prostitution also rendered it more susceptible to exploitation, often by criminal groups.

Historical data as to classes of prostitutes are scanty, but some hierarchy seems inescapable except in small societies. Aside from religious prostitution, prostitutes automatically graduate into classes according to their age, beauty, intelligence, and health; and society treats them accordingly. The independent courtesans who congregated around men of political power—such as the hetaerae of ancient Greece; Theodora, who subsequently married the Byzantine emperor Justinian; and certain of the Japanese geisha—were accorded considerable respect. Females of lesser wit or beauty who catered to the general public were generally denigrated and ill-treated.

The Industrial Revolution brought with it markedly increased urbanization and economic exploitation of large numbers of persons—both factors conducive to prostitution. At the same time the spread of humanist ideas, concern over public health, and changes in the status of women caused an increasing concern over prostitution, which in Western civilization was identified as a social evil and a problem. Colonization of other parts of the world spread that attitude widely.

Varieties of social control. All human societies exercise varying degrees of control over the sexual behaviour of their members, and in the more urban and technologically advanced cultures prostitution has been subjected to particular control because it embodies two major societal interests: sex and money. Before the 19th century the emphasis was upon control or, at least, the localization and identification of the prostitute. The motivation seems to have been partly fiscal (taxes, license fees, graft) and partly moral (to recognize and isolate the sinful). Such isolation served other useful ends; for example, one's favourite prostitute would be unlikely to be admitted to the social groups containing one's wife, fiancee, or employer. Life could be rigorously compartmentalized and the double standard of sexual morality maintained.

Effects of 19th-century social changes

In the 19th century, at least in Western nations, the emphasis tended to shift from control to attempted eradication. The previous laws and municipal ordinances concerned with regulation were superseded by statutes either prohibiting prostitution outright or so restricting its practice as to drive it underground. This change seems to have come about through the fusion of several social developments: the emancipation of women, the growth of humanitarian movements involved in social action, and the optimistic rationale that social problems could be cured by suitably worded laws.

The attempts at public control have, of course, varied in form and severity from nation to nation and so have the responses to these attempted controls. One natural problem is that in all countries the problem of enforcing legislation so closely related to variable moral codes of behaviour is fraught with difficulties; as soon as the law enters the sphere of morals, both its interpretation and its execution may be called in question as unjust or indeed immoral, at least by some members of the community. In Great Britain, for example, the Contagious Diseases Acts of 1864, 1866, and 1869, which introduced a measure of state regulation and inspection of prostitutes, had to be suspended in 1883 and repealed in 1886 as a result of the campaign initiated against them in 1869 by Josephine Elizabeth Butler, leader of the international movement to abolish state regulation (and therefore acceptance) of prostitution. There remained little that the law could do in relation to the prostitutes themselves except to see that the police maintained a certain standard of order.

In some countries, on the other hand, special "morals police" were instituted, with more power than the English "vice squad" and with the function, among others, of observing the registered prostitutes and watching for any who were unregistered; but the arbitrary power that these morals police could exercise caused considerable misgiving. Yet again, some countries, for instance Belgium, favoured the employment of women police to deal specifically with prostitutes. It may be stated, however, that the laws controlling prostitution and kindred offenses in the different countries of the world are very similar, once the fundamental distinction has been made between those of countries in which houses of prostitution have been abolished by law and those of countries that permit brothels and require prostitutes to be registered. (Some countries, of course, cannot be classified in this way.)

In Great Britain, legislation—apart from laws dealing with soliciting and offenses against decency in public places—is directed not at the prostitute or her client but against those third parties—brothel-keepers, procurers, pimps—who find her commerce profitable and easy to exploit. Thus while prostitution itself still is not a penal offense, a series of enactments were developed during the 19th century to prevent procuration, to close brothels (defined as premises used by at least two women for purposes of prostitution), to penalize landlords who rented their buildings for such purposes, and to prohibit a man's living on a prostitute's earnings. The Street Offenses Act of 1959, following recommendations of the Wolfenden Report (the ***Report of the Committee on Homosexual Offensesand Prostitution),*** for the first time prohibited all street solicitation and loitering by prostitutes, with increasing fines for repeated offenses. The act also raised the fines for permitting solicitation in refreshment houses and increased maximum penalties for procuring and for living on the earnings of prostitution.

Problems entailed in outlawing brothels and street-walking

The difficulties that attend the abolition of houses of prostitution in a country where they have been long established are illustrated by the course of events in France. In 1946 state registration was ended and the *maisons* de *tolérance* were closed; then a subsequent law, in the same year, established a card-index system for all prostitutes and regulated their registration for purposes of hygiene (*i.e.*, for contact tracing and the treatment of venereal disease); and a furtherenactment (1948) seemed to make prostitutes subject to examination even before their occupation was proved, the effect being practically a return to the regime of state registration. The law of 1946 had indeed resulted in the closing of the brothels in France, but little was done for the rehabilitation of their inmates, and it soon appeared that the latter were pursuing their old trade under worse conditions than before. Marthe Richard, a national heroine of World Wars I and II, who had been among the first to urge the closing of brothels in Paris and indeed was held to be primarily responsible for the enactment of the law, showed that she had changed her mind about the rightness of the measure in her book ***L'Appel des sexes*** (1951). To make a compromise between the abolitionists and those who wanted to repeal the law of 1946, it was proposed that brothels should be allowed in the neighbourhood of army camps at least.

In the United States, houses of prostitution are illegal in most states, as is procuring, and the majority of the states penalize soliciting and living on the earnings of prostitution. The federal Mann Act (the White-Slave Traffic Act, 1910) prohibits the transporting of a woman across state lines for immoral purposes; and interstate travel or transportation in aid of illegal business activities, including prostitution, was banned by anti-racketeering laws passed in 1961.

The effect of all these laws, however, has been in part to drive prostitution underground, where it can become more disruptive to society than when it is allowed to exist, to some extent, openly. Such a development is to be expected on the closing of brothels when at the same time no fundamental alteration of the social pattern is effected: the removal of the controls exercised by the brothel system clears the way for a "vice racket" in which both prostitute and client are exploited by third parties. In the United States strictly criminal organizations largely took control of prostitution, managing it on a national or regional basis.

B-girls and call girls

With the closing down or repression of the more flamboyant operations of streetwalkers and houses of prostitution, other categories emerged. One was the bar girl, or B-girl, employed to entertain men customers of a bar, tavern, or nightclub and induce them to spend money, often by offering to perform lewd or indecent acts or to engage in prostitution. The B-girl is in the tradition of the dance hall "hostess" of, for example, the cow towns and mining towns of the American West. And a new upper class among prostitutes emerged—the call girl, who may be quite selective in her choice of customers, at least limiting her favours to men who are willing and able to pay high fees. In addition to the call-girl system, massage parlours and other disguisesalso have been adopted. Overall, prostitution was decreased, though not drastically, through the loss of the efficient production-line activity of the brothel. A more serious blow to prostitution appears to be the growing increase in the number of females willing to engage in sexual intercourse without financial recompznse.

In the U.S.S.R., the bold claim was made in the 1930s and 1940s that no prostitution and no brothels or trafficking in the streets existed any longer. The legislation and administrative orders promulgated indicated that the problem had been treated very seriously. Before the Revolution, prostitution existed on a very large scale in Russia. The desire of the revolutionaries to abolish it would seem perhaps to emanate from the urge toward female emancipation and equality of the sexes. With regard to prostitution, the Soviet authorities repeatedly emphasized that the war against it should on no account degenerate into a war against prostitutes. It was maintained that the disappearance of prostitution in the U.S.S.R. was due, in effect, to the changing of the cultural patterns in Russian and Soviet society. The exact meaning of this asseveration is difficult to assess: the U.S.S.R. is a large country comprising a number of republics, each with its separate codes of law and in a varying stage of development; and in some of these republics tribal customs, in particular those connected with child marriage and with the bride price, would seem to have survived for a long time. Occasional reports of clandestine prostitution continued to appear.

Prostitution has been widespread and widely accepted in Asia, with casual sexual relations between both married and unmarried men and prostitutes regarded as a matter of course. Until recent times it was almost the only occupation open to dependent and unattached women. That prostitution was long accepted as a way of life throughout the Middle East and the Far East was held to be related to the inferior position of females. The surge of rising aspirations in the nations of Asia after World War II encompassed strong movements to improve the status of women. These found support in the United Nations in the Universal Declaration of Human Rights, in the Economic and Social Council's efforts to combat and reduce prostitution as incompatible with the dignity and worth of a human being, and in its Convention for the Suppression of the Traffic in Persons and of the Exploitation of the Prostitution of Others.

Prostitution in East Asia

In connection with its attempts to abolish prostitution as a practice imposing indignities on human beings, the UN made a number of surveys in member countries. Surveys of countries in Asia and the Far East covered Burma, Ceylon (now Sri Lanka), India, Indonesia, Japan, the Philippines, and Thailand. With the exception of Thailand, all of these nations had adopted laws before 1960 either to abolish or to prohibit prostitution. In Thailand prostitution was regulated and all prostitutes and brothels were registered. No new prostitutes were permitted a license after 1956, and no new brothels were allowed to open after 1948; the government reported it expected to abolish prostitution eventually.

Despite laws aiming to prohibit or suppress prostitution, it was found still to exist in the other countries mentioned. In Burma, Ceylon, Indonesia, and the Philippines, it was basically an urban phenomenon. In India, on the other hand, the majority of prostitutes (66.5 percent) were from rural areas. In some parts of India prostitution was still associated with girls dedicated to temples, and in some communities certain girls were dedicated to prostitution, although both forms of religious prostitution were forbidden by law. In northern India many dancing girls still became prostitutes.

In Japan licensed prostitution was abolished between 1946 and 1948. Public brothels were closed and offices were set up throughout the country to rehabilitate former prostitutes and to protect girls from becoming engaged in prostitution. Many geisha girls meanwhile have been prostitutes, although others do not participate in this profession.

In the Philippines prostitution was reported in the larger cities, particularly in Manila, where the military reservations and air bases afforded many customers.

In Indonesia prostitution was reported to be common in the villages. This was attributed largely to the fact that many men, who were permitted four wives, divorced one or more wives with little concern for what happened to them; such women often resorted to prostitution. In Cambodia brothels were permitted but were subject both to licensing and to special regulations. In Ceylon prostitution, though it was technically an offense, was not punished as such. It could be punished, however, under the Vagrants Ordinance. Private institutions, including the Salvation Army, tried to rehabilitate prostitutes and help them in securing respectable employment.

Additional surveys in Malaysia, Hong Kong, and Singapore found that measures to prevent prostitution were chiefly incumbent upon the police and immigration officials, who cooperated in checking the immigration of prostitutes and in the repatriation or deportation of prostitutes. Much preventive work was required because of the large number of Chinese refugees, 'and casework services were developed in governmental homes and shelters and by private organizations.

Except for a small group recruited from the upper classes, economic conditions apparently have been a major factor in prostitution in all Asian countries. Nevertheless, the influx of refugees into some areas, the traditionally rigid class restrictions on marriage and the exclusion of women from social life have all been important factors in promoting prostitution. In Japan and the Philippines especially, military installations have resulted in considerable demand for prostitutes despite restrictive legislation.

In mainland China, the Communist government, after it came into power in 1949, abolished prostitution and closed numerous brothels, converting some of the largest into youth centres. A program of re-education for prostitutes was announced, with additional re-education including assignment to hard labour for any backsliders.

(P.H.Ge./Ed.)

SOCIAL AND PSYCHOLOGICAL CHARACTERISTICS

The complexity of modern life, with accelerated cross-cultural diffusion and rapid transportation, makes a brief description of the exact character of prostitution in any given nation impossible. In an Asian country, for example, there may be villages sharing a few local prostitutes; inland towns with organized brothels staffed by indigenous females; and coastal cities with a potpourri of brothels and independent prostitutes of varying races, nationalities, residential stability, and status. All of these situations, as suggested in the survey above, are generally subject to rapid change depending upon political, economic, and social changes and the establishment or removal of military bases, factories, and other important sources of clients.

Types or forms of prostitution. Speaking generally, and with special regard for the Western nations, prostitution operates in three guises. First, there is the brothel—an establishment wherein the prostitutes generally reside, supervised usually by an older female who has acquired sufficient money and made enough social contacts to establish a brothel. One or more males may be on the premises to deal with unruly or homosexual clients. Brothels are quite varied, some catering to particular socioeconomic and ethnic groups, but they are generally confined to particular districts in a city or else relegated to its outskirts just beyond municipal authority. In some cities a given area may be almost wholly given over to prostitution, as was the case in Las Vegas, Nevada; the Calle Amistad of Havana, Cuba; and the Herbertstrasse of Hamburg, Germany. In provinces or nations where prostitution is illegal, brothels tend to be confined to locales where law enforcement is ineffective due to political corruption or to geographic factors such as an adjacent provincial or national border or an ocean. Since clients prefer novelty, prostitutes not infrequently move from one brothel to another in a different city. The brothel owner or supervisor takes a percentage of the prostitutes' earnings, a percentage that can range from 20 percent up to a nearly intolerable proportion.

Second, there is the "call girl," a prostitute who has her own residence (sometimes shared with another prostitute). In return for a percentage of her earnings she is notified by the head of the operation where to meet each client, generally the hotel room of the client and less often his home. The call girl is ordinarily expected to limit her clientele to persons obtained through the calling system and is discouraged from developing contacts on her own initiative since she might not share the revenue from these. The call girl has higher status and price than the average brothel inmate, who is known as a "house girl." Because there is often some screening of new clients, chiefly through recommendation by known persons, the call girl is protected to a considerable degree from undesirable customers and disguised police.

Third, there is the independent prostitute who shares her earnings with no one except hotel employees, taxi drivers, bartenders, her procurer, or others who direct customers to her. For security and companionship, pairs of independent prostitutes sometimes live together. The independent girl is more apt than other prostitutes to pursue this occupation sporadically and in conjunction with some other employment, almost always of low status and pay.

Variations on these three basic forms of prostitution are manifold. A brothel may pass as a massage parlour, a restaurant or bar may have an adjacent room, and escort services and modelling agencies may be disguises. To add to the complexity, there is some specialization among prostitutes in terms of techniques as, for example, those serving sadomasochists. Some prostitutes may largely or wholly avoid coitus: in certain lower class cafes and bars there are females who induce a customer to buy numerous drinks at inflated prices and when he has purchased enough will then lead him to some dimly lit, isolated booth or corner and masturbate him to orgasm. This practice seems commoner in western Europe than in the United States. **A** small number of females eschew physical contact entirely and thereby escape the definition of prostitution by simply engaging in obscene conversation in exchange for drinks (a percentage of the cost of which reverts to them). On occasion prostitutes may be employed to give exhibitions of sexual activity before audiences. In Latin America and parts of Europe such exhibitions are frequently a standard entertainment in certain taverns and brothels; in the United States they have become much less common and are largely confined to occasional acts for men's organizations.

Entry into prostitution

The career and life of female prostitutes. Entry into a career of prostitution may once have involved parents casting out a seduced daughter or "white slavers" exerting duress upon some hapless girl, but this is no longer true in the second half of the 20th century. Entry has become voluntary and often involves little trauma aside from transient pangs of shame or guilt. Some mentor is almost invariably involved—another girl with experience as a prostitute or a male friend who points out the financial advantages and offers to help the neophyte on her new career if she chooses it. A moment of clearly defined decision is generally lacking and the entry is a transitional phase buffered by rationalizations. A typical example would be that of a girl who is accustomed to presents from suitors and who by degrees comes to accept gifts in the form of cash and whose suitors may become more numerous as they become less known to her. Or another common mode of entry is the financial emergency that can be remedied by "being nice" to someone a friend happens to know, the price being disguised as a gift or loan. Subsequent fiscal emergencies arise and ultimately lead to an acknowledged career of prostitution. In any case, the motivation is financial. Nymphomania giving rise to prostitution is extremely rare.

Entry into prostitution generally involves entry into the subculture, and the neophyte must go through a sometimes stressful period of learning a new set of interpersonal relationships, a new system of patterned behaviour, and a new argot. More importantly, she must develop a new self-image. This change necessarily involves cutting most, if not all, ties with her former life, and the prostitute becomes more exclusively involved with and dependent upon the subculture of prostitution. The term "subculture" is appropriate because the individuals think of themselves as a group apart from the rest of society, establish their own mores, have their own distinctive linguistic terms, and share similar ideas and values.

Although one can find embittered individuals who dislike their work and despise their clients, the majority of prostitutes maintain an attitude similar to that of anyone providing services to a diverse clientele. Some clients prove troublesome and are consequently resented; others may be pleasant or unexpectedly generous and hence engender some regard or even affection; but most are regarded with objectivity and neutrality.

Psychological detachment and compartmentalization

The prostitute often simulates passion and sometimes affection for business reasons, yet in reality she is expected to preserve a rigorous attitude of psychological noninvolvement, precisely such as is required of other professionals who deal with human beings. Although the client should be sufficiently pleased to induce him to return, he should be processed efficiently, quickly, and dispassionately. Experiencing sexual arousal or orgasm is regarded not only as unprofessional but also as fatiguing and hence inefficient. Allowing affection to develop for a client is thought of as foolishly making oneself vulnerable to emotional hurt and possible fiscal exploitation.

Having severed her ties with her former life and preserving an emotional aloofness from her clients, the prostitute is prone to be starved for love. This deficiency is remedied by a lover who is frequently also a procurer, or pimp. The pimp is someone whom she can love and who she can imagine returns her love. He gives the sexual pleasure absent in her professional activity. More importantly, the pimp proves that she is needed—if only for mercenary reasons. Many prostitutes take pride in providing well for their "man," whose ostentatious affluence attests to their success. To love, to be loved, and to be needed are psychological necessities for most human beings, and the pimp provides these for the prostitute. In addition, he has other useful functions: he may find clients, protect her from mistreatment, pay her bail, safeguard her savings, and perhaps even join in her professional work if a client wishes homosexual activity or an exhibition. It is easy to see why the pimp is valued even if he is shared, as is often the case, with several other prostitutes, or even if he is sometimes exploitative or brutal.

The average prostitute usually is able to compartmentalize her life successfully: in her work she is seldom consciously sexually aroused and seldom or never reaches orgasm, but in her private life she is as responsive as, or perhaps somewhat more so than, the average housewife. The speculations as to prostitutes' being either sexually frigid or nymphomaniac are not supported by evidence. The compartmentalization may extend to sexual techniques and positions, some of these being employed solely in business relations. This compartmentalization serves a vital buffering protective function and permits the prostitute to keep a tolerable self-image and to engage in the emotional and social relations that are important to human well-being. The prostitute can say that her work is no measure of herself as a person, that it is a thing apart, simply an economic matter. Nevertheless, the defense mechanism cannot wholly negate reality, and the prostitute is to a considerable degree alienated from normal social relations and functions.

Hazards of pregnancy, disease, and criminality

Pregnancy and venereal disease are ordinarily thought of as inescapable occupational hazards for prostitutes. The matter of conception is enormously complicated by varying methods of contraception, the postulated antagonistic effects of one male's semen upon another's, chronic pelvic congestion, consequences of venereal disease, and other factors. It appears, however, that although prostitutes' high coital frequencies do not result in a high incidence of pregnancy, neither does it seem that prostitutes are particularly infertile. The majority have been impregnated by male friends or husbands, but few by clients. On the other hand, venereal disease is an indisputable occupational hazard, and the incidence of having had such a disease at some time or another is far higher among prostitutes than among the general population.

It has been thought that, through overexposure to males and through occasional but repeated unpleasant experiences, the prostitute would turn to other females for affection and sexual gratification. This speculation seems largely unfounded; although prostitutes may be more permissive toward any sexual behaviour, and although they may have had some homosexual experience as a part of their work, the incidence of extensive homosexuality does not appear to be substantially greater among prostitutes.

Because the prostitute is somewhat isolated from normal society, confined to her own subculture, and her professional life labelled as criminal in most states and nations, it is not surprising that criminality or, more commonly, affiliation with criminals often develops. Any lucrative illegal business invites the intrusion of organized crime.

This situation is not wholly a case of prostitutes' being victimized; it is to a great extent a mutually beneficial arrangement because the criminal organization can provide a greater protection from law and social action than could any individual or small group. In addition, more efficient management is often provided. The price for such benefits is, of course, loss of autonomy and having to adhere to financial agreements that are probably rather onerous and that draw severe punishment if broken.

The prostitute herself is not ordinarily criminal in a narrow sense of the word. Any business operator must maintain a good reputation in order to prosper, and hence only the most desperate or disreputable prostitutes rob or blackmail. The independent, lower class prostitute catering to transients is more likely to rob or defraud. The prostitute, however, is rather prone to be indirectly involved as an accomplice or accessory to a crime simply because her lover, pimp, or management organization is engaged in criminal activity. The police are well aware of this and sometimes attempt to coerce prostitutes into serving as informers.

Exiting from prostitution is, unlike entry, not always voluntary. Loss of physical beauty ultimately forces out of "the life" all those except a few who become administrators or supervisors. The more foresighted prostitutes exit before being compelled to do so, some via marriage (generally to someone who is fully aware of their profession), or the already married may simply become housewives precisely as a conventional woman may give up employment after some years of marriage and devote herself to the home. Others intelligent enough to have saved money may simply buy into some legitimate business. The improvident and less intelligent prostitute faces a grim future since she has neither funds nor skills to save her from eventual unemployment. Such an unfortunate generally ends on public relief or working at the most menial tasks. Actually little is known of the lives of former prostitutes because those who have adequately coped with the transition back into society are anxious to conceal their past; one tends to see the failures rather than the successes, although a few of the latter become famous.

The extent of female prostitution is difficult to measure even in those nations that require licensing, but it is no small social phenomenon in all densely populated areas. In the United States the survey data accumulated by Alfred C. Kinsey and his associates indicated that around mid-century roughly one-third of the college-educated and three-quarters of the less-educated white males eventually had had sexual intercourse with a prostitute. There is evidence, however, that in the second half of the 20th century, with the increasing permissiveness toward nonmarital sexual behaviour of women, prostitution is becoming correspondingly less important: the percentage of males having experience with prostitutes seemed to be diminishing, and the frequency of contact was markedly lower.

Male prostitution. Male prostitution has been largely disregarded in treatises on prostitution, and the public knows little of it. Heterosexual male prostitution—that is, males hired by or for females—is extremely rare. Almost any female desirous of sexual activity can, with little difficulty, find a male to oblige her, providing she does not set her standards too high. The gigolo, the male counterpart of the mistress, does not qualify as a prostitute under the definition here employed because the elements of promiscuity and immediate payment are absent.

Homosexual male prostitution, on the other hand, was common in the second half of the 20th century in large cities; and in some cities the male "hustlers" perhaps rivalled the female prostitutes in numbers. Most homosexual male prostitution was of the independent type: "callboy" systems existed but were not commonplace, and male brothels were extremely rare. Some basically heterosexual brothels, however, kept a male around for the convenience of a homosexually inclined client.

In Western civilizations male homosexual prostitution differs radically in many respects from female heterosexual prostitution. There is no pimp, large-scale organization is absent, the price is lower, and the sexual relation with the client is quite different. In female prostitution the prostitute rarely or never reaches orgasm and the client almost invariably does; in male homosexual prostitution the prostitute almost invariably reaches orgasm, but the client frequently does not. This paradox is the result of a curious mythology, which the male hustler and his client feel compelled to enact. The homosexual male ideally seeks a masculine-appearing heterosexual male, and the prostitute attempts to fit this image. Consequently the prostitute can do little or nothing for or to the homosexual client lest he betray a homosexual inclination of his own and ruin the illusion. So the prostitute plays an essentially passive role and has orgasm (this is regarded as a necessary part of the bargain), while the client must ordinarily content himself with psychological arousal, self-masturbation, and body contact. This arrangement is reinforced by the male prostitute's protective image of himself as a "real" and heterosexual man who tolerates homosexual activity solely for financial reasons. In actuality, of course, the hustler has a substantial homosexual component that is necessary or he could not achieve erection and orgasm; and many of them are predominately homosexual in orientation, though loath to admit it. One might regard this as the reverse of female prostitution: the female simulates a passion she does not feel, whereas the male prostitute conceals a passion he does feel. There is some evidence that this curious pattern of feigned indifference is gradually breaking down and that more male prostitutes are taking an active role in the sexual relation while maintaining a masculine image. In societies other than those of Western civilizations, the homosexual prostitute does not disguise his interest and is often as active as, or even more active than, the client (see also SEXUAL DEVIATIONS: Homosexuality).

Differences between male and female prostitution

The socioeconomic demand. Because prostitution is basically an economic matter, it is destined to follow the "laws" of economics. It will grow or diminish according to the number of individuals who find it difficult or impossible to obtain sexual contact without paying for it. These individuals include not only those with physical or cosmetic handicaps and those few with sexual desires too bizarre to be satisfied by most partners but also numerous normal persons who experience temporary difficulty in obtaining a sexual relationship. Travellers and military personnel are good examples of the latter group. Added to these are persons who could establish sexual relationships with nonprostitutes but do not wish to make the effort or do not wish to become emotionally involved. Finally, some individuals seek prostitutes to enjoy sexual techniques that their wives or customary partners refuse them—mouth-genital contact being the prime example.

Prostitution also is reinforced by the double standard of sexual morality and by the affiliations with drinking, dancing, and entertainment. These recreational aspects have been, and in many areas of the world have continued to be, an important component of prostitution.

This almost inescapable and reasonably steady demand for prostitutes is in many societies complemented by a socio-economic treatment of females that is conducive to prostitution. If most females are taught to be financially dependent upon males and discriminated against in employment and salary, a substantial number of them either will be economically forced toward prostitution or will turn to it as an easy and more lucrative alternative. Even in a utopian society, however, there would be some individuals whose skills, personality traits, or intelligence would limit their earnings, or whose real or imagined needs would exceed the beneficence of the state, and some of these persons would prostitute.

It appears impossible to eradicate prostitution in a complex society, particularly one in which sexual gratification is made difficult by mores and law. Moreover, the trend of legalistic and humanitarian thinking has been toward the idea that what consenting adults do sexually in private should not be subject to law, and that view presumably would include prostitution.

BIBLIOGRAPHY. The two major comprehensive works are PAUL LACROIX, ***Histoire de la prostitution*** . . . (1861; Eng. trans., ***History of Prostitution Among All the Peoples of the***

World from the Most Remote Antiquity to the Present Day, 3 vol. 1926); and L. FERNANDO HENRIQUES, *Prostitution and Society:* vol. *1, Primitive, Classical and Oriental* (1962); vol. 2, *Prostitution in Europe and the New World* (1963); and vol. 3, *Modern Sexuality* (1968). Perhaps the best single volume on the subject is that of HARRY BENJAMIN and R.E. MASTERS, *Prostitution and Morality: A Definitive Report* (1964). A broad sociological survey is represented by the BRITISH SOCIAL BIOLOGY COUNCIL, *Women of the Streets: A Sociological Study of the Common Prostitute,* ed. by C.H. ROLPH (1955); while a higher status variety of prostitution is dealt with by HAROLD GREENWALD in *The Call Girl: A Social and Psychoanalytic Study* (1958). The legal aspects of prostitution are the subject of THOMAS E. JAMES, *Prostitution and the Law* (1951). Important data derived from interviews with prostitutes are presented in three journal articles: JAMES H. BRYAN, "Apprenticeships in Prostitution," *Social Problems,* 12:287–297 (1965); WARDELL B. POMEROY, "Some Aspects of Prostitution," *Journal* of *Sex Research,* 1:177–187 (1965); and PAUL H. GEBHARD, "Misconceptions About Female Prostitutes," *Medical Aspects of Human Sexuality,* 3:24–30 (1969). Lastly, the extent to which males in the United States relied upon prostitution is detailed at various points in *Sexual Behavior in the Human Male,* by ALFRED C. KINSEY *et al.* (1948).

Protein

Proteins are highly complex substances that are present in all living organisms. They are of great nutritional value, have numerous industrial uses, and are directly involved in the chemical processes necessary to maintain life. Proteins are both species-specific and organ-specific; for instance, muscle proteins differ from those of the brain and liver.

A protein molecule is very large compared to molecules of sugar or salt and consists of many amino acids joined together to form long chains, much as beads are arranged on a string. There are about 20 different amino acids that occur naturally in proteins. Proteins of similar function have similar amino acid composition and sequence. Although it is not yet possible to explain all of the functions of a protein from its amino acid sequence, established correlations between structure and function can be attributed to the properties of the amino acids of which proteins are composed.

Amino acid production and requirements by plants and animals

Plants can synthesize all of the amino acids; animals cannot, even though all of them are essential for life. Plants can grow in a medium containing inorganic nutrients that provide nitrogen, potassium, and other substances essential for growth. They utilize the carbon dioxide in the air during the process of photosynthesis to form organic compounds such as carbohydrates. Animals, however, must obtain organic nutrients from outside sources. Because the protein content of most plants is low, very large amounts of plant material are required by animals, such as ruminants (*e.g.*, cows), that eat only plant material to meet their amino acid requirements. Nonruminant animals, including man, obtain proteins principally from animals and their products—*e.g.*, meat, milk, and eggs. The seeds of legumes are increasingly being used to prepare inexpensive protein-rich food (see NUTRITION AND DIET, HUMAN).

The protein content of animal organs is usually much higher than that of the blood plasma. Muscles, for example, contain about 30 percent protein, the liver 20 to 30 percent, and red blood cells 30 percent. Higher percentages of protein are found in hair, bones, and other organs and tissues with a low water content. The quantity of free amino acids and peptides in animals is much smaller than the amount of protein. Evidently, protein molecules are produced in cells by the stepwise alignment of amino acids and are released into the body fluids only after synthesis is complete.

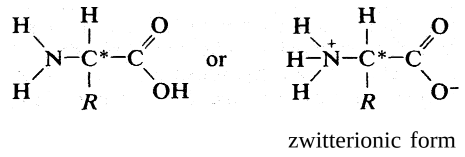
The high protein content of some organs does not mean that the importance of proteins is related to their amount in an organism or tissue; some of the most important proteins, such as enzymes and hormones, occur in extremely small amounts. The importance of proteins is related principally to their function. All enzymes identified thus far are proteins. Enzymes, which are the catalysts of all metabolic reactions, enable an organism to build up the chemical substances necessary for life—proteins, nucleic acids, carbohydrates, and lipids (fats)—to convert them into other substances, and to degrade them. Life without enzymes is not possible. There are several protein hormones. Hormones are regulatory substances formed in endocrine glands and secreted directly into the bloodstream. In all vertebrates, the respiratory protein hemoglobin acts as oxygen carrier in the blood, transporting oxygen from the lung to body organs and tissues. A large group of structural proteins maintains and protects the structure of the animal body.

This article emphasizes the basic structural and functional aspects of proteins as a class of chemical substances. For further information on specialized subjects in which proteins play a major role see BLOOD AND LYMPH; ENZYME; HORMONE; IMMUNITY; GENE.

I. General structure and properties of proteins

THE AMINO ACID COMPOSITION OF PROTEINS

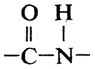
The common property of all proteins is that they consist of long chains of a-amino (alpha amino) acids. The general structure of a-amino acids is shown in Formula 1.



Formula 1: Generalized structure of all a-amino acids. C stands for a carbon atom; C* stands for the α-carbon. H is hydrogen, O is oxygen, and N is nitrogen. R is a general term for any of several different chemical structures that range from one hydrogen atom to large and complex molecular units containing many different atoms. The + and − signs represent electrical charges that exist when the molecule takes the configuration shown at the right.

The a-amino acids are so called because the a-carbon atom in the molecule (shown by an asterisk [*] in Formula 1) carries an amino group $(—NH_2)$; the a-carbon atom also carries a carboxyl group $(-COOH)$. In acidic solutions, when the pH is less than 4, the $-COO-$ groups combine with hydrogen ions (H^+) and are thus converted into the uncharged form $(-COOH)$. In alkaline solutions, at pH above 9, the ammonium groups $(-NH^+_3)$ lose a hydrogen ion and are converted into amino groups $(-NH_2)$. In the pH range between 4 and 8, the amino acids exist almost exclusively in the structure shown at the right side of Formula 1. Because in this form they carry both a positive and a negative charge, they do not migrate in an electrical field. Such structures have been designated as dipolar ions, or zwitterions (*i.e.*, hybrid ions).

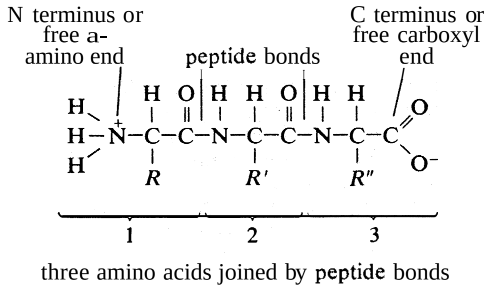
Although more than 100 amino acids occur in nature, particularly in plants, only 20 types are commonly found in most proteins (see Figure 1). In protein molecules the a-amino acids are linked to each other by peptide bonds between the amino group of one amino acid and the carboxyl group of its neighbour; the structure of the peptide bond is given in Formula 2. The condensation (joining) of three amino acids yields the tripeptide shown in Formula 3.



Formula 2: The peptide bond.

Peptide structure

It is customary to write the structure of peptides in such a way that the free a-amino group (also called the N terminus of the peptide) is at the left side and the free carboxyl group (the C terminus) at the right side. Proteins are macromolecular polypeptides—*i.e.*, very large molecules composed of many peptide-bonded amino acids. Most of the common ones contain more than 100 amino acids linked to each other in a long peptide chain. The average molecular weight (based on the weight of a hydrogen atom as 1) of each amino acid is approximately



N terminus or free a-amino end
peptide bonds
C terminus or free carboxyl end

3
three amino acids joined by peptide bonds

Formula 3: A tripeptide. *R′* and *R″* represent the possibility that the three *R* groups (side chains) could be different.

100 to 125; thus, the molecular weights of proteins are usually in the range of 10,000 to 100,000 daltons (one dalton is the weight of one hydrogen atom). The species-specificity and organ-specificity of proteins result from differences in the number and sequences of amino acids. Twenty different amino acids in a chain 100 amino acids long can be arranged in far more than 10^{100} ways (10^{100} is the number one followed by 100 zeroes).

Structures of common amino acids. The amino acids present in proteins differ from each other in the structure of their side (R) chains. The simplest amino acid is glycine, in which R is a hydrogen atom (see Figure 1). In a number of amino acids, R represents straight or branched carbon chains. One of these amino acids is alanine, in which R is the methyl group ($—CH_3$). Valine, leucine, and isoleucine, with longer R groups, complete the alkyl side-chain series. The alkyl side chains (R groups) of these amino acids are nonpolar; this means that they have no affinity for water but some affinity for each other. Although plants can form all of the alkyl amino acids, animals can synthesize only alanine and glycine; thus valine, leucine, and isoleucine must be supplied in the diet.

Two amino acids, each containing three carbon atoms, are derived from alanine; they are serine and cysteine. Serine contains an alcohol group ($—CH_2OH$) instead of the methyl group of alanine, and cysteine contains a mercapto group ($—CH_2SH$). Animals can synthesize serine but not cysteine nor cystine. Cysteine occurs in proteins predominantly in its oxidized form (oxidation in this sense meaning the removal of hydrogen atoms), called cystine. Cystine consists of two cysteine molecules linked by the disulfide bond (—S—S—) that results when a hydrogen atom is removed from the mercapto group of each of the cysteines (see Figure 1). Disulfide bonds are important in protein structure because they allow the linkage of two different parts of a protein molecule to—and thus the formation of loops in—the otherwise straight chains. Some proteins contain small amounts of cysteine with free sulfhydryl (—SH) groups.

Four amino acids, each consisting of four carbon atoms, occur in proteins; they are aspartic acid, asparagine, threonine, and methionine. Aspartic acid and asparagine, which occur in large amounts, can be synthesized by animals. Threonine and methionine cannot be synthesized and thus are essential amino acids—*i.e.*, they must be supplied in the diet. Most proteins contain only small amounts of methionine.

Most abundant amino acids

Proteins also contain an amino acid with five carbon atoms (glutamic acid) and an imino acid (proline), which is a structure with the amino group ($—NH_2$) bonded to the alkyl side chain, forming a ring. Glutamic acid and aspartic acid are dicarboxylic acids--that is, they have two carboxyl groups (—COOH). Glutamine is similar to asparagine in that both are the amides of their corresponding dicarboxylic acid forms; *i.e.*, they have an amide group ($—CONH_2$) in place of the carboxyl (—COOH) of the side chain (see Figure 1). Glutamic acid and glutamine are abundant in most proteins; in plant proteins, for example, they sometimes comprise more than one third of the amino acids present. Both glutamic acid and glutamine can be synthesized by animals. The imino acids proline and hydroxyproline occur in large amounts in collagen, the protein of the connective tissue of animals (see Table 1). Proline and hydroxyproline lack free amino ($—NH_2$) groups because the amino group is enclosed in a ring structure with the side chain; they thus cannot exist in a zwitterion form. Although the imino group ($>NH$) of these amino acids can form a peptide bond with the carboxyl group of another amino acid, the bond so formed gives rise to a kink in the otherwise straight peptide chain—that is, the imino ring structure alters the regular bond angle of normal peptide bonds.

Proteins usually are almost neutral molecules; that is, they have neither acidic nor basic properties. This means that the acidic carboxyl (—COO-) groups of aspartic and glutamic acid are about equal in number to the amino acids with basic side chains. Three such basic amino acids, each containing six carbon atoms, occur in proteins. The one with the simplest structure, lysine, is synthesized by plants but not by animals. Even some plants have a low lysine content. Arginine is found in all proteins; it occurs in particularly high amounts in the strongly basic protamines (simple proteins composed of relatively few amino acids) of fish sperm. The third basic amino acid is histidine. Both arginine and histidine can be synthesized by animals. Histidine is a weaker base than either lysine or arginine. The imidazole ring, a five-membered ring structure containing two nitrogen atoms in the side chain of histidine (see Figure 1), acts as a buffer (*i.e.*, a stabilizer of hydrogen ion concentration) by binding hydrogen ions (H^+) to the nitrogen atoms of the imidazole ring.

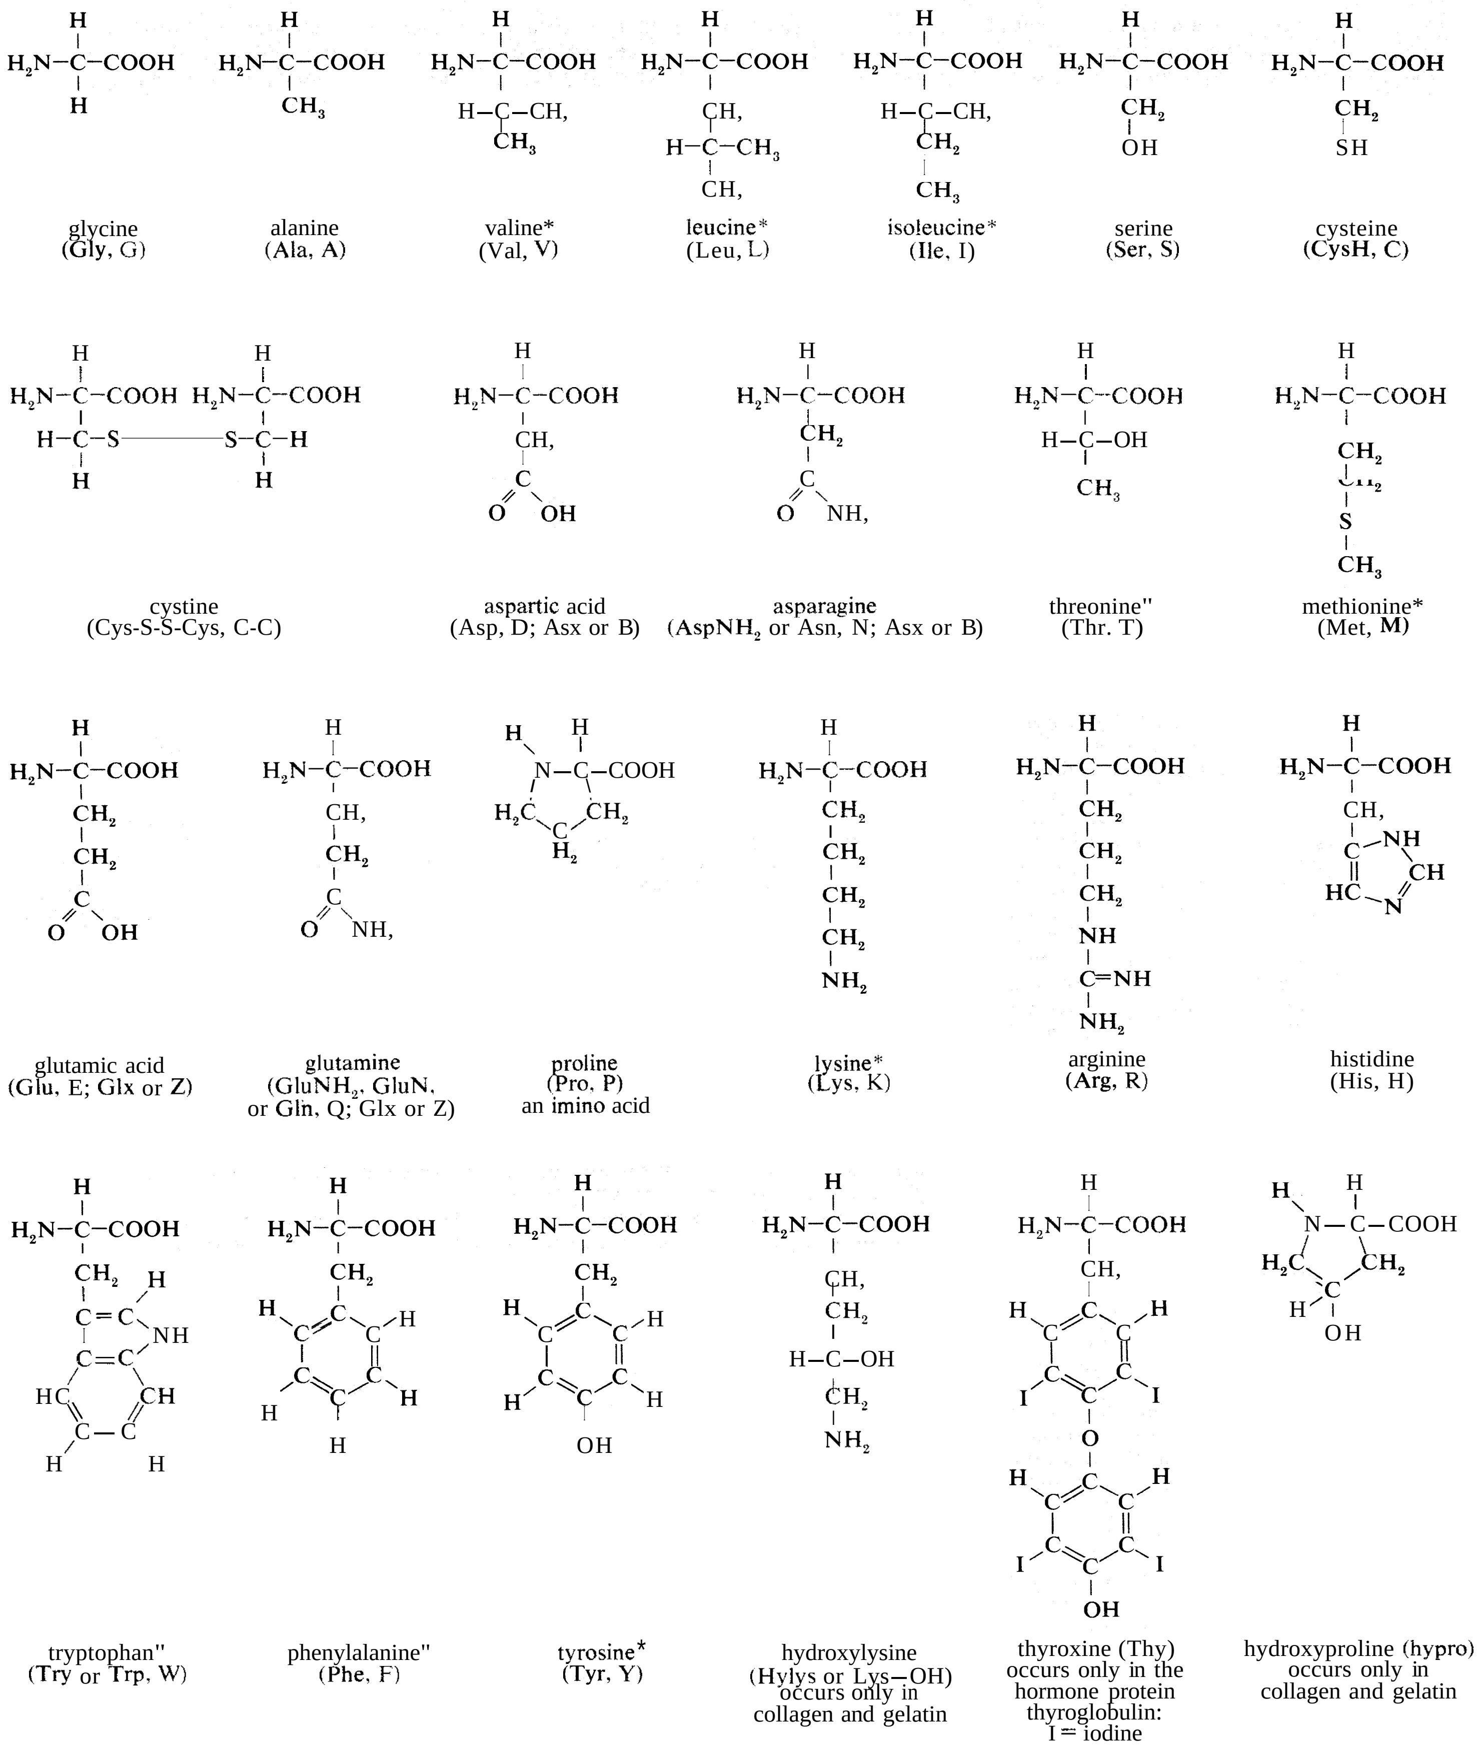
The remaining amino acids—phenylalanine, tyrosine, and tryptophan—have in common an aromatic structure; *i.e.*, a benzene ring is present (see Figure 1). Animals cannot synthesize the benzene ring; therefore these three amino acids are essential ones. Animals can convert phenylalanine to tyrosine, however. Because these three amino acids contain benzene rings, they can absorb ultraviolet light at wavelengths between 270 and 290 nanometres (nm; one nanometre $= 10^{-9}$ metre $=$ ten angstrom units). Phenylalanine absorbs very little ultraviolet light; tyrosine and tryptophan, however, absorb it strongly and are responsible for the absorption band most proteins exhibit at 280–290 nanometres. This absorption is frequently used to determine the quantity of protein present in protein samples.

Most proteins contain only the amino acids described above; however, other amino acids occur in proteins in small amounts. Thyroglobulin, the hormone of the thyroid gland, for example, contains thyroxine, which is an iodine-containing compound derived from tyrosine. The collagen found in connective tissue contains, in addition to hydroxyproline, small amounts of hydroxylysine. Other proteins contain some monomethyl- , dimethyl-, or trimethyllysine—*i.e.*, lysine derivatives containing one, two, or three methyl groups (—CH,). The amount of these unusual amino acids in proteins, however, rarely exceeds 1 or 2 percent of the total amino acids.

Physicochemical properties of the amino acids. The physicochemical properties of a protein are determined by the analogous properties of the amino acids in it.

The α-carbon atom of all amino acids, with the exception of glycine, is asymmetric; this means that four different chemical entities (atoms or groups of atoms) are attached to it. As a result, each of the amino acids, except glycine, can exist in two different spatial, or geometric, arrangements (*i.e.*, isomers), which are mirror images akin to right and left hands (see Formula 4). These isomers exhibit the property of optical rotation.

Optical rotation is the rotation of the plane of polarized light, which is composed of light waves that vibrate in one plane, or direction, only. Solutions of substances that rotate the plane of polarization are said to be optically active, and the degree of rotation is called the optical rotation of the solution. The direction in which the light is rotated is generally designed as plus, or d, for dextrorotatory (to the right), or as minus, or *l*, for levorotatory (to the left). Some amino acids are dextrorotatory; others are levorotatory. With the exception of a few small proteins (peptides) that occur in



glycine (Gly, G)

alanine (Ala, A)

valine* (Val, V)

leucine* (Leu, L)

isoleucine* (Ile, I)

serine (Ser, S)

cysteine (CysH, C)

cystine (Cys-S-S-Cys, C-C)

aspartic acid (Asp, D; Asx or B)

asparagine (AspNH$_2$ or Asn, N; Asx or B)

threonine" (Thr. T)

methionine* (Met, M)

glutamic acid (Glu, E; Glx or Z)

glutamine (GluNH$_2$, GluN, or Gln, Q; Glx or Z)

proline (Pro, P) an imino acid

lysine* (Lys, K)

arginine (Arg, R)

histidine (His, H)

tryptophan" (Try or Trp, W)

phenylalanine" (Phe, F)

tyrosine* (Tyr, Y)

hydroxylysine (Hylys or Lys—OH) occurs only in collagen and gelatin

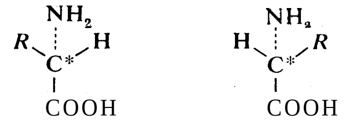
thyroxine (Thy) occurs only in the hormone protein thyroglobulin: I = iodine

hydroxyproline (hypro) occurs only in collagen and gelatin

Figure 1: Structures of amino acids found in proteins. Those amino acids marked with an asterisk (*) must be supplied in the diet of animals, which cannot synthesize them. The abbreviations in parentheses represent the shorthand notations(in three-letter codes and one-letter codes) used when indicating protein structures. The one-letter symbol for an unknown amino acid is X

Configuration of amino acids

bacteria, the amino acids that occur in proteins have the configuration shown on the left of Formula 4. For this reason all the amino acids found in proteins are designed as L-amino acids.



L-amino acid D-amino acid

Formula 4: The tetrahedral (four-faced) arrangement of the bonds around the a-carbon (C*). The solid lines represent bonds that slant upward from the plane of the drawing (*i.e.*, toward the reader). The broken lines represent bonds that recede from the plane of the drawing (*i.e.*, away from the reader).

In bacteria, D-alanine and some other D-amino acids have been found as components of gramicidin and bacitracin. These peptides are toxic to other bacteria and are used in medicine as antibiotics. The D-alanine has also been found in some peptides of bacterial membranes.

In contrast to most organic acids and amines, the amino acids are insoluble in organic solvents. In aqueous solutions they are dipolar ions (zwitterions, or hybrid ions) that react with strong acids or bases in a way that leads to the neutralization of the negatively or positively charged ends, respectively. Because of their reactions with strong acids and strong bases, the amino acids act as buffers—stabilizers of hydrogen ion (H^+) or hydroxide ion (OH–) concentrations. In fact, glycine is frequently used as a buffer in the pH range from 1 to 3 (acid solutions) and from 9 to 12 (basic solutions). In acid solutions, glycine has a positive charge and therefore migrates to the cathode (negative electrode of a direct-current electrical circuit with terminals in the solution). Its charge, however, is negative in alkaline solutions, in which it migrates to the anode (positive electrode). At pH 6.1 glycine does not migrate, because each molecule has one positive and one negative charge. The pH at which an amino acid does not migrate in an electrical field is called the isoelectric point. Most of the monoamino acids (*i.e.*, those with only one amino group) have isoelectric points similar to that of glycine. The isoelectric points of aspartic and glutamic acids, however, are close to pH 3; and those of histidine, lysine, and arginine are at pH 7.6, 9.7, and 10.8, respectively.

Amino acid sequence in protein molecules. Since each protein molecule consists of a long chain of amino acid residues, linked to each other by peptide bonds, the hydrolytic cleavage of all peptide bonds is a prerequisite for the quantitative determination of the amino acid residues. Hydrolysis is most frequently accomplished by boiling the protein with concentrated hydrochloric acid. The quantitative determination of the amino acids is based on the discovery that amino acids can be separated from each other by chromatography on filter paper and made visible by spraying the paper with ninhydrin. The amino acids of the protein hydrolysate are separated from each other by passing the hydrolysate through a column of adsorbents which adsorb the amino acids with different affinities and, on washing the column with buffer solutions, release them in a definite order. The amount of each of the amino acids can be determined by the intensity of the colour reaction with ninhydrin.

To obtain information about the sequence of the amino acid residues in the protein, the protein is degraded stepwise, one amino acid being split off in each step. This is accomplished by coupling the free a-amino group (—NH,) of the N-terminal amino acid with phenyl isothiocyanate; subsequent mild hydrolysis does not affect the peptide bonds; the procedure, called the Edman degradation, can be applied repeatedly; it thus reveals the sequence of the amino acids in the peptide chain.

Unavoidable small losses that occur during each step make it impossible to determine the sequence of more than about 30 to 50 amino acids by this procedure. For this reason the protein is usually first hydrolyzed by exposure to the enzyme trypsin (see below, Catalytic ***proteins:*** Enzymes), which cleaves only peptide bonds formed by the carboxyl groups of lysine and arginine. The Edman degradation is then applied to each of the few resulting peptides produced by the action of trypsin. Further information can be gained by hydrolyzing another portion of the protein with another enzyme, for instance with chymotrypsin, which splits predominantly peptide bonds formed by the amino acids tyrosine, phenylalanine, and tryptophan. The combination of results obtained with two or more different proteolytic (protein degrading) enzymes was first applied by the English biochemist Frederick Sanger, and it enabled him to elucidate the amino acid sequence of insulin. The amino acid sequences shown in formulas 7 to 11 and those of many other proteins have been determined in this manner.

LEVELS OF STRUCTURAL ORGANIZATION IN PROTEINS

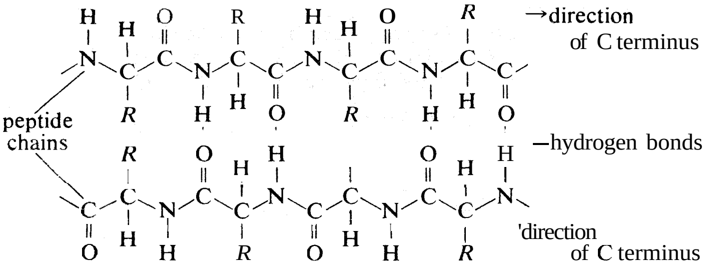
Primary structure. Analytical and synthetic procedures reveal only the primary structure of the proteins—that is, the amino acid sequence of the peptide chains. They do not reveal information about the conformation (arrangement in space) of the peptide chain—that is, whether the peptide chain is present as a long straight thread or is irregularly coiled and folded into a globule. The configuration, or conformation, of a protein is determined by mutual attraction or repulsion of polar or nonpolar groups in the side chains (R groups) of the amino acids. The former have positive or negative charges in their side chains; the latter repel water but attract each other. Some parts of a peptide chain containing 100 to 200 amino acids may form a loop, or helix; others may be straight or form irregular coils.

Definitions of protein structural terms

The terms secondary, tertiary, and quaternary structure are frequently applied to the configuration of the peptide chain of a protein. A nomenclature committee of the International Union of Biochemistry (IUB) has defined these terms as follows: The primary structure of a protein is determined by its amino acid sequence without any regard for the arrangement of the peptide chain in space. The secondary structure is determined by the spatial arrangement of the main peptide chain without any regard for the conformation of side chains or other segments of the main chain. The tertiary structure is determined by both the side chains and other adjacent segments of the main chain, without regard for neighbouring peptide chains. Finally, the term quaternary structure is used for the arrangement of identical or different subunits of a large protein in which each subunit is a separate peptide chain.

Secondary structure. The nitrogen and carbon atoms of a peptide chain cannot lie on a straight line because of the magnitude of the bond angles between adjacent atoms of the chain; the bond angle is about 110". Each of the nitrogen and carbon atoms can rotate to a certain extent, however, so that the chain has a limited flexibility. Because all of the amino acids, except glycine, are asymmetric L-amino acids, the peptide chain tends to assume an asymmetric helical shape; some of the fibrous proteins consist of elongated helices around a straight screw axis. Such structural features result from properties common to all peptide chains. The product of their effects is the secondary structure of the protein.

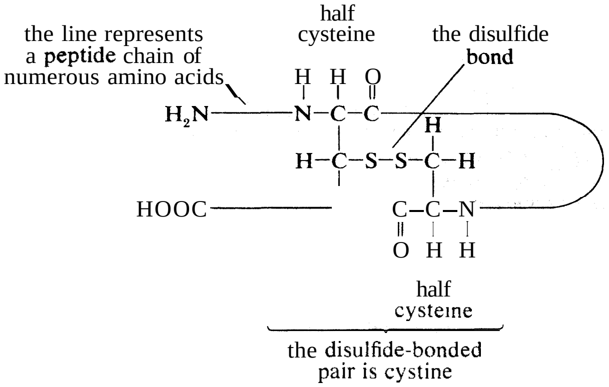
Tertiary structure. The tertiary structure is the product of the interaction between the side chains (R) of the amino acids comprising the protein. Some of them contain positively or negatively charged groups, others are polar, and still others are nonpolar. The number of carbon atoms in the side chain varies from zero in glycine to nine in tryptophan (see Figure 1). Positively and negatively charged side chains have the tendency to attract each other; side chains with identical charges repel each other. The bonds formed by the forces between the negatively charged side chains of aspartic or glutamic acid on the one hand, and the positively charged side chains of lysine or arginine on the other hand, are called salt bridges. Mutual attraction of adjacent peptide chains also results from the formation of numerous hydrogen bonds. They are shown by dotted lines in the diagram of an antiparallel pleated sheet protein structure (see Formula 5). Hydrogen bonds form as a result of the attraction between the nitrogen-bound hydrogen atom (the imide hydrogen) and the unshared pair of electrons of the oxygen atom in the double bonded carbon-oxygen group (the carbonyl group) ($>C{=}O$). The result is a slight displacement of the imide hydrogen toward the oxygen atom of the carbonyl group. Although the hydrogen bond is much weaker than a covalent bond (*i.e.*, the type of bond between two carbon atoms, which equally share the pair of bonding electrons between them), the large number of imide and carbonyl groups in peptide chains results in the formation of numerous hydrogen bonds. Another type of attraction is that between nonpolar side chains of valine, leucine, isoleucine, and phenylalanine; the attraction results in the displacement of water molecules and is called hydrophobic interaction.



Formula 5: The antiparallel pleated sheet structure.

Hydrophobic interaction defined

In proteins rich in cystine, the conformation of the peptide chain is determined to a considerable extent by the disulfide bonds (—S—S—) of cystine. The halves of cystine may be located in different parts of the peptide chain and thus may form a loop closed by the disulfide bond, as shown in Formula 6. If the disulfide bond is reduced (*i.e.*, hydrogen is added) to two sulfhydryl (—SH) groups, the tertiary structure of the protein undergoes a drastic change--closed loops are broken and adjacent disulfide-bonded peptide chains separate.



Formula 6: The disulfide bridge between two cystine halves in an amino acid chain showing how loops in the chain are formed by this amino acid.

Quaternary structure. The nature of the quaternary structure is demonstrated by the structure of hemoglobin. Each molecule of human hemoglobin consists of four peptide chains, two a-chains and two β-chains; *i.e.*, it is a tetramer. The four subunits are linked to each other by hydrogen bonds and hydrophobic interaction. Because the four subunits are so closely linked, the hemoglobin tetramer is called a molecule, even though no covalent bonds occur between the peptide chains of the four subunits. In other proteins, the subunits are bound to each other by covalent bonds (disulfide bridges; see below the structure of insulin in Formula 8).

THE ISOLATION AND DETERMINATION OF PROTEINS

Animal material usually contains large amounts of protein and lipids (fats) and small amounts of carbohydrate; in plants, the bulk of the dry matter is usually carbohydrate. No general method exists for the isolation of proteins from organs or tissues. If it is necessary to determine the amount of protein in a mixture of animal foodstuffs, a sample is converted to ammonium salts by boiling with sulfuric acid and a suitable inorganic catalyst, such as copper sulfate (Kjeldahl method). The method is based on the assumption that proteins contain 16 percent nitrogen, and that nonprotein nitrogen is present in very small amounts. The assumption is justified for most tissues from higher animals but not for insects and crustaceans, in which a considerable portion of the body nitrogen is present in the form of chitin, a carbohydrate. Large amounts of nonprotein nitrogen are also found in the sap of many plants. In such cases, the precise quantitative analyses are made after the proteins have been separated from other biological compounds.

Concentration of protein molecules by dialysis

Proteins are sensitive to heat, acids, bases, organic solvents, and radiation exposure; for this reason, the chemical methods employed to purify organic compounds cannot be applied to proteins. Salts and molecules of small size are removed from protein solutions by dialysis; *i.e.*, by placing the solution into a sac of semipermeable material, such as cellulose or acetylcellulose, which will allow small molecules to pass through but not large protein molecules, and immersing the sac in water or a salt solution. Small molecules can also be removed either by passing the protein solution through a column of resin that adsorbs only the protein or by gel filtration. In gel filtration, the large protein molecules pass through the column, and the small molecules are adsorbed to the gel.

Groups of proteins are separated from each other by salting out—*i.e.*, the stepwise addition of sodium sulfate or ammonium sulfate to a protein solution. Some proteins, called globulins, become insoluble and precipitate when the solution is half-saturated with ammonium sulfate or when its sodium sulfate content exceeds about 12 percent. Other proteins, the albumins, can be precipitated from the supernatant solution (*i.e.*, the solution remaining after a precipitation has taken place) by saturation with ammonium sulfate. Water-soluble proteins can be obtained in a dry state by freeze-drying (lyophilization), in which the protein solution is deep-frozen by lowering the temperature below —15" C (5" F) and removing the water; the protein is obtained as a dry powder.

Most proteins are insoluble in boiling water and are denatured by it—*i.e.*, irreversibly converted into an insoluble material. Heat denaturation cannot be used with connective tissue because the principal structural protein, collagen, is converted by boiling water into water-soluble gelatin.

Fractionation (separation into components) of a mixture of proteins of different molecular weight can be accomplished by gel filtration. The size of the proteins retained by the gel depends upon the properties of the gel. The proteins retained in the gel are removed from the column by solutions of a suitable concentration of salts and hydrogen ions.

Criteria of purity

Although many proteins were originally obtained in crystalline form, crystallinity is not proof of purity; in fact, many crystalline protein preparations contain other substances. Various tests are used to determine whether a protein preparation contains only one protein. The purity of a protein solution can be determined by such techniques as chromatography and gel filtration. In addition, a solution of pure protein will yield one peak when spun in a centrifuge at very high speeds (ultracentrifugation) and will migrate as a single band in electrophoresis (migration of the protein in an electrical field). Only after all of these methods (and others, such as amino acid analysis) indicate that the protein solution is pure, can it be considered so. Because chromatography, ultracentrifugation, and electrophoresis cannot be applied to insoluble proteins, very little is known about them; they may be mixtures of many similar proteins.

Very small (microheterogeneous) differences in some of the apparently pure proteins are known to occur; they are differences in the amino acid composition of otherwise identical proteins and are transmitted from generation to generation; *i.e.*, they are genetically determined; for example, some humans have two hemoglobins, hemoglobin A and hemoglobin S, which differ in one amino acid at a specific site in the molecule. In hemoglobin A the site is occupied by glutamic acid, and in hemoglobin S by valine. Refinement of the techniques of protein analysis has resulted in the discovery of other instances of "microheterogeneity."

The quantity of a pure protein can be determined by weighing or by measuring the ultraviolet absorbancy at 280 nanometres. The absorbency at 280 nanometres depends on the content of tyrosine and tryptophan in the protein (see above The amino acid composition of proteins). Sometimes the slightly less sensitive biuret reaction, a purple colour given by alkaline protein solutions upon the addition of copper sulfate, is used; its intensity depends only on the number of peptide bonds per gram, which is similar in all proteins.

PHYSICOCHEMICAL PROPERTIES OF PROTEINS

The molecular weight of proteins. The molecular weight of proteins cannot be determined by the methods of classical chemistry (*e.g.*, freezing-point depression) because they require solutions of a higher concentration of protein than can be prepared.

If a protein contains only one molecule of one of the amino acids or one atom of iron, copper, or another element, the minimum molecular weight of the protein or a subunit can be calculated; for example, the protein myoglobin contains 0.34 gram of iron in 100 grams of protein. The atomic weight of iron is 56; thus the minimum molecular weight of myoglobin is $(56 \times 100)/0.34 =$ about 16,500. Direct measurements of the molecular weight of myoglobin yield the same value. The molecular weight of hemoglobin, however, which also contains 0.34 percent iron, has been found to be 66,000 or $4 \times 16{,}500$; thus hemoglobin contains four atoms of iron.

Determination of molecular weight by ultracentrifugation

The method most frequently used to determine the molecular weight of proteins is ultracentrifugation; *i.e.*, spinning in a centrifuge at velocities up to about 60,000 revolutions per minute. Centrifugal forces of more than 200,000 times the gravitational force on the surface of the Earth are achieved at such velocities. The first ultracentrifuges, built in 1920, were used to determine the molecular weight of proteins. The molecular weights of a large number of proteins have been determined. Most consist of several subunits, the molecular weight of which is usually less than 100,000 and frequently ranges from 20,000 to 30,000. Proteins of very high molecular weights are found among hemocyanins, the copper-containing respiratory proteins of invertebrates; some range as high as several million. Although there is no definite lower limit for the molecular weight of proteins, short amino acid sequences are usually called peptides.

The shape of protein molecules. In the technique of X-ray diffraction the X-rays are allowed to strike a protein crystal; the X-rays, diffracted (bent) by the crystal, impinge on a photographic plate, forming a pattern of spots. This method reveals that peptide chains can assume very complicated, apparently irregular shapes. Two extremes in shape include the closely folded structure of the globular proteins and the elongated, unidimensional structure of the threadlike fibrous proteins; both were recognized many years before the technique of X-ray diffraction was developed. Solutions of fibrous proteins are extremely viscous (*i.e.*, sticky); those of the globular proteins have low viscosity (*i.e.*, they flow easily). A 5 percent solution of a globular protein—ovalbumin, for example—easily flows through a narrow glass tube; a 5 percent solution of gelatin, a fibrous protein, however, does not flow through the tube because it is liquid only at high temperatures and solidifies at room temperature. Even solutions containing only 1 or 2 percent of gelatin are highly viscous and flow through a narrow tube either very slowly or only under pressure. The elongated peptide chains of the fibrous proteins can be imagined to become entangled not only mechanically but also by mutual attraction of their side chains; in this way they incorporate large amounts of water. Most of the hydrophilic (water-attracting) groups of the globular proteins, however, lie on the surface of the molecules; as a result, globular proteins incorporate only a few water molecules. If a solution of a fibrous protein flows through a narrow tube, the elongated molecules become oriented parallel to the direction of the flow (see Figure 2), and the solution thus becomes birefringent like a crystal; *i.e.*, it splits a light ray into two components that travel at different velocities and are polarized at right angles to each other. Globular proteins do not show this phenomenon, which is called flow birefringence. Solutions of myosin, the contractile protein of muscles, show very high flow birefringence; other proteins with very high flow birefringence include solutions of fibrinogen, the clotting material of blood plasma, and solutions of tobacco mosaic virus. The gamma-globulins of the blood plasma show low flow birefringence; and none can be observed in solutions of serum albumin and ovalbumin.

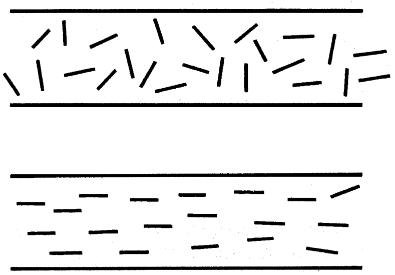


Figure 2: Flow birefringence. The upper diagram shows a solution containing elongated, rodlike macromolecules that, in the resting solution, are randomly oriented. The lower diagram shows the same solution during flow through a horizontal tube.

Hydration of proteins. When dry proteins are exposed to air of high water content, they rapidly bind water up to a maximum quantity, which differs for different proteins; usually it is 10 to 20 percent of the weight of the protein. The hydrophilic groups of a protein are chiefly the positively charged groups in the side chains of lysine and arginine and the negatively charged groups of aspartic and glutamic acid. Hydration (*i.e.*, the binding of water) may also occur at the hydroxyl ($-OH$) groups of serine and threonine or at the amide ($-CONH_2$) groups of asparagine and glutamine.

Polar structure of water molecule

The binding of water molecules to either charged or polar (partly charged) groups is explained by the dipolar structure of the water molecule; that is, the two positively charged hydrogen atoms form an angle of about 105°, with the negatively charged oxygen atom at the apex. The centre of the positive charges is located between the two hydrogen atoms; the centre of the negative charge of the oxygen atom is at the apex of the angle. The negative pole of the dipolar water molecule binds to positively charged groups; the positive pole binds negatively charged ones. The negative pole of the water molecule also binds to the hydroxyl and amino groups of the protein.

The water of hydration is essential to the structure of protein crystals; when they are completely dehydrated, the crystalline structure disintegrates. In some proteins this process is accompanied by denaturation and loss of the biological function.

In aqueous solutions, proteins bind some of the water molecules very firmly; others are either very loosely bound or form islands of water molecules between loops of folded peptide chains. Because the water molecules in such an island are thought to be oriented as in ice, which is crystalline water, the islands of water in proteins are called icebergs. Water molecules may also form bridges between the carbonyl ($>C=O$) and imino ($>NH$) groups of adjacent peptide chains, resulting in structures similar to those of the pleated sheet (see Formula 5) but with a water molecule in the position of the hydrogen bonds of that configuration. The extent of hydration of protein molecules in aqueous solutions is important, because some of the methods used to determine the molecular weight of proteins yield the molecular weight of the hydrated protein. The amount of water bound to one gram of a globular protein in solution varies from 0.2 to 0.5 gram. Much larger amounts of water are mechanically immobilized between the elongated peptide chains of fibrous proteins; for example, one gram of gelatin can immobilize at room temperature 25 to 30 grams of water.

The salting-out Process

Hydration of proteins is necessary for their solubility in water. If the water of hydration of a protein dissolved in water is reduced by the addition of a salt such as ammonium sulfate, the protein is no longer soluble and is salted out, or precipitated. The salting-out process is reversible because the protein is not denatured (*i.e.*, irreversibly converted to an insoluble material) by the addition of such salts as sodium chloride, sodium sulfate, or ammonium sulfate. Some globulins, called euglobulins, are insoluble in water in the absence of salts; their insolubility is attributed to the mutual interaction of polar groups on the surface of adjacent molecules, a process that results in the formation of large aggregates of molecules. Addition of small amounts of salt causes the euglobulins to become soluble. This process, called salting in, results from a combination between anions (negatively charged ions) and cations (positively charged ions) of the salt and positively and negatively charged side chains of the euglobulins. The combination prevents the aggregation of euglobulin molecules by preventing the formation of salt bridges between them. The addition of more sodium or ammonium sulfate causes the euglobulins to salt out again and to precipitate.

Electrochemistry of proteins. Because the α-amino group and a-carboxyl group of amino acids are converted into peptide bonds (see Formula 2) in the protein molecule, there is only one a-amino group (at the N terminus) and one a-carboxyl group (at the C terminus). The electrochemical character of a protein is affected very little by these two groups. Of importance, however, are the numerous positively charged ammonium groups ($-NH_3^+$) of lysine and arginine and the negatively charged carboxyl groups (—COO-) of aspartic acid and glutamic acid. In most proteins, the number of positively and negatively charged groups varies from 10 to 20 per 100 amino acids.

Electrometric titration. When measured volumes of hydrochloric acid are added to a solution of protein in salt-free water, the pH decreases in proportion to the amount of hydrogen ions added until it is about 4. Further addition of acid causes much less decrease in pH because the protein acts as a buffer at pH values of 3 to 4. The reaction that takes place in this pH range is the protonation of the carboxyl group—*i.e.*, the conversion of —COO- into —COOH. Electrometric titration of an isoelectric protein with potassium hydroxide causes a very slow increase in pH and a weak buffering action of the protein at pH 7; a very strong buffering action occurs in the pH range from 9 to 10 (see Figure 3). The buffering action at pH 7, which is caused by loss of protons (positively charged hydrogen) from the imidazolium groups (*i.e.*, the five-member ring structure in the side chain; see Figure 1) of histidine, is weak because the histidine content of proteins is usually low. The much stronger buffering action at pH values from 9 to 10 is caused by the loss of protons from the hydroxyl group of tyrosine and from the ammonium groups of lysine. Finally, protons are lost from the guanidinium groups (*i.e.*, the nitrogen-containing terminal portion of the arginine side chains; see Figure 1) of arginine at pH 12. A curve of the electrometric titration of glycine is shown in Figure 3. Electrometric titrations of proteins yield similar curves. Electrometric titration makes possible the determination of the approximate number of carboxyl groups, ammonium groups, histidines, and tyrosines per molecule of protein.

Electrophoresis. The positively and negatively charged side chains of proteins cause them to behave like amino acids in an electrical field; that is, they migrate during electrophoresis at low pH values to the cathode (negative terminal) and at high pH values to the anode (positive terminal). The isoelectric point, the pH value at which the protein molecule does not migrate, is in the range of pH 5 to 7 for many proteins. Proteins such as lysozyme, cytochrome *c*, histone, and others rich in lysine and arginine (see Table 2), however, have isoelectric points in the pH range between 8 and 10. The isoelectric point of pepsin, which contains very few basic amino acids, is close to 1.

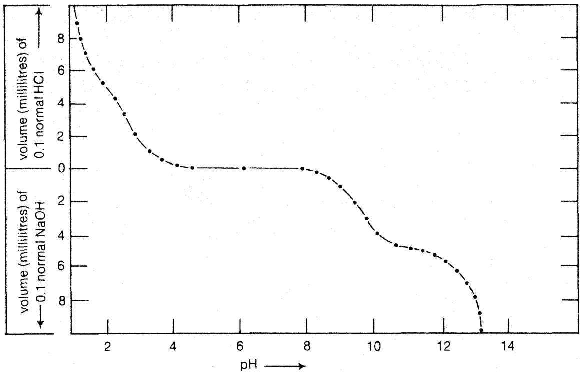

Figure 3: Electrometric titration of glycine. Addition of measured quantities of known-concentration hvdrochloric acid (HCl) to glycine is shown in the upper half of'the diagram; sodium' hydroxide (NaOH) in the lower half. The dots indicate the experimental results. The addition of a trace of acid or base to pure glycine, the isoelectric point of which is close to pH 6.1, causes a strong change in pH. Glycine acts as a buffer, however, in the acidic pH range below 3 and in the alkaline pH range above 8.

Zone electrophoresis

Free-boundary electrophoresis, the original method of determining electrophoretic migration, has been replaced in many instances by zone electrophoresis, in which the protein is placed in either a gel of starch, agar, or polyacrylamide or in a porous medium such as paper or cellulose acetate. The migration of hemoglobin and other coloured proteins can be followed visually. Colourless proteins are made visible after the completion of electrophoresis by staining them with a suitable dye.

CONFORMATION OF GLOBULAR PROTEINS

Results of X-ray diffraction studies. Most knowledge concerning secondary and tertiary structure of globular proteins has been obtained by the examination of their crystals using X-ray diffraction. In this technique X-rays are allowed to strike the crystal; the X-rays are diffracted by the crystal and impinge on a photographic plate, forming a pattern of spots. The measured intensity of the diffraction pattern, as recorded on a photographic film, depends particularly on the electron density of the atoms in the protein crystal. This density is lowest in hydrogen atoms, and they do not give a visible diffraction pattern. Although carbon, oxygen, and nitrogen atoms yield visible diffraction patterns, they are present in such great number—about 700 or 800 per 100 amino acids—that the resolution of the structure of a protein containing more than 100 amino acids is almost impossible. Resolution is considerably improved by substituting into the side chains of certain amino acids very heavy atoms, particularly those of heavy metals. Mercury ions, for example, bind to the sulfhydryl (—SH) groups of cysteine. Platinum chloride has been used in other proteins. In the iron-containing proteins, the iron atom already in the molecule is adequate.

Although the X-ray diffraction technique cannot resolve the complete three-dimensional conformation (that is, the secondary and tertiary structure of the peptide chain), complete resolution has been obtained by combination of the results of X-ray diffraction with those of amino acid sequence analysis. In this way the complete conformation of such proteins as myoglobin, chymotrypsinogen, lysozyme, and ribonuclease has been resolved.

The X-ray diffraction method has revealed regular structural arrangements in proteins; one is an extended form of antiparallel peptide chains that are linked to each other by hydrogen bonds between the carbonyl ($>C=O$) and imino ($>NH$) groups (shown in Formula 5). This conformation, called the pleated sheet, or β-structure, is found in some fibrous proteins. Short strands of the β-structure have also been detected in some globular proteins.

The a-helix

A second important structural arrangement is the α-helix (see Figure 4); it is formed by a sequence of amino acids wound around a straight axis in either a right-handed or a left-handed spiral. Each turn of the helix corresponds to a distance of 5.4 angstroms (= 0.54 nanometre) in the direction of the screw axis and contains 3.7 amino acids. Hence, the length of the a-helix per amino acid residue is 5.4 divided by 3.7, or 1.5 angstroms (one angstrom = 0.1 nanometre = 10^{-10} metre). The stability of the a-helix is maintained by hydrogen bonds between the carbonyl and imino groups of neighbouring turns of the helix. It was once thought, based on data from analyses of the myoglobin molecule, more than half of which consists of a-helices, that the a-helix is the predominant structural element of the globular proteins; it is now known that myoglobin is exceptional in this respect. The other globular proteins for which the structures have been resolved by X-ray diffraction contain only small regions of a-helix. In most of them the peptide chains are folded in an apparently random fashion (see Figure 5), for which the term random coil has been used. The term is misleading, however, because the folding is not random; rather, it is dictated by the primary structure and modified by the secondary and tertiary structures.

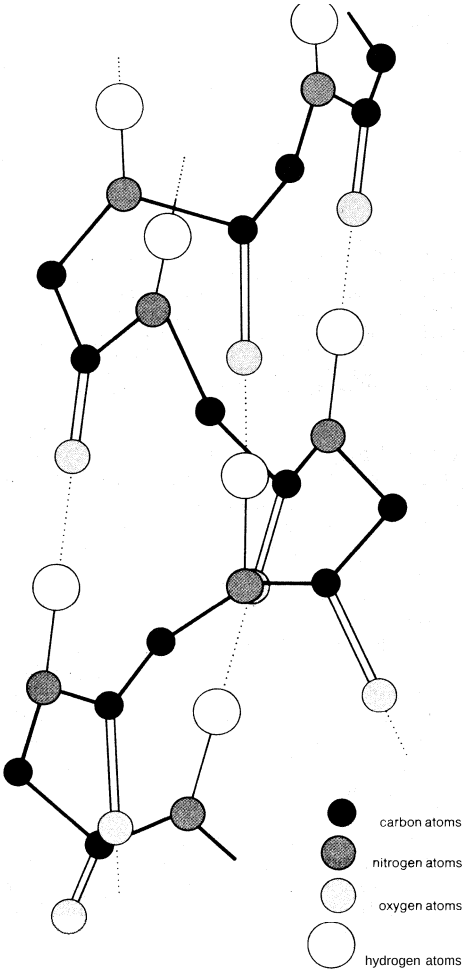

Figure 4: *The a-helix* (see *text).*

The first proteins for which the internal structures were completely resolved are the iron-containing proteins myoglobin and hemoglobin. The investigation of the hydrated crystals of these proteins at Cambridge by Max Perutz and J.C. Kendrew, who won a Nobel Prize for their work, revealed that the folding of the peptide chains is so tight that most of the water is displaced from the centre of the globular molecules. The amino acids that carry the ammonium ($—NH_3^+$) and carboxyl (—COO-) groups were found to be shifted to the surface of the globular molecules, and the nonpolar amino acids were found to be concentrated in the interior.

Other approaches to the determination of protein structure. None of the several other physical methods that have been used to obtain information on the secondary and tertiary structure of proteins provides as much direct information as the X-ray diffraction technique. Most of the techniques, however, are much more simple than X-ray diffraction, which requires, for the resolution of the structure of one protein, many years of work and equipment such as electronic computers. Some of the simpler techniques are based on the optical properties of proteins—refractivity, absorption of light of different wavelengths, rotation of the plane polarized light at different wavelengths, and luminescence.

Spectrophotometric behaviour. Spectrophotometry of protein solutions (the measurement of the degree of absorbance of light by a protein within a specified wavelength) is useful within the range of visible light only with proteins that contain coloured prosthetic groups (the nonprotein components). Examples of such proteins include the red heme proteins of the blood, the purple pigments of the retina of the eye, green and yellow proteins that contain bile pigments, blue copper-containing proteins, and dark brown proteins called melanins. Peptide bonds, because of their carbonyl groups, absorb light energy at very short wavelengths (185–200 nanometres). The aromatic rings of phenylalanine, tyrosine, and tryptophan (see Figure 1), however, absorb ultraviolet light between wavelengths of 280 and 290 nanometres. The absorbance of ultraviolet light by tryptophan is greatest, that of tyrosine is less, and that of phenylalanine is least. If the tyrosine or tryptophan content of the protein is known, therefore, the concentration of the protein solution can be determined by measuring its absorbance between 280 and 290 nanometres.

Optical activity. It will be recalled that the amino acids, with the exception of glycine, exhibit optical activity (rotation of the plane of polarized light; see above, *Physicochemical properties of the amino acids*). It is not surprising, therefore, that proteins also are optically active. They are usually levorotatory (*i.e.*, they rotate the plane of polarization to the left) when polarized light of wavelengths in the visible range is used. Although the specific rotation (a function of the concentration of a protein solution and the distance the light travels in it) of most L-amino acids varies from —30" to +30°, the amino acid cystine has a specific rotation of approximately —300". Although the optical rotation of a protein depends on all of the amino acids, the most important ones are cystine and the aromatic amino acids phenylalanine, tyrosine, and tryptophan. The contribution of the other amino acids to the optical activity of a protein is negligibly small.

Polarized light rotation ranges among proteins

Chemical reactivity *of* proteins. Information on the internal structure of proteins can be obtained with chemical methods that reveal whether certain groups are present on the surface of the protein molecule and thus able to react or whether they are buried inside the closely folded peptide chains and thus are unable to react. The chemical reagents used in such investigations must be mild ones that do not affect the structure of the protein.

The reactivity of tyrosine is of special interest. It has been found, for example, that only three of the six tyrosines found in the naturally occurring enzyme ribonuclease can be iodinated (*i.e.*, reacted to accept an iodine atom). Enzyme-catalyzed breakdown of iodinated ribonuclease is used to identify the peptides in which the iodinated tyrosines are present. The three tyrosines that can be iodinated lie on the surface of ribonuclease; the others, assumed to be inaccessible, are said to be buried in the molecule. Tyrosine can also be identified by using other techniques; *e.g.*, treatment with diazonium compounds or tetranitromethane. Because the compounds formed are coloured, they can easily be detected when the protein is broken down with enzymes.

Cysteine can be detected by coupling with compounds such as iodoacetic acid or iodoacetamide; the reaction results in the formation of carboxymethylcysteine or carbamidomethylcysteine, which can be detected by amino acid determination of the peptides containing them. The imidazole groups of certain histidines can also be located by coupling with the same reagents under different conditions. Unfortunately, few other amino acids can be labelled without changes in the secondary and tertiary structure of the protein.

Association of protein subunits. Many proteins with molecular weights of more than 50,000 occur in aqueous solutions as complexes: dimers, tetramers, and higher polymers—*i.e.*, as chains of two, four, or more repeating basic structural units. The subunits, which are called monomers or protomers, usually are present as an even number. Less than 10 percent of the polymers have been found to have an odd number of monomers. The arrangement of the subunits is thought to be regular and may be cyclic, cubic, or tetrahedral. Some of the small proteins also contain subunits. Insulin, for example, with a molecular weight of about 6,000, consists of two peptide chains linked to each other by disulfide bridges (—S—S—). Similar interchain disulfide bonds have been found in the immunoglobulins. In other proteins, hydrogen bonds and hydrophobic bonds (resulting from the interaction between the amino acid side chains of valine, leucine, isoleucine, and phenylalanine) cause the formation of aggregates of the subunits. The subunits of some proteins are identical; those of others differ. Hemoglobin is a tetramer consisting of two a-chains and two p-chains.

Protein denaturation. When a solution of a protein is boiled, the protein frequently becomes insoluble—*i.e.*, it is denatured—and remains insoluble even when the solution is cooled. The denaturation of the proteins of egg white by heat—as when boiling an egg—is an example of irreversible denaturation. The denatured protein has the same primary structure as the original, or native, protein. The weak forces between charged groups and the weaker forces of mutual attraction of nonpolar groups are disrupted at elevated temperatures, however; as a result, the tertiary structure of the protein is lost. In some instances the original structure of the protein can be regenerated; the process is called renaturation.

Methods of denaturation

Denaturation can be brought about in various ways. Proteins are denatured by treatment with alkaline or acid, oxidizing or reducing agents, and certain organic solvents. Interesting among denaturing agents are those that affect the secondary and tertiary structure without affecting the primary structure. The agents most frequently used for this purpose are urea and guanidinium chloride. These molecules, because of their high affinity for peptide bonds, break the hydrogen bonds and the salt bridges between positive and negative side chains, thereby abolishing the tertiary structure of the peptide chain. When denaturing agents are removed from a protein solution, the native protein re-forms in many cases. Denaturation can also be accomplished by reduction of the disulfide bonds of cystine—*i.e.*, conversion of the disulfide bond (—S—S—) to two sulfhydryl groups (—SH). This, of course, results in the formation of two cysteines. Reoxidation of the cysteines by exposure to air sometimes regenerates the native protein. In other cases, however, the wrong cysteines become bound to each other, resulting in a different protein. Finally, denaturation can also be accomplished by exposing proteins to organic solvents such as ethanol or acetone. It is believed that the organic solvents interfere with the mutual attraction of nonpolar groups.

Some of the smaller proteins, however, are extremely stable, even against heat; for example, solutions of ribonuclease can be exposed for short periods of time to temperatures of 90° C (194" F) without undergoing significant denaturation. Denaturation does not involve identical changes in protein molecules; a common property of denatured proteins, however, is the loss of biological activity—*e.g.*, the ability to act as enzymes or hormones.

Although denaturation had long been considered an all-or-none reaction, it is now thought that many intermediary states exist between native and denatured protein. In some instances, however, the breaking of a key bond could be followed by the complete breakdown of the conformation of the native protein.

Although many native proteins are resistant to the action of the enzyme trypsin, which breaks down proteins during digestion, they are hydrolyzed by the same enzyme after denaturation. Evidently, the peptide bonds that can be split by trypsin are inaccessible in the native proteins but become accessible during denaturation. Similarly, denatured proteins give more intense colour reactions for tyrosine, histidine, and arginine than do the same proteins in the native state. The increased accessibility of reactive groups of denatured proteins is attributed to an unfolding of the peptide chains.

Unfolded peptide chains in denatured proteins

If denaturation can be brought about easily and if renaturation is difficult, how is the native conformation of globular proteins maintained in living organisms, in which they are produced stepwise, by incorporation of one amino acid at a time? Experiments on the biosynthesis of proteins from amino acids containing radioactive carbon or heavy hydrogen reveal that the protein molecule grows stepwise from the N terminus to the C terminus; in each step a single amino acid residue is incorporated. As soon as the growing peptide chain contains six or seven amino acid residues, the side chains interact with each other and thus cause deviations from the straight or p-chain configuration shown in Formula 3. Depending on the nature of the side chains, this may result in the formation of an a-helix (Figure 4) or of loops closed by hydrogen bonds (Formula 5) or disulfide bridges (Formula 6). The final conformation is probably frozen when the peptide chain attains a length of 50 or more amino acid residues.

Conformation of proteins in interfaces. Like many other substances with both hydrophilic and hydrophobic groups, soluble proteins tend to migrate into the interface between air and water or oil and water; the term oil here means a hydrophobic liquid such as benzene or xylene. Within the interface, proteins spread, forming thin films. Measurements of the surface tension, or interfacial tension, of such films indicate that tension is reduced by the protein film. Proteins, when forming an interfacial film, are present as a monomolecular layer; *i.e.*, a layer one molecule in height. Although it was once thought that globular protein molecules unfold completely in the interface, it has now been established that many proteins can be recovered from films in the native state. The application of lateral pressure on a protein film causes it to increase in thickness and finally to form a layer with a height corresponding to the diameter of the native protein molecule. Protein molecules in an interface, because of Brownian motions (molecular vibrations), occupy much more space than do those in the film after the application of pressure. The Brownian motion of compressed molecules is limited to the two dimensions of the interface, since the protein molecules cannot move upward or downward.

The motion of protein molecules at the air–water interface has been used to determine the molecular weight of proteins. The technique involves measuring the force exerted by the protein layer on a barrier.

When a protein solution is vigorously shaken in air, it forms a foam, because the soluble proteins migrate into the air–water interface and persist there, preventing or slowing the reconversibn of the foam into a homogeneous solution. Some of the unstable, easily modified proteins are denatured when spread in the air–water interface. The formation of a permanent foam when egg white is vigorously stirred is an example of irreversible denaturation by spreading in a surface.

CLASSIFICATION OF PROTEINS

Classification by solubility. After two famous German chemists Emil Fischer and Franz Hofmeister independently stated in 1902 that proteins are essentially polypeptides consisting of many amino acids, an attempt was made to classify proteins according to their chemical and physical properties, because the biological function of proteins had not yet been established. (The protein char-

Methods of classification

acter of enzymes was not proved until the 1920s.) Proteins were classified primarily according to their solubility in a number of solvents. This classification is no longer satisfactory, however, because proteins of quite different structure and function sometimes have similar solubilities; conversely, proteins of the same function and similar structure sometimes have different solubilities. The terms associated with the old classification, however, are still widely used. They are defined below.

Albumins are proteins that are soluble in water and in water half-saturated with ammonium sulfate. On the other hand, globulins are salted out (*i.e.*, precipitated) by half-saturation with ammonium sulfate. Globulins that are soluble in salt-free water are called pseudoglobulins; those insoluble in salt-free water are euglobulins. Both prolamins and glutelins, which are plant proteins, are insoluble in water; the prolamins dissolve in 50 to 80 percent ethanol, the glutelins in acidified or alkaline solution. The term protamine is used for a number of proteins in fish sperm that consist of approximately 80 percent arginine and therefore are strongly alkaline. Histones, which are less alkaline, apparently occur only in cell nuclei, where they are bound to nucleic acids. The term scleroproteins has been used for the insoluble proteins of animal organs. They include keratin, the insoluble protein of certain epithelial tissues such as the skin or hair, and collagen, the protein of the connective tissue. A large group of proteins has been called conjugated proteins, becanse they are complex molecules of protein consisting of protein and nonprotein moieties. The nonprotein portion is called the prosthetic group. Conjugated proteins can be subdivided into mucoproteins, which, in addition to protein, contain carbohydrate; lipoproteins, which contain lipids (fats); phosphoproteins, which are rich in phosphate; chromoproteins, which contain pigments such as iron-porphyrins, carotenoids, bile pigments, and melanin; and finally, nucleoproteins, which contain nucleic acid.

The weakness of the above classification lies in the fact that many, if not all, globulins contain small amounts of carbohydrate; thus there is no sharp borderline between globulins and mucoproteins. Moreover, the phosphoproteins do not have a prosthetic group that can be isolated; they are merely proteins in which some of the hydroxyl groups of serine are phosphorylated (*i.e.*, contain phosphate). Finally, the globulins include proteins with quite different roles—enzymes, antibodies, fibrous proteins, and contractile proteins.

Classification by biological functions. In view of the unsatisfactory state of the old classification, it is preferable to classify the proteins according to their biological function. Such a classification is far from ideal, however, because one protein can have more than one function. The contractile protein myosin, for example, also acts as an ATPase (adenosine triphosphatase), an enzyme that hydrolyzes adenosine triphosphate (removes a phosphate group from ATP by introducing a water molecule). In addition, the definite function of a protein frequently is not known. A protein cannot be called an enzyme as long as its substrate (the specific compound upon which it acts) is not known. It cannot even be tested for its enzymatic action when its substrate is not known.

II. Special structure and function of proteins

Despite its weaknesses, a functional classification is used here in order to demonstrate, whenever possible, the correlation between the structure and function of a protein. The structural, fibrous proteins are presented first, because their structure is simpler than that of the globular proteins and more clearly related to their function, which is the maintenance of either a rigid or a flexible structure.

STRUCTURAL PROTEINS

Scleroproteins. Collagen. Collagen is the structural protein of bones, tendons, ligaments, and skin. For many years collagen was considered to be insoluble in water. Part of the collagen of calf skin, however, can be extracted with citrate buffer at pH 3.7. A precursor of collagen called procollagen is converted in the body into collagen.

Structure of collagen

Procollagen has a molecular weight of 120,000. Cleavage of one or a few peptide bonds of procollagen yields collagen, which has three subunits, each with a molecular weight of 95,000; therefore, the molecular weight of collagen is 285,000 (3 × 95,000). The three subunits are wound as spirals around an elongated straight axis. The length of each subunit is 2,900 angstroms, and its diameter is approximately 15 angstroms. The three chains are staggered, so that the trimer has no definite terminal limits.

The amino acid composition of collagen is shown in Table 1. It differs from all other proteins in its high content of proline and hydroxyproline. Hydroxyproline does not occur in significant amounts in any other protein except elastin. Most of the proline in collagen is present in the sequence glycine–proline-*X*, in which X is frequently alanine or hydroxyproline. Collagen does not contain cystine or tryptophan and therefore cannot substitute for other proteins in the diet. The presence of proline causes kinks in the peptide chain and thus reduces the length of the amino acid unit from 3.7 angstroms in the extended chain of the β-structure to 2.86 angstroms in the collagen chain. In the intertwined triple helix, the glycines are inside, close to the axis; the prolines are outside.

Table 1: Amino Acid Content of Some Proteins

amino acid*	protein					
	α-casein	gliadin	edestin	collagen (ox hide)	keratin (wool)	myosin
Lysine	60.9	4.45	19.9	27.4	6.2	85
Histidine	18.7	11.7	18.6	4.5	19.7	15
Arginine	24.7	15.7	99.2	47.1	56.9	41
Aspartic acid†	63.1	10.1	99.4	51.9	51.5	85
Threonine	41.2	17.6	31.2	19.3	55.9	41
Serine	63.1	46.7	55.7	41.0	79.5	41
Glutamic acid†	153.1	311.0	144.9	76.2	99.0	155
Proline	71.3	117.8	32.9	125.2	58.3	22
Glycine	37.3	—	68.0	354.6	78.0	39
Alanine	41.5	23.9	57.7	115.7	43.8	78
Half cystine	3.6	21.3	10.9	0.0	105.0	86
Valine	53.8	22.7	54.6	21.4	46.6	42
Methionine	16.8	11.3	16.4	6.5	4.0	22
Isoleucine	48.8	90.8‡	41.9	14.5	29.0	42
Leucine	60.3		60.0	28.2	59.9	79
Tyrosine	44.7	17.7	26.9	5.5	28.7	18
Phenylalanine	27.9	39.0	38.4	13.9	22.4	27
Tryptophan	7.8	3.2	6.6	0.0	9.6	—
Hydroxyproline	0.0	0.0	0.0	97.5	12.2	—
Hydroxylysine	—	—	—	8.0	1.2	—
Total	839	765	883	1,058	863	832
Average residual weight	119	131	113	95	117	120

'Number of amino acids is given per 100,000 daltons of protein—*i.e.*, the number of gram molecules of amino acid per 100,000 grams of protein.
†The values for aspartic and glutamic acid include asparagine and glutamine, respectively. ‡Isoleucine plus leucine.

Native collagen resists the action of trypsin but is hydrolyzed by the bacterial enzyme collagenase. When collagen is boiled with water, the triple helix is destroyed, and the subunits are partially hydrolyzed; the product is gelatin. The unfolded peptide chains of gelatin trap large amounts of water, resulting in a hydrated molecule.

When collagen is treated with tannic acid or with chromium salts, cross links form between the collagen fibres, and it becomes insoluble; the conversion of hide into leather is based on this tanning process. The tanned material is insoluble in hot water and cannot be converted to gelatin. On exposure to water at 62" to 63° C (144" to 145" F), however, the cross links formed by the tanning agents collapse, and the leather contracts irreversibly to about one-third its original volume.

Collagen seems to undergo an aging process in living organisms that may be caused by the formation of cross links between collagen fibres. They are formed by the conversion of some lysine side chains to aldehydes (compounds with the general structure RCHO), and the combination of the aldehydes with the ε-amino groups of intact lysine side chains. The protein elastin, which occurs in the elastic fibres of connective tissue, contains similar cross links and may result from the combination of collagen fibres with other proteins. When cross-linked collagen or elastin is degraded, products of the cross-linked lysine fragments, called desmosins and isodesmosins, are formed.

Keratin. Keratin, the structural protein of epithelial cells in the outermost layers of the skin, has been isolated from hair, nails, hoofs, and feathers. Keratin is completely insoluble in cold or hot water; it is not attacked by proteolytic enzymes (*i.e.*, enzymes that break apart, or lyse, protein molecules), and therefore cannot replace proteins in the diet. The great stability of keratin results from the numerous disulfide bonds of cystine. The amino acid composition of keratin differs from that of collagen (see Table 1). Cystine may account for 24 percent of the total amino acids. The peptide chains of keratin are arranged in approximately equal amounts of antiparallel and parallel pleated sheets, in which the peptide chains are linked to each other by hydrogen bonds between the carbonyl ($>C{=}O$) and imino ($>NH$) groups.

Pleated-sheet structure of keratin

Reduction of the disulfide bonds to sulfhydryl groups results in dissociation of the peptide chains, the molecular weight of which is 25,000 to 28,000 each. The formation of permanent waves in the beauty treatment of hair is based on partial reduction of the disulfide bonds of hair keratin by thioglycol, or some other mild reducing agent, and subsequent oxidation of the sulfhydryl groups (—SH) in the reoriented hair to disulfide bonds (—S—S—) by exposure to the oxygen of the air.

The length of keratin fibres depends on their water content. They can bind approximately 16 percent of water; this hydration is accompanied by an increase in the length of the fibres of 10 to 12 percent.

The most thoroughly investigated keratin is hair keratin, particularly that of wool. It consists of a mixture of peptides with high and low cystine content. When wool is heated in water to about 90" C (190" F), it shrinks irreversibly. This is attributed to the breakage of hydrogen bonds and other noncovalent bonds; disulfide bonds do not seem to be affected.

Others. The most thoroughly investigated scleroprotein has been fibroin, the insoluble material of silk. The raw silk comprising the cocoon of the silkworm consists of two proteins. One, sericin, is soluble in hot water; the other, fibroin, is not. The amino acid composition of the latter differs from that of all other proteins. It contains large amounts of glycine, alanine, tyrosine, and serine; small amounts of the other amino acids; and no sulfur-containing ones. The peptide chains are arranged in antiparallel β-structures. Fibroin is partly soluble in concentrated solutions of lithium thiocyanate or in mixtures of cupric salts and ethylene diamine. Such solutions contain a protein of molecular weight 170,000, which is a dimer of two subunits.

Little is known about either the scleroproteins of the marine sponges or the insoluble proteins of the cellular membranes of animal cells. Some of the membranes are soluble in detergents; the membrane of the red blood cells contains an insoluble membrane protein that consists of a single peptide chain of molecular weight 200,000.

The muscle proteins. The total amount of muscle proteins in mammals, including man, exceeds that of any other protein. About 40 percent of the body weight of a healthy human adult weighing about 70 kilograms (150 pounds) is muscle, which is composed of about 20 percent muscle protein. Thus, the human body contains about five to six kilograms (11 to 13 pounds) of muscle protein. An albumin-like fraction of these proteins, originally called myogen, contains various enzymes—phosphorylase, aldolase, glyceraldehyde phosphate dehydrogenase, and others; it does not seem to be involved in contraction, The globulin fraction contains myosin, the contractile protein, which also occurs in blood platelets, small bodies found in blood. Similar contractile substances occur in other contractile structures; for example, in the cilia or flagella (whiplike organs of locomotion) of bacteria and protozoans. In contrast to the scleroproteins, the contractile proteins are soluble in salt solutions and susceptible to enzymatic digestion.

Occurrence of contractile proteins

The energy required for muscle contraction is provided by the oxidation of carbohydrates or lipids. The term mechano-chemical reaction has been used for this conversion of chemical into mechanical energy. Although the molecular process underlying the reaction is not yet completely understood, it is known to involve the fibrous muscle proteins, the peptide chains of which undergo a change in conformation during contraction.

Myosin, which can be removed from fresh muscle by adding it to a chilled solution of dilute potassium chloride and sodium bicarbonate, is insoluble in water. Myosin, solutions of which are highly viscous, consists of an elongated—probably double-stranded—peptide chain, which is coiled at both ends in such a way that a terminal globule is formed. The length of the molecule is approximately 160 nanometres and its average diameter 2.6 nanometres. The equivalent weight of each of the two terminal globules is approximately 30,000; the molecular weight of myosin is close to 500,000. Trypsin splits myosin into large fragments called meromyosin. Myosin contains many amino acids with positively and negatively charged side chains (see Table 1); they form 18 and 16 percent, respectively, of the total number of amino acids. Myosin catalyzes the hydrolytic cleavage of ATP (adenosine triphosphate). A smaller protein with properties similar to those of myosin is tropomyosin. It has a molecular weight of 70,000 and dimensions of 45 by 2 nanometres. More than 90 percent of its peptide chains are present in the α-helix form.

Myosin combines easily with another muscle protein called actin, the molecular weight of which is about 50,000; it forms 12 to 15 percent of the muscle proteins. Actin can exist in two forms--one, G-actin, is globular; the other, F-actin, is fibrous. Actomyosin is a complex molecule formed by one molecule of myosin and one or two molecules of actin. In muscle, actin and myosin filaments are oriented parallel to each other and to the long axis of the muscle. The actin filaments are linked to each other lengthwise by fine threads called S filaments. During contraction the S filaments shorten, so that the actin filaments slide toward each other, past the myosin filaments, thus causing a shortening of the muscle (see MUSCLE CONTRACTION for a detailed description of the process).

Fibrinogen and fibrin. Fibrinogen, the protein of the blood plasma, is converted into the insoluble protein fibrin during the clotting process. The fibrinogen-free fluid obtained after removal of the clot, called blood serum, is blood plasma minus fibrinogen. The fibrinogen content of the blood plasma is 0.2 to 0.4 percent.

Fibrinogen can be precipitated from the blood plasma by half-saturation with sodium chloride. Fibrinogen solutions are highly viscous and show strong flow birefringence. In electron micrographs the molecules appear as rods with a length of 47.5 nanometres and a diameter of 1.5 nanometres; in addition, two terminal and a central nodule are visible. The molecular weight is 340,000. An unusually high percentage, about 36 percent, of the amino acid side chains are positively or negatively charged.

The clotting process in blood proteins

The clotting process is initiated by the enzyme thrombin, which catalyzes the breakage of a few peptide bonds of fibrinogen; as a result, two small fibrinopeptides with molecular weights of 1,900 and 2,400 are released. The remainder of the fibrinogen molecule, a monomer, is soluble and stable at pH values less than 6 (*i.e.*, in acid solutions). In neutral solution (pH 7) the monomer is converted into a larger molecule, insoluble fibrin; this results from the formation of new peptide bonds. The newly formed peptide bonds form intermolecular and intramolecular cross links, thus giving rise to a large clot, in which all molecules are linked to each other. Clotting, which takes place only in the presence of calcium ions, can be prevented by compounds such as oxalate or citrate, which have a high affinity for calcium ions.

ALBUMINS, GLOBULINS, AND OTHER SOLUBLE PROTEINS

The blood plasma, the lymph, and other animal fluids usually contain one to seven grams of protein per 100 millilitres of fluid, which includes small amounts of hundreds of enzymes and a large number of protein hormones. The discussion below is limited largely to the proteins that occur in large amounts and can be easily isolated from the body fluids. For further information on enzymes and hormones, see ENZYME and HORMONE.

Proteins of the blood serum. Human blood serum contains about 7 percent protein, two-thirds of which is in the albumin fraction; the other third is in the globulin fraction. Electrophoresis of serum reveals a large albumin peak and three smaller globulin peaks, the alpha-, beta-, and gamma-globulins. The amounts of alpha-, beta-, and gamma-globulin in normal human serum are approximately 1.5, 1.9, and 1.1 percent, respectively. Each globulin fraction is a mixture of many different proteins, as has been demonstrated by immuno-electrophoresis. In this method, the serum of a rabbit injected with human serum is allowed to diffuse into the four protein bands—albumin, alpha-, beta-, and gamma-globulin—obtained from the electrophoresis of human serum. Because the rabbit has previously been injected with human serum, its blood contains antibodies (substances formed in response to a foreign substance introduced into the body) against each of the human serum proteins; each antibody combines with the serum protein (antigen) that caused its formation in the rabbit. The result is the formation of about 20 regions of insoluble antigen–antibody precipitate, which appear as white arcs in the transparent gel of the electrophoresis medium. Each region corresponds to a different human serum protein.

Globulin fractions of serum

Serum albumin is much less heterogeneous (*i.e.*, contains fewer distinct proteins) than are the globulins; in fact, it is one of the few serum proteins that can be obtained in a crystalline form. Serum albumin combines easily with many acidic dyes (*e.g.*, Congo red and methyl orange); with bilirubin, the yellow bile pigment; and with fatty acids. It seems to act, in living organisms, as a carrier for certain biological substances. Present in blood serum in relatively high concentration, serum albumin also acts as a protective colloid, a protein that stabilizes other proteins. Albumin (molecular weight of 68,000) has a single free sulfhydryl (—SH) group, which on oxidation forms a disulfide bond with the sulfhydryl group of another serum albumin molecule, thus forming a dimer. The isoelectric point of serum albumin is pH 4.7.

The alpha-globulin fraction of blood serum is a mixture of several conjugated proteins. The best known are an ***a***-lipoprotein (combination of lipid and protein), and two mucoproteins (combinations of carbohydrate and protein). One mucoprotein is called orosomucoid, or m,-acid glycoprotein; the other is called haptoglobin because it combines specifically with globin, the protein component of hemoglobin. Haptoglobin contains about 20 percent carbohydrate.

The beta-globulin fraction of serum contains, in addition to lipoproteins and mucoproteins, two metal-binding proteins, transferrin and ceruloplasmin, which bind iron and copper, respectively. They are the principal iron and copper carriers of the blood.

The gamma-globulins are the most heretogeneous globulins. Although most have a molecular weight of approximately 150,000, that of some, called macroglobulins, is as high as 800,000. Because typical antibodies are of the same size and exhibit the same electrophoretic behaviour as y-globulins, they are called immunoglobulins. The designation IgM or gamma M (γM) is used for the macroglobulins; the designation IgG or gamma G (γG) is used for y-globulins of molecular weight 150,000.

Milk proteins. Milk contains an albumin, α-lactalbumin; a globulin, beta-lactoglobulin; and a phosphoprotein, casein. If acid is added to milk, casein precipitates. The remaining watery liquid (the supernatant solution), or whey, contains lactalbumin and lactoglobulin. Both have been obtained in crystalline form; their molecular weights are 16,000 and 18,500, respectively. Lactoglobulin also occurs as a dimer of molecular weight 37,000. Small variation? known to occur in the amino acid composition of lactoglobulin result from genetic variations. The amino acid composition and the tertiary structure of lactalbumin resemble that of lysozyme, an egg protein (see below).

Casein is precipitated not only by the addition of acid but also by the action of the enzyme rennin, which is found in gastric juice. Rennin from calf stomachs is used to precipitate casein, from which cheese is made. Milk fat precipitates with casein; milk sugar, however, remains in the supernatant (whey). Casein is a mixture of several similar phosphoproteins, called a-, β-, y-, and κ-casein, all of which contain some serine side chains combined with phosphoric acid. Approximately 75 percent of casein is a-casein (see Table 1). Cystine has been found only in κ-casein. In milk, casein seems to form polymeric globules (micelles) with radially arranged monomers, each with a molecular weight of 24,000; the acidic side chains occur predominantly on the surface of the micelle, rather than inside.

Composition of casein

Egg proteins. About 50 percent of the proteins of egg white are composed of ovalbumin, which is easily obtained in crystals. Its molecular weight is 46,000 and its amino acid composition differs from that of serum albumin. Other proteins of egg white are conalbumin, lysozyme, ovoglobulin, ovomucoid, and avidin. Lysozyme is an enzyme that hydrolyzes the carbohydrates found in the capsules certain bacteria secrete around themselves; it causes lysis (disintegration) of the bacteria. The molecular weight of lysozyme is 14,100; its amino acid composition is shown in Table 2. Its three-dimensional structure, shown in Figure 5, is similar to that of a-lactalbumin, which stimulates the formation of lactose by the enzyme lactose synthetase. Lysozyme has also been found in the urine of patients suffering from leukemia.

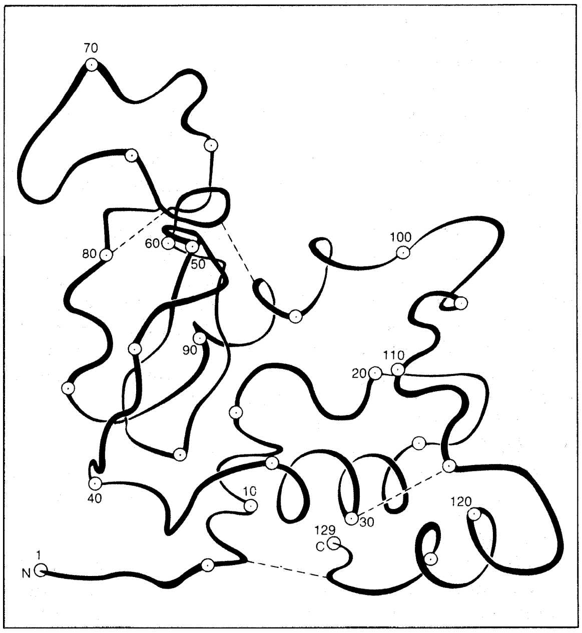

Figure 5: Conformation of lysozyme. Lysozyme from hen's egg white has a single peptide chain of 129 amino acids. The diagram shows the structure in simplified form. The amino acid residues are numbered from the terminal a amino group (N) to the terminal carboxyl group (C). Every fifth residue is shown by a circle, and every tenth residue is numbered. The four disulfide bridges are shown by broken lines. Alpha-helices are visible in the ranges 25 to 35.90 to 100, and 120 to 125.

Avidin is a glycoprotein that combines specifically with biotin, a vitamin. In animals fed large amounts of raw egg white, the action of avidin results in "egg-white injury." The molecular weight of avidin, which forms a tetramer, is 16,200. Its amino acid sequence is known.

Egg-yolk proteins contain a mixture of lipoproteins and livetins. The latter are similar to serum albumin, α-globulin, and β-globulin. The yolk also contains a phosphoprotein, phosvitin. Phosvitin, which has also been found in fish sperm, has a molecular weight of 40,000 and an unusual amino acid composition; one third of its amino acids are phosphoserine.

Protamines and histones. Protamines are found in the sperm cells of fish. The most thoroughly investigated protamines are salmine from salmon sperm and clupeine

Table 2: Number of Amino Acids per Protein Molecule

amino acid	protein*						
	Cyto	Hb a	Hb β	RNase	Lys	Chgen	Fdox
Lysine	18	11	11	10	6	14	4
Histidine	3	10	9	4	1	2	1

Total	104	141	146	124	129	245	97

*Cyto = human cytochrome c; Hb a = human hemoglobin A, a-chain; Hb β = human hemoglobin A, 0-chain; RNase = bovine ribonuclease; Lys = chicken lysozyme; Chgen = bovine chymotrypsinogen; Fdox = spinach ferredoxin. †The values recorded for aspartic and glutamic acid include asparagine and glutamine.

from herring sperm. The protamines are bound to deoxyribonucleic acid (DNA), forming nucleoprotamines. The amino acid composition of the protamines is simple; they contain, in addition to large amounts of arginine, small amounts of five or six other amino acids. The composition of the salmine molecule, for example, is: Arg_{51}, Ala,, Val,, Ile_1, Pro,, and Ser,, in which the subscript numbers indicate the number of each amino acid in the molecule. Because of the high arginine content, the isoelectric points of the protamines are at pH values of 11 to 12; *i.e.*, the protamines are alkaline. The molecular weights of salmine and clupeine are close to 6,000. All of the protamines investigated thus far are mixtures of several similar proteins.

Protamine composition

The histones are less basic than the protamines. They contain high amounts of either lysine or arginine and small amounts of aspartic acid and glutamic acid. Histones occur in combination with DNA as nucleohistones in the nuclei of the body cells of animals and plants, but not in animal sperm. The molecular weights of histones vary from 10,000 to 22,000. In contrast to the protamines, the histones contain most of the 20 amino acids, with the exception of tryptophan and the sulfur-containing ones. Like the protamines, histone preparations are heterogeneous mixtures. The amino acid sequence of some of the histones has been determined.

Plant proteins. Plant proteins, mostly globulins, have been obtained chiefly from the protein-rich seeds of cereals and leguminous plants (*i.e.*, members of the pea family). Very small amounts of albumins are found in seeds. The best known globulins, insoluble in water, can be extracted from seeds by treatment with 2 to 10 percent solutions of sodium chloride. Many plant globulins have been obtained in crystalline form; they include edestin from hemp, molecular weight 310,000; amandin from almonds, 330,000; concanavalin A (42,000) and B (96,000); and canavalin (113,000) from jack beans. They are polymers of smaller subunits; edestin, for example, is a hexamer of a subunit with a molecular weight of 50,000, and concanavalin B a trimer of a subunit with a molecular weight of 30,000. After extraction of lipids from cereal seeds by ether and alcohol, further extraction with water containing 50 to 80 percent of alcohol yields proteins that are insoluble in water but soluble in water–ethanol mixtures and have been called prolamins. Their solubility in aqueous ethanol may result from their high proline and glutamine content (see Table 1). Gliadin, the prolamin from wheat, contains 14 grams of proline and 46 grams of glutamic acid in 100 grams of protein; most of the glutamic acid is in the form of glutamine. The total amounts of the basic amino acids (arginine, lysine, and histidine) in gliadin are only 5 percent of the weight of gliadin. None of the prolamins has yet been obtained in a pure crystalline state. Because the lysine content is either low or nonexistent, human populations dependent on grain as a sole protein source suffer from lysine deficiency.

CONJUGATED PROTEINS

Combination of proteins with prosthetic groups. The link between a protein molecule and its prosthetic group is a covalent (electron-sharing) bond in the glycoproteins, the biliproteins, and some of the heme proteins. In lipoproteins, nucleoproteins, and some heme proteins, the two components are linked to each other by noncovalent bonds. The noncovalent bonding results from the same forces that are responsible for the tertiary structure of proteins; namely, hydrogen bonds, salt bridges between positively and negatively charged groups, disulfide bonds, and mutual interaction of hydrophobic groups. In the metalloproteins (proteins with a metal element as a prosthetic group), the metal ion usually forms a centre to which various groups are bound.

Chemical bonding in conjugated proteins

Some of the conjugated proteins have been mentioned in preceding sections because they occur in the blood serum, in milk, and in eggs. Other conjugated proteins will be discussed below in sections dealing with respiratory proteins and enzymes.

Mucoproteins and glycoproteins. The prosthetic groups in mucoproteins and glycoproteins are oligosaccharides (carbohydrates consisting of a small number of simple sugar molecules) usually containing from four to 12 sugar molecules; the most common sugars are galactose, mannose, glucosamine, and galactosamine. Xylose, fucose, glucuronic acid, sialic acid, and other simple sugars sometimes also occur. Some mucoproteins contain 20 percent or more of carbohydrate, usually in several oligosaccharides attached to different parts of the peptide chain. The designation mucoprotein is used for proteins with more than 3 to 4 percent carbohydrate; if the carbohydrate content is less than 3 percent, the protein is sometimes called a glycoprotein or simply a protein.

Mucoproteins, highly viscous proteins originally called mucins, are found in saliva, in gastric juice, and in other animal secretions. Mucoproteins occur in large amounts in cartilage, synovial fluid (the lubricating fluid of joints and tendons), and egg white. The mucoprotein of cartilage is formed by the combination of collagen with chondroitinsulfuric acid, which is a polymer of either glucuronic or iduronic acid and acetylhexosamine or acetylgalactosamine. It is not yet clear whether or not chondroitinsulfate is bound to collagen by covalent bonds.

Lipoproteins and proteolipids. The bond between the protein and the lipid portion of lipoproteins and proteolipids is a noncovalent one. It is believed that some of the lipid is enclosed in a meshlike arrangement of peptide chains, and becomes accessible for reaction only after the unfolding of the chains by naturi[illegible]. [illegible]lth[illegible]gh lipoproteins in tl[illegible] α- and [illegible]ɔt[illegible] fraction f[illegible]ɔd serum are soluble in water (but insoluble in organic solvents), some of the brain lipoproteins, because they have a high lipid content, are soluble in organic solvents; they are called proteolipids. The β-lipoprotein of human blood serum is a macroglobulin with a molecular weight of about 1,300,000, 70 percent of which is lipid; of the lipid, about 30 percent is phospholipid and 40 percent cholesterol and compounds derived from it. Because of their lipid content, the lipoproteins have the lowest density (mass per unit volume) of all proteins. They are usually classified as LDL (low density lipoproteins) and HDL (high density lipoproteins).

Coloured lipoproteins are formed by the combination of protein with carotenoids. Crustacyanin, the pigment of lobsters, crayfish, and other crustaceans, contains astaxathin, which is a compound derived from carotene; a similar pigment is found in lobster eggs. Among the most interesting of the coloured lipoproteins are the pigments of the retina of the eye. They contain retinal, which is a compound derived from carotene and which is formed by the oxidation of vitamin A. In rhodopsin. the red pigment of the retina. the aldehyde group (—CHO) of retinal

Pigments of the eye

forms a covalent bond with an amino (—NH,) group of opsin, the protein carrier. Colour vision is mediated by the presence of several visual pigments in the retina that differ from rhodopsin either in the structure of retinal or in that of the protein carrier.

Metalloproteins. Proteins in which heavy metal ions are bound directly to some of the side chains of histidine, cysteine, or some other amino acid are called metalloproteins. Two metalloproteins, transferrin and ceruloplasmin, occur in the globulin fractions of blood serum; they act as carriers of iron and copper, respectively. Transferrin has a molecular weight of 84,000 and consists of two identical subunits, each of which contains one ferric ion (Fe^{3+}) that seems to be bound to tyrosine. Several genetic variants of transferrin are known to occur in man. Another iron protein, ferritin, which contains 20 to 22 percent iron, is the form in which iron is stored in animals; it has been obtained in crystalline form from liver and spleen. A molecule consisting of 20 subunits, its molecular weight is approximately 480,000. The iron can be removed by reduction from the ferric (Fe^{3+}) to the ferrous (Fe^{2+}) state. The iron-free protein, apoferritin, is synthesized in the body before the iron is incorporated.

Green plants and some photosynthetic and nitrogen-fixing bacteria (*i.e.*, bacteria that convert atmospheric nitrogen, N_2, into amino acids and proteins in their own bodies) contain various ferredoxins. They are small proteins containing 50 to 100 amino acids (see Table 2) and a chain of iron and disulfide units (FeS_2), in which some of the sulfur atoms are contributed by cysteine; others are sulfide ions (S^{2-}). The number of FeS_2 units per ferredoxin molecule varies from five in the ferredoxin of spinach to ten in the ferredoxin of certain bacteria. Ferredoxins act as electron carriers in photosynthesis and in nitrogen fixation.

Function of ceruloplasmin

Ceruloplasmin is a copper-containing globulin with a molecular weight of 151,000; the molecule consists of eight subunits, each containing one copper ion. Ceruloplasmin is the principal carrier of copper in organisms, although copper can also be transported by the iron-containing globulin transferrin. Another copper-containing protein, erythrocuprein (molecular weight 64,000), has been isolated from red blood cells; it has also been found in the liver and the brain. The molecule, which consists of four subunits with a molecular weight of 16,000 each, contains four copper and four zinc ions. Because of their copper content, ceruloplasmin and erythrocuprein may have some catalytic activity in oxidation–reduction reactions. Another copper-containing protein, hemocyanin, is described below (see *Respiratory* proteins).

Many animal enzymes contain zinc ions, which are usually bound to the sulfur of cysteine. Horse kidneys contain the protein metallothionein, which, in addition to 2.2 percent zinc, contains 5.9 percent cadmium; both are bound to sulfur. A vanadium-protein complex (homovanadin) has been found in surprisingly high amounts in yellowish-green cells (vanadocytes) of tunicates, which are marine invertebrates.

Heme proteins and other chromoproteins. Although the heme proteins contain iron, they are usually not classified as metalloproteins, because their prosthetic group is an iron-porphyrin complex in which the iron is bound very firmly. The intense red or brown colour of the heme proteins is not caused by iron but by porphyrin, a complex cyclic structure. All porphyrin compounds absorb light intensely at or close to 410 nanometres. Porphyrin consists of four pyrrole rings (five-membered closed structures containing one nitrogen and four carbon atoms) linked to each other by methine groups (—CH=). The iron atom is kept in the centre of the porphyrin ring by interaction with the four nitrogen atoms. The iron atom can combine with two other substituents; in oxyhemoglobin, one substituent is a histidine of the protein carrier, the other is an oxygen molecule. In some heme proteins, the protein is also bound covalently to the side chains of porphyrin. Heme proteins important as respiratory proteins and enzymes are described below (see Respiratory proteins and Oxidoreductases).

Little is known about the structure of the chromoprotein melanin, a pigment found in dark skin, dark hair, and melanotic tumours. It is probably formed by the oxidation of tyrosine, which results in the formation of red, brown, or dark-coloured derivatives.

Green chromoproteins called biliproteins are found in many insects, such as grasshoppers, and also in the eggshells of many birds. The biliproteins are derived from tbe bile pigment biliverdin, which in turn is formed from porphyrin; biliverdin contains four pyrrole rings and three of the four methine groups of porphyrin. Large amounts of biliproteins, the molecular weights of which are about 270,000, have been found in red and blue-green algae; the red protein is called phycoerythrin, the blue one phycocyanobilin. Phycocyanobilin consists of eight subunits with a molecular weight of 28,000 each; about 89 percent of the molecule is protein. It also contains considerable amounts of carbohydrate.

Nucleoproteins. When a protein solution is mixed with a solution of a nucleic acid, the phosphoric acid component of the nucleic acid combines with the positively charged ammonium groups ($—NH_3^+$) of the protein to form a protein–nucleic acid complex. The nucleus of a cell contains predominantly deoxyribonucleic acid (DNA) and the cytoplasm predominantly ribonucleic acid (RNA); both parts of the cell also contain protein. Protein–nucleic acid complexes, therefore, form in living cells. It has not yet been definitely established whether the protein–nucleic acid complexes isolated from biological material are indeed formed during the life of the organism or whether they are artifacts produced during the isolation procedure.

The only nucleoproteins for which some evidence for specificity exists are nucleoprotamines, nucleohistones, and some RNA and DNA viruses. The nucleoprotamines are the form in which protamines occur in the sperm cells of fish; the histones of the thymus and of pea seedlings and other plant material apparently occur predominantly as nucleohistones. Both nucleoprotamines and nucleohistones contain only DNA.

Proteins of the tobacco mosaic virus

Some of the simplest viruses consist of a specific RNA, which is coated by protein. One of the best known RNA viruses, tobacco mosaic virus (TMV), has the shape of a rod. RNA comprises only 5.1 percent of the mass of the virus. The complete sequence of the virus protein, which consists of about 2,130 identical peptide chains, each containing 158 amino acids, has been determined. The protein is arranged in a spiral around the RNA core.

DNA has been found in most bacterial viruses (bacteriophages) and in some animal viruses. As in TMV, the core of DNA is surrounded by protein. Phage protein is a mixture of enzymes and therefore cannot be considered as the protein portion of only one nucleoprotein.

Respiratory proteins. Hemoglobin. Hemoglobin is the oxygen carrier in all vertebrates and some invertebrates. In oxyhemoglobin (HbO_2), which is bright red, the ferrous ion (Fe^{2+}) is bound to the four nitrogen atoms of porphyrin; the other two substituents are an oxygen molecule and the histidine of globin, the protein component of hemoglobin. Deoxyhemoglobin (deoxy-Hb), as its name implies, is oxyhemoglobin minus oxygen (*i.e.*, reduced hemoglobin); it is purple in colour. Oxidation of the ferrous ion of hemoglobin yields a ferric compound, methemoglobin, sometimes called hemiglobin or ferrihemoglobin. The oxygen of oxyhemoglobin can be displaced by carbon monoxide, for which hemoglobin has a much greater affinity, preventing oxygen from reaching the body tissues.

The hemoglobins of all mammals, birds, and many other vertebrates are tetramers of two *a*- and two β-chains (see Table 2). The molecular weight of the tetramer is 64,500; the molecular weight of the α- and β-chains is approximately 16,100. each, and the four subunits are linked to each other by noncovalent interactions. If hemin (the ferric porphyrin component) is removed from globin (the protein component), two molecules of globin, each consisting of one *a*- and one β-chain, are obtained; the molecular weight of globin is 32,200. In contrast to hemoglobin, globin is a rather unstable protein that is easily denatured. If native globin is incubated with a solution of hemin at pH values of 8 to 9, native hemoglobin is reconstituted. Both the hemoglobin of the lamprey (of the vertebrate class Agnatha) and the myoglobin, the red pigment of mammalian muscles, are monomers with a molecular weight of 16,000.

Mammalian hemoglobins

The mammalian hemoglobins differ from each other in their amino acid composition and therefore in their secondary and tertiary structure. Rat and horse hemoglobin cystallize very easily, but those of man, cattle, and sheep, because they are more soluble, are difficult to crystallize. The shape of hemoglobin crystals varies in different species; moreover, decomposition and denaturation occur at different rates in different species. It was also found that the blood of newborn children contains two different hemoglobins, about 20 percent of an adult hemoglobin (hemoglobin A) and 80 percent of a fetal hemoglobin (hemoglobin F). Hemoglobin F persists in the child for the first seven months of life. The same hemoglobin F has also been found in the blood of patients suffering from thalassemia, an anemia that occurs in the countries of southern Europe. Hemoglobin F contains, as does hemoglobin A, two a-chains; the two β-chains, however, have been replaced by two quite different γ-chains. When the technique of electrophoresis was first applied to the hemoglobin of Negroes suffering from sickle cell anemia in 1949, a new hemoglobin (hemoglobin S) was discovered. More than 100 different human hemoglobins now are known. They differ from normal hemoglobin A in the amino acid composition of either the a- or the β-chain.

The hemoglobins of some of the lowest fishes are monomers containing one iron atom per molecule. Hemoglobin-like respiratory proteins have been found in some invertebrates. The red hemoglobin of insects, mollusks, and protozoans is called erythrocruorin. It differs from vertebrate hemoglobin by its high molecular weight.

Although green plants contain no hemoglobin, a red protein, called leg-hemoglobin, has been discovered in the root nodules of leguminous plants. It seems to be produced by the nitrogen-fixing bacteria of the root nodules and may be involved in the reduction of atmospheric nitrogen to ammonia and amino acids.

Other respiratory proteins. A green respiratory protein, chlorocruorin, has been found in the blood of the marine worm Spirographis. It has the same high molecular weight as erythrocruorin, but differs from hemoglobin in its prosthetic group. A red metalloprotein, hemerythrin, acts as a respiratory protein in marine worms of the phylum Sipuncula. The molecule consists of eight subunits with a molecular weight of 13,500 each. Hemerythrin contains no porphyrins and therefore is not a heme protein.

Hemocyanin

A metalloprotein containing copper is the respiratory protein of crustaceans (shrimps, crabs, etc.) and of some gastropods (snails). The protein, called hemocyanin, is pale yellow when not combined with oxygen, and blue when combined with oxygen. The molecular weights of hemocyanins vary from 300,000 to 9,000,000. Each animal investigated thus far apparently has a species-specific hemocyanin.

CATALYTIC PROTEINS: ENZYMES

Crystalline urease and pepsin were the first enzymes shown to be pure proteins, free of any nonprotein material. It is now known that all enzymes are either pure or conjugated proteins. Enzymes can be defined as catalytically active proteins. In many enzymes that are conjugated proteins, the prosthetic group is the catalytically active site. The protein carrier of the prosthetic group is designated the apoenzyme. The International Union of Biochemistry (IUB) recommended in 1964 classification of the enzymes, according to their mode of action, into six classes: (1) oxidoreductases, (2) transferases, (3) hydrolases, (4) lyases, (5) isomerases, and (6) ligases, or synthetases. Each class is further divided in subclasses, sub-sub-classes, etc; for example, the oxidoreductases (class 1) are divided into 14 subclasses according to the chemical group that undergoes oxidation. The first subclass is further subdivided into four categories according to the electron acceptor involved. More than 600 enzymes were listed in 1964, and their number increases each year. Enzymes catalyze chemical reactions in which energy is released (exergonic reactions); they cannot catalyze energy-requiring reactions (endergonic reactions) unless energy is supplied by another reaction. The mechanism of many enzymatic reactions involves an activator; for example, the enzyme amylase, which catalyzes the hydrolysis of starch to smaller carbohydrate units called oligosaccharides, requires chloride ions (Cl^-) as an activator. The activators of oxidoreductases, usually called coenzymes, have complicated structures; they either accept or donate electrons during the catalytic process. The forces involved in the combination of an enzyme with the compound with which it acts (substrate) and with activators or coenzymes are the same as those that determine the conformation of proteins—*e.g.*, hydrogen bonds, electrostatic interaction between positively and negatively charged groups, and mutual attraction of nonpolar groups. Because each enzyme catalyzes a limited type of reaction and frequently reacts with only one substance, its active site is assumed to have a rather rigid conformation, enzyme and substrate fitting each other like a lock and key. Intermolecular forces can then induce a definite orientation of the substrate and render some of its groups more capable of undergoing chemical change; as a result, the reaction converting substrate into product can take place.

Oxidoreductases. Most oxidoreductases, usually called dehydrogenases, either have an iron-porphyrin as the prosthetic group or require a coenzyme. The specificity of enzyme action is determined by the apoenzyme (protein moiety). Almost 90 enzymes act on the alcohol group (—CHOH—); 70 require nicotinamide adenine dinucleotide (NAD^+) or its phosphate ($NADP^+$) as an electron acceptor. The electron acceptors in the others are either oxygen, ferricytochrome *c*, or an as yet unknown substance. Dehydrogenases also catalyze other types of reactions—the oxidation of aldehydes and ketones to carboxylic acids, the dehydrogenation of amino acids, and the oxidation of xanthine.

Some dehydrogenases have been isolated. Glyceraldehydephosphate dehydrogenase, the active site of which contains cysteine, forms about 10 percent of the soluble proteins of muscle. Lactate dehydrogenase contains four subunits in a molecule with a molecular weight of 150,000; the two types of subunits, α and β, exist in five different combinations, called isozymes. Each isozyme occurs in different tissues and has lactate dehydrogenase activity.

Not all dehydrogenations are mediated by the coenzymes NAD^+ and NADP', which are loosely bound to their apoenzymes. Another coenzyme that transfers electrons, riboflavin, is firmly bound to its apoenzyme. Accordingly, the enzymes are called flavoproteins, or yellow enzymes (*flavus* is the Latin word for yellow). The oxidation (dehydrogenation) of the L-amino acids and xanthine, a compound found in most body tissues and some plants, is catalyzed by flavoproteins.

Because tissues contain only limited amounts of coenzymes, a mechanism exists by which the hydrogenated (*i.e.*, reduced) forms can be reoxidized, so that they can accept more hydrogen. The mechanism involves the reduction of oxygen, the principal hydrogen acceptor in all organisms, to water. Oxygen does not react directly with reduced NAD or reduced flavoproteins; rather, hydrogen and electrons are transferred through a series of enzymes called cytochromes to oxygen. Cytochromes are typical heme proteins: the most thoroughly investigated one is cytochrome c from heart muscle. The complete amino acid sequence of a large number of cytochromes *c* of vertebrates, invertebrates, plants, protozoans, and bacteria has been elucidated (see Table 2); as a result, the evolution of the cytochrome c molecule has been clarified. Several other cytochromes are involved in the mechanism by which electrons are transferred from reduced NAD, reduced NADP, and reduced flavoproteins to oxygen (see METABOLISM).

Although most biological oxidations involved in metabolism require the re-oxidation of reduced coenzymes via a series of cytochromes, tyrosinase and similar copper-containing enzymes catalyze the direct transfer of electrons from phenol derivatives to oxygen, frequently forming hydrogen peroxide. The enzyme peroxidase catalyzes the transfer of hydrogen atoms from hydrogen donors to hydrogen peroxide. Catalase catalyzes the splitting of two hydrogen peroxide molecules into oxygen and water. Both peroxidase and catalase are heme proteins.

Function of some copper-containing enzymes

Transferases. Transferases catalyze the transfer of various chemical groups from one compound to another. Phosphate-transferring enzymes, or phosphokinases, for example, catalyze the transfer of phosphate from adenosine triphosphate (ATP) to a sugar or some other compound. One of the most thoroughly investigated transferases, ribonuclease (RNase), has a molecular weight of 13,700; it consists of one peptide chain, the complete amino acid content and sequence of which is known (see Table 2). The chain contains four disulfide bonds (—S—S—); when they are reduced to sulfhydryl groups (— SH), the enzyme is no longer active as a catalyst; activity can be regained by re-oxidation.

Hydrolases. Hydrolases catalyze the hydrolysis of ester bonds (between an acid and a base) in lipids, glycoside bonds (between sugar molecules) in carbohydrates, and amide or peptide bonds (in proteins, peptides, and a few other substrates such as urea). Many hydrolases can be isolated in large amounts and therefore have been investigated thoroughly, particularly enzymes that catalyze the hydrolysis of peptide bonds—trypsin, chymotrypsin, pepsin, and papain. The molecular weights (24,000, 24,300, 32,700, and 21,000, respectively) and the complete amino acid sequences of each have been resolved. Trypsin and chymotrypsin occur in the pancreatic juice in an inactive form called trypsinogen and chymotrypsinogen, respectively. The inactive form of pepsin, pepsinogen, is found in the gastric juice of the stomach. Papain is present in the juice of papaya fruit.

These proteolytic enzymes hydrolyze peptide bonds inside the peptide chain; however, the enzyme carboxypeptidase, which occurs in pancreatic juice, hydrolyzes the C terminal peptide bond; *i.e.*, the bond joining the amino acid with a free carboxyl group (—COOH) to the rest of the protein. The N terminal peptide bond—*i.e.*, the bond joining the amino acid with a free amino group (—NH_2) to the rest of the protein—is hydrolyzed by leucine aminopeptidase, which is found in the intestinal juice. Amide bonds (—CONH,) are hydrolyzed by asparaginase, glutaminase, arginase, and urease (molecular weight 480,000).

Little is known about the chemical structure and the active sites of the enzymes that hydrolyze glycoside bonds such as amylase, which hydrolyzes starch and occurs in saliva and pancreatic juice.

Lysozyme catalyzes the hydrolysis of the glycosidic bond between N-acetylmuramic acid and glucosamine in complex compounds called mucopolysaccharides. The molecular weight of lysozyme is 14,400; like ribonuclease, it contains four disulfide bonds in one peptide chain. Its amino acid sequence is known, and its conformation has been resolved by X-ray diffraction (see Figure 5). Enzymes that hydrolyze ester bonds include lipase, phospholipase A, and cholinesterase.

Structural features of lysozyme

Lyases, isomerases, and ligases. Lyases include a large number of enzymes that catalyze the cleavage of carbon–carbon, carbon–oxygen, and carbon–nitrogen bonds. Carbon–carbon bonds are split by the action of decarboxylases, which remove carbon dioxide from carboxyl groups. Amino acids are converted by bacterial decarboxylases into amines; thus, for example, the group —$CHNH_2$. COOH is converted into —CH_2NH_2 and carbon dioxide is released in the process. Carbonic anhydrase, a zinc protein, catalyzes the release of CO, from bicarbonate and thus enables the removal of CO_2 from man and other vertebrates.

Isomerases catalyze the conversion of various substrates into their isomeric (mirror-image) forms—for example, the conversion of L-alanine into D-alanine or vice versa (see Formula 4). The enzyme that catalyzes this reaction is called alanine racernase. The conversion of a-D-glucose into β-D-glucose is catalyzed by a mutarotase. Numerous other isomerases exist.

Ligases catalyze the formation of carbon–oxygen, carbon–sulfur, carbon–nitrogen, and carbon–carbon bonds. The formation of these bonds is an energy-requiring reaction that cannot take place without the simultaneous occurrence of an energy-releasing reaction. The latter is in most instances the conversion of ATP (adenosine triphosphate) into AMP (adenosine monophosphate).

PROTEIN HORMONES

Some hormones that are products of endocrine glands are proteins or peptides; others are steroids. (The origin of hormones, their physiological role, and their mode of action are dealt with in the article HORMONE.) None of the hormones has any enzymatic activity. Each has a target organ in which it elicits some biological action; *e.g.*, secretion of gastric or pancreatic juice, production of milk, production of steroid hormones, or the production of substances that cause dilation or constriction of blood vessels. The mechanism by which the hormones exert their effects is not yet fully understood. Cyclic adenosine monophosphate is involved in the transmittance of the hormonal stimulus to the cells whose activity is specifically increased by the hormone.

Functional aspects of hormones

Hormones of the thyroid gland. Thyroglobulin, the active groups of which are two molecules of the iodine-containing compound thyroxine (see Figure 1), has a molecular weight of 670,000.

Thyroglobulin also contains thyroxine with two and three iodine atoms instead of the four shown in Figure 1, and tyrosine, with one and two iodine atoms. Injection of the hormone causes an increase in metabolism; lack of it results in a slowdown. Another hormone, calcitonin, which lowers the calcium level of the blood, occurs in the thyroid gland. The structure of human calcitonin is given in Formula 7 (see Figure 1 for structures of amino acids corresponding to the one-letter codes).

The amino acid sequences of calcitonin from pig, beef, and salmon differ from human calcitonin in some amino acids. All of them, however, have the half-cystines and the prolinamide in the same position. Porcine calcitonin has been synthesized in the laboratory.

The parathyroid hormone (parathormone), which is produced in small glands that are embedded in or lie behind the thyroid gland, is essential for the maintenance of the calcium level of the blood. Its lack results in the disease hypocalcemia. Bovine parathormone has a molecular weight of 8,500; it contains no cystine or cysteine and is particularly rich in aspartic acid, glutamic acid, or their amides.

Pancreas hormones. Although the structure of insulin has been known since 1949, repeated attempts to synthesize it gave very poor yields because of the failure of the two peptide chains to combine forming the correct disulfide bridge. The ease of the biosynthesis of insulin is explained by the discovery in the pancreas of proinsulin, from which insulin is formed. The single peptide chain of proinsulin loses a peptide consisting of 33 amino acids and called the connecting peptide, or C peptide, during its conversion to insulin. The structure of porcine proinsulin is shown in Formula 8.

In aqueous solutions insulin exists predominantly as a complex of six subunits, each of which contains an *A*- and a B-chain. The insulins of several species have been isolated and analyzed; their amino acid sequences differ

Formula 8: The amino acid sequence of porcine proinsulin. The arrows indicate the direction from the N terminus of the B chain to the *C* terminus of the A chain. In the C peptide the N terminus is at the right (A = alanine) end and the *C* terminus is at the left end in order to show the connection with the A and *B* chains. Insulin is released when the two peptide bonds at the ends of the *C* peptide (broken lines) are hydrolyzed (broken by the introduction of a water molecule).

somewhat, but all apparently contain the same disulfide bridges between the two chains.

Opposite functions of insulin and glucagon

Although the injection of insulin lowers the blood sugar, administration of glucagon, another pancreas hormone, raises the blood sugar level. Glucagon consists of a straight peptide chain of *29* amino acids. Its structure, which is free of cystine and isoleucine, is given in Formula *9*. It has been synthesized; the synthetic product has the full biological activity of natural glucagon.

Formula 9: Amino acid sequence of the pancreas hormone glucagon.

Pituitary hormones. The pituitary gland has an anterior lobe, a posterior lobe, and an intermediate portion; they differ in cellular structure and in the structure and action of the hormones they form. The posterior lobe produces two similar hormones, oxytocin and vasopressin. The former causes contraction of the pregnant uterus; the latter raises the blood pressure. Both are octapeptides formed by a ring of five amino acids (the two cystine halves count as one amino acid) and a side chain of three amino acids. The structure of oxytocin is given in Formula *10*. The two cystine halves are linked to each other by a disulfide bond, and the **C** terminal amino acid is glycinamide. The structure has been established and confirmed. Human vasopressin (Formula *10)* differs from oxytocin in that isoleucine is replaced by phenylalanine and leucine by arginine. Porcine vasopressin contains lysine instead of arginine.

A Cys.Tyr.Ile.GluN.Asn.Cys.Pro.Leu.Gly($CONH_2$)

B Cys.Tyr.Phe.GluN.Asn.Cys.Pro.Arg.Gly($CONH_2$)

Formula 10: Amino acid sequence of the two similar hormones of the posterior lobe of the pituitary gland. (A) Oxytocin. (B) Human vasopressin. The solid line represents the disulfide bond between the two halves of cystine.

The intermediate part of the pituitary gland produces the melanocyte-stimulating hormone (MSH), which causes expansion of the pigmented melanophores (cells) in the skin of frogs and other batrachians. Two hormones, called α-MSH and β-MSH, have been prepared from hog pituitary glands. a-MSHconsists of *13* amino acids (see Formula *11*); its N terminal serine is acetylated (*i.e.*, the acetyl group, CH_3CO—, of acetic acid is attached), and its C terminal valine residue is present as valinamide. β-MSH contains in its *18* amino acids many of those occurring in α-MSH (see Formula *11*).

The anterior pituitary lobe produces several protein hormones—a thvroid-stimulating hormone, molecular weight *28,000;* a lactogenic hormone, molecular weight *22,500;* a growth hormone, molecular weight *21.500;* a luteinizing hormone, molecular weight 30,000; and a follicle-stimulating hormone, molecular weight *29,000.* The thyroid-stimulating hormone (TSH, thyrotropin) consists of a and β subunits with a composition similar to the subunits of luteinizing hormone. When separated, neither of the two subunits has hormonal activity; when combined, however, they regain about *50* percent of the original activity. The lactogenic hormone (prolactin) from sheep pituitary glands contains *190* amino acids. Their sequence has been elucidated; a similar peptide chain of *188* amino acids that has been synthesized not only has *10* percent of the biological activity of the natural hormone but also some activity of the growth hormone. The amino acid sequence of the growth hormone (somatotropic hormone) is also known; it seems to stimulate the synthesis of RNA and in this way to accelerate growth, The luteinizing hormone (LH) consists of two subunits, each with a molecular weight of approximately *15,000;* when separated, the subunits recombine spontaneously. LH is a mucoprotein containing about *12* percent carbohydrate. The urine of pregnant women contains chorionic gonadotropin, the presence of which makes possible early diagnosis of pregnancy. The amino acid sequence is known. The sequence of *160* of its *190* amino acids is identical with those of the growth hormone; *100* of these also occur in the same sequence as in lactogenic hormone. The different pituitary hormones and the chorionic gonadotropin thus may have been derived from a common substance that, during evolution, underwent differentiation.

Derivation of pituitary hormones

Peptides with hormonelike activity. Small peptides have been discovered that, like hormones, act on certain target organs. One peptide, angiotensin (angiotonin or hypertensin), is formed in the blood from angiotensinogen by the action of renin, an enzyme of the kidney. It is an octapeptide and increases blood pressure. Similar peptides include bradykinin, which stimulates smooth muscles; gastrin, which stimulates secretion of hydrochloric acid and pepsin in the stomach; secretin, which stimulates the flow of pancreatic juice; and kallikreine, the activity of which is similar to bradykinin.

IMMUNOGLOBULINS AND ANTIBODIES

Antibodies, proteins that combat foreign substances in the body, are associated with the globulin fraction of the immune serum (see IMMUNITY). As stated previously, when the serum globulins are separated into α-, p-, and y-fractions, antibodies are associated with the y-globulins. Antibodies can be purified by precipitation with the antigen (*i.e.*, the foreign substance) that caused their formation, followed by separation of the antigen–antibody complex. Antibodies prepared in this way consist of a mixture of many similar antibody molecules, which differ in molecular weight, amino acid composition, and other properties. The same differences are found in the y-globulins of normal blood serums. It is believed that the y-globulin of normal blood serum is a mixture of thousands of different y-globulins, each of which occurs in

Formula 11: The amino acid seauence of hormones produced by the intermediate part of the pituitary gland. The amino acid sequence, M.E.H.F.R.W.G. occurs in all melanocyte-stimulating hormones and in adrenocorticotropic hormones (corticotropins).

amounts too small for isolation. Because the physical and chemical properties of normal y-globulins are the same as those of antibodies, the y-globulins are frequently called immunoglobulins. They may be considered to be antibodies against unknown antigens. If solutions of y-globulin are resolved by gel filtration through dextran, the first fraction has a molecular weight of 800,000. This fraction is called IgM or γM; Ig is an abbreviation for immunoglobulin and M for macroglobulin. The next two fractions are IgA (γA) and IgG (γG), with molecular weights of about 300,000 and 150,000, respectively. Two other immunoglobulins, known as IgD and IgE, have also been detected in much smaller amounts in some immune sera.

γ-globulins of blood serums

The bulk of the immunoglobulins is found in the IgG fraction, which also contains most of the antibodies. The IgM molecules are apparently pentamers—aggregates of five of the IgG molecules. Electron microscopy shows their five subunits to be linked to each other by disulfide bonds in the form of a pentagon. The IgA molecules are found principally in milk and in secretions of the intestinal mucosa. Some of them contain, in addition to a dimer of IgG, a "secretory piece," the structure of which is not yet known. The IgM and IgA immunoglobulins and antibodies contain 10 to 15 percent carbohydrate; the carbohydrate content of the IgG molecules is 2 to 3 percent.

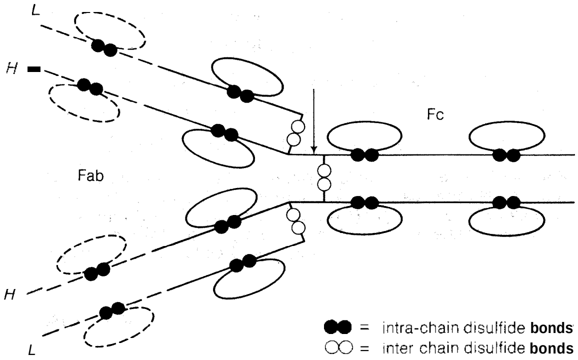
IgG molecules treated with the enzyme papain split into three fragments of almost identical molecular weight of 50,000. Two of these, called Fab fragments, are identical; the third is abbreviated Fc. Reduction to sulfhydryl groups of some of the disulfide bonds of IgG results in the formation of two heavy, or H, chains (molecular weight 55,000) and two light, or *L*, chains (molecular weight 22,000). They are linked by disulfide bonds in the order *L*–*H*–*H*–*L*.Each *H* chain contains four intrachain disulfide bonds, each *L* chain contains two. The structure of antibodies and normal immunoglobulins of the IgG type is shown in Figure 6.

Antibody preparations of the IgG type, even after removal of IgM and IgA antibodies, are heterogeneous. The *H* and *L* chains consist of a large number of different *L* chains and a variety of *H* chains. Pure IgG, IgM, and IgA immunoglobulins, however, occur in the blood serum of patients suffering from myelomas, which are malignant tumours of the bone marrow. The tumours produce either an IgG, an IgM, or an IgA protein, but rarely more than one class. A protein called the Bence-Jones protein, which is found in the urine of patients suffering from myeloma tumours, is identical with the *L* chains of the myeloma protein. Each patient has a different Bence-Jones protein; no two of the more than 100 Bence-Jones proteins that have been analyzed thus far are identical. It is thought that one lymphoid cell amona hundreds of thousands becomes malignant and multiplies rapidly, forming the mass of a myeloma tumour that produces one y-globulin.

Bence-Jones proteins

Analyses of the Bence-Jones proteins have revealed that the L chains of man and other mammals are of two quite different types, kappa (κ) and lambda (A). Both consist of approximately 220.amino acids. The N–terminal halves of κ- and A-chains are variable, differing in each Bence-Jones protein. The C–terminal halves of these same L chains have a constant amino acid sequence of either the κ- or the A-type. The fact that one half of a peptide chain is variable and the other half invariant is contradictory to the view that the amino acid sequence of each peptide chain is determined by one gene (see GENE). Evidently, two genes, one of them variable, the other invariant, fuse to form the gene for the single peptide chain of the *L* chains. Whereas the normal human L chains are always mixtures of the κ- and A-types, the H chains of IgG, IgM, and IgA are different. They have been designated as gamma (y), mu (μ), and alpha (α) chains, respectively. The N terminal quarter of the H chains has a variable amino acid sequence; the C terminal three-quarters of the H chains have a constant amino acid sequence, as indicated in Figure 6.

Some of the amino acid sequences in the L and H chains are transmitted from generation to generation. Thus, the constant portion of the human *L* chains of the κ-type has in position 191 either valine or leucine. They correspond to two alleles (character-determining portions) of a gene; the two types are called allotypes. The valine-containing genetic type has been designated as InV(a$^+$), the leucine-containing type as InV(b$^+$). Many more allotypes, called Gm allotypes, have been found in the gamma chains of the human IgG immunoglobulins; more than 20 Gm allotypes are now known. Certain combinations of Gm types occur; the combination of Gm types 5, 6, and 11 has been found in Caucasians and Negroes but not in Chinese; the combination of 1, 2, and 17 has not been found in Negroes; and the combination of 1, 4, and 17 has not been found in Caucasians. Allotypes have also been discovered to occur in rabbits, mice, and other animals.



L
H
Fc
Fab
H
L
●● = intra-chain disulfide bonds
○○ = inter chain disulfide bonds

Figure 6: Diagram of an IgG immunoglobulin. Two heavy chains (*H*) and two light chains (*L*) are linked to each other by inter-chain disulfide bonds. Intra-chain disulfide bonds cause loops to form in the 12 peptide portions, each of which contains about 110 amino acid residues. The 12 peptide regions have cystine residues at similar positions and other similarities in their amino acid sequences. The broken lines represent variable portions and the solid lines represent constant portions of the chains. Specific sites that bind antigens are formed by the variable portions. The vertical arrow indicates cleavage of the IgG molecule into two Fab fragments and one Fc fragment by the action of the enzyme papain.

It is understandable from the occurrence of a large number of allotypes that antibodies, even if produced in response to a single antigen, are mixtures of different allotypes. The existence of several classes of antibodies, of different allotypes, and of adaptation of the variable portions of antibodies to different regions of an antigen molecule results in a multiplicity of antibody molecules even if only a single antigen is administered. For this reason it has not yet been possible to unravel the amino acid sequence in the variable portion of antibody molecules. Much of the amino acid sequence in the constant regions of the *L* and H chains of man and rabbit immunoglobulins, however, has been resolved.

Protestantism

Protestantism, characterized by its belief in the doctrine of justification by grace through faith, the authority of the Bible, and the universal priesthood of believers, is (along with Roman Catholicism and Eastern Orthodoxy) one of the three major branches of Christianity.

This article is divided into the following sections:

NATURE AND SIGNIFICANCE

The origin and meaning of the term Protestant. The name Protestant was given to a collection of Christian parties at the Diet of Speyer, an assembly of the Holy Roman Empire, in Germany in 1529. It has since been applied to virtually all non-Roman Catholic Western Christianity. Though such a negative definition ("non-Roman Catholic") may be emotionally unsatisfying to Protestants, and though it may impart almost no clue as to the doctrinal substance of this branch of Christianity, it is perhaps the only terminology that is both inclusive and accurate.

Principle of protest

In theory, Protestantism has stood for a principle of protest that calls under judgment not only the beliefs and institutions of others but also one's own movements and causes. On those grounds, however, most students of Protestantism would recognize that the Protestant tradition has not been substantially more successful than have other faiths at remaining self-critical or at rising above institutional self-defensiveness.

Within the spectrum of non-Roman Catholic Western Christianity, a great variety of doctrinal views and polities have been expressed. Not all Western non-Roman Catholic Christians have been ready to be included in Protestantism. Some Anglicans and Lutherans, for instance, have been so eager to stress their continuity with the historic Roman Catholic Church and their distance from extreme Protestantism that they have asked for separate designations. Courtesy suggests that such appeals be taken seriously; however, ultimately habits of speech and sociological usage tend to predominate and, despite their protestations, these groups are usually included in the Protestant cluster.

Historical and cultural importance. However difficult it may be to define Protestantism, there are no problems in indicating its world-historical importance. The rise of the Reformers in the 16th century meant the beginning of the end of a unified religious force in the Western world. Never again could the civil and religious realms cohere on a transnational basis. The ancient spiritual centre of the culture had been criticized and questioned, and Western men could never again so easily unite on values as they had before the rise of Protestantism.

Hundreds of millions of people have found in Protestantism a means to express their faith. Whole populations (in Germany, Scandinavia, The Netherlands, the British Isles, and early America) have been termed "Protestant" by demographers. From these bases, Protestant culture has been transported, along with Western technology, capitalism, democratic government, and educational ideals, throughout the world.

The problem of an "essential" Protestantism

Those who argue that there is an "essential" Protestantism usually stress its witness to the gracious justification of man by God or to Protestant reverence for and submission to the Bible. Others point to its stress and enlargement of the role of the laity. Some parts of each of these teachings, however, are adhered to by many Roman Catholics and denied by many Protestants. It seems inadvisable, therefore, to speak of an essential Protestantism and instead more suitable to seek for unifying strands, positions of consensus, and varieties of historical manifestations.

HISTORY

The heritage of the magisterial Reformers (classical Protestantism). Protestantism is older than the Diet of Speyer. It has often been traced to some late medieval reformist elements in the Roman Catholic Church, among them the Hussites (followers of Jan Hus, 1371–1415) in Bohemia, the Wycliffites and Lollards (followers of John Wycliffe, died 1384) in England, and the followers of Girolamo Savonarola (1452–98) in Italy. These reformist beginnings were consolidated and advanced in the heart of the European continent in the second decade of the 16th century, when the Catholic monk Martin Luther (1483–1546) experienced a rediscovery of grace and began to propagate his teachings at the expense of his and others' loyalty to the existing Catholicism.

Almost simultaneously, Protestantism took rise in Switzerland, first under the efforts of Huldrych Zwingli (1484–1531) and his colleagues and later through John Calvin (1509–64). From there, Reformed Christianity spread to the Lowlands and to Scotland. In England, during the reign of Henry VIII (1509–47), submission to the pope was rejected, and the Church of England was born as still another manifestation of Protestantism, under the tutelage of Thomas Cranmer (1489–1556) and others. These men and hundreds of almost as well-known associates helped spread the Protestant movement into northern and central Europe and, a century later, to North America.

Rejection of the medieval Catholic system

At the heart of earliest Protestantism was a rejection of the medieval Catholic system, wherein men were regarded as having been brought back to God in part through their own merits and efforts and also through the mediation of a sacramental and clerical system. The Protestants wanted to see men free of that system, more immediately responsible to God, and freer to experience grace. The conservative Reformers at first trembled at what they were doing, fully aware of the personal risks involved as well as conscious of what they were doing to the fabric of social life and of inherited theology and piety. They believed that compensatory values were present, however: truth would be served even if old vows of obedience had to be broken.

These conservative Reformers, sometimes called "magisterial" (established), were often reluctant to push ahead. They engaged in prolonged efforts to make their early efforts intelligible to Rome and seemed genuinely reluctant to spawn separate movements in their own names. One by one, however, they were excommunicated or made uncomfortable in Roman Catholicism, or they saw that their doctrinal or ecclesiastical positions drove them increasingly from its sphere of influence. The Protestant movement thus evolved into groups of churches, often organized according to the outlines on the map of the modern nations that were beginning to be formed in that period.

Variations in forms of church government

Without recent precedent for their acts, they turned to the Bible for guidance about church governance. Some of them, the Anglicans in particular, retained bishops as part of the "apostolic succession" and thus shared some Roman Catholic views of church order. Lutherans ordinarily retained bishops, but on differing rationales, without always claiming the succession or arguing that episcopacy was essential to the life of the church. On Calvinist Reformed soil, the presbyterian order, also with biblical precedent, was established; in it, lay elders helped govern, and their "synods" allowed for common action between congregations. Still other Protestants, including most of those who belonged to the radical Reformation parties (*e.g.*, Anabaptists), considered that the only way to keep a pure church was to follow what they regarded to be the New Testament policy of having local control in congregations. The result was a crazy-quilt pattern of Protestant views of church authority, and non-Roman Catholic Christianity in the West was never able to resolve its differences or to find the kind of unity Roman Catholics had under the pope.

The heritage of the radical Reformers ("left-wing" Protestantism). Repudiation of the Roman Catholic sacramental system did not mean that Protestants would do without sacraments, but they never agreed on their meaning. This was typical of a fundamental problem that haunted the evangelical, or Protestant, parties: how sweeping should reform be? Some Reformers, psychologically attuned to people's love of tradition and habit, wanted to be moderate and to save everything they had known except that which manifestly stood in the path of the Gospel. The radical Reformers believed that the church of their day was grossly apostate and could not be rescued; instead, there was to be restoration or restitution of original and primitive (New Testament) Christianity.

The question of the extent of reform led to persecution within Protestantism, for the conservative parties tended to be established by the respective states and were embarrassed by their radical cousins as much as Catholic Christians were. They viewed the radicals as threats to both the civil order and their own ministries, and they made every kind of effort, including persecution and the making of martyrs, to bring the radical sectarians into line. Their efforts, however, were without consistent success.

Theological and social movements in Europe and the Americas that modified the Reformation heritage. Original Protestantism went through many developments. It is possible, however, to see considerable coherence from denomination to denomination on an international basis through more than four and a half centuries. To say that is to note that the Protestant witness is often shaped by "the spirit of the times" and that some common problems produced similar solutions that transcended confessional or creedal differences. A chronological survey of Lutheranism, then, would find many of the same kinds of forces present in differing epochs as would a comparable survey of Calvinism or Anglicanism. While it will be important through most of this article to concentrate on the original definitions and early transformations, a survey of these epochs or episodes will provide background for understanding Protestant development.

Influence of "the spirit of the times"

Reformation social movements. During the origins of Protestantism in the Reformation period there was an outbreak of reform and experiment. Sociologists of religion regularly note that the first generation of a movement often relies on the sometimes erratic, exciting words and actions of charismatic prophets who cannot give stability or provide settlement. In the case of Protestantism, this meant years of at first timid and then violent rejection of the church, of efforts at common work that were soon frustrated in competition of Lutherans versus Reformed, Continent versus England, and other rivalries. This was a period of polemics, of occasional vandalism and image burning, of called-for and aborted revolution (*e.g.*, the Peasants' Revolt of 1524–25 in Germany), and of a full range of options from a conservative tampering with liturgy to claims that new messiahs with special revelations were present.

By the middle of the 16th century there were attempts at political settlements of religious problems. Wherever in Europe the Reformation eventually prevailed, the classical Reformation churches (*i.e.*, Lutheran, Anglican, Reformed) early became well established, but some minor religious wars and some truces (*e.g.*, the Peace of Augsburg in 1555 or the Elizabethan settlement, beginning in 1559) were necessary before permanent forms could be recognized. The accent later fell on regularizing church order, developing hymns and liturgies, preserving the writings of the various Protestant founders, and learning responsibility for churchmanship.

Periods of Protestant orthodoxy, Puritanism, and Pietism. The end of the 16th century and the first half of the 17th was a period of another interterritorial and transconfessional phenomenon, a time of doctrinal definition. Even the radical Reformers, who were sometimes anti-intellectual in outlook, found themselves impelled to articulate their dogmatic positions. To a greater extent, men with a passion for orthodoxy and a love of intellectualization used the Protestant-dominated universities of northwestern Europe as a base for formulating creedal positions. As authors of huge, multivolume works of doctrine, they prided themselves on their ability to relate their Reformers' positions to the various philosophies then prevailing.

Intellectualization and piety

By the end of the 17th century in almost every Protestant region, reaction had set in. In England, Puritanism carried the Reformation further; it passed through a time of intellectualization toward a new kind of piety that often verged on mysticism. On Reformed and Lutheran soil the movement known as Pietism served as a counterpart to this phase of Puritanism. The Pietists, typified by the German Philipp Jakob Spener (1635–1705), were not ill at ease in intellectual circles. They even established universities of their own. But the Pietists undervalued intellect and made more of religious devotion and passion. Not eager to upset the whole established order, they did want to vivify it. Consequently they developed smaller, more intimate circles for prayer and worship. They learned to speak to each other of their hearts' concerns. They traded on the doctrine of the orthodox period but wanted to help produce new works of love. Significantly, they helped initiate the period of Protestant missionary and benevolent activities.

Rationalist and Evangelical Protestantism. Just as Pietism appeared almost wherever Protestantism did, so did its heir, its successor, and its competitor, Rationalist Protestantism. In Germany, men like the philosophers Gottfried Wilhelm Leibniz (1646–1716) and Gotthold Ephraim Lessing (1729–81) drew on Protestant resources. In The Netherlands, Hugo Grotius (1583–1645) had incorporated "natural law" philosophies into his Christian system. In England, the moderate Deists related positively to some forms of witness, and Anglicanism produced latitudinarian clerics---men of an Arminian persuasion (*i.e.*, adherents of the views of the liberal Dutch Calvinist Jacobus Arminius) who stressed the benevolence of the deity, the capability of man, the importance of morality and reasonableness, and the need for tolerance. Many of them occupied Anglican pulpits and even bishoprics, or taught in theological faculties. From the Pietist era they carried over a view that minimized doctrinal differences, but they were now much more interested in the mental and moral aspects of man's life than they were in his piety.

That late 18th-century form of Protestantism may have been more or less restricted to its clerical and theological leadership, but its viewpoint seeped into the broader streams of the laity. The subsequent Protestant phase, often called "evangelicalism," was a very widespread popular movement, attracting clergy and laymen of all Protestant communions. Evangelicalism reacted against the elitism of rationalism and the intellectualism of both orthodoxy and the Enlightenment.

Emphases of evangelicalism

Generally conservative in its theological position, evangelicalism emphasized doctrines concerning the person and work of Jesus Christ, particularly those dealing with his sacrificial death for man's experience of a relation in grace to God and his motive for Christian living. From Pietism it absorbed paradigms for humanitarian, benevolent, and missionary activity. This was the form of Protestantism that, beginning in Germany in the late 18th century, England in the 1790s, and the U.S. in the 1820s, went literally "into all the world" with its message. It was impelled by the new techniques of revivalism and gave birth to a new hymnody. The genius of the era was the British Anglican who came to lead Methodism, John Wesley (1703–91). Despite all the assaults of modernity, this movement lived on through the 19th century and has much influence even today.

Ecumenism ***and encounter with secularism.*** In the 20th century, however, the rise of still another international Protestant movement came into being, one which affected all the divided bodies. This was the tendency toward reunion, first of Protestant and later of all Christian churches, a tendency that was channelled into the ecumenical movement. In part the result of disaffection by Protestants with the undercutting of each other's mission, the ecumenical movement produced organizations such as the World Council of Churches and various national councils of churches and helped each confession (*e.g.*, Anglican, Baptist, Congregational, Lutheran) set its own house in order.

Goals of desacralization

At the heart of the Protestant world of thought throughout four and a half centuries, and especially in the recent past, has been the effort to come to terms with the complex process of secularization, which has sometimes been seen to be concurrent with Protestantism and, for many, to be in part the result of the Protestant impulse. The Protestant wanted to see the world disenchanted, or deprived of its magic and mystery, so that man under God could dominate creation and produce effects that would serve man.

It was the Protestant who often wanted to desacralize politics, which meant that he was ready to see the eventual end of the "divine right of kings" and was willing, as in the United States, to help write constitutions or charters for nations without employing positive references to deity. He did this not because he believed that God had nothing to do with the political order but because he had come to believe that coercive governments could not properly impose religious views or that religion was most healthy when it did not live off the support of the civil ruler.

These disenchanting and desacralizing movements evolved into a force that, much like Protestantism, claimed to stand in the biblical prophetic tradition. From there it learned to bring judgment on rulers, to counter ecclesiastical authorities, and to work critically for an improved world. The benefits of the secular movements have been balanced by liabilities and limitations, however. Secularization has led many persons to remove themselves from the sphere of Protestant interpretations of life, to drift from or to rebel against a witness to God, as Protestants have "traditionally" propagated this witness, or to lose themselves in worldly concerns that bring them beyond easy reach of Christian witness. The relationship of Protestantism to a secular world no doubt will remain a central issue in the future, and the terms for the relations will probably be set by the original witness of Protestantism in the 16th century.

TEACHING. WORSHIP, AND ORGANIZATION

Common principles, ideas, and practices of the magisterial Reformers and their successors. ***Justification by grace through faith.*** The original Protestant leaders united in their contention that what separated them from the Roman Catholicism of their day was their teaching that man is justified by grace through faith. Devotion to this teaching has been central to Protestantism throughout its history. Although there have been subtle variations in the differing Protestant church bodies, a central core of shared belief was at first easily discernible.

Concern for "justification"

Concern for "justification" was related to the obsession that the 16th-century person often expressed in terms of finding himself on good terms with God. He drew his metaphors from the courts of law. Aware of his shortcomings, his ignorance, his sin, and his guilt, he saw himself standing before a bar of justice presided over by God. Without help, he could expect nothing but God's wrath and condemnation. This meant that he would perish everlastingly, and his present life would be full of torment. Yet the Bible also presented him with a picture of a loving and gracious God, who may very well desire happiness for him. The question was: how could he be sure that God would reveal his gracious, and not his wrathful, side? How could he have the confidence that he was included in the positive loving action of God?

The teaching of the Reformers becomes most intelligible when seen over against the Western Catholic doctrines (*e.g.*, sin, grace, atonement), as they saw them. In the Protestant view, the late medieval Catholic teaching held that man was brought back to God only when so much grace had been infused into his soul that he merited the favour of God. God could not have been expected to accept someone who was unacceptable, but he could impart something that would make man acceptable. This something was grace, and its flow depended upon the merits of God's perfect Son, the man Christ Jesus. The church, according to medieval Catholicism, in a sense controlled the flow through the sacramental system and through its hierarchy. To the Reformers, the Roman Catholic sacramental system seemed to be part of a transaction that was always going on between man and God. In it, men made sacrifices designed to appease and please God. They would attend the mass, bring offerings, show sorrow, do penance—which might involve self-punishment or compensatory good works—until God would be gracious. The leaders of the church, from priests through bishops and popes, mediated the transaction. The Reformers believed that such an arrangement could easily be misused as a political instrument for forcing rulers to comply with the church's wishes and as a personal instrument for keeping people in uncertainty or terror. It was this vision of Catholicism that helped inspire the Protestant leadership to rebel and to define justification in other terms.

Influence of the writings of St. Paul

The terms for this Protestant teaching came from the Bible, especially from the New Testament, and even more so from the writings of St. Paul. In St. Paul they saw a religious hero and thinker who had endured a spiritual quest similar to their own. He could be described as having been brought up in a legalistic version of Judaism, a system in which he was constantly striving to please God by following his Law, particularly as set forth in the Old Testament through the Ten Commandments. Yet, Paul failed and was assailed by doubts about his worthiness and his salvation. His conversion meant a radical turning and a free acceptance of God's favour "in Christ." This meant that in faith man could be so identified with Jesus Christ that when God looked at him, he saw instead the merit that Christ had won through his self-sacrifice on the cross. God looked, in short, at the sinner; but he did not see the sinner. He saw his perfect Son. So he could declare the man righteous; he could justify him--even though the man was still a sinner.

When taken out of the historical context of St. Paul's teachings in the letters to the Romans or the Galatians and transferred to their own times, the Reformers' teaching of justification relied heavily on the work of the Holy Spirit. The Holy Spirit, in effect, made Christ's action contemporaneous with the sinner's quest. God was working now on behalf of the man in need. Through the preaching of the Word of God, man was exposed to the story of Jesus Christ's sacrifice and death. If he believed this historical narrative and, more importantly, if by the power of the Holy Spirit he believed that it was told and enacted for him, he stood before God in a new light. He did not have grace infused into him to the point that he became acceptable and pleasing to God. Instead, while man was still a sinner, God accepted him favourably and justified him. Christ's death on the cross was then the only "transaction" that mattered between God and man. The sacraments reinforced the relation and brought new grace, but no pretense was made that the human subject had achieved satisfaction before God or produced enough merit to inspire God to act.

Man's freedom and the problem of "good works"

In the Reformers' view, the new situation was one of freedom. Whereas Catholic man constantly stood in fear as to whether he had provided enough merits, had achieved enough good works, or had pleased the church as God's bargaining agent, the Reformers' version had man standing before God completely freed of these nagging questions. He was liberated both from the terrors of sin, death, and the devil, on one hand, and, on the other hand, from the enslaving pride that went with men's belief that they had achieved or at least had substantially cooperated in their own salvation.

This left the Reformers with a serious question, one to which their Roman Catholic opponents regularly referred. What had happened, in this teaching of justification and freedom, to the biblical accent on good works? Jesus himself, in the Synoptic Gospels (Matthew, Mark, and Luke), was constantly preoccupied with the effort of making men better, of having them bring forth "good fruit" and good works. Even Paul shared such concerns. Had the Protestant movement slighted these concerns in its desire to free man from the necessity of merits and good works?

The literature of Protestantism is rich in its expression of answers to such problems and questions. The Reformers were virtually unanimous: good works did not produce appeasement of God or salvation, yet they inevitably flowed from the forgiven heart and were always the consequence of the justified person's life. The Law of God could never be used as the saving path along which man walked, as a sort of obstacle path or road map to God. Instead, the Law of God measured man's shortcomings and judged him. A gracious God acting through his Gospel brought man back to him.

Man as simultaneously righteous and sinful

The Reformers' vision of man implied in such teachings was doublesided. They believed that from God's point of view, the justified man was so identified with Jesus Christ that he shared Christ's perfection. The same man, throughout all his life, left to his own devices or when seen by God apart from Christ's sacrificial work, remained a sinner of the worst kind. The difference came through God's gracious initiative; nothing that man did started the process of his justification. To the eyes of many in subsequent generations, the result was an apparently pessimistic and gloomy view of man's potential in Protestantism. His will was bound, apart from God's loving activity. He had no merits or good works that would satisfy God. Sometimes the phrase total depravity was used to describe his condition, though it must be said that the term had connotations in the 16th century that were different from those that it has today. It was used not so much to provide lurid connotations for descriptions of the depth of his sin but rather to describe its extent; man as a total being was in trouble. Even his good works, his piety, his religiousness, and his efforts, apart from justification by grace through faith, fell under God's curse. On the other hand, the justified sinner could be described in the most lavish terms, as one who could be "as Christ" or even sometimes "a Christ."

Those who have heard this Protestant teaching outlined through the centuries have regularly seen the difficulties it raises insofar as the portrait of God's character is concerned. Protestants never came up with logically satisfying answers to the resultant questions, though they were convinced that they were faithful witnesses to biblical teachings concerning the mystery of God's nature. The central question: if everything depended upon God's initiative and yet the majority of men are not saved, does this not mean that God is responsible for creating men only to have them suffer; is he not guilty of the worst kind of cruelty by being the sole agent of their damnation?

In facing the question, Protestant leaders differed slightly from each other. Some said that whenever men were saved, it was to God's credit; whenever they were lost, it was through their own fault. They were free to hear the Word; they were free to respond and accept the gift of grace in Christ; their own hardness of heart kept them from freedom and new life. Others ran the risk of presenting cruel pictures of God's nature and action, in their interest to witness to his sovereignty and initiative. The view that God predestined some men to be saved and others to be damned was called "double predestination." Some theologians argued that God did this predestining before men fell into sin; others saw it as a new act of God consequent upon man's fall. Those Protestant parties that were generally non-Calvinist in outlook were usually less systematic and less logical in their statements. The non-Calvinists taught a doctrine called "single predestination." They shared the Calvinists' affirmation of God's total responsibility for man's salvation; but they tended to be silent or to relegate to the area of mystery and unanswerable questions, the issue of how God could then be other than responsible for man's damnation. In general, the Protestants saw themselves to be more successful at preserving the teaching of God's sovereignty and the corollary of human helplessness than they were at making his character attractive to all. They saw themselves overcoming this problem in biblical terms by a stress on his loving relation to men in sending his own Son, Jesus Christ, to suffer for them.

Predestination

*The "priesthood of **all** believers."* If the teaching of justification had important consequences for the doctrines of God and of man in Protestantism, it had equal import for any statement of the meaning of the church and especially of clergy–laity relations. The medieval system, sacramental and hierarchical, in effect gave the priests a monopoly in monitoring the transaction between God and man. The Protestant teaching of justification broke this down and the Protestant leaders reverted to what they held to be the biblical view, that all believers have a share in spreading the word of grace and the acts of forgiveness. The result was an emphasis that stressed not the privileges of a priestly caste but rather "the priesthood of all believers."

The Reformers viewed this teaching as being based on the free-flowing sense of authority that existed between Christ and his Apostles, who had been pictured in the Gospels as being active apart from an elaborate clerical church order. At the same time, they believed that their doctrine would effectively displace the Roman Catholic hierarchical thought and action. Now all men were to be enjoined to take the responsibility for each other's salvation; any Christian man could represent the needs of all others before God. Originally the priesthood of all believers was basically an enlargement of the view that all Christians had intercessory powers, that they could all pray for one another. But it came to refer to the whole Protestant view of an equality of status between clergy and laymen and to the common calling of all Christians to be agents of God's Word and grace.

Priesthood and coresponsibility

The affirmation of the priesthood of all believers had widespread implications in society. In Protestant areas and nations the privileges of the clergy were limited and the scope of lay activity enlarged. All men shared a "vocation" (calling), and priestly vocations were not considered to be more meritorious or nobler than lay vocations. Monastic vocations were almost entirely swept away, and restorations of the monastic ideal have been rare and exceptional in Protestant history. Protestants kept, for the most part, a rite of ordination (though some Anabaptists dispensed with all acts that seemed to imply separation between a ministry of ordained persons and laymen) but did not regularly view it as a sacrament. That is to say, ordination conferred no special grace on men. In part, a ministry was kept on a pragmatic basis; the clergy were to tend to the business of studying and preaching the Word, properly administering the sacraments, and caring professionally for the health of the church. A set-aside ministry was also derived from biblical precedent in the Book of Acts and early Christian letters.

Protestants, while giving lip service to the equality of laymen and clerics in the priesthood of all believers, have not always seen themselves to be so successful in clarifying the laity's role. In most cases, laymen were not to be the preachers in public worship, and administration of the sacraments usually remained in clerical hands. By demanding of preachers expertise at expounding the Bible, Protestants often have made educational requirements a basis for ordained ministry, at the expense of a full lay involvement. Yet their views did greatly enhance both the theological and practical status of laymen, when contrasted to the situation in medieval Catholicism.

If all believers were priests, then no single church could monopolize the mediation of grace, since Protestants saw that there were believers in all churches, Roman Catholic and Protestant, Lutheran or Calvinist or Anglican. As a result, the teachings inherited from medieval Catholicism about the visible and the invisible church were called into question. To many Reformers, most notably Luther, the church was always visible because it was made up of

The visible and invisible church

people. But its limits and borders were invisible since one could not examine the heart of others to see exactly who were the true believers. This inability to define the boundaries of the church led other Reformers, among them Calvin, to continue to employ the distinction between a visible church and an invisible one, the latter referring to the people who were saved, even if they were in churches where full doctrinal purity had not been achieved. Men see the visible, humanly organized church of Christ, but they cannot simply identify this with the Bible's one, holy, catholic, and apostolic church, which is properly discerned only by God and hence invisible to men. The visible church, in the Reformers' view, almost certainly contained a mixture of members of the invisible church, on the one hand, and hypocrites, or false believers, on the other.

The Word of God and the Bible

Authority of the Word. Justification by grace through faith and the priesthood of all believers were affirmations that challenged the inherited Catholic views of authority because they undercut the monopoly of the hierarchy in the system of grace. Downgrading the medieval system of authority left a vacuum that Protestantism hastened to fill. Full of variety and pluralism as the movement was from the first, it was rarely characterized by a love of anarchy or indiscipline, and the Reformers set to work at once to establish the locale and extent of authority in the church and the believer's life. Almost unanimously, they saw final authority to reside in the Word of God, which tended in the minds of many to be simply equated with the Bible. The Protestant movement's need for authority enhanced its view of Scripture just as, one might argue, the rediscovery of scriptural teaching was seen to be the impetus behind the Protestant movement.

Later generations of Protestant thinkers sometimes resorted to scholastic philosophical definitions similar to those of the medieval Catholic theologians; in such definitions, justification became the material (or substantive) principle of the Reformation, while the matter of scriptural authority became the equally important formal (or structural) principle. In some epochs, debate about the nature of the Word of God or the Bible was even more preoccupying than was discussion of justification. Protestants often have portrayed medieval Catholicism as being a nonbiblical or even an antibiblical faith, one that denied the Bible to the laity. The expense of reproducing manuscripts led many libraries to chain books to the wall, and the Bible chained to the wall entered Protestant mythology as a symbol of the denial of lay access to the Bible in Roman Catholicism. In many circles, Protestantism has been celebrated as a religion of the "open Bible" in opposition to the closed book of Catholicism.

Interpretation of the Bible

Mythology aside, Protestants without exception concentrated on biblical teaching, and this led to a new passion for translating the Bible into the vernacular and disseminating it as widely as possible, an activity aided by the almost simultaneous invention of movable type and the resultant progress in printing technology. It was to be put into the hands of as many ministers and laymen as possible. Thus, they also had to be taught to read, and the Protestant movement claims some credit for hastening the modern impetus toward the ideal of universal literacy. While the Bible was ordinarily read in the churches and interpretation was shaped by the old and new traditions of these churches (Anglicans read the Bible's teachings on apostolic succession in a way different from that of Anabaptists, for example), what came to be called "the right of private judgment" was often exalted.

While Protestants could agree that the Word of God was authoritative in matters of faith and that the Bible as the book inspired by the Holy Spirit had unique status, they did not agree on all interpretations of the Scripture, nor did they unite in a single doctrine of scriptural authority. The Anabaptists, and later the Quakers, stressed an immediate experience of God and thus tended to qualify the impact of the Bible in shaping Christian life. But even among the Lutherans, Calvinists, and Anglicans there were differences of opinion about the Bible.

Latter-day Protestant Fundamentalists have argued that scriptural authority, if it is to be believable and if it is indeed the Word of an all-knowing, perfect God, dare not be described as including errors, even errors in historical or geographical detail. They have backed up this contention with citations from John Calvin and Martin Luther. At the same time, subsequent Protestant contenders for a more open and critical attitude toward biblical literature are equally capable of citing the Reformers — Luther, for example. Luther often spoke of the Bible as "the cradle in which Christ lies" and as a book that derives its authority from Christ and not from an a priori (presumed) doctrine of inerrant inspiration. So he could quite freely relegate some books of the Bible to secondary status or criticize the argument of others, even as he could complain of Paul's grammar or illogical argumentation, and point to errors of detail. Part of the confusion results from the fact that the Reformers in their era did not see questions regarding truth in the same terms as they have been recognized in the later scientific world, and, also, they could accept the full and governing authority of the Bible without elaborating theories concerning its perfection in detail.

De-emphasis of institutional bases of authority

The unquestionable elevation of the Bible as the authority in matters of faith led to a corollary downgrading of other authorities in the church. The hierarchy, and especially, the pope, were hardest hit, and papal authority was denied in almost every sector of Protestantism. More regard was paid, at least by conservative reformers, to the Fathers (doctrinal teachers and interpreters) of the early church, who were sometimes cited in the confessional writings of the various Protestant bodies. The Fathers were revered as guides rather than as final authorities. Similarly, a critical attitude toward councils of the church came to prevail. On the one hand, it was widely asserted that councils can and do err, and historical studies pointed to contradictions between various conciliar statements and to unsubstantiated assertions by past councils. On the other hand, many formulas and creedal statements of the ecumenical councils, particularly as these referred to the Trinity or to the Person and work of Jesus Christ, were highly regarded, and many Protestant churches took the chief creedal statements of past councils into their own official body of teaching.

Canon law, which was the inherited body of legal materials that regulated faith and morals, quite naturally also suffered because of the high regard for the Bible. In most Protestant circles, it was difficult to make legislation binding upon conscience unless it was based on clearly affirmed biblical legal teaching; more important, accent on the Gospel of grace led most Protestants to want to undervalue the whole role of law in the life of the church. At the same time, new church order soon developed, and it must be said that Protestants often acted as legalistically as did the Roman Catholics, whom they were repudiating. Most Protestant bodies, notably the Anglicans, developed their own versions of canon law or rules of church older and discipline.

Concern for further reformation

The ongoing reformation of the church. The church that is to be judged not by the pope but by a normative Bible, grounded in a priesthood of all believers, and critically affirmative of Church Fathers and councils and that rejects inherited codes of canon law differed vastly from medieval Catholicism. In few respects did it differ more than in its establishment of the principle of an ongoing reformation. While most of the Reformers, once established, tended practically to resist extensions of reformation that would jeopardize their status and definition, almost all Protestants, at least nominally, assented to the idea that "ecclesia reformata semper reformanda"—*i.e.*, that the church was always reformed and always in need of further reformation. The Protestant movement, then, was conceived as an unfinished product, constantly to be judged by a reading of the Bible, its polity continually subject to debate, its policy open to ongoing appraisal and change. It was in that climate that the sacramental teaching of Protestant churches was argued and developed.

Emphasis on *the* sacraments. On few points did Protestants disagree more than in their interpretation of the sacraments, but they did unite in their rejection of some aspects of Roman Catholic teaching. Since attack on the sacramental-hierarchical system of salvation was at the heart of their reform, almost nothing of it survived intact. In place of the churchly system, the new accent fell on the limitation of sacramental teaching to those acts clearly commanded by Christ and connected with his promise in the Scriptures. One can argue that, since "sacrament" was not a biblical term, the debate had to do simply with definitions. Most Protestants define sacraments, then, as acts that impart grace and the new life. They must combine the Word of God and some visible means (like bread, wine, and water); they must have been established by God and instituted by Christ. On these terms, five of the seven chief Roman Catholic sacraments failed to meet the definitional tests: marriage, ordination, confirmation, penance (now called repentance), and extreme unction (now called anointing of the sick). Not in every case did Protestants abolish these acts from their rites, but they ruled them out of consideration as sacraments. Thus the Protestant teaching on marriage was normally as "high" as Catholic doctrine, and it may be considered quasi-sacramental. But it was seen chiefly as a civil act blessed by the church, and it did not convey grace to the participants, nor was there a visible "means."

The sacraments commanded by Christ

Though Protestants—with a few exceptions, chiefly Anabaptist and Quaker—had little difficulty limiting the number of sacraments and perpetuating a high regard for those that survived the change in definition, they were far apart in their understandings of what went on in sacramental acts. Basically, three views were debated. To the "right," as one might call it, was the Lutheran view, which critics saw to be quite close to Roman Catholicism. Luther seemed to bring with him something of a medieval world-view, in which symbols of the material world were transparent to another invisible, divine order. This made it possible for him to make much of the material objects in the sacraments. When he connected them with biblical words, he was able to say of bread and wine that these are the body and blood of Christ, and of Baptism, that it effected a change in the believers' status before God.

At the "left" was the view of Huldrych Zwingli and other Swiss Reformers, who accented the spiritual side and downgraded the material. In some respects, they shared more of a modern view of matter and spirit, in which the symbols were opaque, disengaged from an invisible "other order." Such teaching meant that what mattered most in the sacraments was the following of Christ's commands, the reminiscence of his participation in the world of his disciples, and the spiritual intentions brought to the acts of believers. For Zwingli, the bread and the wine merely represented the body and blood of Christ, and Baptism was more a sign of a Covenant with God than a supernatural imparter of grace. Between the Lutheran and Zwinglian views were Calvinist and Anglican attitudes and definitions. All Reformers agreed in their criticism of the Catholic teaching called "transubstantiation," which held that the actual "substance" of the bread and wine in the Lord's Supper was turned into the body and blood of Christ. But they did not agree over the alternatives to that teaching, and debate over the sacrament did as much as any other theological factor to contribute to internal Protestant division.

Relationship between the community of the baptized and the political community. Equally varied were the attitudes toward civil authority among the various Protestant parties. Martin Luther expressed what in theory could have been a most radical theological view of the separation of civil and religious realms through his doctrine of "the two kingdoms." He could reduce his teaching virtually to an aphorism: God's Gospel ruled in the churchly realm and his Law ruled in the civil society. To rule the church by the Law or the civil realm by the Gospel would be to bring legalism to the sphere of grace and sentimentalism into the orbit of justice and thus dethrone God and enthrone Satan. In practice, however, the Lutheran Reformation worked to keep its ties to the civil order and was the established religion wherever it predominated in Germany and Scandinavia. In many territories, princes actually took on the superintending roles that bishops had known in Roman Catholicism.

Separation of church and state

John Calvin made less of a theoretical effort to separate civil and religious realms. For him, Geneva was to be a theocracy in which the saints would rule. God's covenanted community was to be based on his Law, as revealed in the Scripture. No detail of civil or community life was too remote, too secular, or too petty to escape inclusion by the Calvinists in the ecclesiastical sphere of supervision or regulation. Huldrych Zwingli taught a variation of this version, one that asked the Christian to be a zealot or patriot in the civil society—a teaching that he confirmed with his blood, for he was killed in battle in 1531. In the Anglican approach there was also no attempt to separate the civil and religious realms; in England the church was given the mandate to press conscientious matters upon the king and other civil authorities. These established Protestant views were to be subverted or countered by radical Reformers who did want a separation from civil spheres. These views were also constantly revised in later Protestant history, with the rise of the modern secular state.

Modes of expression of the ideas of the magisterial Reformers and their successors. Protestantism was forced to find means to propagate and sustain itself through time. Reformers had removed many of the inherited props or means and developed, within a century, parallel structures of most of those that had been repudiated along with Roman Catholicism. Lacking papal authority, canon law, and "international" connection with civil authority (as there had been in the old Holy Roman Empire), along with the binding power of church councils or a single philosophy on the basis of which to argue their case, they came up with alternatives or surrogates for most of these, though the new systems were more varied than the at least nominally homogeneous Catholic skein.

Most notable among the structural necessities was the formulation of "confessions," or creedal statements—and Protestants met frequently and regularly to write them—by which they could define their positions for the benefit of their adherents and their opponents. The Lutheran Augsburg Confession (1530), Reformed documents such as the Second Helvetic Confession (1566) and the Westminster Confession (1646), Anglican affirmations such as the Thirty-nine Articles (1563), and Anabaptist confessions such as that of Dordrecht (1632), all gave evidence of the Protestant impulse to define their positions. The Protestant leaders recognized that their movement could not long exist or continue with the fervour and ferment of first-generational impulses.

Protestant confessions

Confessions of the church appealed to the minds of theologians, the administrative passions of leaders, and the legalistic spirit of those who would impose them as doctrinal standards, but they did not warm believers' hearts. Thus Protestant leaders had to concern themselves with the affective side of church life in order to hold the attention of masses of people and to give them opportunity to express their faith and life in God. The chief instruments to achieve these aims were liturgies and hymns. The inherited liturgies included much of the Roman Catholic sacramental teaching. As such, they were given over too much to an accent on the sacrificial character of the mass and thus had to be purged. Conservative Reformers retained the shell, or outline, at least, of these formulas for worship, though they took great pains to bring both these outlines and the nuances of expression into line with what they considered to be a more evangelical teaching. Since worship is perhaps the chief public expression of gathered Christians, all Reformers had to give attention to its detail.

Liturgies and hymns

Martin Luther initiated the process with his ***Formula Missae*** ("Formula of the Mass") of 1523, a service which retained the Latin language; but he soon devised (in 1526) a ***Deutsche Messe*** ("German Mass"), ***a*** vernacular and folk expression of greater informality. At about the same time, Huldrych Zwingli was producing a Reformed order with two liturgies for the Word and the Lord's Supper in 1525, soon to be followed by Martin Bucer's (1491–1551) work on Psalms and church practice in 1539 and John Calvin's ***Form of Church Prayers in*** 1542 and 1545. Across the English Channel, the Anglicans were preserving stately forms of worship used in subsequent centuries, chiefly in ***The Book of Common Prayer*** of 1549 and 1552, and in Scotland John Knox helped formulate Presbyterian worship in ***The Forms of Prayers*** in 1556.

Emphasis on preaching

While Protestant orders were somewhat less ceremonial than the Roman Catholic liturgies they replaced, the human impulse to routinize ceremonies prevailed, and almost everywhere these forms for worship took on a more or less formal character. They differed from Catholicism chiefly in their elevation of the act of preaching the Word of God. Preaching was viewed as the means of grace whereby men were encouraged to repent and accept the grace of God through faith in Christ, just as the sermon was used to shape the community and give guidance for interpretation and action in life. For some, this accent on preaching meant a downgrading of the Lord's Supper; for others, there was to be a parity, with the sacrament providing a necessary parallel means of conveying grace. Communion "in both kinds," with reception of both bread and wine, prevailed (whereas in the Catholicism of the era of the Reformers, the cup was withheld from the laity), and, except in Anabaptist circles, the Catholic practice of infant baptism by means other than total immersion was retained. The Protestants, for the most part, took over existing Roman Catholic church buildings for worship, or they met in academic or civil halls or homes; but as time passed, they also took responsibility for erecting church buildings.

Hymnody played a major role in giving voice to Reformation sentiment, never more successfully than in the activity of Martin Luther, whose "A Mighty Fortress Is Our God" came to be called "the battle hymn of the Reformation." The Genevan Reformation and the Presbyterian churches in general tended to prefer simple and sometimes stolid hymnody in the form of rephrased and parsed psalms, such as ***The Genevan Psalter*** of 1563. The rejection of hymns and attention to sung versions of Scripture also prevailed in early Anglicanism, not so much because of principle but because of the failure of Anglican Reformers to devote themselves to the propagation of their movement through song. The great tradition of Protestant hymn writing developed later, in the 18th and early 19th centuries.

Systematic theologies and dogmatics

Liturgies and hymns appealed to the heart and soul, but Protestants also addressed the mind through an impressive outpouring of works in systematic theology and dogmatics. John Calvin was the supreme systematizer of first and second generation Protestantism, and his ***Institutes of the Christian Religion*** (1536) is a classic on even the shortest shelves of Christian doctrinal literature. Luther was, of course, a first-rate theologian, but he made less effort to be systematic, and his scores of volumes of theology usually grew out of comments on issues that agitated him or inspired or disturbed his movement at any moment. His disciple and colleague Philipp Melanchthon, in the ***Loci Communes*** of 1521, showed more systematic discipline.

In the 17th century the Protestant movement tended toward more rigid doctrinal expressions, as individuals interpreted the confessional statements of the earlier century with an almost fanatic attention to detail. Huge works of Lutheran and Reformed dogmatics poured forth from presses, most of them based on a kind of Protestant reversion to the type of scholastic philosophy that had prevailed in the late medieval period. Leaders in the period of Lutheran orthodoxy were Martin Chemnitz (1522–86) and Johann Gerhard (1582–1637); Reformed Orthodoxy was marked by the scholarship of Theodore Beza (1519–1605) or, in England, men like William Perkins (1558–1602). The ponderous and often lifeless writings of lesser orthodoxists than these were often expressions of internecine Protestant warfare, and the Reformation parties frequently used theology as an instrument of verbal warfare in that period. Debates raged over the sacraments, over the two natures of Christ, over the relations of ecclesiastical and civil realms, and over the part man played in salvation. Almost never did these debates lead to concord, and despite occasional irenic figures, such as Georg Calixtus (1586–1656) or Hugo Grotius, Protestantism was fated to remain divided, at least until the ecumenical movement in the 20th century began to produce new amity and common purpose or assent.

Common principles, ideas, and practices of the radical Reformers and their successors. The interpretation of Protestantism up to this point has been, with only a few noted exceptions, based on the majority view among the 16th-century Protestant movements. No single term adequately covers the Lutheran-Calvinist-Anglican complex, though "magisterial," "establishment," mainline," "conservative," and "classical" have frequently been applied to these movements. Of considerable parallel significance was the Protestant activity of another, and even more complicated, cluster of movements, for which also no single term can be agreed upon. Some historians speak of "the radical" Reformation or "the left-wing of the Reformation"; others have concentrated on components, such as the Anabaptist-sectarian or the spiritual-mystic or the rationalist-unitarian versions. In almost every case, these were the expressions of the economically and socially deprived classes in the 16th-century societies, though their latter-day heirs have sometimes known or sought the favour of civil authority and social arbiters.

The "radical" Reformation was radical in that it deliberately chose to repudiate as much as possible of traditional Roman Catholicism, in various acts of "restitution" of what it held to be the obscured and eclipsed but true original apostolic church. The "conservative" or "magisterial" Reformation, on the other hand, tended to keep whatever it could of the medieval ecclesiastical tradition and to affirm continuities in the life of the church wherever possible.

Problems of generalizations about the radical reform movements

The varieties of radical expressions are rich and bewildering. They grew in virtually every Protestant land, sometimes as an extension of the logic of the conservative Reformation but more often as original movements bearing a logic of restitution all their own. The radical Reformation also occurred in Catholic territories, such as Italy, where the mainline Protestant movement never knew much success. In Lutheran circles, men like Karlstadt (c. 1477/1481–1541) and Thomas Müntzer (c. 1490–1525) set out, in Luther's prime years, to shatter much of what he wanted to retain and to carry reform in new directions. Debates over the Lord's Supper and Baptism led to new radical movements in Switzerland, southern Germany, and Bohemia-Moravia. In Strassburg, a significant group of radicals, including Kaspar Schwenckfeld (1489–1561), Melchior Hofmann (died 1543/1544), and Sebastian Franck (c. 1499–c. 1542), gathered around 1529. The north of Germany and the Netherlands were havens of early Anabaptism (re-Baptism), and in the southern Netherlands, Menno Simons (c. 1496–1561) spread the movement that has come to be called Mennonitism. In Poland and eastern Europe, the radical Reformation often took spiritualist and unitarian (anti-Trinitarian) turns, as it did in Italy. "Radical reform" was also behind some of the Puritan and separatist movements in England. Because they were by nature competitive, free-formed, and varied, it is difficult to generalize about the radical Reformation movements, but some assertions common to major segments are possible, and the study of these movements is important because of the role they were to play in shaping modern Protestantism, especially as it developed in North America.

The gathered church. The radical Reformers were united in their opposition to established Protestantism's view of ecclesiastical continuity with the church of Christ in every age. The mainstream Reformers were radical in their rejection of what they regarded to be false teaching in the medieval church and almost never had kind words to say about any of its forms. But they did believe that God had kept a body of faithful teachers and respondents through the millennium or so after what they considered to be the "fall" of the church during the closing years of the Roman Empire, and this view of the succession of believers was integral to their doctrine of the church. Just as emphatic was rejection of this view in radical circles. Some radicals were willing and eager to trace a kind of continuity from John the Baptist down to the 16th century, but it was significant that they found virtually every evidence of true faith only in the sectarian movements that had separated themselves from official Roman Catholicism or that were condemned, harassed, and persecuted by Catholics. Among these were the Waldenses (a medieval religious movement espousing voluntary poverty and lay preaching); the Albigenses, also called Cathari (medieval sect espousing dualism and asceticism); some forms of Spiritual Franciscanism (branch of the Franciscan order espousing poverty); and other reform movements of the Middle Ages. Just as often, however, radicals taught that the true church had died not long after Christ and had to be restored as if from the foundation itself.

The "believer's church"

The repudiation of continuity was paralleled by rejection of a tie between the civil and ecclesiastical realms. The bond between these two, in the era of the Roman emperor Constantine (died 337), was viewed by the radical Reformers as the root of the church's fall and later vicissitudes or death. From that experience, it was argued, the church ought to have learned not to let the spiritual infection of political authority prevail nor to permit any one to be regarded as a member of the church without an explicit personal affirmation of faith. In a phrase that is often widely used, the church was to be "the believer's church," made up of assenting and consenting people of decision who chose to respond to God's Covenant. This view appeared in contrast to the view held by those who argued that Baptism of infants, who of course could not make personal decisions, conferred church membership and that, thus, virtually entire populations of territories could be members.

The keystone of the concept of the believer's church is that men voluntarily choose to be members. No one can be coerced into it nor can he become a member automatically, as it were, through a sacramental act. It was on this ground that infant Baptism was condemned by almost all radical Reformers. A result of this accent on voluntaryism has been a strong stress on the will of the believer and the giving of a voice to all believers in the questions of the governance and destiny of the church.

The theological counterpart to the teachings that disengaged radical Protestantism from Catholic continuity or established life was the view that no human authority determined modes of church life. The church is Christ's, and not man's. As such, it seeks to transcend territorial, racial, and ethnic bounds in theory, even if it is rarely consistent or successful in practice. As Christ's church, it is capable of representing him fully in each place, and thus local governance or authority, and even autonomy, was universally stressed.

The radical Reformation almost always restored the sense of an apostolate (missionary outreach); whereas the conservative Reformers had often neglected a sense of witness and missionary activity, and some even ruled it out from the church's present-day mandate. Anabaptists and spiritualists and "free" church (nonstate) advocates tended to be missionary, even if this meant a kind of subversion of established Protestant churches, filled as these were—in radicals' eyes—with unbelievers or inadequate believers.

Concern for the "last times"

Relationships between church and state. Churches as disengaged as these were from established structures were in principle devoted to, and in practice successful in adhering to, ideas that called for sharp distinctions between Christian and non-Christian, sacred and secular, religious and worldly life. This is not to say that radicals took no interest in the civil or social realm; they often did, indeed. But they brought a special viewpoint. They were "eschatological"; that is, they almost always were moved by dramatic views of the future, in which Christ would come again or the Kingdom or Day of the Lord would be announced to change everything. Worldly conditions were temporary and were judged by the saints as ephemeral and corrupting, even if they found it necessary to live with or to employ earthly instruments in the meantime. At the same time, for the sake of the freedom and purity of the believer's church, its members advocated separation from the civil realm, permitting no intrusion by civil authorities in church affairs and seeking no direct involvement in administration of the state by ecclesiastical figures.

Because many of the radicals believed that Christ's new order was imminent, they took a negative view of most human means of facing problems. Many of them advocated a rejection of warfare and saw in the Gospels a support of pacifist positions. The modern "peace church" witness of Mennonites, Brethren, and Quakers was born of this impulse. Paradoxically, other radicals (such as Thomas Müntzer) on occasion saw violence and warfare as legitimate means for them to help hasten Christ's new order.

Church discipline. Separation between the church and the world, and membership based on clear commitment, made it possible for radicals to insist on higher standards of church membership and stricter means of church discipline than could their magisterial counterparts. Social control was more feasible in these smaller and well-defined groups than in the established churches, and "the ban," as a form of excommunication, was the instrument which supported discipline. The use of the ban meant expulsion from the congregation of believers and, with it, social exclusion. The ban was not conceived as merely a punitive measure; brotherly admonition and discipline were to continue, with the hope that the wayward could be rescued.

Rejection of infant Baptism

Believers' Baptism. A special word must be said concerning Baptism since it gave its name Anabaptism to part of the movement and was one of the radicals' most dramatic points differentiating them from the rest of Protestantism. Infant Baptism, from the radicals' viewpoint, cheapened the standard of church membership and was not clearly designated or foreseen in the New Testament documents that chartered the church. Michael Sattler (*c.* 1500–1527), Menno Simons, and Balthasar Hubmaier (1485–1528) led the opposition to infant Baptism. Radicals would follow Jesus, who underwent Baptism as an adult, and they also would be "buried" (in water) with him, as St. Paul said baptized people would be. "New birth" would come from this act, and the reborn believers would restore the church.

Doctrine of the ministry. The concept of ministry was also changed more drastically in radical groups than in the more established Protestant circles. When priests became Lutherans, Calvinists, or Anglicans, there could be a rather subtle transition in their calling. The Anabaptists and spiritual Reformers, however, wanted a clean break with the past. The minister was viewed chiefly as a prophet, not as priest. As an agent of a new order, anticipating Christ's fulfilled Kingdom, he was not to care about earthly prerogatives or routines. Some men, such as Menno Simons, believed that the only way to take on the new ministerial vocation was to repudiate their Roman Catholic ordination. But such conversions from Catholic to radical clergy were rare, and the radical wing of the Reformation more frequently expressed its views on the ministry by simply placing a low valuation on ordination. The classical Reformers wanted university-trained, theologically expert ministers. The radicals, on the other hand, permitted laymen to be ministers: leaders such as Kaspar Schwenckfeld and Konrad Grebel (*c.* 1498–1526) were probably never ordained.

The suffering of persecution. The radical Reformation and the believer's church were made up of people who were prepared to suffer for their faith at the hands of both civil authorities and Catholic and other Protestant ecclesiastical leaders. The story of the rise of Anabaptism is one of persecution, of exiles and fugitives, and of a pilgrim church. The story of the rationalist form of Reformation, as in the case of Michael Servetus (anti-Trinitarian; *c.* 1511–53), often ended in something that can be called a Protestant Inquisition, in which men died for their ideas. Though some erratic personalities may have revealed a desire for martyrdom, more characteristic were those who upheld the idea of patterning one's life after Jesus, the great example. He had not known status or security and was eventually condemned to death; how could his true followers evade a similar path?

Doctrinal variations. Doctrinal varieties among the radicals were many, and it is hardly fair to cluster the various emphases. Certain features stand out, however. First of all, the role of Christ, central to Protestant Christianity, shifted subtly but significantly. The emphasis on Christ's priestly work, in which he brought sacrifice for men before the altar of God, was displaced by a new regard for his prophetic role. He had thundered against the powers of religion and civil society, against established forces, and against the rich; so would his followers. He was seen less as an agent in a divine-human transaction culminating in death on the cross as a sacrifice, and more as the supreme exemplar and leader.

Christ as the prophet and example

The radicals spoke critically of scholastic philosophy and the intellectualized theology built upon it, so they displayed a distaste for the more arcane expressions of classical theology. Faustus Socinus (1539–1604) in Poland and Michael Servetus in Strassburg became shapers of modern Unitarianism. They believed that the doctrine of the Trinity was an unscriptural abstraction and that simple monotheism could best be protected if Christ were not defined as a full expression of the Godhead. Unitarianism remained a distinctly minority emphasis in the radical Reformation. The Bible was usually highly regarded, but whereas the magisterial Reformers tended to see it in the context of tradition, the radicals stressed contemporary personal experience and often allowed for or claimed new special revelation.

PROTESTANTISM'S INFLUENCE IN THE MODERN WORLD

Influence on nationalism. Protestantism eventually became the majority faith throughout northwestern Europe and in England and English-speaking America. From there, in the great 19th-century Protestant missionary movement, it was carried into all parts of the world, joining Roman Catholicism as a minority presence in Asia and Africa and at the same time also establishing beachheads in largely Catholic Latin America. It is impossible to separate Protestantism from the general history of the North Atlantic nations, where it was firmly established for centuries and where its "free" churches or, after "separation of church and state," its voluntary churches, still predominated.

Thus it is possible to speak of Protestantism's contribution to modern nationalism, one of the major historic forces of recent centuries. It shared in shaping this force initially by helping bring to an end the Holy Roman Empire, which was disintegrating already at the time of the Reformation but which finally collapsed in 1806. The old *corpus Christianum* (body of Christ; *i.e.*, Christian society) did not survive; the Christendom initiated by the Emperor Constantine had not envisaged formal Christian division, and the presence of Protestantism spelled the doom of an international, transterritorial, unified Christianity under one head. Protestantism's desire to cultivate literacy and to spread regard for the vernacular served to remove the Latin linguistic bond of older Christendom and to encourage the rise of national boundaries based on languages. All but the radicals tended to make much of loyalty to the existing state, and Protestants often provided an ideological base for each new state as it rose to self-consciousness—as was the case in Prussia or in the United States.

Influence on social ethics. Similarly, many social thinkers, economists, and historians have discerned a much-debated "Protestant ethic," which purportedly had a decisive significance in forming modern attitudes toward raw materials, waste, production, and capital expansion. Max Weber (1864–1920) in *The Protestant Ethic and the Spirit of Capitalism* traced the roots of capitalism to those cities where Calvinism was strong. Today not many historians see such a simple connection: there has been capitalism before and apart from Calvinist influence, and Calvinism has not always produced capitalism. Still, in the Protestant doctrine of the "calling," wherein men at machines or desks could be fulfilling God's purpose as profoundly as did any monk or nun in a convent, men have seen the rise of a new seriousness toward work. In Protestant doctrines of the use of the earth and of stewardship, scholars have noticed a major contribution to the industrial ethos.

Positive concept of work

Influence on the arts. Protestant attitudes toward the arts have been ambivalent and therefore have produced mixed results. For the most part, Reformed and spiritualist Protestants have been uneasy about the arts, fearing lest the symbol be confused with the reality—and lest, therefore, the symbol be idolized and the reality forgotten. Thus Calvin and Zwingli found little place for the visual arts, though Luther showed interest and was a friend of some artists of his time, including Lucas Cranach (1472–1553). Luther also revealed a more affirmative attitude toward music than did the Swiss Reformers, though through the centuries most of Protestantism encouraged the use of music. When Protestant historians want to point to past glories in the aesthetic realm, they cite men like John Milton (1608–74) in literature, Rembrandt (1606–69) in painting, and Johann Sebastian Bach (1685–1750) in music, though such a group has few heirs in more recent centuries.

Ecumenical concerns. While it is clear that Protestantism by nature had to allow for great variety, not all Protestants have rested content with division and separation. They were caught between two biblical mandates. One commanded them to seek the truth and not to express full fellowship with those they considered to be in error. The other stressed the values of Christian unity as a witness in the mission of the church and as a foretaste of the eschatological, or fulfilled, life of Christians when, all agreed, they will all be one. The ferment of the 16th century and the doctrinal formulations of the 17th century led to ever-increasing divisions and hardening of lines or positions. The 18th-century Enlightenment, which in its British and German forms lived off and fought against Protestantism just as the French forms similarly related to Roman Catholicism, tended to breed a spirit of consensus. The Enlightenment placed an exceedingly high value on toleration of differences even as its spokesmen worked for agreement on doctrines based on a search for what they viewed as natural in reason and law. Such a tendency inevitably served to minimize doctrinal differences among Protestants.

Protestant discontent with division and separation

The 20th century, however, has seen more effort toward producing consensus than did the previous three and a half centuries. The modern ecumenical movement, today thoroughly Protestant-Catholic-Orthodox in its outlook, was first born and institutionalized on Protestant soil by men who saw the mission of the church frustrated by competition and division. Beleaguered, huddled together like sheep in a storm, to use a familiar picture, they sought each other's company.

At the same time, modern transportation and communication techniques effectively reduced their world and made uniting symbols accessible. A theological recovery was fused with a new vision of common tasks to produce a Protestantism eager for common statement and often for common action in an ecumenical era. The ecumenical movement has led to denominational mergers and to conciliar organizations, on both confessional and transconfessional lines.

In the meantime, the openness of Roman Catholicism, particularly exemplified in the career of Pope John XXIII (1881–1963), has led to new amity and concord between Protestants and Roman Catholics. In the last third of the 20th century, both of the old warring parties, without formally repudiating their polemical positions of the 16th century, have tended to move beyond its terms and to find new bases for meeting. Modern Catholic biblical commentators speak in what sounds much like Protestant terms of grace and faith. Protestants have new appreciation for a Roman Catholic view of the interconnectedness of the components of the church. More and more, Protestants view the Scriptures as rooted in a tradition and tradition as rooted in the Scriptures. Thus they have a new sympathy for Catholic views of tradition—even as some Catholics criticize unreflective responses to ecclesiastical authority on coercive lines in their own communion. Protestants and Eastern Orthodox Christians, generally quite spatially separated, have begun to understand each other through agencies and organizations such as the World Council of Churches.

CONCLUSION

"The end of the Protestant era"

In the latter half of the 20th century, many heirs of Protestantism, among them the philosophical theologian Paul Tillich (1886–1965), have begun to speak of "the end of the Protestant era," or of the times as being "post-Protestant." This does not mean that they all waver in their faith in Protestantism's general witness. Tillich, for one, argued that "the Protestant principle" of prophetic criticism had to be included in any authentic expression of church life and that it was a genuine value in the secular world. But these thinkers believed that the cultural dominance of Protestantism on its own historic soil was waning.

Emerging at the time of the Renaissance and developing during the Enlightenment, the adherents of Protestantism saw their thought-world repeatedly challenged from without. During the 19th century, with the rise of industrialism and urbanization, a changing world presented new problems to "sociological Protestantism." Meanwhile, ideologues, some of them avowed "god-killers," rose up on Protestantism's territory to challenge its deepest beliefs: the economic theorist Karl Marx (1818–83), the evolutionary theorist Charles Darwin (1809–82), and the philosophical nihilist Friedrich Nietzsche (1844–1900), to take three examples, were thoroughly at home with the Protestant experience and used it as a foil to develop many of their own views.

In the 20th century, Protestantism has become uncertain about its "foreign mission" of expansion in a postcolonialist, anti-imperialist world. The modem appreciation for values in non-Christian religions has led many Protestants to adopt positive attitudes toward these at the expense of the desire to extirpate or displace them with an expanding Protestantism. Totalitarian forces, particularly in Nazi Germany, absorbed some Protestant emphases and changed them beyond recognition, or they persecuted those Protestants who radically opposed suppression.

The attractions of modern life, secularization, and a crisis of faith, all have contributed to a general Protestant decline, beginning with a measurable decrease in church membership, first on the Continent in the 19th century and then in England around the turn of the century. Therefore, while huge majorities of the population (as in Scandinavia and England) are baptized members of established Protestant churches, only a small percentage of these are attendants at worship services or responsive to the disciplines and mandates of the church. Those who use church attendance and support of ecclesiastical appeals as indicators of Protestant fortunes unite with those who see that Protestant dogma no longer defines belief, nor do its divisions any longer excite Western man—and then note the end of the Protestant era.

On the other hand, Protestantism is deeply integrated into so many elements of Western culture that it can be expected to continue to assert subtle influence. It has experienced ebb and flow or revival and decline periodically and now may be going through an extended period of decline. At the same time, it lacks little so far as devoted members in many parts of the world are concerned, and they may rally as they have in the past to spread their version of belief in Christ and their loyalty to a Christian way of life.

Protestantism, History of

Protestantism, beginning in northern Europe in the early 16th century in reaction to medieval Roman Catholic doctrines and practices, became, along with Roman Catholicism and Eastern Orthodoxy, one of three major forces in Christianity. After a series of European religious wars, and especially in the 19th century, it spread rapidly in various forms throughout the world. Wherever Protestantism gained a foothold, it influenced, to a greater or lesser extent, the social, economic, political, and cultural life of the area.

This article is divided into the following sections:

I. "Protestantism"

MEANING OF THE TERM

Origin of the term Protestant

Protestantism, one of the three major branches of Christianity, was given its name at the Diet of Speyer in 1529. At that imperial assembly the Roman Catholic princes of Germany, along with the Holy Roman emperor Charles V, rescinded most of what toleration had been granted to the followers of Martin Luther three years earlier. On April 19, 1529, a protest was read against this decision, on behalf of 14 free cities of Germany and six Lutheran princes, who declared that the decision did not bind them because they were not a party to it, and that if forced to choose between obedience to God and obedience to Caesar they must choose obedience to God. They appealed from the diet to a general council of all Christendom or to a congress of the whole German nation. Those who made this protest became known as Protestants. The name was adopted not by the protesters but by their opponents, and gradually it was applied as a general description to those who adhered to the tenets of the Reformation, especially of those outside of Germany. In Germany the adherents of the Reformation preferred the name evangelicals and in France Huguenots.

The name Protestant was also attached not only to the disciples of Luther (*c.* 1483–1546) but to the Swiss disciples of Huldrych Zwingli (1484–1531) and later of John Calvin (1509–64). The Swiss Reformers and their followers in Holland, England, and Scotland, especially after the 17th century, preferred the name Reformed.

VARIOUS USES OF THE TERM

In the 16th century the name Protestant was used primarily in connection with the two great schools of thought that arose in the Reformation, the Lutheran and the Reformed. In England in the early 17th century the word Protestant was used in the sense of "orthodox Protestant," as opposed to those who were regarded by Anglicans as unorthodox, such as the Baptists or the Quakers. Roman Catholics, however, used it for all who claimed to be Christian but opposed Catholicism (except the Eastern churches). They therefore included under the term Baptists, Quakers, and Catholic-minded Anglicans. Before the year 1700 this broad usage was accepted, though' the word was not yet applied to Unitarians. The English Toleration Act of 1689 was entitled "an Act for exempting their Majesties' Protestant subjects dissenting from the Church of England." But the act provided only for the toleration of the opinions known in England as "orthodox dissent" and conceded nothing to Unitarians. Throughout the 18th century the word Protestant was still defined in relation to the historical reference of the 16th century Reformation. Samuel Johnson's dictionary (1755), which is characteristic of other dictionaries in that age, defines the word thus: "one of those who adhere to them, who, at the beginning of the reformation, protested against the errours of the church of Rome."

II. The Reformation period

THE IMPULSE OF THE REFORMATION

The role of Luther. In 1517 Martin Luther published at Wittenberg his Ninety-five Theses on the subject of indulgences (the remission of temporal penalties for sins) and other matters, arguing that an external act, such as buying an indulgence, could never be a substitute for inward penitence. Since the theory of indulgences rested upon the authority of the pope, an attack upon them soon broadened into an attack upon the pope's particular claims to authority. Germany was full of discontent against papal interference, and the German people rose in support of Luther.

The person of Luther was a key to understanding the way in which Protestantism developed, for his experience conditioned Protestant theology. Before 1517 he had attempted faithfully to practice the life of a monk but had found that his efforts brought him no peace of soul. By the study of St. Paul and St. Augustine he was led to an ever-growing trust in God's help and an ever-growing distrust of his own efforts. Between 1512 and 1518 (probably in 1512) he had an experience in the tower of the Austin Friars at Wittenberg in which he apprehended the full force of St. Paul's text (Rom. 1:17): "The just shall live by faith." Henceforth justification by grace through faith was to be the doctrine central to Luther and thereafter to the Protestant churches. Almost all forms of Protestantism have repudiated doctrines such as merit or works of supererogation, which implied that a man could by good conduct set up claims upon God or win his own way toward heaven.

Importance of doctrines of justification and the authority of the Bible

The role of the Bible. The Protestant churches appealed to the Bible and the primitive church and therefore aimed in a measure to imitate, whether in ministry, or in organization, or in simplicity of worship (Lutherans and Anglicans, however, made little effort to imitate the primitive church in worship), what they took to be the conditions of primitive Christendom. They aimed to purify and simplify the church; but for all their use of the word reformation, which suggested a looking back, they looked forward toward a time of what they believed would be purer sacraments, devout preaching, godly ministry, and moral conscience among Christian people. Though Luther and Calvin aimed primarily at a doctrinal reformation, a drive toward what they thought to be a better morality, both private and public, was the most marked feature of other leaders of the Protestant movement of the 16th and early 17th centuries. Protestant emphasis was on the reconciliation of men not by their own endeavours but by God's help, which was granted to them through what Christ had done and suffered and received through the willing assent of the heart. Protestants had a deep sense of the sinfulness of the human race, of its fearful predicament before the judgment of God, and of its powerlessness to save itself.

Protestantism made its basic appeal to the Bible as the ground of its belief. In the early 17th century the English theologian William Chillingworth defined it thus: "By the religion of Protestants I do not understand the doctrine of Luther, or Calvin, or Melanchthon . . . nor the articles of the Church of England; no, nor the harmony of Protestant Confessions; but that wherein they all agree . . . that is, the Bible." It is true that the varieties of Protestants have included thinkers who would not quite accept Chillingworth's definition. But the common factor in Protestantism has been the acceptance of the supremacy of the Bible over the churches; the belief that ecclesiastical ministries or hierarchies were to be tested against the Bible as the word of God; the doctrine that all things necessary to salvation were to be found in Holy Scripture; the belief, summarized in the phrase "priesthood of all believers," that truth may not be with constituted authority but with the ordinary soul quietly following the leading of God.

This led to a flowering of biblical commentaries and exegetical, or interpretive, works. Luther and Calvin were famous for their commentaries upon books of the Bible. Luther finished a translation of the Bible into German in 1534, and that version was important in the further development of the German Reformation and in influencing Protestant translations into other languages (Danish, Swedish, Dutch, Lithuanian, and English).

Emphasis on the sermon and education

Protestants laid much emphasis on the delivery of the Word of God to the people, and the sermon became a most important part, sometimes the most important part, of every Protestant act of public worship. The major Reformers placed much stress upon education and from the time of Luther onward emphasized catechisms—*i.e.*, classes before confirmation—and the common devotional study of the Bible. Martin Bucer (1491–1551), the Reformer of Strassburg, introduced confirmation as a formal act, after a period of preparation, in which the vows taken on behalf of an infant at Baptism were renewed. The Reformers also sought to take the Bible into the household and, with their belief in the priesthood of the laity, created family prayers in middle-class homes.

THE ESTABLISHMENT OF THE REFORMATION CHURCHES, 1521–80

The development of territorial churches. In the early days of the Reformation period, the Protestant states were saved from suppression because they could have been suppressed only if the Holy Roman emperor in Germany had been given power to suppress them, and many rulers who were not Protestants---other German princes, the king of France above all, and even at times the pope himself—were afraid to give any German ruler such vast powers.

Between 1521 and 1580 most of northern Europe became Protestant. The strength of the movement lay in the educated middle classes and the tradesmen of the towns, for many inhabitants of which the Renaissance and northern humanistic studies had made some of the traditional practices of the medieval church appear to be superstition or magic. The cities of Germany and Switzerland—Nürnberg, Bern, Geneva, Zurich, Strassburg—were free cities and among the earliest to go Protestant. By 1539 a league of Protestant States included Saxony, Brandenburg, Prussia, Württemberg, Hesse, Brunswick, Anhalt, and half of Switzerland. By 1560 Protestantism carried England and Scotland, Sweden, Norway, and Denmark and looked as though it might soon include France. From 1565 on there was a possibility of a Protestant Netherlands, and Protestantism was spreading rapidly in Austria, Bohemia, Poland, and Transylvania. Between 1521 and 1580 the Protestant map of Europe was drawn, almost as it has re-

Advances and retreats of Protestantism

mained. It suffered its severest setbacks in France (where long civil wars prevented the Huguenots from becoming more than a minority but where they were able to achieve toleration by the Edict of Nantes (1598), in the southern Nethlerlands (Belgium) and the nearby prince-bishoprics of the Rhineland (which Spanish troops helped to preserve for Catholicism), in Austria and Bohemia (where the Thirty Years' War—1618–48—forcibly re-Catholicized those regions), and in Ireland (where the Irish population identified resistance to Protestantism with resistance to the English). In Spain and Italy, though some distinguished converts were made, Protestants never constituted more than a few small groups. In the Eastern churches Protestantism affected only a few theologians who had been educated in the West, especially Cyril Lucaris, the patriarch of Constantinople who was murdered in 1638.

From the earliest years of the Reformation, Protestants were divided primarily into Lutheran and Reformed groups. Lutheran states included Sca'ndinavia, north Germany, and Wiirttemberg. Reformed states included Holland, Scotland, and French cities of the Huguenots. England was Reformed for the most part but suspected by other Reformed churches as leaning too much towards the Lutherans.

Ecclesiastical reforms of the Reformation churches (16th to the early 17th century). ***Worship.*** Luther and his colleague Philipp Melanchthon (died 1560) were conservative in their ideas of reform. They had little sense of a breach with the church of the past and thought of themselves as purifying it from abuses. The Lutheran liturgies were merely simpler forms of the Latin mass, and for a time some of them retained the Latin language in parts of the service. In their worship, Lutherans emphasized the doctrine of the Real Presence (of Christ) in the sacrament of the Lord's Supper.

Zwingli, the Reformer of Ziirich, however, held that what was not in the Scripture was not permitted. The forms of prayer in Swiss Reformed churches were simple—readings, prayers, sermons, psalms. The psalms were at first said, not sung, but metrical versions of the psalms with tunes were soon introduced. A French version of the psalms by Clément Marot (c. 1497–1544) and the English version by Thomas Sternhold (died 1549) and John Hopkins (died 1570) became the hymnbooks of the Reformed congregations. A simple and austere congregational worship, suspicious of ritual as a way toward formalism, became a major characteristic of Reformed Protestant worship. Lutherans, however, had a hymnody that did not confine itself to the psalms. Luther wrote 37 hymns and hymn singing became a moving feature of worship in Lutheran churches. The congregational hymn or psalm was a distinctive innovation made by Protestants in Christian worship. More than any other development, it transformed the character of lay worship.

Organization. Besides their forms of worship, another difference between Lutheran and Reformed churches lay in their views on church organization. Churches were reformed by governments (princes or city councils), though they often acted in response to a popular movement. The necessary legal changes required that governments intervene. All Protestant states dissolved monasteries and nunneries and discouraged or suppressed the monastic life; and since the monasteries possessed land and endowments, government had to deal with the legal and personal consequences.

One of the fundamental consequences of the Reformation was the diminution of the legal force of Canon Law when Protestant states declared that no outside authority (church, bishop, or pope) had the power to make laws binding upon some of its subjects without the consent of the government of that state. Thus the Protestant movement not only depended for its success upon the development of the modern sovereign state but by its success assisted that development.

The development of the consistory and presbytery

Where the prince, as in Luther's Saxony, actually took charge of the Reformation, the device for reorganizing the church was called the consistory (an ecclesiastical court of law), whose members were appointed by the prince, sometimes with the prince as its chairman, and which usually consisted of lawyers and clergy in equal numbers. In the German states the consistory became the supreme court, appointing clergy, visiting parishes, and reorganizing church life. In a free city the city council, as in Zwingli's Ziirich, took charge of the Reformation. The city council itself acted as the government of the church as well as of the state.

In Geneva, however, Calvin argued that this mode of church government was unscriptural, that although the government of the state was indeed an instrument of God, the government of the church was divinely ordered in the Scriptures and was not the same thing. God, he asserted, had established the offices of pastors and elders as authorities in the congregation; and these pastors and elders had rights in the government of the congregation that no civil authority could overrule. Thus the Calvinist consistory, though called by the same name as the Lutheran, was an entirely different body; it was created by the pastors and the congregation as a Christian and spiritual, but not as a civil, body, with supreme authority in all spiritual matters--especially moral rebuke and excommunication. This was the basis of the Presbyterian system of church government as it came to exist among all the disciples of Calvin—in Scotland, the Netherlands, some of the German cities in the northwest, the Palatinate after 1570, and the French Huguenots. It became the characteristic organization of Reformed Protestantism, based upon a scriptural authority, strong in its own authority, and yet relying upon an element of Christian democracy.

In Sweden, as in England, the monarchy retained the supreme power in the church and it also retained the bishops. There was, therefore, no normal consistory in Lutheran Sweden. The same, or similar, condition existed in Denmark and Norway.

The development of English church government

The English Reformation was different. There, King Henry VIII, between 1533 and 1547, tried to maintain Catholicism without the pope, dissolved the monasteries or forced them to dissolve themselves, introduced Bibles into the churches, and elevated a scholarly and hesitant Protestant, Thomas Cranmer (1489–1556), as archbishop of Canterbury. Under Henry's successor, Edward VI (1547–53), the Council reformed the church, inclining more toward the Swiss pattern of reformation than to the Lutheran, with a simplified liturgy, a transformed appearance in churches, and a belief in the symbolic presence of Christ in the bread and wine in the Lord's Supper. Protestantism, however, was not yet a popular movement in England and went little deeper than the city of London, the universities, and the merchant class. Under Edward's successor, Mary (1553–58), England submitted without enthusiasm to the Pope, and Cranmer, Hugh Latimer (*c.* 1485–1555), Nicholas Ridley (c. 1503–55), and several other leading Protestants were burnt at the stake. When Elizabeth (1558–1603) ascended the throne, the country was finally Protestant. But the previous swings in public opinion, the Queen's personal position, and the desire not to offend Spain and the more conservative reformers in Germany meant that the Reformation under Elizabeth allowed room for both Catholic and reformed elements. A growing body of English Calvinists, drawing strength from communications with Geneva, the Palatinate, Holland, and Scotland, became discontented with the Catholic inheritances preserved in the worship services and the office of bishops and led directly to the Puritan and separatist movement in England.

The development of the congregation

Though not recognized by the established Protestant bodies, another organizational form appeared—the congregation. In the congregation a group of men and women came together, elected their own pastor or dismissed him, organized their own worship, studied the Scriptures themselves, and remained sovereign, as a democratic group, over their own church life.

In Germany and Switzerland in the 16th century these congregational groups were loosely called Anabaptists (rebaptizers). Organized in small groups, they were usually agreed upon denying the validity of infant Baptism, upholding the sovereignty of the congregation, and declaring that the congregation must have nothing to do

"The Massacre of St. Bartholomew's Day," oil painting by François Dubois (1529–84). The Huguenot leader, Gaspard de Coligny, is shown twice, hanging from a window of his house and lying beheaded in front of the house with the Duc de Guise standing over him. with the civil magistrate. They were world denying, and usually pacifist, in their way of life. In the 16th century, however, many groups of dissenters were called Anabaptists, whatever their doctrines or practices might be, and under this name were heaped together persons holding mystical doctrines, such as Kaspar Schwenckfeld (1489–1561) and Hans Denck (1495–1527); those who would introduce the Kingdom of God by force, such as at Miinster in 1533–34; and those groups advocating a form of religious communism, such as the Hutterites of Bohemia. They suffered severe persecution from Protestants and Catholics alike. For a time they found refuges in Bohemia, Poland, and Hungary, until they were suppressed by force in the 17th century. But their concept and form of church organization later became a prevailing pattern in much of Protestantism. An "Anabaptist" leader in the northern Rhineland, Menno Simons (1496–1561), gave his name to a moderate group of such congregations, the Mennonites, and Holland reluctantly granted asylum to them.

In Elizabethan England many Puritans believed that the state church had not been fully reformed and pressed for further reformation—in discipline, polity, and simplicity of ritual. Since further reformation was not conceded, some of them began to argue for separate congregations. In 1582 Robert Browne (c. 1550-1633) published at Middelburg ***A Treatise of Reformation** without **Tarrying for Any*** and argued for independent congregations that would bind themselves by a covenant, would not attempt to embrace all the world but should gather men and women out of the world, and would have no relations with the state. These features of early Separatist or Independent church views resembled those of some of the groups descended from the Anabaptists and of the Mennonites of Holland, who had an influence on some of these early anti-establishment English groups. The Pilgrims who sailed on the "Mayflower" transplanted these ideas to New England in 1620, and after John Winthrop and his company had settled Massachusetts, the colony worked, in effect, under a state policy of Congregationalism. The experience of the early American colonies was influential in the development of English Congregationalism. During the English Civil War (1642–51) the Parliament became identified with Presbyterianism, and Oliver Cromwell (1599–1658) and his officers with Separatism. English Congregationalists have often looked back with respect toward Cromwell and his regime of comparative toleration of various forms of religious organizations. In 1658 deputies from 120 congregations met at the Savoy Chapel in London and issued the Savoy Declaration, containing a confession of faith and a platform of discipline.

Church organizations and doctrines of Baptists and Friends

Closely associated with the Congregationalists were Baptists, who in origin differed from Separatist congregations only in believing infant Baptism to be wrong. Through the Mennonites of Holland, they were descended from the Anabaptists of the Reformation, but most of them, like the Congregationalists, were Calvinist in their thought and were thus known as Particular Baptists, to distinguish them from a smaller group of General Baptists who were not Calvinist. The English Particular Baptists dated their origins from 1633, and the General Baptists from the forming of a church by Roger Williams in 1639 at Providence in Rhode Island. They both suffered from the English authorities up to 1640 but profited from the toleration practiced during Cromwell's regime.

Of the many little groups that flowered under Cromwell's rule, one became permanent and influential—the Friends, or Quakers, who were organized by George Fox (1624–91) in 1668, when he issued a "Rule for the Management of Meetings." The Quakers became especially known for their emphasis on pacifism and their doctrine of the authority of the "inner light," which was a kind of mystical revelation to the awaiting Friend.

Religious liberty and moral reform. In several Protestant states the Reformation became a symbol of national freedom and independence as well as of ecclesiastical and moral reform, which helps to explain the great influence of Protestant ideas in the later history of Europe and America.

Holland secured its independence from Spain by the wars of 1568–1648. In Scotland the Reformation, under the guidance of John Knox (c. 1514–72) between 1559 and 1564, was successful against the will of two successive Catholic sovereigns, Mary of Guise (1516–58) and Mary, Queen of Scots (1542–87). Under the Stuart monarchs of the 17th century the Presbyterian policy established by Knox became the centre of Scottish resistance to English and royal domination. Despite the existence of a Roman Catholic minority in the Highlands, Protestantism became identified with Scottish nationalism. Protestantism also became identified with an English nationalism, when, after the reign of the Catholic Queen Mary, the English people under Queen Elizabeth I fought against the threat of Catholic conquest by King Philip II of Spain. Though the papacy had long since ceased to be a political force that could dominate all of Europe, the English regarded the pope as a potential threat to their

liberties. In France, the Huguenots achieved the right to exist as a result of the most terrible wars of the 16th century, including the infamous Massacre of St. Bartholomew's Day, August 24, 1572. When the edict of toleration, the Edict of Nantes (1598), was revoked by King Louis XIV in 1685, they fled from France. The French Huguenot exiles in England, Germany, and America carried with them the conviction that Catholicism and freedom were incompatible.

Calvinist efforts to reform church and society

The Protestants set out to reform the church, involving not only its doctrine but, as they saw it, the morals of Europe as well. They promoted education, simplicity, and hard work and discouraged luxury, fornication, extortion, and drunkenness. Within the Calvinist churches especially, the drive to reform was both effective and controversial because of the nature of the Calvinist consistory, with its independent government and its special task of supervising public and private morality. The tradition of the Calvinist churches, whether in Switzerland, Holland, Scotland, or New England, was distinguished by austere simplicity, an immediate sense of vocation (of an individual life calling), a deep attention to biblical texts, and a refusal to compromise. The Calvinists' belief that they were of the "elect" gave them an assurance of salvation and a sense of total dependence upon God.

The name Puritan was first applied to these Calvinists as a term of abuse in England, and there the movement became controversial because it was caught up in the constitutional conflict between crown and Parliament. The alliance between church and king tended to create an alliance between Puritans and the parliamentarians who were against the king, though some parliamentarians were far from Puritan and some Puritans were royalists. Under the rule of Parliament during the Civil War of 1642–51, the Puritan Westminster Assembly attempted to reform the Church of England, by making it a Presbyterian Church in association with the Church of Scotland. The fall of Parliament before Cromwell's army in 1647–48 meant that the Presbyterian system was never fully established in England; but the tone of Cromwell's England was, in general, Puritan. With the restoration of King Charles II (1660) the royalists reacted against everything Puritan, and the movement was driven underground, to be revived later among the Methodists.

III. The late 17th through the 19th century

THE LATE 17TH AND 18TH CENTURIES

Catholic recovery of Protestant territories. After the Peace of Westphalia in 1648 that ended the Thirty Years' War, Catholicism regained some territories from Lutheran Protestantism: first, because the rise of toleration was somewhat more rapid in Protestant countries than in Catholic lands and, secondly, because Louis XIV identified French power with universal French acceptance of the Roman Catholic faith and in 1685 revoked the Edict of Nantes and expelled thousands of Huguenots, who thus fled to England, Holland, or Germany, much to the advantage of those countries. Several of the French refugees became prominent in English religious life, and in Prussia groups of them founded flourishing congregations known as the French Reformed. In 1702 a determined group of Huguenots in the mountains of the Cévennes in France, known as the Camisards, rose in rebellion but were suppressed by military power two years later. There was a further small outbreak of war in 1709. For a time the few surviving Huguenot congregations met only in secret. They were led by Antoine Court (1695–1760), who secured ordination from Ziirich and founded (1730) a college at Lausanne to train pastors. French Protestants barely held out until the French Revolution, after which they had a revival.

Survival of French Protestantism

The gaining of Alsace in 1648 for France had enabled Catholics to increase rapidly, and Protestants decreased in strength. Strassburg, once one of the leading cities of the Protestant Reformation, returned its cathedral to the Catholics (1681) and became a town with a large Catholic population. Louis XIV ruled the Palatinate for nine years and allowed the French Catholics to share the churches with the Protestants; and though he was compelled to surrender the country at the Treaty of Rijswijk (1697) to the Holy Roman Empire, a clause (the *Simultaneum*) of the treaty (added at the last moment and not recognized by the Protestants) preserved certain legal rights and endowments of Catholics in Protestant churches. The consequence of the increased power of France was to diminish Protestant authority in the Rhineland between Switzerland and the Netherlands.

Another shock to Protestantism was the conversion of Augustus II, Elector of Saxony, to Roman Catholicism in 1697. It appeared as though Protestantism was not even safe in its original home. The conversion involved political motives; Augustus was a candidate for the throne of Poland and was loyal to his new allegiance, assisting the Catholic Church in Poland and also, somewhat, in Saxony; but such assistance had no effect on the Lutheranism of Saxony.

Protestant scholasticism. The second half of the 17th century was at once the high age of Protestant systematic orthodoxy and the age when the first signs of its dissolution appeared. The axioms of the Reformation were worked out in a great and systematic body of doctrine.

The theologians defended and the pastors taught Luther's or Calvin's dogmatic systems—relying also upon authoritative sources such as the Formula of Concord (1577) in Lutheranism or the conclusions of the Synod of Dort (1618) in Calvinism—which were extended and made into a tradition. Even when the system was not of the ordinary Protestant tradition, it was generally worked out in many volumes, based upon coherent axioms, defended against all assailants, appealing always to reason and to biblical authority and seldom to feeling or conscience. This age has sometimes been known as the age of Protestant scholasticism. But that pejorative term came from a posterity that would no longer accept the axioms on which the systems were founded. These were the last scriptural theologians before the period of the Enlightenment, when the understanding of Scripture was altered. The old axioms were changed by Pietism, science, and philosophy.

The influence of P.J. Spener and his *Pia Desideria*

Pietism. The Pietists, groups of earnest students of the Bible and seekers after faith and moral experience, were founded by P.J. Spener (1635–1705), an Alsatian Lutheran of Strassburg. At Frankfurt am Main in 1667 he initiated Sunday devotional meetings for laymen, and in 1670 the *collegia pietatis* ("assemblies of piety"), which were held twice a week in his house for the discussion of the previous Sunday's sermon or of some religious book. In 1675 he published *Pia Desideria* ("Pious Desires"), a plea for a deepening of church devotion, charging the clergy with lacking self-denial, theology with being little but controversial, and the universities with teaching knowledge useless for pastoral concerns. The *Pia Desideria* exercised a great influence throughout Germany and gave birth to many small groups of pious laymen meeting to study the Bible.

In 1694 the Elector of Brandenburg (Frederick 111), under Spener's influence, founded the University of Halle, brought A.H. Francke (1663–1727) there, and filled other chairs with men of his views. Halle became the centre of German Pietism with rapidly rising numbers of students. Francke administered an orphanage with printing house and schools. The Halle faculty, which ceased to be Pietist before 1750, showed the strength and weakness of the movement. It was deeply concerned with saving souls and with the practical and pastoral work of the church; it laid much stress upon the need for conversion and held up before young men high standards of moral responsibility. Pietism attempted to show men that religion was true only if it was personal and individual. It was inclined to be censorious of weaker folk. Also, it was little concerned about the formal accuracy of doctrine and thus was able to cross the barriers that divided denominations. The Pietists raised the general standards of church life. Yet because they shattered the conventional and formal Protestant theological systems, the Pietists opened the way toward more questioning attitudes. They demolished old theological structures and served as a bridge between orthodox and 19th-century theological thought. From Spener onward the movement cared for education and gave impetus to the creation of schools for the poor and also for the rich. Under Pietistic influence confirmation became almost universal among the German churches. The Pietists also first directed the German churches toward foreign missions. One of the Pietistic groups, the Moravians, led by Graf von Zinzendorf (1700–60), established missions in the West Indies (1732), Greenland (1773), and Georgia (1735). The Pietistic movement reached Sweden (where it met much opposition), Denmark, and Norway by the beginning of the 18th century. Under Danish sponsorship, two Pietist missionaries (B. Ziegenbalg and H. Plütschau) established the first Protestant mission in India.

Rationalism. The first signs of a Rationalist movement, which was to have as powerful an influence on Protestantism as the Pietists had had, may be traced back to those few who at the end of the 16th century attacked Calvinism on grounds of reason. In Leyden, the Netherlands, Jacob Arminius (1560–1609) reacted against Calvinist doctrines of predestination (God's foreordaining men to heaven or hell). Though anyone not a Calvinist after a time came to be called Arminian, there were groups so designated in Holland and England that contained men who were more marked by their use of reason in theology than by their opposition to Calvin. In England, the enemies of such liberal theologians gave them the name Latitudinarians. The so-called Latitudinarians sought to maintain church unity based upon a few fundamental articles of faith and otherwise to allow for a wide diversity of doctrine, polity, and ways of worship. Their best representatives were the Cambridge Platonists—philosophical theologians at Cambridge (*c.* 1640–80)—who claimed that reason is the reflection of the divine mind in the soul.

During the 17th century, philosophy, hitherto considered a handmaid to theology, was expanded beyond the limits of Aristotle and the Bible and—partly due to natural science and partly due to the reflections of thinkers from Francis Bacon (1561–1626) and René Descartes (1596–1650) onwards—developed its independence. The successes of science, especially to be noted in the work of Sir Isaac Newton (1642–1727), persuaded many men of the power of reason and, by 1680, of the necessity that all things be tested by reason, including even those realms of the conscience or spirit that hitherto had been thought to be above reason or inaccessible to reason. The symbols of the age of Rationalism were: the rapid decline of belief in witchcraft; the slow and painful rise of a belief in toleration; a more widespread spiritualizing of conceptions like heaven and hell; and the recognition of the small size of the planet Earth within the universe. On the Continent Spinoza (1632–77) and G.W. Leibniz (1646–1716), in England John Locke (1632–1704), were regarded as the philosophers of the age. Among the German theologians Christian Wolff (1679–1754) of Halle approached theology almost as if it were a form of mathematics, seeking for a truth that would be incontrovertible among all reasonable men. He believed that he could demonstrate the truths of God and immortality and allowed the possibility of other languages of revelation as probable in the light of those proofs. Under prompting from Pietists of Halle, he was expelled from Prussia in 1723. But before Wolff's death, Rationalist theologians had displaced the Pietists in control of Halle University and had made it the centre of Rationalist theology among Protestants.

Effects of Rationalism

In England the same trend among the disciples of John Locke issued in the Deists (especially John Toland, 1670–1722) for whom Christianity was never mysterious and was understood only as a republication of the natural religion of the human race. Like Wolff and his disciples, the English Deists had no permanent influence on the history of Protestantism, except by forcing the theologians to answer them and thereby to treat the philosophy of religion with seriousness. The most important of all the answers to the Deists lay in the work of Bishop Joseph Butler (1692–1752), whose sermons and *Analogy of Religion* formed the most cogent defense of the basis of Christian philosophy known in that age.

Rationalist theology, working at the same time as, though certainly not in harmony with, Pietism and evangelicalism, began to modify or even destroy the traditional orthodoxies—*i.e.*, Lutheran or Calvinist—of the later Reformation. The Rationalist theologians insisted that goodness in God could not be different in kind from goodness in men, and therefore that God cannot do what in a man would be immoral. Though for the most part they accepted the miracles of the New Testament—until toward the end of the 18th century—the Rationalists were critical of miracles outside the New Testament, since they suspected everything that did not fit their mechanistic view of the universe.

The role of John Wesley

Methodism. Closely parallel to the Pietists in Germany was the evangelical, or Methodist (named from the use of methodical study and devotion), movement in England led by John Wesley (1703–91). While a fellow of Lincoln College, Oxford, Wesley gathered a group of earnest students of the Bible about him, made a missionary expedition to Georgia, and became a friend of the Moravians. Henceforth, like the Pietists, he laid much emphasis upon the necessity of conversion and devoted the remainder of his life to evangelistic preaching in England. He did not intend any separation, but the parish system of the Church of England as then organized was incapable of adjustment to his plan of free evangelism and lay preachers. In 1744 Wesley held the first conference of his preachers; soon this became an annual conference, the governing body of the Methodist societies, and was given a legal constitution in 1784. The Methodist movement had remarkable success, especially where the Church of England was failing—in the industrial parishes, in the deep countryside, in little hamlets, and in hilly country, such as Wales, Cumberland, Yorkshire, and Cornwall. In 1768 Methodist emigrants in the American colonies opened a chapel in New York, and thereafter the movement spread rapidly in the United States. It also succeeded in French-speaking cantons of Switzerland.

The evangelical, or Methodist, movement seized upon the elements of feeling and conscience that Protestant orthodoxy had tended to neglect. It gave a renewed and devotional impetus to the doctrines of grace and justification and to the tradition of moral earnestness, which had once appeared in Puritanism but which had temporarily faded during the reaction against Puritanism in the middle and late 17th century. In England, it slowly began to strengthen the tradition of free churchmanship over against the tradition of the established church, though for a century or more many English Methodists believed themselves to be much nearer the Anglican Church from which they had issued than any other body of English Protestants. It enabled hymns—hitherto confined (except for metrical psalms) to the Lutheran churches—slowly to be accepted in other Protestants bodies, such as the Church of England, the Congregationalists, and the Baptists. The evangelical movement of the 18th century produced several of the most eminent of Christian hymn writers, especially Philip Doddridge (1702–51) and Charles Wesley (1707–88).

Though John Wesley himself had not been Calvinist, in Wales the Methodists retained both the name and the theology of Calvinistic Methodists. In the United States Methodism made even more rapid progress.

The development of Protestantism in the English colonies. Churches in the 13 colonies of the American states practiced the Congregational or Baptist church polity on a scale not known in Europe. The small Anabaptist groups had required evidence of faith, and this sometimes meant public testimony to the experience of conversion. In the larger congregations of America a similar testimony—because it was given to a wider circle—became more evident, more solemn, and at times more emotional. The pastors of the Calvinistic tradition of New England, trying to escape from the religion of forms and to seek the religion of the heart, gave unusual stress to the necessity for an immediate experience of salvation. Pastors found that under certain conditions a wave of emotion could sweep through an entire congregation and believed that they could here observe conversion and its subsequent issue in a better life. The movement owed something to the German Pietist T.J. Frelinghuysen (1691–c. 1748) and something to John Wesley's colleague George Whitefield (1714–70). The chief mind at the beginning of the Great Awakening, however, was that of an intellectual mystic rather than of a conventional Calvinist preacher. Jonathan Edwards (1707–58) was the Congregational pastor at Northampton in Massachusetts, where the conversions began in 1734–35. In the middle years of the 18th century waves of revivals and conversions spread through the colonies. Though the revivals were led by Congregationalists and Presbyterians, many small, independent Bible-centred groups, which often professed allegiance to Baptist teaching, came into being because of the revivals. As Wesley in England and Zinzendorf in Germany had been forced to carry their new methods outside the established churches of their lands, so also was the experience of American revivalistic leaders. Emotional phenomena and disorders were not welcomed by conservative churchmen who cared for decorous reverence in church.

The Great Awakening

The movement was not native to America. But the conditions of the American frontier gave this kind of evangelicalism a new vigour, and from America it permanently influenced the future development of Protestantism. In the towns and new cities with moving populations, Protestantism found methods that became a feature of evangelical endeavours to reach the unregenerate or the unchurched crowds of the coming industrial cities.

THE 19TH CENTURY

Effects of the American and French Revolutions. The American Revolution and the French Revolution changed history and within it the history of the Protestants. The American Constitution, with its inferred separation of state and churches, owed something to the spirit of free churchmanship inherited from colonial days, something to the religious mixture of immigrants from Europe, something to the reaction against the "Church and King" alliance that prevailed in Britain, and something to the secular spirit of the Enlightenment. With the French Revolution and Napoleon, the idea of the secular state became an ideal for many European liberals, especially among the anticlericals in Roman Catholic countries. The American pattern was probably more influential than the Napoleonic in Protestant Europe. The Protestant states of Germany, Scandinavia, Holland, Switzerland, England, and Scotland, all accustomed to established Protestant churches. for a time met no strong demand anywhere for disestablishment. In all those countries the members of the free, or dissenting, churches won complete toleration and civil rights during the 19th century, but in no Protestant country was the formal link between state and an established church totally broken during the 19th century, except in Ireland (1871) and in Wales (1914–19), where the Church of England was a minority. But, at least as an outward and historical form, established churches remained in England, Scotland, and all the Scandinavian countries.

Developments in Europe. Early in the 19th century the greatest acts leading to reunion since the Reformation were initiated.

During the later 17th century the states of Europe—especially as they allowed for citizens of more than one denomination—moved toward toleration for all men as long as they were good citizens, though this advance toward tolerance was very slow. The Christian leaders, especially of the new Rational, or Latitudinarian, school, sought to show that the doctrines that divided Protestants from each other (if not Protestants from Catholics) mattered less than the truths upon which they agreed. Among the Lutheran and Reformed, the German theologian George Calixtus (1586–1656) already had sought to prove their essential unity, by showing that the doctrines that divided them were not essential to faith. A Scotsman, John Durie (1596–1680), travelled from England to eastern Germany and from Sweden to Switzerland on practical endeavours to persuade churchmen to unite. In 1631 the Huguenot Synod of Charenton (France) agreed to accept Lutherans who married Reformed or were godparents, without compelling them to abandon their special beliefs, on the ground that there was a sufficient agreement in the essential gospel between the Lutheran and Reformed. Lutherans (except for Calixtus and his school) could not take this view. Neither Calixtus nor Durie had much influence. Leibniz (1646–1716) and the French Roman Catholic bishop Jacques Bénigne Bossuet (1627–1704) corresponded about the possibility of union between Catholics and Protestants, but in vain. In Prussia, with a mainly Lutheran population and a dynasty of Reformed princes, the policy of reconciliation became more effective. In 1708 King Frederick I built a "union-church" in Berlin, with the Lutheran Catechism and the Heidelberg Catechism side by side on the altar. In 1817, in a Prussia stimulated by the national revival that followed the fall of Napoleon (1815), King Frederick William III (1770–1840) used the third centenary of the Reformation to unite the Lutheran and Reformed of

The Prussian Union

Prussia by royal decree (the Prussian Union), and despite resistance, the union was slowly accepted by the majority of Prussian congregations. Other, though not all, German states succeeded in uniting their Protestant communities about the same time. Many of the more conservative Lutherans, rejecting the Prussian Union, emigrated to the United States.

The rise of American Protestant influence in the world. Since the 16th century, the two centres of Protestant political power had been Germany and England. With German unity effected under Prussia and the rise to world power of Britain, the political force of Protestantism was stronger during the 19th century than at any time since the Reformation. But about 1860 it began to be clear that a third force was emerging in the United States. After 1820 there was an extraordinary development of the American nation. American frontier conditions helped to extend the variety of Protestant forces, and denominations such as the Disciples of Christ, formed in 1832 from revivalist groups, arose. These Protestant denominations in time extended their influence beyond America. Many of the immigrants to America were Catholic, and in time the largest single denomination in the United States was to be the Roman Catholic. But the tone of American leadership and culture remained Anglo-Saxon, liberal, and Protestant, and this was one of the great moments in the history of Protestantism. Many Germans and Scandinavians, usually of the Lutheran persuasion, emigrated to America, and American Lutheranism expanded until it became a centre of Lutheran life and thought of a weight equal to the original homes of Lutheranism in Germany and Scandinavia. Because the Lutheran leadership came largely from European Pietistic groups, the American Lutheran churches tended to be more conservative in theology and discipline than the churches in Germany. The element of revivalism in American Christianity continued throughout the 19th century and helped the concept of a personal Christian faith to penetrate deeply into the American way of life. To an observer like the Frenchman Alexis de Tocqueville (1805–59), the culture seemed to be evangelical: usually individualistic, free, emotional, with far more interest in practical consequences than in theology, and manifold in its variety.

The era of Protestant expansion. With this background of European strength in Germany and Britain, with the rising strength of the United States, and with the longest period of peace that Europe had ever known, the Protestant churches entered their greatest period of expansion. At home, they were confronted by the new cities of the century and developed social services on a scale hitherto unknown, such as in hospitals, nursing, orphanages, temperance work, care of the old, extension of education to the young and to working adults, Sunday schools, boys' and men's clubs in city slums, and the countless organizations demanded by the new city life of the 19th century. Abroad, they carried Protestantism effectively into all those parts of Africa that were not under French or **Por-**

Social service and **missionary activities** tuguese influence, so that in southern Africa the Bantu became largely a federation of Protestant peoples. In India, British and American missionaries steadily increased the strength of the newer Indian Christian churches. In China, Christianity had been hitherto confined to the seaports and the survivors of Roman Catholic missions in the 17th century; but now a variety of evangelical groups, mostly financed from England or America and led by the China Inland Mission (founded 1865), created congregations deep in the interior of China. Japan had been closed to Christianity since 1630, and after its reopening in 1859 American and British missionaries created Japanese Christian churches. American missionaries developed Protestant congregations in the countries of South and Central America. All of the main Protestant denominations—Lutherans, Presbyterians, Anglicans, Congregationalists. Baptists, Methodists-developed into worldwide bodies, and all suffered strain in adjusting their organizations to meet these extraordinary new needs.

Revivalism in England and Scandinavia

Revivalism in the 19th century. One of the most prominent features of Protestantism in the 19th century was the development of revivalist methods to meet the needs of an industrial and urban society. It appeared that though many urban poor seldom went to church, they would listen to evangelical preachers in halls or theatres, or on street corners. Methodists and Baptists, familiar with revivalistic methods, made many strides forward, especially in the United States. These endeavours were not confined simply to reaching the working class. The English Baptist Charles H. Spurgeon (1834–92) secured a large audience in London and helped to make the ministry of Protestant dissent very powerful. His mission was for the most part to the educated rather than to the urban poor. For the lowest end of the social scale, a former Methodist preacher, William Booth (1829–1912), and his wife, Catherine, created in east London the agency of evangelism that was known from 1878 as the Salvation Army. They directed their mission to the men on the street corners, using brass bands, and even dancing, to attract attention. They differed from the Methodist revivalist tradition, from which they had sprung, by their belief in the necessity of a strong central government under a "general" appointed for life, and by abandoning the use of sacraments. Their noise in the street at first met much hostility and even persecution, but by the end of the 19th century the Salvation Army had securely established its place in British life and had become a worldwide organization.

In Sweden a Methodist preacher influenced Karl Olof Rosenius (1816–68), who introduced revivalism into Swedish Lutheranism. He and some disciples also were influenced by the movement that stemmed from Zinzendorf. Though there were links with Pietism, the new movement was quite unlike the little groups of Pietism. The Pietists wanted to gather men to salvation out of the world, whereas the Bornholmers (as they later came to be called in Denmark because of a famous episode in evangelism on the island of Bornholm) wanted to declare salvation to the world. The movement had effects in Norway and Denmark and in the Lutheran Church—Missouri Syqod in the United States but never became as separate as the Salvation Army.

Revivalism in the United States

In the United States the development of revivalism was particularly marked in the expansion of the moving frontier. The memory of the Great Awakening (c. 1725–50) was always powerful, and in halls of cities as well as in the camps of the west, revivalistic preaching methods were effective. Protestantism was exceptionally strong because, in many cases, immigrant groups found in religion that link with their historic past that secular society could not for the time give them. Famous evangelists appeared to meet the need of the cities, especially Charles Grandison Finney (1792–1875) and Dwight Lyman Moody (1837–99).

Thus, some of the evangelistic power in Protestantism of the 19th century was drawn away from the traditional churches of the Reformation—Lutheran, Calvinist, and Anglican—and tended to create new forms of church life and new organizations. These almost always used lay preachers, were far more concerned with bringing the individual to conversion and little concerned with church order, and were sometimes content if they could draw a soul to Christ without worrying if it were drawn into a historic Christian community as understood since the Reformation. Consequently, they developed a tendency, not common before the Pietist movement, to identify Protestantism with individualism in religion. Because the evangelistic endeavours subsequently produced separate organizations, the separate denominations and the varieties of Christianity that still called themselves—and with justice—Protestant were rapidly increased.

The secular state allowed or even stimulated the Protestant churches to establish further and powerful varieties of religious groups. Among radical Protestants, the 19th century produced several important groups or new churches, and several of them were apocalyptic (involving the expected intervention of God in history) and owed their origin to expectation of the Second Coming of Christ. In Britain appeared the Plymouth Brethren, founded in 1827 by John Nelson Darby (1800–82), who separated themselves from the world in preparation for the imminent coming of the Lord. The Catholic Apostolic Church, formed in 1832 largely by the Scotsman Edward Irving, likewise prepared for an imminent coming. Apocalyptic groups and sects were successfully established in the United States, probably because of the absence in new areas of any settled or habitual church polity. The Seventh-day Adventists were founded by William Miller (1782–1849) of New York, again with an expectation of an immediate end of the world. Though not self-proclaimed Protestants, the Mormons (Church of Jesus Christ of the Latter-day Saints), founded by Joseph Smith (1805–44), came out of a parallel waiting upon the end. Another set of groups arose from the revival of faith healing, the most important being the Christian Scientists, founded in 1879 by Mary Baker Eddy (1821–1910), who set up her first church in Boston. There also were holiness churches influenced by Methodism, which taught the gift of perfection in this life, and Pentecostal churches, which looked for an immediate outpouring of the Holy Spirit, such as in speaking in tongues. In the 20th century these Pentecostal churches were to develop into the most expansive of all the many groups that appeared during the 19th century.

Toleration. The great Protestant advance depended in part on the existence of the secular state and toleration. As late as 1715 the Austrian government had denied all protection of the law to the numerous Hungarian Protestants. But after the French Revolution the few survivals of this old church-state unity were rapidly whittled away. Even in countries in which one church was established, all churches were given some form of protection; Protestant groups could spread, though slowly and under difficulty, in Spain or Italy. Even in tsarist Russia, which did not recognize toleration, Baptists obtained a foothold from which they were to build the second largest Christian denomination of Soviet Russia. Wherever western European and American ideas were influential, Protestant evangelists could work fairly freely, especially in the colonial territories of Africa and India.

The issue of church and state relationships

Though the secular state thus helped Protestant (and Roman Catholic) expansion and variety, it also confronted all churches with urgent new problems. The American pattern, in which the state must have no constitutional connection with religion, stemmed as much from the old Congregational tradition as from the ideas of the Enlightenment and was never antireligious in intention. It was influential among the older churches of Europe. In Protestant countries where state and church had been in alliance since the Reformation, the effect was twofold: the state became more neutral in its attitude toward the leading denominations of its territory; and the state church pressed harder toward independence from all forms of state control. Lutheran Germany produced a strong movement toward independence in the mid-19th century. In Scotland the evangelical movement demanded independence from the state in the appointment of ministers to parishes, and when this was refused by the courts and by the government, nearly half the Church of Scotland (1843) under the leadership of Thomas Chalmers (1780–1847) left the established church to found the Free Church of Scotland. The two churches continued side by side (until their eventual reunion in 1929). In Switzerland a Reformed theologian, Alexandre-Rodolphe Vinet (1797–1847), pressed for the separation of church and state and (1845) founded the Free Church.

The Oxford Movement and the revival of Protestant communal orders

In England the move toward independence in a state church was a feature of the Oxford Movement, founded by John Henry Newman (1801–90) in 1833. Here the movement took a course unique in Protestantism. It asserted independence by emphasizing all the Catholic elements within the traditional heritage of Protestantism and so created a school of thought that, though remaining within a Protestant Church, came close to repudiating the Protestant tradition as it was then commonly understood in Europe and America. Newman himself became a Roman Catholic in 1845 and was made a cardinal in 1879. Under the leadership of the survivors, the Oxford Movement brought about a transformation in the worship, organization, and teaching of the Church of England, within the traditional polity of an established and Protestant church. The remarkable sign of this change was the revival from 1840 on of nunneries and from 1860 on of monasteries. In German Lutheranism, under the influence of Pietism, Theodor Fliedner (1800–64) established in 1836 a "mother-house" for deaconesses that became a model for the many successor diaconate orders in Germany, Scandinavia, and the United States. These were the first such to appear in Protestant communities since the dissolution of monastic communities during the Reformation. In the mid-20th century France produced one celebrated community at Taizé, devoted to ecumenical prayer and study.

On the whole, the trend was always, though slowly, toward a free church in a free state. A few powerful conservative theorists, especially Friedrich Julius Stahl (1802–61) among German Lutherans, strenuously defended one version or another of the old link between throne and altar, and the necessity for a single privileged church if revolution or rationalism were to be avoided. These theorists were usually viewed, however, as survivals from a past age. Much more powerful and contemporary were the theorists who, in resisting the trend toward denominationalism and pluralism, saw the church as the religious side of the nation and therefore wanted to broaden its doctrines and liberalize its polity. In England Frederick Denison Maurice defended the established church upon these liberal lines; and in Denmark, more easily because the population was so largely Lutheran, Nikolai Fredrik Severin Grundtvig (1783–1872) shrank from every form of denomination or confessionalism and wanted to make Christianity the spiritual aspect of Danish national life. Grundtvig's movement had extraordinary success; but Denmark, and to a lesser extent Sweden and Norway, were exceptions to the trend. The older Protestant churches steadily moved fuither away from the state and unsteadily but gradually secured more autonomy in their organization.

Churches and social change. Attacks on the churches during the 19th century (and after) were twofold: intellectual and social. On the one hand were the thinkers who declared that the advance of science and of history proved the Bible, and therefore Christianity, untrue. On the other hand, the city and industry created a proletariat estranged from religious life. Many of the political leaders, especially in Europe, claimed that the churches were bulwarks of that order of society which must be overthrown if justice was to be secured for the working man. Some of the earlier forms of socialism were atheistic or at least deistic and suspected free churches as fiercely as they suspected an alliance between altar and throne. Social and economic thinkers, such as Karl Marx (1818–83), told the working man that religion was the opium of the people, that it bade men be content with their lot when they ought to be discontented.

Christian Socialists and the Social Gospel

In response to such views, in nearly every European country, Catholic or Protestant, there came into existence groups of "Christian Socialists," men who believed (at least) in the doctrine that the working man had a right to social and economic justice, and that a Christian ought in conscience to work toward those political conditions that would achieve more social justice for the working man. Except for these basic views, the Christian Socialists varied greatly in their outlook and ideas, whether political or theological. Adolf Stocker (1835–1909), a court preacher in Berlin, was an anti-Semitic radical politician, and Charles Kingsley (1819–75), a clergyman novelist in England, was a warmhearted conservative who deeply sympathized with and understood the working man. The most profound of all the Christian Socialists was Frederick Denison Maurice (1805–72), a theologian of King's College in London till he was ejected in 1853, then a London pastor, and finally a professor of moral philosophy at Cambridge.

But in England and America, the radical wing of Protestants—especially Baptists and primitive Methodists—did as much for the workingman's religion as the intellectual leadership of a few Anglican theologians. In some cases the endeavours made Socialist parties possible for the Christian voter, in others they persuaded Christian voters or politicians—without actually voting for a Socialist party—to adopt policies that led toward a welfare state. Nevertheless, they made Christians more conscious of a social responsibility. In America the Social Gospel excited much influence in the churches at the end of the 19th century, and its most influential leader was a Baptist, Walter Rauschenbusch (1861–1918). Whereas in Catholic countries political parties arose that especially appealed to Christian voters and often used the word Christian in their name, in all the Protestant countries all political parties needed to appeal to Christian voters, and few avowedly secular parties have as yet had political success (except the Social Democrats in Germany after 1918 and the Communists in East Germany after 1945). Even the Nazis in Germany at first needed to make a show of defending the Christiantity of the Germans against Bolshevism.

Biblical criticism. Besides political, social, and economic criticism, Protestantism was encountering an intellectual onslaught on Christianity. The question of biblical criticism was first posed in the German universities; *i.e.*, whether a man might be a Christian and even a good Christian though he held some parts of the Bible to be not true. This became the great question for Protestantism, if not for all Christendom, in the 19th century. On the one hand, Protestantism stood by the Bible and declared that the truth of God came from the Bible. On the other, it rested in part on a fundamental conviction of the liberty of the human spirit as it encountered the Bible. Protestantism was thus seldom friendly to the tactic of meeting sane and reverent argument merely by excommunication or by the blunt exercise of church authority. The theological faculties of German universities, being state faculties and not church institutions, suffered much internal stress, but they arrived at last at the conviction that reasoned criticism-even when it produced conclusions opposed to traditional Christian thinking—should be met rather by refutation than by the way of authority. Thus German Protestantism showed at length an elasticity, or openmindedness, in the face of new knowledge, which was as influential in the development of the Christian churches as the original insights of the Reformation. Owing in part to this German example, the Protestant churches of the main tradition—Lutheran, Reformed, Anglican, Congregational, Methodist, and many Baptist communities—adjusted themselves relatively easily (from the intellectual point of view) to the advances of science, to the idea of evolution, and to progress in anthropology or comparative religion.

Influence of philosophical thought on biblical criticism

In such a flux of ideas, with the Protestant tradition seemingly under attack from Protestants, there was naturally a wide variety of approaches, both in philosophy and history. There was an opinion, represented by the German philosopher G.W.F. Hegel (1770–1831), that Christianity should be restated as a form of Idealistic philosophy. This view was influential for a time in Germany and afterward among Oxford philosophers of later Victorian England. Such restatements were subjected to destructive attacks, of which the most powerful were published by the Danish philosopher Søren Kierkegaard (1813–55), chiefly because such reasoned philosophy failed altogether to account for the depths and tragedies of human existence. An earlier opinion sought to base the justification of Christian faith in the religious feelings commonly found in humanity. A German philosopher, F.D.E. Schleiermacher (1768–1834), sought to infer the Christian and biblical system of thought from an examination of human religious experience. Schleiermacher's attempt had much influence on Protestant thought. Throughout the 19th century the appeal to religious experience was fundamental to liberal Protestant thinking, especially in the attempt to meet the views of modern science. Probably the most important of the successors of Schleiermacher was Albrecht Ritschl (1822–89), who wholly rejected the ideas of Hegel and the philosophers; he distinguished himself sharply from Schleiermacher by repudiating general religious experience and by resting all his thought upon the special moral impact made by the New Testament on the Christian community. Between 1870 and 1918 the Ritschlian school was one of the leading theological schools of thought within the Protestant churches.

Historical criticism of the Bible

Meanwhile, scholars made long strides in the study and exposition of the Bible. Freed from the necessity of defending every one of its details as historical truth, professors at Protestant universities were able to put the books of the Bible into a historical setting. This made an important difference in the study of the New Testament but was a revolution so far as the Old Testament was concerned, where the entire earlier accepted chronology was changed. German Rationalist or Hegelian historians were the first to study the problems with freedom. Ferdinand Christian Baur (1792–1860), of the University of Tübingen, applied the methods of Hegelian philosophy to the documents of the New Testament, which he conceived to be products of the clash between the Jewish Christians led by Peter and the Gentile Christians led by Paul. This theory, known as the Tiibingen theory, soon receded in influence; but in aid of this theory, Baur expounded the texts with such ability as to make his study a landmark in the study of the Bible. Among a large number of excellent biblical students, Joseph Barber Lightfoot (1828–89) of Cambridge finally demolished the Tiibingen theory by showing the 1st century origin of most of the New Testament texts; and Adolf von Harnack (1851–1930) of Berlin by the end of the century summarized the results of a century that was revolutionary in the area of biblical study.

IV. The 20th century

NEW CHALLENGES

The effects of wars. The war of 1914–18 broke Europe's waning self-confidence in the merits of its own civilization. Since it was fought between Christian nations, it weakened worldwide Christianity. The seizure of power by a formally atheist government in Russia in 1917 brought a new negative pressure into the world of Christendom and sharpened the social and working class conflicts of western Europe and America. During the following 40 years the Protestant churches suffered inestimable losses.

The effect of Nazi control in Germany

Germany under Adolf Hitler (in power 1933–45) professed to save Europe from the threat of Bolshevism; and the Nazi rule was at first welcomed by many German churchmen. Disillusionment was not slow to follow. From September 1933 there already existed a partial schism between churchmen willing to cooperate with the government in church matters—especially over the Aryan clause that demanded that no Jew should hold office in the church—and those, led by Martin Niemoller (1892–   ), who were not willing to cooperate in church matters. With the support of the state-aided Lutheran churches in the south (Bavaria and Wiirttemberg), Niemoller's group was able to form the Confessing (or Confessional) Church, and the schism was made manifest when the Confessing Church held the Synod of Barmen in May–June 1934. For a time the Confessing Church was strong throughout Germany; but when the German government provided a less doctrinaire government under the minister of church affairs Hanns Kerrl (1887–1941), the Confessing Church was itself divided—into those who were willing to cooperate and Niemoller's men, who were not willing to cooperate because it was a church government imposed by the Nazi government. At the Synod of Bad Oeynhausen (February 1936) the Confessing Church broke up and was never again so strong. In the later stages, especially during the war of 1939–45 (World War II) when the extreme Nazis secured complete control of Hitler's government, the churches came under increasing pressure and toward the end were struggling in some areas to survive. Bishop Theophil Wurm of Wiirttemberg (1868–1953) was a leader in protesting to the government against its inhumane activities, and Pastor Heinrich Griiber (1891–   ), until his arrest, ran the Buro Griiber, which sought to evacuate and protect Jews. Some church leaders, notably the theologian Dietrich Bonhoeffer (1906–45), paid with their lives for their associations with resistance to the Nazi government.

The results of World War II in Protestant Europe

The end of the war saw Russian armies in control 'of eastern Europe and Germany divided. All the churches in the area came under pressure. Most Germans were evacuated or deported from the three Baltic states of Lithuania, Estonia, and Latvia, and though Lutheran communities remained there, they were subjected to persecution, especially under the rule of Stalin. The Lutherans in Transylvania (Romania) and the Reformed in Hungary came under less severe pressure but were much diminished in numbers. The Protestants of Czechoslovakia, led by the theologian Joseph Hromadka (1899–1969), succeeded in maintaining more dialogue with Marxist thinkers than elsewhere in Europe. From the viewpoint of Protestant strength the greatest losses were suffered through the division of Germany. The settlement between the victorious powers gave large areas of former German-speaking (and largely Lutheran) areas to Poland, and many (approximately 8,000,000) East Germans were expelled; most went to western Germany. The East German state, as constructed in 1945, included Wittenberg and most of the original Protestant homeland. East Germany (the German Democratic Republic) was the sole country in which a Marxist government ruled a largely (70 percent) Protestant population. For a time the Lutheran churches were the chief link between East and West Germany and the annual meeting, or *Kirchentag*, the single expression of a lost German unity. But the building of the Berlin Wall in 1961 stopped this communication and isolated the East German churches. Despite governmental pressure, especially in relation to money, education, and church building, and in the national (and anti-Christian) form of youth dedication, the East German Protestants worked courageously and flourished. The 450th anniversary of the Reformation on October 31, 1967, showed how strong a hold the Protestant churches still possessed over the affections of a large number of people.

In Russia, before the Revolution of 1917 a deeply Orthodox state, the 40 years after the Revolution witnessed a growth in the Baptist community. The flexibility and simplicity of Baptist organization made it in some respects more suitable to activity under difficult legal conditions. In the years after Stalin's death in 1953 there was evidence of rapid advance; but after 1960 the Baptist communities, like the Orthodox, again came under pressure, which at times was severe.

The effect of the decline of the British Empire

The material losses that Great Britain suffered in World War II, and the end of the British Empire in the years after 1947, had serious effects on the Protestant churches in former British territories. The home country could no longer provide resources in money and men to the overseas churches on the same scale, and in a few areas church government was handed over to leaders who were not ready to take over church leadership. But in other areas the change of status for Britain hastened the process of change in leadership that had been proceeding slowly; and some of the failing resources were supplemented from elsewhere, especially from the United States, Canada, and Australia. Thus the so-called younger churches came to be a new fact of world Christianity, led by men who no longer saw the history of Christianity solely through European eyes and had an impatience partly derived from a different attitude to the Christian past. This was to be of primary importance in the ecumenical movement. Meanwhile, the secularizing trend of a technological age, as it developed in all the advanced countries, assailed the old European churches and had an even greater effect upon the areas where the younger churches ministered.

In 1948–49 the Communist seizure of power in China effectively ended Protestant missions there. By 1951 there were hardly any European missionaries in the country, and the Chinese churches had to stand without outside aid in men or money. They came under severe pressure, especially during the so-called cultural revolution in the 1960s. They could no longer evangelize and sought barely to survive.

Theological movements. Meanwhile, a certain reaction could be observed in the Protestant tradition of theology. This was partly due to a general doubt about European liberalism after World War I and particularly due, in its further development, to a reaction against attempts by the Nazis to use liberal theology for some of their views of society.

In both the 19th and 20th centuries, liberal theology met much criticism on the ground that it narrowed Christianity to the limits of what men believed themselves to be experiencing or turned what was objective truth into subjective feeling. Though himself no conservative, Kierkegaard was the most extreme of these critics. All the conservative theologians—including the earliest members of the Oxford Movement in England, the evangelical tradition generally, and those many who stood by the inerrant word of the Bible and in the 20th century came to be called by the name Fundamentalist—opposed the liberals on the same grounds. But in the 20th century there was a reaction even within the liberal camp. Beginning in 1918, a reaction against all theologies emphasizing religious experience was led by Karl Barth (1886–1968) of Basel and Emil Brunner (1889–1966) of Ziirich. This theological movement, called Neo-orthodoxy, widely influenced Protestant thinking in Europe and America. Barth and his disciples regarded their work as a reassertion of the true sovereignty of Scripture and as a return to the authentic principles of the Reformation. In America Reinhold Niebuhr (1892–1971) was almost as influential in reacting against liberal Christian philosophies as they applied to society and to man. Yet, that the questions the older theologians had sought to meet still remained was shown by the influence exerted by the German theologian Rudolf Bultmann (1884–) of Marburg, who sought to "demythologize" the New Testament by discovering its core truths and thus allowing its significance for faith to be more fully disclosed. Refugees from Nazi Germany, such as Paul Tillich (1886–1965), interpreted European developments to Americans.

The rise of Neo-orthodoxy

The continuity of the liberal tradition was strengthened by the rise of the United States to the position of leadership of Protestantism after 1945. Germany was divided, Britain was troubled by the loss of Empire, and the United States was stronger than ever. It could provide men and money on a scale that no other country could equal. Without American help it is possible that some of the younger African churches could barely have survived. American Protestantism, however, was more radical in character, and more varied in its diversity, than Protestantism in Europe. Therefore, the rise of the United States to leadership meant a greater influence by the radical Protestant groups in the general counsels of Protestantism and a keener concern to understand, and if possible remedy, the differences in religion through the ecumenical movement. Without American leadership and money the World Council of Churches, formed in 1948, could not have done nearly so much—*e.g.*, social and relief work—and would have been a weaker body.

The general missionary expansion of Protestantism thus took on a more radical appearance. The traditional Protestant churches still evangelized in Africa, South America, and India. But the most rapidly spreading groups were of the Protestant left wing, such as Pentecostal, Holiness, and other churches. An emphasis on the inspiration and the immediate guiding of the Holy Spirit marked all such movements, which first attracted public notice in America 1905–06 and in Britain from 1907 on. The movement won many converts in Brazil, Scandinavia, East Africa, and North America and in the 1950s and 1960s was numerically probably the most rapidly growing Protestant movement. Often it was associated with services for healing.

Expansion of left-wing Protestant churches

THE ECUMENICAL MOVEMENT

The ecumenical movement was in origin exclusively Protestant (though Eastern Orthodox leaders soon took part), and was at first largely dominated by Protestant thinking. Its origins lay principally in (1) the new speed of transport across the world and the movement of populations that mixed the denominations as never before; (2) the world reach of traditional denominations; (3) the variety of religion within America and the problems that such a variety created; and (4) the younger churches of Africa and Asia and their contempt for barriers raised by events of European history for which they felt no special concern. There was always a strong link with the missions, and an American missionary leader, J.R. Mott (1865–1955), whose travels did as much as anything to raise the various ecumenical endeavours into a single organization, represented in his own person the harmony of missionary zeal with desire for Christian unity. A conference of Edinburgh in 1910, which marks the beginning of the movement proper, was a World Missionary Conference. From it sprang conferences on Life and Work (led by the Swedish Lutheran archbishop Nathan Söderblom, 1866–1931), dealing with practical problems, and on Faith and Order, at which theologians sought to examine their theological differences with sympathy. At first Roman Catholics refused to participate; the Eastern Orthodox participated only through exiles in the Western dispersion; and the Nazi government refused to allow Germans to go far in participating. The end of World War II in 1945 created a new atmosphere, and the World Council of Churches was formally constituted at the Amsterdam conference in 1948. The entire movement depended for most of its money and for part of its drive on the Americans; but its headquarters was in Geneva, and, led by the Dutch ecumenical administrator W.A. Visser t'Hooft, it never lost sight of the fact that the traditional problems of divided Christian Europe had to be met if it was to succeed.

Formation of the World Council of Churches

Many problems remained. Fundamentalist and other conservative Protestants suspected the liberal theological views prominent in the ecumenical movement and refused to take part. Most of the British Methodists were successfully united; most of the Presbyterians and Congregationalists created the United Church in Canada. Crossing the border between episcopal and nonepiscopal church governments, the Church of South India in 1947 was created out of Anglicans, Presbyterians, Congregationalists, Methodists, and Baptists; a number of other unions were successfully brought about. But others failed altogether or made slow headway. An especial failure occurred in Britain in 1969, when a scheme for uniting Methodists to the Church of England failed to secure sufficient Anglican support. The ecumenical movement did more to change the understanding between the churches than to unite their separate organizations. In the United States, the Consultation on Church Union, involving the merger of some major Protestant churches, progressed slowly after its start in 1960, but suffered a setback in the early 1970s.

In the years after 1948 the ecumenical movement brought Protestants into an ever-growing dialogue with the Eastern Orthodox and the Roman Catholics. After John XXIII became pope in 1958, the Roman Catholics at last began to participate in the ecumenical movement. Although the definitions of the second Vatican Council (1962–65) were unacceptable to most Protestants, they had a breadth quite unlike the definitions of the first Vatican Council in 1870 and gave hope to those (usually liberal) Protestants who hoped in time to lower this greatest of barriers raised by the 16th century.

Protozoa

Protozoa is a phylum of mostly microscopic, one-celled organisms. In number of individuals, protozoans rival the bacteria and are almost as ubiquitous, being found wherever there is enough moisture for active life. Some species are worldwide, while others are restricted to special habitats. Probably the most widely scattered are the free-living marine protozoans that are part of the plankton and the parasites of man, including the amoeba that causes a form of dysentery. Living species of protozoans approach 30,000; probably even greater numbers are extinct.

Earlier, attention was focussed on the parasites that caused malaria and sleeping sickness, stimulating research in tropical medicine. More recently, with improvement in laboratory techniques for cultivating protozoans, these organisms are becoming biochemical tools, replacing conventional laboratory animals in many investigations, such as bioassays of vitamins and drugs, and in ecological research.

GENERAL FEATURES

The variety of form of protozoans is endless, from the flowing, protean blobs of amoebas to the exquisitely fashioned "sunbursts" of radiolarians and the delicate shells of foraminifers. The range in size is considerable, from the small blood parasite ***Babesia,*** only two micrometres (pm) long (a small red blood cell can easily contain a dozen such organisms), to the largest foraminiferan shell, almost five centimetres (cm) in diameter.

Disputed status

Although yrotozoans are often described as one-celled animals, some protozoologists prefer to think of them as being noncellular or acellular protistans, neither animal nor plant. The simplest protozoans, comparable in structure to a cell of higher animals, contain only a nucleus and the usual cytoplasmic inclusions (mitochondria, stored food, etc.). More complex species may be equipped with many nuclei, a variety of locomotor and feeding organelles, and sometimes with fibrils and contractile elements.

Many Protozoa seem to be as closely related to plants as to animals. Certain phytoflagellates, for example, form an apparently continuous series with typical algae. The slime molds are claimed by botanists as well as by zoologists. Accordingly, the protozoologist's concept of the phylum Protozoa is based in part upon arbitrary decisions that may or may not reflect the true relationships of these organisms. To this extent, the phylum represents a somewhat artificial assemblage.

IMPORTANCE

Significance in nature. As primary producers (phototrophs or autotrophs), photosynthetic flagellates share with typical algae a position near the base of the aquatic food chain. These photosynthetic organisms occupy much the same ecological position in fresh and salt waters as that filled by the grasses of terrestrial environments. There is some hope that the plankton of the oceans can be cultivated as "forage" to increase the yields of aquatic animals eaten by man.

The occurrence of population "blooms" and "red tides" reveals a harmful influence of dinoflagellates on other organisms. Certain species of ***Gonyaulax*** and ***Gymnodinium*** produce potent neurotoxins. ***Gonyaulax*** toxin qualifies as one of the most deadly poisons known. Similar neurotoxins from ***Gymnodinium brevis*** and ***G. veneficum*** also have been related to fish kill during blooms. In cultures of ***Gorryaulax monilata*** the toxin seems to be liberated when the flagellates disintegrate at death. Red tides kill marine fish in large numbers; occasionally other marine animals are affected. Mussels may retain dangerous concentrations of dinoflagellate toxin for several months after a bloom. Animals eating such shellfish may suffer severe or fatal effects. Seabirds are sometimes victims, as in the 1968 outbreak along the Northumberland coast in England. Man also has suffered from mussel poisoning. The first well-publicized outbreak occurred in 1927 in the San Francisco area (over 100 cases, 6 fatal); an outbreak occurred in England in 1968 (almost 100 cases, but none fatal),

The hemolytic (blood-destroying) toxin of ***Prymnesium parvum*** (a chrysomonad) has caused much loss of fish during blooms in brakish commercial fish ponds in Israel.

Soil protozoans

The effects of Protozoa on other micro-organisms in the soil have been disputed. The usual soil Protozoa are consumers (heterotrophs) rather than producers. One theory is that soil amoebas and ciliates are detrimental to maintenance of soil fertility because they reduce the number of beneficial bacteria. There is, however, no convincing evidence to confirm this theory. Furthermore, some observations suggest that ammonification and nitrogen fixation proceed more rapidly with Protozoa in the soil. The resolution of such a contradiction requires more carefully controlled observations than those reported so far.

Agents of disease. The importance of Protozoa in causing disease is well known. Endemic malaria, due to sporozoan parasites of the genus ***Plasmodium,*** remains a public health problem of major importance throughout much of Africa, the Pacific Islands, and southern and southeastern Asia. Estimates place the annual number of cases at about 100,000,000, with perhaps 1,000,000 deaths. Among the other sporozoan parasites, Coccidia ***(Eimeria, Isospora)*** are important primarily for their effects on domestic and certain game animals. They cause serious problems for poultry raisers. ***Eirneria bovis*** can be an important pest, particularly in young calves.

Visceral leishmaniasis (kala-azar), which attacks deep tissue, is still rated an important cause of death in southeastern and southern Asia and, to a lesser extent, in parts of Africa where the disease is still endemic. Dermal and mucocutaneous leishmaniasis, Old World and New World diseases, are less important overall but are serious enough to the victims.

Infections with trypanosomes, spread by tsetse flies, occur in an area of about 4,000,000 square miles in tropical Africa. Parasites of man cause African sleeping sickness, milder forms of trypanosomiasis, and acute infections in which the patients do not live long enough to develop sleeping sickness. As a secondary effect, even the milder cases may reduce general resistance and thus increase susceptibility of infected individuals to other diseases. Indirectly, man is affected also by those trypanosomes that make it difficult or impossible for him to maintain cattle and certain other domestic animals in some parts of tropical Africa. South American trypanosomiasis, or Chagas' disease, is estimated to affect 7,000,000 persons. It is sometimes fatal to children and is a frequent cause of heart failure in adults. The disease is spread by tropical and subtropical blood-sucking bugs.

Intestinal amebiasis, although seldom lethal, can progress to amebic dysentery; and even a mild infection may lead to liver abscess. The number of cases in the United States has been estimated at about 10 percent of the population. The general effects of even the mild cases result in an appreciable loss of human efficiency that cannot be estimated accurately. Toxoplasmosis has been rated as one of the most prevalent infections of man and domestic animals. The causative organisms (*Toxoplasma* species) are intracellular parasites probably spread by cats. Reported estimates of incidence are: man, 30–60 percent of urban populations; cattle, 1–2 percent; hogs, 24 percent; and sheep, 9–10 percent. Human infections are commonly asymptomatic, but an acute infection often occurs in infants or fetuses (congenital infections); and Toxoplasma seems to be responsible for many abortions, cases of hydrocephalus, and often a mild to serious mental deficiency in surviving infants.

Toxoplasmosis

Laboratory tools. The discovery of the malarial parasites and then trypanosomes and other important parasites of man furnished the initial practical stimulus for interest in the Protozoa. Several European nations with colonial interests in the tropics established institutes for research on tropical diseases, thereby stimulating research in protozoology. More recently, with increased knowledge of protozoan physiology and marked improvements in laboratory techniques, a number of species have been grown in pure culture (axenically) in chemically defined media. Determination of specific growth requirements has been possible in such cases. The result is an array of biochemical tools that can replace conventional laboratory animals in many investigations, with cost and time savings. Protozoa have been used extensively in bioassay of vitamins in biological materials and in estimating the vitamin content of fresh and salt waters. A few species have helped in tracing the action of drugs (antihistamines, herbicides, anticonvulsants, thalidomide, tumour-inducers, etc.), often with the aim of identifying metabolic and morphological effects on cells. Tissue cultures of parasitic Protozoa have been tried as substitutes for the natural hosts, the aim being closer and more precise observation of such parasites, which may lead to better methods of control.

NATURAL HISTORY

Ecology. Distribution. Free-living protozoans live in the soil and in fresh and salt water. Parasites occur in body cavities and tissues, some inside tissue cells. Differences among free-living species depend on the nature and abundance of food and other ecological factors. Other members of the community may significantly influence survival of any protozoan species. Laboratory analysis of such relationships is difficult. With direct competition, one species may replace another, or the competitors may both survive in reduced numbers. A species also may benefit from metabolic products of another, or antibiotic products may harm susceptible associates. Distribution of parasites depends upon distribution of their hosts.

Certain organisms form colonies characteristic of particular groups. Discoid and spheroid colonies—Gonium, Pandorina, *Volvox*, and certain ciliates—contain organisms embedded in a jellylike matrix. In branching colonies the framework is often a stalk, as in Epistylis and *Zoothamnium*, or plates (loricae) attached in a specific pattern, as in Dinobryon and Hyalobryon. Temporary aggregations include chains of dinoflagellates and phytomonads.

Environmental factors. In unravelling ecological relationships, conclusions based on field studies are not as precise as might be desired, while more specific conclusions from laboratory experiments often can be applied to natural conditions only with reservations. It is clear, nevertheless, that survival is influenced by factors characteristic of a particular environment. These factors include food supply, light (for photosynthetic species), temperature, oxygen and carbon dioxide (CO_2) tension, aci ty of the medium, and, for active life, the necessary water. Food requirements are critical. For photosynthetic flagellates, phosphorus and nitrogen sources are most likely to limit their distribution. Certain vitamins (thiamine, B_{12}, biotin), although their fluctuations influence the abundance of organisms requiring them, are seldom scarce enough to prevent bare survival of some protozoans. Except for an organic energy source, chlorophyll-free phytoflagellates need much the same foods as green flagellates. Other heterotrophic organisms, requiring more organic foods, may be more restricted in ecological relationships. In nature, however, they seldom suffer seriously from vitamin deficiency in tolerable environments because organic foods usually contain sufficient vitamins. Consumers may show certain dietary "preferences" that might influence distribution.

Food requirements and temperature range

Increases in food supply may cause striking increases in populations, as in blooms and red tides. Dinoflagellate red tides often follow heavy rains that carry food-laden water into the coastal waters. The increased food stimulates aquatic bacteria to produce vitamin B_{12}, which in turn promotes dinoflagellate growth. Data on distribution show that a few Protozoa can tolerate high temperatures. Among strains of Tetrahymena *pyriformis*, one from a cold mountain stream grows well at 35° C, while a "tropical" strain has failed to survive at that temperature. Parasitism may add complications. Young stages (mosquito phase) of Plasmodium *relictum* are injured quickly at 35" C; older stages last three to four days, and sporozoites (infective for pigeons) survive about two weeks. Unfavourable effects of high temperatures may depend partly upon increased food requirements. In cultures of *Ochromonas* shifted from 34" C to 38° C, the thiamine requirement is increased about one thousandfold, the B_{12} requirement even more.

There is little evidence that low temperatures are a serious natural hazard to Protozoa. In laboratory tests, free-living and parasitic species have survived temperatures well below freezing. At —95" C about 11 percent of a *Trichomonas* foetus population survived more than 5½ years. At the same temperature, Tetrahymena pyriformis can live at least four months. In these experiments, however, the medium contained a chemical protectant; survival time may be much shorter under more nearly natural conditions.

In relation to oxygen requirements, data on natural distribution may need careful interpretation. Many protozoan parasites of deep tissues are strict anaerobes (require an oxygen-free environment); others can adjust to a range of oxygen levels but do best at the lower end of the range. Even among oxygen-requiring protozoans (aerobes), different species are favoured by different oxygen levels. Some protozoans live under conditions apparently insuring anaerobiosis—ciliates in the rumina of cows, flagellates of the termite intestine, and ciliates in the bottom ooze of deep lakes or in sewage tanks. Dissolved oxygen in ponds and lakes increases in winter and spring, favouring aerobes, and decreases in summer and fall, favouring anaerobes. Less important daily fluctuations in shallow waters may be correlated with photosynthesis. Carbon dioxide, dissolved gas, or bicarbonates show fluctuations inversely proportional to those of dissolved oxygen. An adequate supply of CO_2 is essential for photosynthetic species, but little or nothing is known about quantitative needs of consumers. Bottom, or benthic, zones of ponds and lakes with dense bacterial populations show a high CO_2 concentration, which could possibly rise to levels unfavourable to certain Protozoa. The acidity–alkalinity range (pH) of the medium can limit the distribution of certain species. There is some evidence that protozoan population growth is most rapid at a particular pH level, which may vary with the medium. The general range for growth is approximately 2.2–9.2, although few species (*e.g.*, Polytomella caeca) can grow throughout most of this range. In general, the pH of the medium affects uptake of foods, so that pH relationships vary with the

pH optima

substrate. The rate of ingestion and activity also are influenced by pH. In films of moisture on soil particles, active life goes on in the upper few inches of the soil, where protozoan populations probably average 40,000 to 50,000 per gram. In rich soils populations may be several times as great. Small flagellates (Cercomonas, *Heteromita*, Oicomonas) and amoebas (Hartmannella, Naegleria) are usually predominant; ciliates (Colpoda species) form a small percentage of the population. Indigenous species represent perhaps 10 percent of the 250 or so reported; the rest are occasional invaders. Sand, as distinct from ordinary soil, also has a characteristic protozoan fauna including over 100 species of ciliates and a unique euglenoid (Pentamonas).

Species interactions. Symbiosis involving Protozoa includes associations in which the host is larger than its protozoan symbiotes and associations in which the protozoan is the host of symbiotic micro-organisms. Representing the first type, termite flagellates ingest wood chips swallowed by the insect and produce materials useful both to themselves and to the host. The hayeating ciliates of the cow's rumen perform a similar service. Dinoflagellates symbiotic in corals stimulate calcium metabolism of their hosts, possibly by contributing growth factors. In relationships of the second type, a strain of *Crithidia* oncopelti carries a bacterial symbiote that synthesizes useful amino acids. In Paramecium *bursaria* the symbiotic alga Chlorella contributes useful material; during starvation, a decrease in number of Chlorella suggests that the ciliates consume their algae. Association involving infection of a protozoan parasite is often termed hyperparasitism; intestinal flagellates, amoebas, and ciliates may serve as hosts of small amoebas, microsporidians, or bacteria.

Survival of a protozoan parasite may depend upon particular substances available in its natural host. *Trypanosoma* lewisi, a rat parasite, can live only a few hours in laboratory mice; however, as long as the mice are injected daily with normal rat serum, T. lewisi can survive. In some cases, protozoans can adapt to an unnatural host. Plasmodium malariae, which normally causes malaria in man, can produce infections in chimpanzees; likewise, P. cynomolgi of monkeys can be transferred to man by a mosquito and also from man to man and back to the monkey.

Pathogens and disease

Virulent strains of a pathogen can invade susceptible hosts and cause appreciable damage. In two-host cycles the vertebrate host is usually the one damaged by the parasite; Trypanosoma rangeli, in contrast, is pathogenic in the insect vector but relatively nonpathogenic in vertebrates. Pathogenicity may appear occasionally in species usually considered harmless—Naegleria gruberi was reported in fatal cases of amoebic meningoencephalitis. Virulence is inherited in strains of a species and may be controlled by deoxyribonucleic acid (DNA). Treatment of a nonvirulent strain of Trichomonas *gallinae* with homogenates of a virulent strain transformed the former into the latter type. More recently, a 1:10 mixture of DNA and ribonucleic acid (RNA) from a virulent strain produced the expected effect.

Life cycle and reproduction. Protozoan life cycles include reproductive stages and a stage for dispersal; the latter may or may not be encysted in a protective envelope. The period of active living (trophic phase) may, in some species, include more than one stage and may also involve a sexual stage. The survival value of sexual phenomena varies. In some species, sexual activity is sporadic. In others, syngamy, coupling to form a single cell or zygote, may be essential; in malarial parasites, for example, syngamy must occur within the mosquito for completion of the parasite's cycle (see Figure 1).

Range of life cycles. The simplest life cycles include a trophic phase and a cyst; ability to encyst has been lost in some species. Modifications include more than one trophic stage, different kinds of cysts, and a sexual phase. The simplest modifications involve the trophic phase—amoeba/flagellate alternations in certain mastigophorans and sarcodines; amoeba/plasmodium in certain sarcodines; and flagellated/nonflagellated stages in certain mastigophorans. With the addition of sexual phenomena, modifications become more complicated (as in coccidians and malarial parasites). Metamorphosis is involved in cycles with two or more trophic stages. In Leishmania, a leptomonad in an insect host or a culture alternates with a nonflagellated leishmania1form in vertebrate cells. In certain trypanosomes vector stages contain a functional cytochrome system; stages from vertebrate blood lack this system (replaced by a glyceraldehyde dehydrogenase system for electron transport). Temperature may affect such cycles. Trypanosoma conorhini remains flagellated in cultures at 37" C, but at 28° C it assumes the characteristically flagellated vector form.

Encystment

Protective cysts typically enclose a dedifferentiated stage, in phytomonads a zygote. Coccidian macrogametes (*e.g.*, Eimeria) may produce such a cyst (oocyst) just before syngamy, leaving a pore for entrance of a microgamete. Also in coccidians, division products (sporoblasts) of the zygote may produce spores inside the oocyst. In the usually compound wall of the protective cyst, the outer or middle layer is typically thicker than the others. Protective efficiency varies. Cysts of Didinium remain viable for years if kept moist; cysts of Colpoda resist drying for several years. Soil amoebas and flagellates have survived for 49 years in dry soil samples. Such cysts are important in dispersal. Reproductive cysts (enclosing stages of fission or sometimes gametogenesis) have thin walls. Reproduction is not limited strictly to reproductive cysts, however; in Eimeria and related genera, the encysted zygote divides.

Production of a protective cyst in ciliates usually involves resorption of cilia, and the organism often rounds up and undergoes partial dehydration. Respiration may drop to about one-tenth'the trophic rate. Prior to secretion of the cyst wall, some species accumulate reserves such as glycogen. Chromatoid bodies also are reserves to be used during encystment. Induction of encystment has been attributed to starvation, vitamin deficiency, evaporation of the medium, critical pH changes, etc. Excystment and resumption of the trophic phase occurs when environmental conditions are again favourable.

Reproduction. Protozoan reproduction is not necessarily associated with sexual processes. Syngamy, the fusion of two protozoans, for example, produces one organism (the zygote); after syngamy, reproduction may begin. This process must sometimes initiate a reproductive phase.

Reproduction involves nuclear division and the separation of newly formed units. Separation may occur through simple cell division (binary fission), budding, plasmotomy, or schizogony (see Figure 2).

Binary fission

Binary fission, much like mitotic cell division in higher organisms, produces two new daughter organisms of equal size (see CELL AND CELL DIVISION). Budding pro-

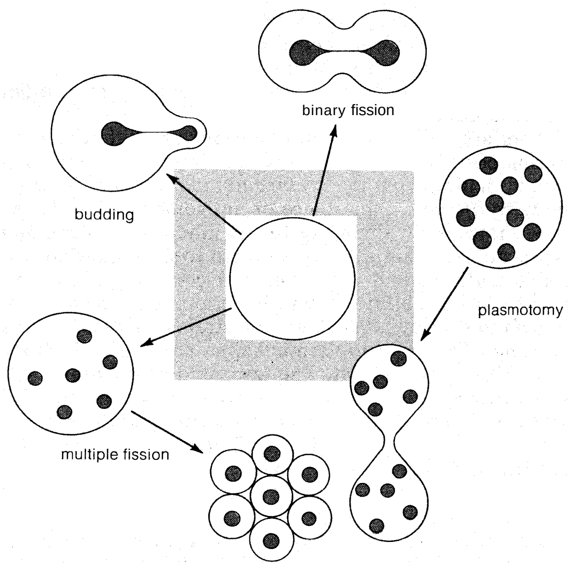

Figure 2: Asexual reproductive patterns in protozoans.

duces one large and one small organism. Buds usually develop at the surface, but in certain suctorians they develop within a brood pouch, from which they leave as larvae. Schizogony, common in sporozoans (see Figure 3), is synchronized production of a number of young from a multinucleate stage. In small schizonts of Eimeria, bodies called merozoites are separated from one another by a sort of cleavage without the usual peripheral budding typical of the larger schizonts. Schizogony probably favours transfer of sporozoan parasites to a new host and also may facilitate completion of a reproductive phase before the host develops an immunity. Plasmotomy involves the division of multinucleate types into a number of organisms.

Reproduction may occur in an active or an inactive stage. Most ciliates reproduce in motile stages, but Colpodidae, like certain phytoflagellates, divide within a reproductive cyst. Fission may involve extensive reorganization. Hypotrichs (*e.g.*, Euplotes) may resorb ventral tufts (cirri) and produce new ones from new groups of special organelles called kinetosomes. In a holotrich, new kinetosomes arise next to old ones in alternate fashion; hairlike cilia then sprout from the kinetosomes during elongation of the ciliary rows during fission. Formation of a new mouth may involve extensive reorganization. In dinoflagellates that divide the old cell covering, or theca, the two daughters must build different missing portions. Shelled rhizopods may secrete new plates or collect extraneous materials for building a shell in the next fission. Behaviour of organelles in fission varies—the kinetoplast apparently divides, while the parabasal body is typically resorbed and replaced.

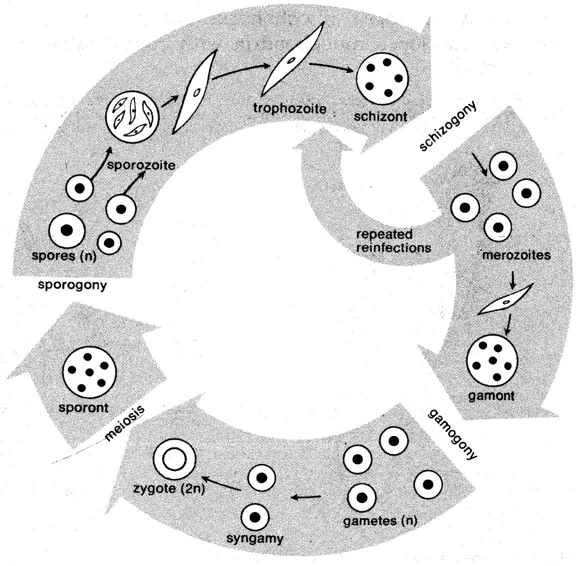

Figure 3: Basic sporozoan life cycle.

Regeneration after amputation has been investigated especially in *Stentor*, in which a fragment less than 1/100 the adult volume may regenerate a complete organism. In order for regeneration to occur, a micronucleus is essential in certain ciliates but not in others, although a portion of the macronucleus is always needed. Regeneration of flagella and cilia is a common phenomenon. Chlamydomonas loses its flagella during fission, and each daughter cell soon regenerates new ones. Hypotrichs also resorb and then regenerate locomotor organelles during fission.

Sexual phenomena. Sexual stages added to the life cycle include production of special gametic nuclei and formation of a fertilization nucleus (synkaryon) by fusion of such nuclei. Chromosome reduction (meiosis) occurs in early divisions of the synkaryon giving rise to a haploid phase (with a single set of chromosomes), from which the sex cells (gametes) are produced. This type of meiosis occurs in phytomonads, sporozoans, and certain parasitic flagellates. Gametic meiosis occurs in the production of sex cells (gametogenesis) of diploid organisms (with double sets of chromosomes) such as heliozoians, which undergo nuclear reorganization without benefit of a sexual partner (autogamy). Intermediate meiosis occurs in foraminiferans, with an alternation of generations, a haploid phase alternating with a diploid phase in which meiosis occurs. Syngamy may be between similar gametes (isogamous) or between obviously different gametes (anisogamous). Apparent isogamy may involve physiologically differentiated gametes (+ and − types), as in Chlamydomonas. Colonial phytomonads may show heterothallic and homothallic strains as well as monoecious and dioecious strains. Homothallic strains produce both types of gametes within a single colony. Heterothallic strains contain two kinds of flagellates; both must be present to insure gametogenesis and syngamy. In Gonium pectorale (strains often heterothallic) each flagellate becomes a gamete and leaves the colony. Gametes pair, and each resulting zygote encysts. Germination with meiosis produces a four-cell stage, which soon divides into four 16-cell colonies. In Pandorina morum (usually heterothallic) germination involves meiosis and degeneration of several nuclei, leaving one haploid flagellate to produce a new colony. In Volvox, a few reproductive cells are scattered in the colony; in Eudorina, reproductive cells are limited to the posterior hemisphere. In the life cycle of V. aureus a reproductive cell may produce microgametes (sperm), daughter colonies, or a macrogamete (egg). Released sperm packets stick to a presumptive female colony whose matrix promptly develops an opening; the microgametes enter and adhere to a reproductive cell, stimulating it to become a macrogamete. The complementary cells then fuse, becoming a zygote. Differentiation of an immature colony into a male is induced by a heat-sensitive factor liberated from mature male colonies. A comparable factor in V. carteri stimulates gonidia to become female colonies. In Chlamydomonas eugametos, a factor from female gametes induces differentiation of male gametes, and vice versa. Sexual activities are complicated by mating types and "varieties" (syngens) analogous to those of ciliates. Strains belonging to different syngens may be unable to mate. Compatible + and − strains produce gametes when mixed, and fusion results; with incompatible strains, no gametes appear.

Syngamy: fusion of gametes

Foraminiferans produce flagellated or amoeboid gametes that fuse in syngamy. Certain life cycles are complicated by alternation of generations comparable to that of plants. The diploid forms reproduce asexually and sooner or later undergo meiosis to produce haploid forms; these reproduce asexually also but eventually produce gametes. Syngamy forms a zygote, which develops into a new diploid form, and the cycle begins anew.

tary mating types within one syngen. Pairing of ciliates from different syngens typically is unsuccessful and results in abortive conjugation. Pairing is induced by specific proteinaceous substances in the ciliate; even free cilia, as in ***Paramecium bursaria,*** agglutinate with intact ciliates of a complementary mating type. After pairing, each conjugant undergoes a complicated nuclear reorganization in which three micronuclear divisions (including meiosis) produce gametic nuclei. Migratory nuclei are exchanged; fusion of a migratory with a stationary nucleus produces a synkaryon in each conjugant (see Figure 4). Each old macronucleus subsequently disappears, while the synkaryon divides into several nuclei, among which survivors differentiate into new macronuclei and micronuclei. Macronuclear differentiation includes chromosomal replication. The developing nucleus increases in size and, in many species, also changes form. The normal nuclear number is restored in reorganization fissions. In ***Paramecium,*** old macronuclear fragments are distributed to each daughter organism. A small amount of cytoplasm is transferred in ***Tetrahymena.*** In ***Vorticella,*** one conjugant is so small that it fails to survive. In autogamy (diploid organisms mostly) a single organism produces haploid nuclei, which then fuse into a synkaryon. In ***Paramecium*** such nuclear activities parallel those of conjugation. Both autogamy and syngamy occur in certain flagellates of the wood roach; in others (Rhynchonympha), only autogamy occurs.

Variation and heredity. In investigations on the haploid ***Chlamydomonas*** and ***Polytoma,*** Mendelian inheritance has been reported for such traits as size, shape, rate of swimming (normal and "lazy"), photosynthesis (normal and slow), storage of volutin (normal and excessive), etc. Linkage has been established for certain pairs of traits, and crossing-over has been demonstrated in several cases.

Observations on traits inherited through conjugation range from size and fission rate to specific enzyme systems, some of the latter observations involving pure cultures of ***Tetrahymena pyriformis.*** For example, the wild strain of ***T. pyriformis*** is unable to synthesize serine and must have this amino acid in defined media. The ability to synthesize serine, known in certain mutant strains, seems to be inherited in Mendelian fashion as a recessive trait. The status of the pyridoxine requirement in T. ***pyriformis*** is similar. Strains that grow without a source of pyridoxine and synthesize it appear to be homozygous recessives. When these are mated with the normal type (pyridoxine-requiring), all the progeny require pyridoxine. Mating types in ***Paramecium,*** *Tetrahymena*, and ***Euplotes*** also seem to be inherited in Mendelian fashion, although the genetic pattern may vary from one variety to another within a species.

There are indications that macronuclear differentiation during postconjugant divisions may influence determination of mating types in ***Paramecium aurelia*** and ***Tetrahymena pyriformis.*** Inheritance of antigenic types in ***P. aurelia*** shows some similarity to the inheritance of mating types, although antigenic types seem to be somewhat less stable under certain environmental conditions. Also inherited is the ability of certain strains of ***Paramecium aurelia*** to destroy other ***P. aurelia*** strains. "Killer" strains of ***P. aurelia*** bear cytoplasmic kappa particles, which secrete killer particles into the surrounding medium. All sensitive strains of paramecia die when they contact killer particles. Kappa particles seem to be self-reproducing, but their persistence in individual ciliates is ultimately dependent upon a gene (or genes).

FORM AND FUNCTION

Form varies in amoeboid types but is fairly constant in species with skeletons, tests, or thick pellicles; the form of colonies is determined by the material holding the colony together. Form may change within a life cycle and also may be modified by environmental conditions. Many protozoan species contain a single spheroid nucleus, whose fine structure resembles that of other nuclei (see CELL AND CELL DIVISION). Some groups, however, have two distinct kinds of nuclei (see Figure 5). The ciliates, for example, have a smaller micronucleus and a larger macronucleus, differing in function and structure. The micronucleus participates in conjugation and autogamy. The macronucleus exerts genetic influence. In addition. ***Paramecium*** cannot survive without a macronucleus,' even with extra micronuclei equalling the macronuclear mass. This may be correlated with the known synthesis of RNA in the macronucleus. A macronucleus is sometimes elongated, branched, or nodular and contains many small granules (chromatin, possibly condensed chromosomes) and usually some nucleoli. Except for ciliates, foraminiferans, and possibly some radiolarians, multinucleate species have nuclei of one kind.

Cytoplasmic inclusions

The cytoplasm. Protozoan cytoplasm contains various particles and organelles. Mitochondria are tiny bodies whose intense enzymic activity is associated with cellular respiration and protein synthesis. The mitochondrion of trypanosomids (*e.g.*, ***Trypanosoma conorhini)*** is tubular and relatively long. Mitochondria1 structure and activity vary with conditions. During growth of ***T. pyriformis,*** mitochondria are normal, peripheral, and may divide; in old populations, they are shorter and smaller, drift into the endoplasm, lose ribosomes, and accumulate lipid globules. Blood stream trypanosomes (T. ***brucei*** group) have poorly developed mitochondria, but cultured forms have well-developed mitochondria with considerable enzymic activity.

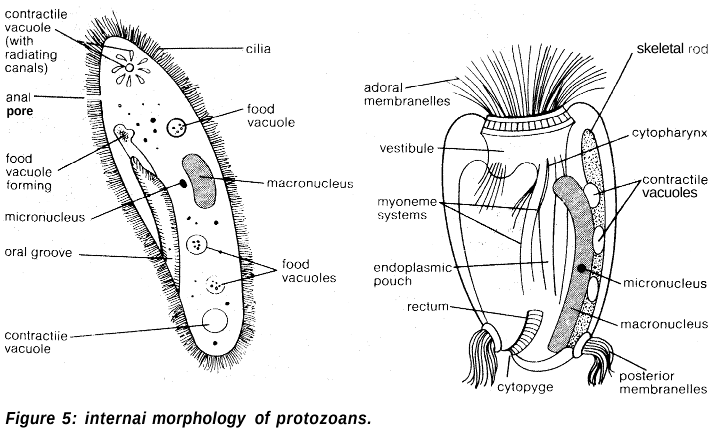

Figure 5: internai morphology of protozoans. (Left) Paramecium. (Right) Spirotrichan ciliate.

Portions of the membranous endoplasmic reticulum are smooth, others rough. Glycogen granules may be synthesized in the reticulum, and rough vesicles underlying the pellicle also may take part in secretion. Ribosomes may be free or associated with the endoplasmic reticulum; they are often clumped into polyribosomes.

Golgi material often consists of stacks of flattened vesicles (cisternae), but single vesicles occur. During acetate starvation of bleached Euglena gracilis Golgi bodies expand, producing lysosome particles that in a short time contain mitochondria and cytoplasmic material and also show enzymic activity. Coccoliths are formed in association with Golgi material in *Cricosphaera cai terae.*

Pigment granules (violet to red) occur in many phytoflagellates and certain other Protozoa. Carotenoids accumulate in certain euglenoids and phytomonads, the predominant type varying with the species. Reddish pigment in Euglena rubra moves to the periphery of the cell with increases in light intensity or temperature. The pink pigment of *Blepharisma* is changed by bright light into a derivative that is toxic to Protozoa (including *Blepharisma*) and rotifers.

Vacuoles. Water elimination vesicles (contractile vacuoles) maintain osmotic equilibrium by eliminating excess water in freshwater species and in certain marine and parasitic species. Hydrostatic pressure on the vacuole causes a discharge of fluid and the collapse of the vesicle. The vesicle is refilled with water from a variety of collecting devices.

Gastrioles

Digestive vacuoles (gastrioles) are formed during ingestion. In Amoeba, part of the cell covering apparently is brought in to line the gastriole. In ciliates with a mouth, a gastriole grows out from the cytopharynx. In Suctoria, gastrioles develop at the bases of tentacles. Flotation vacuoles form a foamy zone of thin-walled vesicles. So-called sensory vacuoles of certain ciliates contain granules (statoliths) of uncertain function.

Pigment bodies. Chromatophores, limited to phytoflagellates (but lacking in many), contain chlorophylls and accessory pigments, some abundant enough to mask the green chlorophyll. Specific pigments vary in different orders. Chromatophores in *E. gracilis* contain DNA and ribosome-associated RNA that are structurally different from nuclear DNA and cytoplasmic RNA. Mutant strains of E. *gracilis* without chromatophores lack a satellite DNA found in normal flagellates. Species of Euglena differ in the presence or absence of pyrenoids, bodies within or attached to chromatophores. Euglenoid pyrenoids are usually covered with paramylum, which may act as a food reserve.

A stigma, or eyespot, common in green flagellates, occurs also in a few colourless species. In Chlamydomonas, the stigma lies inside a chromatophore; in Euglena, it lies in the reservoir from which the flagellum emerges. Composed of one or more plates of reddish globules, the stigma is involved in light reception. The stigma in Euglena periodically shades the paraflagellar body, resulting in flagellar activity directed toward maintaining a favourable orientation to the light source.

Protective coverings. Some phytoflagellates have a covering (theca) composed of cellulose or pectin, resembling a plant cell wall. Mineral-impregnated thecae form rigid coverings and occur as fossils. The dinoflagellate theca, composed of three to four membranes, often shows characteristically arranged plates between the second and third membranes. A conical or tubular rigid covering (lorica), with a wall and an opening for partial extrusion of the organism, occurs in certain flagellates and ciliates. Loricae may adhere to produce colonies.

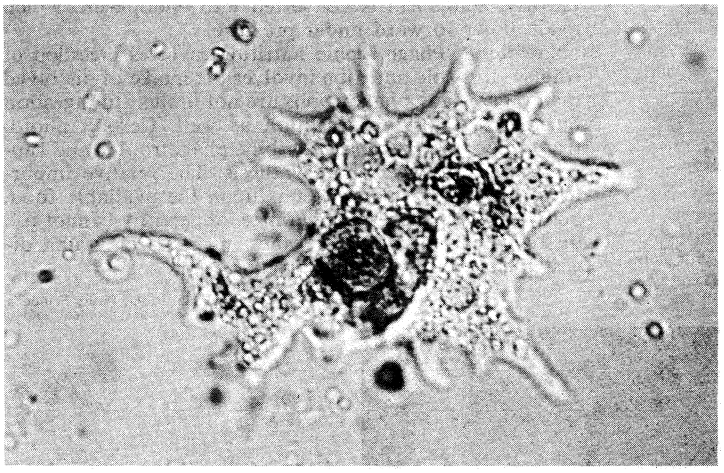
Formation of shells

Foraminiferan shells, or tests, are usually calcareous (sometimes siliceous), often with perforate walls; but *Allogromia* and related types produce a proteinaceous test. Others bind extraneous particles with a glycoprotein. Cytoplasm extruded through the pores may cover the test, or the pores may be filled with a secretion continuous with the calcite layers. Primitive foraminiferans have one-chambered tests with a large aperture; more specialized ones build several to many chambers, in specific patterns. For each new chamber some of the pseudopodia coalesce to form a template on which the chamber wall is secreted. Many radiolarians have siliceous skeletons; those of acantharians are mostly made of strontium sulfate.

So-called protective structures include toxicysts of predatory ciliates (*e.g.,* Dileptus). These organelles contain toxins that can paralyze rotifers and Protozoa, and actually disintegrate them. In Paramecium, a few filamentous trichocysts at a time are partially extruded for anchorage while feeding. Protozoa are covered with a pellicle complex of two or three layers. The pellicle may be decorated with nipples or ridges; in certain gregarines (*Rhynchocystis*) long hairlike cytopilia extend from pellicular ridges. The cortex of ciliates and gregarines, including the pellicle and underlying cytoplasm, is a specialized zone containing a variety of structures.

Appendages. Locomotor and feeding devices include pseudopodia, flagella, and cilia. Most pseudopodia are contraction-hydraulic or two-way sliding types. In the first (*e.g.,* Amoeba proteus), the outer layer is denser than the inner cytoplasm. The second type shows two distally continuous filaments, flowing in opposite directions on opposite sides. These sticky filaments make effective food traps, as in the extensive networks found in foraminiferans. In many heliozoans and acantharians, each axopodium, or "ray," contains an axial filament or cylinder.

Hugh Spencer



The constanfly changing form of Amoeba.

Flagella and cilia

Flagella and cilia have a sheath, continuous with the pellicular complex, and an axoneme, ending basally in a blepharoplast or kinetosome. The axoneme contains one central and nine peripheral pairs of fibrils (peripheral bases forming the blepharoplast). Sometimes the sheath bears lateral fibrils (mastigonemes) that increase the surface and, when rigid, may control direction of the effective force. In Crithidia fasciculata the sticky sheath makes the flagellum a holdfast organelle.

Flagella commonly arise anteriorly and extend forward. Dinoflagellates, however, usually have two fibrils arising near the middle, one extending posteriorly and the other twisted spirally around the body. A trailing flagellum, arising anteriorly, may beat freely or adhere to the edge of a membrane, as in Trichomonas. Flagella range from one to four in most free-living species to dozens in certain parasites. A flagellum may be associated with certain organelles, especially in parasites.

Cilia are arranged in rings or spiral rows. Cilia may be fused into membranes, membranelles, and spiny cirri. Fibrillar systems often seem to join kinetosomes. Contractile fibres, or myonemes, in certain ciliates, gregarines, and flagellates, typically cause changes in form, as when avoiding obstacles, and in the helical coiling of the vorticellid stalk. Myonemes of gregarines and certain flagellates may represent a basic gliding mechanism.

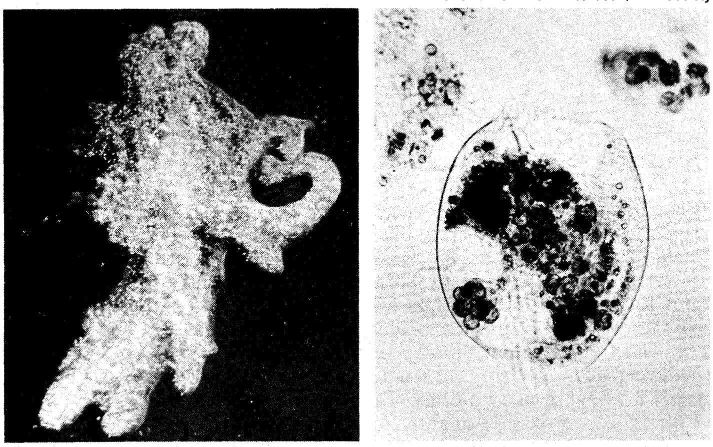
Locomotion. Flagellate locomotion usually involves flagellar activity. In flagellates such as Leptochloris and *Medusochloris,* myoneme-induced contractions expel water from a posterior cavity, driving the organism forward. In Mixotricha paradoxa, swimming results from the svnchronized activity of many spirochetes that attach to and propel the flagellate, whose flagella serve as rudders. Gliding in ***Petalomonas*** involves latero-posterior beating of one flagellum while a second acts like a sled runner. An anterior flagellum also pulls ***Peranema*** and ***Entosiphon.*** The characteristic gliding and creeping in ***Euglena*** (euglenoid movement) are not yet explained satisfactorily. Swimming involves various flagellar activities, while undulatory waves push or pull.

Ciliates use cilia or their derivatives for locomotion; hypotrichs can "walk" on coalesced cilia or cirri. A cilium of ***Paramecium*** beats in a helical wave from base to tip. In swimming forward the ciliary movements in a row pass posteriorly, each cilium slightly out of phase with its anterior and posterior neighbours (metachronal rhythm) but in phase with its lateral neighbours in adjacent rows (isochronal rhythm).

Movements involve pseudopodia in sarcodines and some stages in life cycles of certain mastigophorans and sporozoans. The two-way sliding type functions in locomotion but the mechanism is somewhat uncertain. Contractile-hydraulic movements are exemplified by ***Amoeba proteus.*** An interior fluid (endoplasm) flows forward under pressure from the exterior gel (ectoplasm); on reaching the tip of a developing pseudopodium, the fluid turns backward against the ectoplasm and changes into gel. Posteriorly, ectoplasm is converted into endoplasm, which again flows forward under pressure.

Nutrition. Phagotrophic nutrition involves ingestion of solids; saprozoic nutrition involves the intake of dissolved materials. Many phagotrophs are not limited to ingestion but utilize saprozoic nutrition as well. Certain phototrophs ***(e.g. Ochromonas)*** combine phagotrophic and saprozoic feeding with photosynthesis. The relative importance of phagotrophy depends upon the available food. Such rumen ciliates as ***Entodinium*** apparently cannot use dissolved carbohydrates, yet they ingest starch grains, digest them, and utilize the products.

(Left) Roman Vishniac. (right) Philip Feinberg. Fellow. New York Microscopical Society



(Left) Amoeba catching a ciliate. (Right) Euplotes digesting algae; movement of cilia has started a whirlpool of algae at right.

The process of ingestion

During ingestion, amoebas may form food cups or sometimes invaginations simulating a cytopharynx. In ***Actinophrys sol,*** a flagellate captured on a sticky pseudopodium is moved toward the body surface, where contact stimulates extension of a food cup. The pseudopodial net of foraminiferans is more effective, but the mechanism is similar. Some flageliates ingest food in amoeboid fashion. A few, such as ***Peranema*** and ***Heteronema,*** have a rod apparatus for puncturing prey, whose contents are then sucked down the cytopharynx. Ciliates that eat small organisms commonly have a buccal cavity. In many, an oral groove leads to this cavity. The buccal cavity contains a membrane and membranelles or bands of cilia, which drive particles to the mouth, or cytostome. Mucus in the oral groove or buccal cavity agglutinates particles on their way to the cytostome. Ciastrioles evaginate from the cytopharynx to accept ingested food. When a suctorian host contacts with a ciliate prey, the host's tentacle fuses with the prey, forming a tube down which the ciliate's protoplasm flows into a gastriole of the host. As digestion gets under way, smaller vacuoles are pinched off the gastriole, possibly distributing soluble materials throughout the organism.

Pinocytosis involves saclike infoldings of the cell surface, followed by pinching off of vacuoles internally. Pinocytosis may be a major method of feeding in saprozoic organisms.

Digestion of cellulose occurs in various free-living herbivores and certain parasites. Digestion of starches and glycogens is common, and many protozoan species can digest lipids.

Phototrophs need only light for energy, but a few are able to grow well in darkness in suitable media. Many phototrophs grow on a nitrate or an ammonium salt medium, with supplies of magnesium, calcium, phosphate, sometimes a chloride, and trace metals; in addition, some need one or more vitamins.

As the only carbon source, CO_2 is adequate for certain phytoflagellates but not for other Protozoa. Acetate is an excellent source of carbon for heterotrophic phytoflagellates and can be used to some extent by *Acanthamoeba* and certain other heterotrophs. Glucose is useless to ***Chilomonas*** and is used only by certain strains of ***Astasia*** and ***Euglena,*** yet various chrysomonads ***(e.g., Ochromonas)*** and certain others ***(e.g., Cryptothecodinium)*** use glucose readily.

Vitamin needs

With respect to vitamin requirements, two protozoan groups are distinguishable: (1) The phytoflagellate type usually needs vitamin B_{12}, thiamine, and biotin; (2) heterotrophs require most or all of the following: thiamine, biotin, pantothenic acid, pyridoxine (or pyridoxamine or pyridoxal), riboflavin, nicotinic acid, thioctic acid foi ciliates, folic acid, hematin for certain trypanosomids, and biopterin for ***Crithidia fasciculata.*** Certain heterotrophs also require lipids: a sterol, varying with the species; a tocopherol derivative; and a long-chain fatty acid. Determination of food requirements has encouraged use of Protozoa as sensitive bioassay organisms in medical and ecological research. The choice of organisms is determined by such practical matters as rate of growth and suitability for spectrophotometric measurement of growth. Vitamin B_{12} has been assayed, even in body fluids, with ***Euglena gracilis*** and with ***Ochromonas malhamensis,*** the former being a very sensitive indicator but slightly less specific than the latter in that it responds to pseudo–B_{12} compounds as well. ***Ochromonas*** *malhamensis* also is a sensitive assay organism for thiamine in body fluids, while thioctic acid can be assayed with ***Tetrahymena pyriformis.***

Oxygen requirements

There is a wide range in oxygen needs among Protozoa. Obligate aerobes are limited to habitats with adequate oxygen concentrations; certain aerobes, however, grow best at oxygen tensions below that of the normal atmosphere. Obligate anaerobes, on the other hand, are restricted to environments lacking oxygen—*e.g.*, natural waters loaded with putrefying material, the lower levels of deep lakes, Imhoff sewage tanks, the intestines of vertebrates, etc.

Typical aerobes utilize the cytochrome system—a terminal oxidative system characteristic of aerobic organisms—in their major oxidative pathway. The genus ***Trypanosoma,*** however, is interesting in that certain species are sensitive to cyanide poisoning, which blocks the cytochrome pathway, while others are rather insensitive.

Excretion and secretion. Excretion involves elimination of wastes through the surface. The major nitrogenous waste is ammonia (accounting for about 90 percent of the total in ***Paramecium caudatum).*** In addition, small amounts of a few amino acids and products of purines and pyrimidines are eliminated by certain ciliates. Waste products of carbon metabolism include CO_2 and, in fermentation of carbohydrates, organic acids and sometimes hydrogen (H_2). Secretions include materials for shells, mucous trails for gliding, cements, the matrix of colonies, and component plates.

EVOLUTION AND PHYLOGENY

The geological age of Protozoa is uncertain but estimates run as high as 1,500,000,000 to 3,000,000,000 years. Fossils dating from the Early Paleozoic, with ages of approximately 450,000,000 years, include skeletons of radiolarians, loricae of tintinnid ciliates, and thecae of dinoflagellates. Some phytoflagellate-like fossils may be several times as old. Each of the Paleozoic groups represents fairly specialized members of its class or order, so that protozoan evolution must have been well along when these organisms were alive.

Origin of Protozoa

Although fossil records supply data for estimating ages of a few protozoan groups, tracing the phylogenetic relationships of modern Protozoa is a different matter. Any phylogenetic tree is extremely hypothetical at best. It is based upon available collateral information, which forms a basis for speculation. A biochemical approach to estimating degrees of relationship among protozoans involves extracting DNA from different species and testing for shared nucleotide sequences, the inference being that the higher the number of shared nucleotide sequences the closer the relationship of the organisms in question. As for the origin of the Protozoa, it is often assumed that some ancient "plant-animal" group (ancestral phytoflagellates) split up into several different stocks, each of which gave rise to the more immediate ancestors of modern Protozoa. This theory of polyphyly, or origin from several ancestral forms, is inferred from the distinct protozoan lines represented in living groups: (1) the algal stocks that gave rise to modem algae and phytomastigophorans; (2) the amoeboid stocks that produced modern sarcodines, apparently representing several distinct lines; (3) the flagellate stocks leading to zoomastigophorans (possibly also to the opalinates); (4) the sporozoan stocks leading to gregarines, coccidians, and toxoplasmas; (5) the stocks that produced the myxosporidians, microsporidians, and haplosporans; and (6) the stocks leading to modern ciliate groups. The phylogenetic origins of Protozoa may be traced thiough an uncertain number of different stocks to a remote hypothetical group of ancestral "plant-animals" presumably representing unspecialized phytoflagellates able to undergo diversification.

CLASSIFICATION

Protozoans are eucaryotic organisms; that is, they have distinct nuclear material. Their disposition into taxa is based primarily on differences in locomotion, number of nuclei, organelles, life cycle, and mode of reproduction. Nutrition, whether plantlike (capable of photosynthesis) or animallike and whether free-living or parasitic, is important in the ranking of lower taxonomic groups.

Many protozoology textbooks will flatly state, "protozoans are unicellular animals." Others consign certain types to the botanists as unicellular plants. Proposals to assign the protozoans a place within the Protista because of structural and evolutionary closeness to slime molds, fungi, and algae have not met with whole-hearted endorsement. Protozoa, however, are not "animals" in the same sense that higher animals are. They are, nevertheless, the most animallike of protists. A collective term for the four major groups of protozoans is desirable as a matter of convenience. On such grounds, the continued use of the term Protozoa seems satisfactory.

The following system, proposed by the Society of Protozoologists in 1964, represents a compromise, proposed hopefully to stimulate further interest in protozoan classification.

PHYLUM PROTOZOA

About 30,000 living species described; fossil types are probably more numerous. Eucaryotic organisms, 1 to many nuclei; organisms single or associated in colonies; majority heterotrophic, but chromatophores present in many phytoflagellates; other organelles vary in complexity; many taxa contain a few to many (or only) parasitic species.

Subphylum Sarcomastigophora

Locomotor organelles are flagella or pseudopodia, sometimes both; nuclei are uniform (except particular stages in life cycles of certain Forarniniferida); reproduction by fission, budding, or plasmotomy.

Superclass Mastigophora (flagellates)

About 6,000 species (not including fossils) Solitary or colonial; with flagella, except in certain-stages of life cycle; mostly heterotrophic, but many phytoflagellates have chromatophores.

Class Phytamastigophorea (phytoflagellates)

Many with chromatovhores: food requirements simvler than those of other flagellates; rarely more than 1 or 2 flagella; mostly free-living; syngamy only in certain groups.

Order Chrysomonadida. Marine and freshwater; 1 or 2 active flagella, some with a third inactive flagellum; chromatophores, 1 or 2, yellow to brown; stored leucosin and lipids; cyst wall siliceous; life cycles may include flagellate, amoeboid, or palmella stages, any one of which may be dominant. (Ochromonas, *Dinobryon*, *Mallomonas*, Prymnesium.)

Order *Silicoflagellida.* Marine; uniflagellate; numerous greenish-brown chromatophores; leucosin stored; siliceous skeleton characteristic; many fossils known. (*Dictyocha.*)

Order Coccolithophorida (coccoliths). Mostly marine or brackish-water, very few freshwater types; biflagellate; chromatophores yellow to brown; peripheral zone of calcareous coccoliths. (Discosphaera, Hymenomonas, Rhabdosphaera.)

Order Heterochlorida. Flexible periplast; typically 2 unequal flagella; 1 to several yellow to greenish-yellow chromatophores; leucosin and lipids stored; cyst bivalved; some have amoeboid, plasmodial, or palmella stages. (*Chloromeson*, Nephrochloris, Myxochloris.)

Order Cryptomonadida. Marine and freshwater; 2 flagella, emerging from a ventral groove or pouch lined with refractile inclusions ("trichocysts"); usually 2 chromatophores—brown, blue-green, green, or red; starch and lipids stored. (Chilomonas, Cryptomonas, Nephroselmis.)

Order *Dinoflagellida* (dinoflagellates). Mostly marine, some freshwater; one flagellum typically trailing, the other lying in transversely spiral girdle; theca common, often with differentiated plates; chromatophores (if present) numerous, yellow-green to brown, sometimes blue-green; some are phagotrophs. (Ceratium, Gymnodinium, *Gonyaulax*, Peridinium, Noctiluca.)

Order Ebriida. Marine, planktonic; biflagellate; no chromatophores; typically with siliceous skeleton, internal; fossils fairly numerous. (Ebria, Hermesinum.)

Order *Euglenida.* Mostly freshwater, some marine; 1 or 2 flagella, rarely more, emerging from a pouch (reservoir); chromatophores (if present) fairly numerous, green; some species accumulate red pigment; species with thin pellicle complex undergo metaboly (euglenoid movement). (Euglena, *As*tasia, Peranema, Trachelomonas.)

Order Chloromonadida. Freshwater body usually flattened dorsoventrally; 2 flagella (one trailing) arising from anterior pouch or groove; numerous bright green chromatophores; lipids, glycogen stored. (*Gonyostomum*, *Vacuolaria.*)

Order Volvocida. Mostly freshwater; chromatophores green, also some species colourless; some accumulate red pigment; flagella apical, 2 or 4; solitary or colonial; starch and lipids stored; syngamy common, sometimes marked anisogamy (*Volvox*, etc.). (Chlamydomonas, Haematococcus, *Po*lytoma, Gonium, Pandorina.)

Class Zoomastigophorea (zooflagellates)

Without chromatoyhores; organelles other than flagella more varied than in Phytomastigophorea; syngamy and autogamy reported in a few.

Order *Choanoflagellida.* Mostly freshwater; anterior collar surrounds base of single flagellum; solitary or colonial forms, typically sessile, with or without stalk; lorica in some species. (Codonosiga, *Diplosiga*, Salpingoeca.)

Order Bicosoecida. Freshwater; loricate, colonial; 1 flagellum extends from lorica, the other anchors the flagellate to the base of its lorica. (Bicosoeca.)

Order Rhizomastigida. Mostly freshwater, some parasitic; more or less amoeboid, usually with 1 to 4 flagella; Histomonas causes enterohepatitis in chickens and turkeys. (Histomonas, Mastigella, Mastigamoeba.)

Order Kinetoplastida. Mostly parasitic; kinetoplast characteristic; 1 to 4 flagella; life cycles may involve more than 1 host. (Bodo, Trypanosoma, Leishmania, Crirhidia.)

Order Retorfomonadida. Parasitic; 2 to 4 flagella, one extending posteriorly in a cytostomal groove bordered by fibrils. (Chilomastix,Retortomonas.)

Order Diplomonadida. Mostly parasitic; binucleate, bilaterally symmetrical; organized as 2 karyomastigonts, each with four flagella and associated organelles. (Giardia, *Hexami*ta, Trepomonas.)

Order *Oxymonadida.* Parasitic; uninucleate or multinucleate; 1 or more karyomastigonts, each usually with 4 (sometimes 8 or 12) flagella; some attach to gut wall of termites and wood roaches by extensible rostellum; syngamy in certain species. (Dinenympha, Pyrsonynzpha, uninucleate; *Microrhopalodina,* Barroella, multinucleate.)

Order Trichomonadida. Parasitic; each mastigont contains 3 to **6** flagella, a parabasal body, and an axostyle; uninucleate or multinucleate. (Devescovina, *Calonympha, Trichomonas,* Snyderella.)

Order Hypermastigida. Parasitic; uninucleate, multiflagellate; parabasal apparatus multiple; blepharoplasts distributed in rows or plates, flagella in rows or bundles; some ingest wood chips; gut of termites, wood roaches, cockroaches. (Trichonympha, Holomastigotoides, Mixotricha.)

Superclass *Opalinata*

About 200 species. Parasites; resemble both Mastigophora and Ciliophora; cilia-like organelles forming oblique rows over body; 2 to many monomorphic nuclei; plane of fission oblique, not transverse as in typical ciliates; syngamy reported. (Opalina, Protoopalina.)

Order Opalinida. The only order under this superclass.

Superclass Sarcodina

About 11,500 living species (many fossils, about 28,000 Foraminifera alone); mostly free-living; some have flagella in certain stages of the life cycle. Syngamy in certain groups; pellicle usually thin and flexible; tests in certain group;; endoskeletal elements in some.

Class Rhizopodea

Temporary flowing appendages called pseudopodia; no foamy peripheral cytoplasm; tests are common.

Subclass Lobosia. Fingerlike pseudopodia (lobopodia).

Order Amoebida (amoebas). Marine and freshwater; mostly uninucleate; mostly free-living. (Amoeba, Thecamoeba, Entamoeba.)

Order Arcellinida. Freshwater; tests characteristic, secreted or arenaceous; pseudopodia extruded through aperture of test. (Arcella, Centropyxis, *Difflugia.*)

Subclass Filosia. Pseudopodia slender, branching, rarely anastomosing.

Order Aconchulinida. Without tests; little known.

Order Gromiida. Mostly freshwater; tests mostly chitinous, aperture distinct; flagellate stages in certain species; anastomosis of pseudopodia not marked. (Gromia.)

Subclass Granuloreticulosia. Pseudopodia delicate, showing moving granules.

Order *Athalamida.* No tests; little-known group.

Order Foraminiferida (forams). Mostly marine and brackish-water; about 4,200 living species, approximately 28,000 fossil types; tests with 1 to many chambers, secreted (calcareous predominantly, siliceous rarely) or arenaceous; during growth, multilocular types add new chambers in characteristic patterns; reticulopodia extend from aperture or partly from cytoplasm covering test; extensive reticulopodial network characteristic. (Allogromia, *Patellina,* Saccamina, *Cyclammina,* Bathysiphon.)

Order Xenophyophorida. Deep-sea; discoid or fan-shaped, reaching several centimetres across; consist of fine tubes in agglutinated foreign particles; finer tubules contain multinucleate protoplasm; iiving forms not yet investigated: relationships uncertain. (Psammetta, Stanomma.)

Subclass Mycetozoia. Young amoebas develop into aggregates or into large plasmodia; resemble fungi in production of "sporangia" enclosing "spores" (cysts), from which hatch amoeboid stages.

Order Acrasida. Soil, decaying plants; aggregates are pseudoplasmodia; flagellate stages unknown; free-living. (Acrasis, Dictyostelium.)

Order Eumycetozoida (slime molds). Rotting leaves, logs; plasmodium often shows many channels containing flowing endoplasm; many produce sporangia at maturity. (Fhysarum, Fuligo, Arcyria.) (See SLIME MOLDS.)

Order Plasmodiophorida. Parasitic; mature stage a plasmodium inside a plant cell; cysts ("spores") develop inside the plasmodium. (Plasmodiophora, Sorosphaera, Textramyxa.)

Subclass Labyrinthulia. Mostly marine, on eelgrass and certain algae; spindle-shaped organisms that secrete tubular "tracks" by means of which the organisms glide; swimming stages (1 anterior, 1 trailing flagellum) described as similar to fungal zoospores.

Order *Labyrinthulida.* The only order. (Labyrinthula.)

Class Piroplasmea

Parasitic; transferred by ticks; attacks vertebrate red blood cells; reproduction by fission; taxonomic position debatable.

Order Piroplasmida. The only order in the class. (Babesia.)

Class *Actinopodea*

Mostly freshwater; pseudopodia slender, radially arranged; true axopodia in some genera; test present or absent; may have skeletal elements of silica or strontium sulfate; a central capsule in many; syngamy (pedogamy) in certain genera.

Subclass Radiolaria. Marine; about 4,800 living, 2,400 fossil species; central capsule dividing cytoplasm into **2** zones; a siliceous skeleton, or separate spicules; pseudopodia may be filopodia, reticulopodia or, rarely, axopodia.

Order Porulosida. Pores distributed over surface of spherical central capsule; a few have no skeleton; in others, spicules, a perforated test, or both may be present; colonies formed in some genera. (*Collozoum,* Pipetta, Cenosphaera.)

Order Oculosida. Pores limited to a few fields in the capsule. (*Lithocircus,* Aulacnntha, *Challengeron.*)

Subclass Acantharia. Mostly marine; skeletons composed mainly of strontium sulfate; primary skeletal elements are rods extending radially from centre, passing through the central capsule; a latticework test at the surface may be fused with the radial rods (20, or some multiple of **20**), which form a characteristic pattern; outer layer of cytoplasm often joined to rods by contractile fibrils; axopodia present.

Order Acanthometrida. Skeleton composed of rods, no latticework test. (Acanthometra, Zygacanthidiurn.)

Order Acnnthophractida. Latticework test present. (*Dorotaspis,* Lithoptera.)

Subclass Heliozoia. Mostly freshwater; skeletal elements (if present) often limited to scales and spines, but test in some; no central capsule; axopodia or filopodia.

Order Actinophryida. Scales and spines lacking; outer cytoplasm often highly vacuolated; uninucleate or multinucleate; axopodia present. (Actinophrys, Actinosphaerium.)

Order Centrohelida. Central granule (centroplast) present; axonemes of axopodia often converge in centroplast; skeletal plates and spines often present. (Acanthocysiis, *Raphidocystis.*)

Order Desmothoracida. No centroplast; skeleton a nonsiliceous test, with pores through which slender granular pseudopodia extend. (Choanocystis, Hedriocystis, Clathrulina.)

Subclass Proteomyxidia. Parasitic; slender granular pseudopodia or filopodia present; no skeletal elements; many are invaders of Volvocida, filamentous algae, and cells of higher plants.

Order Proteomyxida. The only order. (Pseudospora, Vampyrella, Leptomyxa.)

Subphylum Sporozoa

Abont 3,600 species known. Parasites of invertebrates and vertebrates, or both in certain species; life cycle with asexual and sexual phases, reproduction in each (except in most gregarines); majority produce spores; syngamy in most, if not all, sometimes with flagellated gametes; locomotion by gliding, sometimes by pseudopodia; reproduction by schizogony typical.

Class Telosporea

Syngamy, followed by sporulation, just before or after transfer to a new host; pseudopodia obvious only in growth stages of certain groups; sporozoites (often encysted, forming a spore) transferred to a new host, or from vector to vertebrate.

Subclass Gregarinia (gregarines). Parasites of invertebrates, mostly in body cavity and digestive tract; gamonts (gametocytes) often associate in pairs before gametogenesis; mature organisms large, extracellular.

Order Archigregarinida. Parasites of annelids, sipunculids, hemichordates, urochordates; life cycle shows intracellular schizogony; only gamonts are extracellular. (Selenidium, *Schizocystis.*)

Order Eugregarinida. Parasites of annelids, insects, crustacea, echinoderms, sipunculids, urochordates; no merogony in asexual phase of cycle. (Gregarina, Monocystis, Porospora.)

Order Neogregarinida. Mostly parasites of insects; schizogony in asexual phase; each gametocyte produces 1 spore. (Ophryocystis, Merogregarina.)

Subclass Coccidia. Parasites of invertebrates and vertebrates; trophozoites mature intracellularly, much smaller than those of gregarines; reproduction in asexual and sexual phases of cycle.

Order Protococcida. Elongated nematode-like organisms; no intracellular schizogony; rare. (Selenococcidium, first reported from marine crab.)

Order Eucoccida. Parasites mostly in epithelial or blood cells; intracellular merogony characteristic. (Eimeria, Adelea, *Isospora,* Plasmodium.)

Class Toxoplasmea

lntracellular parasites, common in man and other vertebrates; reproduction by fission or a peculiar internal budding; locomotion (without flagella or pseudopodia) involves a gliding similar to that of Plasmodium sporozoites; life cycle completed in 1 host; a number of parasites accumulate in host cell, remnants of which form a pseudocyst.

Order Toxoplasmida. The only order in the class. (*Toxoplasma*, Besnoita, similar to Toxoplasma in morphology and antigenic composition, probably belongs here.)

Subclass *Haplosporea.* Parasites of fishes and tunicates, and of mollusks, annelids, and other invertebrates; mature stage a plasmodium; flagella absent; infective amoeba stage may invade tissue cell or develop in body cavity; syngamy described in Coelospora, Minchinia, unknown in others. (*Coelosporidium*, Coelospora, Haplosporidiunz, Minchinia.)

Subphylum Cnidospora

About 1,100 species known. Parasites producing spores (cysts) with 1 or more polar filaments and 1 or more infective stages (sporoplasms); young trophozoite typically develops into a plasmodium; structure of spore differentiates classes.

Class Myxosporidea

Spore membrane composed of 2 or 3 valves; spore of "multicellular" origin, containing 1 or more sporoplasms.

Order Myxosporida. Parasites of lower vertebrates; spore membrane composed typically of 2 valves; spore contains 1 or 2 sporoplasms and usually 2 (sometime 1 to 6) polar filaments. (*Unicapsula,* Myxidium, Ceratomyxa, Myxobolus.)

Order Actinomyxida. Parasites of invertebrates (mostly annelids); spore membrane composed of 3 valves, each sometimes drawn out into a spine; 3 polar filaments; 1 to many sporoplasms. (Triactinomyxon, Sphaeractinomyxon, Guyenotia.)

Order Helicosporida. Parasites of arthropod larvae; mature spore contains 3 sporoplasms surrounded by spirally wound filaments; spore membrane not differentiated into valves. (Helicosporidium.)

Class Microsporidea

Parasites mostly in arthropods and fishes (usually skin, muscles); spores small (about 2-20 μm long), membrane not differentiated into valves; one polar filament.

Order Microsporida. The only order in this class. (*Coccomyxa*, *Nosema,* Telomyxa.)

Subphylum Ciliophora (Ciliates)

About 6,000 living species. Marine and freshwater; cilia or derivatives in at least 1 stage of the life cycle; 2 kinds of nuclei characteristic; conjugation (also autogamy in some) rather than syngamy; plane of fission typically transverse to major axis.

Class *Ciliatea*

Characteristics of the subphylum.

Subclass Holotrichia. Most free-living, few parasitic; less specialized than other Ciliatea; somatic ciliature often uniform.

Order Gymnostomatida. Marine, freshwater, some predatory; no buccal organelles; cytostome opens at surface; circumpharyngeal trichites often present; ciliature often uniform, but cilia limited to ventral surface in 1 group of flattened types; some feed on algae, protozoans, rotifers. (Coleps, *Dileptus*, Didinium, Chilodonella.)

Order Trichostomatida. Fresh-water, some commensal or parasitic; no buccal organelles, but vestibular ciliature may be specialized; cytostome often at base of groove or pit; somatic ciliature usually uniform; found in the stomach of certain ruminants and in the intestine of many vertebrates, including man. (Colpoda, Conidiophrys, Balantidium, Trichospira.)

Order Chonotrichida. Marine (except one genus), commensals mostly on crustacea; somatic ciliature absent in mature forms; vase-shaped body typical; peristomial funnel equipped with cilia derived from those of larval stage. (*Stylochona*, Trichochona, Chilodochona.)

Order Apostomatida. Parasites mostly of marine crustacea; ciliature spiral at maturity; life cycles typically polymorphic, minute cytostome near peculiar "rosette" of uncertain function. (Chromidina, Foettingeria, Polyspira, *Gymnodinioides*.)

Order Astomatida. Parasitic, mostly in earthworms, a few in snails, flatworms, and amphibians; no cytostome; somatic ciliature usually uniform; anterior holdfast organelle common; chains common in some families. (Anoplophrya, Corlissiella, Maupasella, Haptophrya, Hoplitophrya.)

Order Hymenostomatida. Marine, freshwater, some parasitic; buccal organelles (tetrahymenal type) include membrane (on right) and typically three membranelles (on left); somatic ciliature essentially uniform; buccal cavity ventral. (Tetrahymena, Colpidium, Glaucoma, Paramecium.)

Order Thigmotrichida. Generally parasitic in bivalve mollusks;-tuft of thigmotactic cilia commonly present near anterior end; bucca organelles (if present) are ventral and in posterior half (or at posterior end). (*Boveria*, *Conchophthirius*, Hypocoma, Heterocinefa.)

Subclass Peritrichia. Marine, freshwater, some parasitic; somatic ciliature absent at maturity, but apical ciliature winds counterclockwise to cytostome; mostly sessile at maturity, attached by a stalk (product of a scopula) or adhesive basal disk; larval stages migratory, with ciliary girdle; many are colonial.

Order *Peritrichida.* The only order in this subclass. (*Vorticella, Carchesium,* Trichodina, *Epistylis.*)

Subclass Suctoria. Marine, freshwater, free-living predators; ciliature (but not kinetosomes) absent in mature stage; mostly sessile, attached by stalk (scapula-produced); astomatous larva, produced by budding, develops sparse ciliature from inherited kinetosomes; adults feed mostly on other ciliates by means of suctorial tentacles.

Order *Suctorida.* The only order in this sublcass. (*Tokophrya*, Podophrya, Ephelota, *Dendrosoma.*)

Subclass Spirotrichia. Marine, freshwater, some commensal or parasitic; somatic ciliature sparse (except in Heterotrichida); conspicuous buccal organelles include many membranelles, in zone winding clockwise to cytostome.

Order *Heterotrichida.* Marine, freshwater, some parasitic; ciliature commonly uniform, but restricted to ventral surface in 1 family; membrane often present at right of peristome; a few sessile types loricate, with a migratory larva. (*Bursaria, Stentor, Blepharisma, Spirostomum, Folliculina.*)

Order Oligotrichida. Mostly marine; somatic ciliature reduced or lacking (persisting somatic ciliature often arranged in tufts); conspicuous buccal membranelles often form apical zone around end of body. (Strombidium, Halteria, *Strobilidium*.)

Order Tintinnida. Nearly all marine; all loricate; buccal membranelles conspicuous when extended from lorica. (*Tintinnus,* Codonella, Favella, Tinrinnidium.)

Order Entodiniomorphida. Commensals; ciliature much reduced, limited to organelles arranged in tufts or bands; adoral membranelles extend spirally to cytostome lying in apical disk; the firm pellicular complex may be drawn out into posterior spines; found in the rumen of ruminants and in the intestine of certain other herbivores. (Diplodinium, *Entodinium*, *Ophryoscolex*, Cycloposthium.)

Order *Odontostomatida.* Nearly all freshwater; small laterally compressed, wedge-shaped; somatic ciliature much reduced; only eight buccal membranelles; firm pellicular complex, often drawn out into spines. (Saprodinium, Mylestoma, Epalxis, Atopodinium.)

Order Hypotrichida. Marine, freshwater, few parasitic; cilia replaced by cirri, arranged in specific patterns on ventral surface (also near margin of body in some genera); adoral zone of membranelles conspicuous; typically flattened dorsoventrally, often with firm pellicle. (*Euplotes,* Stylonychia, Uronychia.)

Critical Appraisal. Protozoa as a taxon meets the criterion of convenience in current classifications. Troubles begin primarily when the essential artificiality of the Phylum Protozoa is disregarded. The system outlined above recognizes four major groups of Protozoa, each ranked as a subphylum. Whatever their ranks, the groups differ in degree of homogeneity. The Sarcomastigophora, the least homogeneous, include two groups of Mastigophora that differ considerably in morphological and biochemical features, although sharing the ability to produce flagella. The Phytomastigophorea, essentially, are a heterogeneous collection of algae that protozoologists choose to call Protozoa. The Zoomastigophora are clearly animallike in many characteristics. A subphylum containing both groups must be considered polyphyletic. Furthermore, the Sarcomastigophora also include the Sarcodina, and there are sound reasons for concluding that this subdivision likewise contains two major groups (differing in their mechanisms of locomotion). The other subphyla—Ciliophora, Sporozoa, and Cnidospora — are more nearly homogeneous than the Sarcomastigophora. The degree of relationship between any two of the four is quite uncertain at present; and the only safe conclusion, if a common phytoflagellate ancestry is assumed, is that the four groups have evolved independently for a long time. A collective term for the four major groups is desirable as a matter of convenience. On such grounds, continued use of the taxon Protozoa seems satisfactory.

One recent proposal would assign most of the Protozoa to a Kingdom Protista, elevating a number of presently subordinate taxa to the rank of phylum. This would result in taxonomic equivalence of such groups as the Order Euglenida (Euglenophyta) and the Subphylum Ciliophora (presently including 15 orders). The average protozoologist will find little philosophical or utilitarian advantage in such a system, which obviously would require extensive revision of our current concepts of taxa.

So far as the Protozoa are concerned, the interests of taxonomy would probably be served best by continued attempts to collect pertinent data and to devise less subjective methods for estimating degrees of relationship. There seems to be little fundamental benefit to be derived from a mere reshuffling of taxonomic names.

Proudhon, Pierre-Joseph

Pierre-Joseph Proudhon, libertarian Socialist, is celebrated as the first man to call himself an Anarchist. Mikhail Bakunin, the Russian aristocrat who gained more notoriety in that role, once remarked that "Proudhon was the master of us all," and in the sense that Anarchism as a movement derived from Proudhon's teachings and his immediate disciples, the statement was correct. Yet Proudhon was not the first to enunciate the doctrine that is now called Anarchism; before he claimed it, it had already been sketched out by, among others, the English philosopher William Godwin in prose and by his follower, Percy Bysshe Shelley, in verse.

There is no evidence, however, that Proudhon, who was born in Besançon, France, January 15, 1809, ever studied the works of either Godwin or Shelley; and his characteristic doctrines of Anarchism (society without government), Mutualism (workers' association for the purpose of credit banking), and federalism (the denial of centralized political organization) seem to have resulted from an original reinterpretation of French revolutionary thought modified by personal experience.

Early life and education

Proudhon was born into poverty as the son of a feckless cooper and tavern keeper, and at nine he worked as a cowherd in the Jura Mountains. His country childhood and peasant ancestry influenced his ideas to the end of his life; and his vision of the ideal society almost to the end remained that of a world in which peasant farmers and small craftsmen like his father could live in freedom, peace, and dignified poverty, for luxury repelled him and he never sought it for himself or others.

Proudhon at an early age showed the signs of intellectual brilliance, and he won a scholarship to the college at Besançon. Despite the humiliation of being a child in sabots (wooden shoes) among the sons of merchants, he developed a taste for learning and retained it even when his family's financial disasters forced him to become an apprentice printer and later a compositor. While he learned his craft, he taught himself Latin, Greek, and Hebrew; and in the printing shop he not only conversed with various local liberals and Socialists but also met and fell under the influence of a fellow citizen of Besançon, the utopian Socialist Charles Fourier.

Proudhon and his children, oil painting by Gustave Courbet, c. 1865. In the Musée du Petit Palais, Paris.
Giraudon

With other young printers, Proudhon later attempted to establish his own press, but bad management destroyed the venture; and it may well have been compounded by his own growing interest in writing, which led him to develop a French prose difficult to translate but admired by writers as varied as Flaubert, Sainte-Beuve, and Baudelaire. Eventually, in 1838, a scholarship awarded by the Besançon Academy enabled him to study in Paris. Now, with leisure to formulate his ideas, he wrote his first significant book, ***What Is Property?*** (1840). This created a sensation, for Proudhon not only declared, "I am an anarchist"; he also stated, "Property is theft!"

His first book, ***What Is Property?***

This slogan, which gained much notoriety, was an example of Proudhon's inclination to attract attention and mask the true nature of his thought by inventing striking phrases. He did not attack property in the generally accepted sense but only the kind of property by which one man exploits the labour of another. Property in another sense—in the right of the farmer to ***possess*** the land he works and the craftsman his workshop and tools—he regarded as essential for the preservation of liberty; and his principal criticism of Communism, whether of the utopian or the Marxist variety, was that it destroyed freedom by taking away from the individual control over his means of production.

In the somewhat reactionary atmosphere of the July monarchy in the 1840s, Proudhon narrowly missed prosecution for his statements in ***What Is Property?;*** and he was brought into court when, in 1842, he published a more inflammatory sequel, ***Warning*** to ***Proprietors.*** On this first of his trials, Proudhon escaped conviction because the jury conscientiously found that they could not clearly understand his arguments and therefore could not condemn them.

In 1843 he went to Lyons to work as managing clerk in a water transport firm. There he encountered a weavers' secret society, the Mutualists, who had evolved a protoanarchist doctrine that taught that the factories of the dawning industrial age could be operated by associations of workers and that these workers, by economic action rather than by violent revolution, could transform society. Such views were at variance with the Jacobin revolutionary tradition in France, with its stress on political centralism. Nevertheless, Proudhon accepted their views and later paid tribute to his Lyonnais working-class mentors by adopting the name of Mutualism for his own form of Anarchism.

As well as encountering the obscure working-class theoreticians of Lyons, Proudhon also met the feminist Socialist Flora Tristan and, on his visits to Paris, made the acquaintance of Karl Marx, Mikhail Bakunin, and the Russian Socialist and writer Aleksandr Herzen. In 1846 he took issue with Marx over the organization of the Socialist movement, objecting to Marx's authoritarian and centralist ideas. Shortly afterward, when Proudhon published his *System of Economic Contradictions: or the Philosophy of Poverty* (1846), Marx attacked him bitterly in a book-length polemic, *The Poverty of Philosophy* (1847). It was the beginning of a historic rift between libertarian and authoritarian Socialists and between Anarchists and Marxists which. after Proudhon's death, was to rend Socialism's First International apart in the feud between Marx and Proudhon's disciple Bakunin and which has lasted to this day.

Rift with Karl Marx

Early in 1848 Proudhon abandoned his post in Lyons and went to Paris where in February he started the paper *Le Représentant du peuple.* During the revolutionary year of 1848 and the first months of 1849 he edited a total of four papers; the earliest were more or less regular Anarchist periodicals and all of them were destroyed in turn by government censorship. Proudhon himself took a minor part in the Revolution of 1848, which he regarded as devoid of any sound theoretical basis. Though he was elected to the Constituent Assembly of the Second Republic in June 1848, he confined himself mainly to criticizing the authoritarian tendencies that were emerging in the revolution and that led up to the dictatorship of Napoleon III. Proudhon also attempted unsuccessfully to establish a People's Bank based on mutual credit and labour checks, which paid the worker according to the time expended on his product. He was eventually imprisoned in 1849 for criticizing Louis-Napoleon, who had become president of the republic prior to declaring himself Emperor Napoleon III, and Proudhon was not released until 1852.

His conditions of imprisonment were——by 20th-century standards—light. His friend could visit him, and he was allowed to go out occasionally in Paris. He married and begat his first child while he was imprisoned. From his cell he also edited the last issues of his last paper (with the financial assistance of Herzen) and wrote two of his most important books, the never translated *Confessions d'un révolutionnaire* (1849) and *The General Idea of the Revolution in the Nineteenth Century* (1851). The latter —in its portrait of a federal world society with frontiers abolished, national states eliminated, authority decentralized among communes or locality associations, and with free contracts replacing laws—presents perhaps more completely than any other of Proudhon's works the vision of his ideal society.

After Proudhon's release from prison in 1852 he was constantly harassed by the imperial police; he found it impossible to publish his writings and supported himself by preparing anonymous guides for investors and other similar hack works. When, in 1858, he persuaded a publisher to bring out his three-volume masterpiece *De la justice dans la Rkvolution et darts l'église,* in which he opposed a humanist theory of justice to the church's transcendental assumptions, his book was seized. Having fled to Belgium, he was sentenced *in absentia* to further imprisonment. He remained in exile until 1862, developing his criticisms of nationalism and his ideas of world federation (embodied in *Du Principe fkdkratif,* 1863).

On his return from Paris, Proudhon began to gain influence among the workers; Paris craftsmen who had adopted his Mutualist ideas were among the founders of The First International just before his death on January 19, 1865. His last work, completed on his death bed, *De la capacité politique des classes ouvrières* (1865), developed the theory that the liberation of the workers must be their own task, through economic action.

Assessment

Proudhon was a solitary thinker who refused to admit that he had created a system and abhorred the idea of founding a party. There was thus something ironical about the breadth of influence that his ideas later developed. They were important in the First International and later became the basis of Anarchist theory as developed by Bakunin and the Anarchist writer Peter Kropotkin. His concepts were influential among such varied groups as the Russian populists, the radical Italian nationalists of the 1860s, the Spanish federalists of the 1870s, and the syndicalist movement that developed in France and later became powerful in Italy and Spain. Until the beginning of the 1920s, Proudhon remained the most important single influence on French working-class radicalism, while in a more diffuse manner his ideas of decentralization and his criticisms of government had revived in the later 20th century, even though at times their origin was not recognized.

BIBLIOGRAPHY. There are four books in English on Proudhon that together give a comprehensive view of his life and theories: D.W. BROGAN, *Proudhon* (1934); HENRI DE LUBAC, *Proudhon et le christianisme* (1945; Eng. trans., *The Un-Marxian Socialist: A Study of Proudhon,* 1948); GEORGE WOODCOCK, *Pierre-Joseph Proudhon* (1956); and ALAN RITTER, *The Political Thought of Pierre-Joseph Proudhon* (1969). Relatively little of Proudhon's own writing has been translated into English; in addition to *What Is Property?* (including *Warning to Proprietors), The General Idea of the Revolution in the Nineteenth Century,* and *System of Economic Contradictions,* there are only two volumes of selections: *Proudhon's Solution of the Social Problem* (1927) and *Selected Writings of Pierre-Joseph Proudhon* (1969).

(G.W.)

Proust, Marcel

The entire climate of the 20th-century novel has been affected by Marcel Proust, whose novel *À la recherche du temps perdu (Remembrance of Things Past)* is one of the supreme achievements of world literature. "My instrument," Proust said, "is not a microscope but a telescope directed upon Time." Taking as raw material the author's past life, *À la recherche* is ostensibly about the irrecoverability of time lost, about the forfeiture of innocence through experience, the emptiness of love and friendship, the vanity of human endeavour, the triumph of sin and despair; but Proust's conclusion is that the life of every day is supremely important, full of moral joy and beauty, which, though man may lose them through faults inherent in human nature, are indestructible and recoverable. Proust's style is one of the most original in all literature, unique and self-engendered in its union of speed and protraction, precision and iridescence, force and enchantment, classicism and symbolism. His reputation as a writer of genius continues to rise.

Proust, oil painting by Jacques-Emlie Blanche (1861–1942). In a private collection.

Life and works. Marcel Proust, born on July 10, 1871, at Auteuil, then a still rural suburb of Paris, was the son of Adrien Proust, an eminent physician of provincial French Catholic descent, and his wife Jeanne, *née* Weil,

Influence of Bergson

of a wealthy Jewish family. After a first attack in 1880, he suffered from asthma throughout his life. His childhood holidays were spent at Illiers and Auteuil (which together became the Combray of his novel) or at seaside resorts in Normandy with his maternal grandmother. At the Lycée Condorcet (1882–89) he wrote for class magazines, fell in love with a little girl named Marie de Benardaky in the Champs-Élysées, made friends whose mothers were society hostesses, and was influenced by his philosophy master Alphonse Darlu. He enjoyed the discipline and comradeship of military service at Orléans (1889–90) and studied at the Ecole des Sciences Politiques, taking *licences* in law (1893) and in literature (1895). During these student days his thought was influenced by the philosopheis Henri Bergson (his cousin by marriage) and Paul Desjardins and by the historian Albert Sorel. Meanwhile, via the bourgeois salons of Madames Straus, Arman de Caillavet, Aubernon, and Madeleine Lemaire, he became an observant *habitué* of the most exclusive drawing rooms of the nobility. In 1896 he published *Les Plaisirs et les jours,* a collection of short stories at once precious and profound, most of which had appeared during 1892–93 in the magazines *Le Banquet* and *La Revue Blanche.* From 1895 to 1899 he wrote *Jean Santeuil,* an autobiographical novel that, though unfinished and ill-constructed, showed awakening genius and foreshadowed A *la recherche.* A gradual disengagement from social life coincided with growing ill health and with his active involvement in the Dreyfus affair of 1897–99, when French politics and society were split by the movement to liberate the Jewish army officer Alfred Dreyfus, unjustly imprisoned on Devil's Island as a spy. Proust helped to organize petitions and assisted Dreyfus's lawyer Labori, courageously defying the risk of social ostracism. (Although Proust was not, in fact, ostracized, the experience helped to crystallize his disillusionment with aristocratic society, which became visible in his novel.) Proust's discovery of John Ruskin's art criticism in 1899 caused him to abandon *Jean Santeuil* and to seek a new revelation in the beauty of nature and in Gothic architecture, considered as symbols of man confronted with eternity: "Suddenly," he wrote, "the universe regained in my eyes an immeasurable value." On this quest he visited Venice (with his mother in May 1900) and the churches of France and translated Ruskin's *Bible of Amiens* and *Sesame and Lilies,* with prefaces in which the note of his mature prose is first heard.

Involuntary revival of a childhood memory

The death of his father in 1903 and of his mother in 1905 left him grief stricken and alone but financially independent and free to attempt his great novel. At least one early version was written in 1905–06. Another, begun in 1907, was laid aside in October 1908. This had itself been interrupted by a series of brilliant parodies—of Balzac, Flaubert, Renan, Saint-Simon, and others of Proust's favourite French authors—called "L'Affaire Lemoine" (published in *Le Figaro*), through which he endeavoured to purge his style of extraneous influences. Then, realizing the need to establish the philosophical basis that his novel had hitherto lacked, he wrote *Contre Sainte-Beuve,* attacking the French critic's view of literature as a pastime of the cultivated intelligence and putting forward his own, in which the artist's task is to release from the buried world of unconscious memory the ever-living reality to which habit makes us blind. In January 1909 occurred the real-life incident of an involuntary revival of a childhood memory through the taste of tea and a rusk biscuit (which in his novel became *madeline* cake); in May the characters of his novel invaded his essay; and, in July of this crucial year, he began À *la recherche du temps perdu.* He thought of marrying "a very young and delightful girl" whom he met at Cabourg, a seaside resort in Normandy that became the Balbec of his novel, where he spent summer holidays from 1907 to 1914; but, instead, he retired from the world to write his novel, finishing the first draft in September 1912. The first volume, *Du côté* de *chez Swann,* was refused by the best-selling publishers Fasquelle and Ollendorff and even by the intellectual *La Nouvelle Revue Française,* under the direction of the novelist André Gide, but was finally issued at the author's expense in November 1913 by the progressive young publisher Bernard Grasset and met with some success. Proust then planned only two further volumes, the premature appearance of which was fortunately thwarted by his anguish at the flight and death of his secretary Alfred Agostinelli and by the outbreak of World War I.

During the war he revised the remainder of his novel, enriching and deepening its feeling, texture, and construction, increasing the realistic and satirical elements, and tripling its length. In this majestic process he transformed a work that in its earlier state was still below the level of his highest powers into one of the profoundest and most perfect achievements of the human imagination. In March 1914, instigated by the repentant Gide, the *La Nouvelle Revue Française* offered to take over his novel, but Proust now rejected them. Further negotiations in May–September 1916 were successful, and in June 1919 A *l'ombre des jeunes filles en fleurs* appeared simultaneously with a reprint of *Swann* and with *Pastiches et mélanges,* a miscellaneous volume containing "L'Affaire Lemoine" and the Ruskin prefaces. In December 1919, through Léon Daudet's recommendation, À *l'ombre* received the Prix Goncourt, and Proust suddenly became world famous. Three more installments appeared in his lifetime, with the benefit of his final revision, comprising *Le Côté de Guermantes* and *Sodome et Gomorrhe.* He died in Paris on November 18, 1922, of pneumonia, succumbing to a weakness of the lungs that many had mistaken for a form of hypochondria and struggling to the last with the revision of *La Prisonnière.* The last three parts of À *la recherche* were published posthumously, in an advanced but not final stage of revision: *La Prisonnière, Albertine disparue* (originally called *La Fugitive,* though the new title may well have had Proust's authority), and *Le Temps retrouvé.*

Raw material of his novel

His autobiography in the novel. Proust's enormous correspondence (3,000 letters have appeared in print; many more await publication), remarkable for its communication of his living presence, as well as for its elegance and nobility of style and thought, is also highly significant as the raw material from which a great artist built his universe. For À *la recherche du temps perdu* is the story of Proust's own life, told as an allegorical search for truth.

Its fictional narrative. At first, the only childhood memory available to the middle-aged narrator is the evening of a visit from the family friend, Swann, when the child forced his mother to give him the goodnight kiss that she had refused. But, through the accidental tasting of tea and a *madeleine* cake, the narrator retrieves from his unconscious memory the landscape and people of his boyhood holidays in the village of Combray. In an ominous digression on love and jealousy, the reader learns of the unhappy passion of Swann (a Jewish dilettante received in high society) for the courtesan Odette, whom he had met in the bourgeois salon of the Verdurins during the years before the narrator's birth. As an adolescent the narrator falls in love with Gilberte (the daughter of Swann and Odette) in the Champs-Élysées. During a seaside holiday at Balbec, he meets the handsome young nobleman Saint-Loup, Saint-Loup's strange uncle the Baron de Charlus, and a band of young girls led by Albertine. He falls in love with the Duchesse de Guermantes but, after an autumnal visit to Saint-Loup's garrison-town Doncières, is cured when he meets her in society. As he travels through the Guermantes's world, its apparent poetry and intelligence is dispersed and its real vanity and sterility revealed. Charlus is discovered to be homosexual, pursuing the elderly tailor Jupien and the young violinist Morel, and the vices of Sodom and Gomorrah henceforth proliferate through the novel. On a second visit to Balbec the narrator suspects Albertine of loving women, carries her back to Paris, and keeps her captive. He witnesses the tragic betrayal of Charlus by the Verdurins and Morel; his own jealous passion is only intensified by the flight and death of Albertine. When he attains oblivion of his love, time is lost; beauty and meaning have faded from all he ever pursued and won; and he renounces the book he has always hoped to write. A long absence in a sanatorium is interrupted by a wartime visit to Paris, bombarded like Pompeii or Sodom from the skies. Charlus, disintegrated by his vice, is seen in Jupien's infernal brothel, and Saint-Loup, married to Gilberte and turned homosexual, dies heroically in battle. After the war, at the Princesse de Guermantes's afternoon reception, the narrator becomes aware, through a series of incidents of unconscious memory, that all the beauty he has experienced in the past is eternally alive. Time is regained, and he sets to work, racing against death, to write the very novel the reader has just experienced.

The notion of time regained

Its structure and meaning. Proust's novel has a circular construction and must be considered in the light of the revelation with which it ends. The author reinstates the extratemporal values of time regained, his subject being salvation. Other patterns of redemption are shown in counterpoint to the main theme: the narrator's parents are saved by their natural goodness, great artists (the novelist Bergotte, the painter Elstir, the composer Vinteuil) through the vision of their art, Swann through suffering in love, and even Charlus through the Lear like grandeur of his fall. Proust's novel is, ultimately, both optimistic and set in the context of human religious experience. "I realized that the materials of my work consisted of my own past," says the narrator at the moment of time regained. An important quality in the understanding of A *la recherche* lies in its meaning for Proust himself as the allegorical story of his own life, from which its events, places, and characters are taken. In his quest for time lost, he invented nothing but altered everything, selecting, fusing, and transmuting the facts so that their underlying unity and universal significance should be revealed, working inward to himself and outward to every aspect of the human condition. *À la reclzerche* is comparable in this respect not only with other major novels but with such creative and symbolic autobiographies as Johann Wolfgang von Goethe's *Dichtung und Walrrheit* and the Vicomte de Chateaubriand's *Mémoires d'outre-tombe*, both of which influenced Proust.

Proust's projection of his own sexual inversion upon his characters is aesthetically justified by his literary use of this propensity and of snobbism, vanity, and cruelty as a major symbol of original sin. His insight into women and the love of men for women (which he himself experienced for the many female originals of his heroines) remained unimpaired, and he is among the greatest novelists in the fields of both heterosexual and homosexual love.

Reputation and influence. Other frequent charges against Proust are as misleading as those of pessimism, antireligion, or obsession with homosexuality. He has been thought idle, unproductive, weak willed, corrupted by snobbism, ill equipped in philosophy, and absorbed in microscopic detail. In fact, research has shown that he worked unceasingly, prolifically, and with iron will from early youth, always in the direction of his great novel. He was an anti-snob with genuine interest in a brilliant and dying culture, a metaphysician with academic training and individual genius, and an impressionist whose detail is an imagery subordinated to the totality of hie creation. In general, hostile criticism of Proust, being based on assumptions or on misuse of the biographical approach, has tended to reveal deficiencies not in Proust but in the scholarship or sensibility of its exponents. Proust's mature prose is remotely influenced by such varied precursors as the 17th-century moralist La Bruyère, the harsh social memoirist Saint-Simon, the innovating arch-Romantic Chateaubriand, the novel cycle of Balzac, the humanism of Renan and Ruskin, and by such contemporary acquaintances as the novelist Anatole France, the symbolist poets Stéphane Mallarmé, Anna de Noailles, and Francis Jammes, and the decadent Robert de Montesquiou (the chief model for Baron de Charlus). Even so, his style remains one of the most original in all literature. His own direct influence is evident in such works as André Gide's *Les Faux-Monnayeurs (The Counterfeiters)*, Jacques de Lacretelle's *Silbermann*, Virginia Woolf's *The Waves*, and Anthony Powell's novel sequence *The Music of Time*. His reputation, though still imperfectly liberated from the superficial and semihostile assessments of the first generation of Proustian criticism. has always been safe with the general reader, and continues to rise. A new critical tendency, in which Proust's work is considered sympathetically from within and on its own terms, may well predominate in the final judgment.

Proust's interest in a dying culture

MAJOR WORKS

NOVELS: *Jean Santeuil* (first published 1952; Eng. trans. by Gerard Hopkins, 1955); A *la recherche du temps perdu*, consisting of *Du côté de chez Swann* (1914), *A l'ombre des jeunes filles en fleurs* (1918–19), *Le Côté de Guermantes I* (1920), *Le Côté de Guermantes II* together with *Sodome et Gomorrhe 1* (1921), *Sodome et Gomorrhe II*, 3 vol. (1922), *La Prisonnière* (published posthumously 1923), *Albertine disparue* (posthumously 1925), and *Le Temps retrouvé* (posthumously 1927), standard text, ed. by Pierre Clarac and André Ferré, 3 vol. (1954); *Remembrance of Things Past*, 12 vol., trans. by C.K. Scott Moncrieff (1922–30), vol. 12 by Stephen Hudson (1931) and Andreas Mayor (1970), consisting of *Swann's Way, Within a Budding Grove, The Guermantes Way, Cities of the Plain, The Captive, The Sweet Cheat Gone*, and *Time Regained.*

OTHER WORKS: *Les Plaisirs et les jours* (1896; *Pleasures and Regrets*, trans. by Louise Varbse, 1950), short stories; *La Bible d'Amiens* (1904), and *Sésame et les lys* (1906), translations from Ruskin; *Pastiches et mélanges* (1919), parodies and prefaces to the Ruskin translations; *Contre Sainte-Beuve* (written 1908–09, first published 1954; *By Way of Sainte-Beuve*, trans. by Sylvia Townsend-Warner, 1958), critical studies.

BIBLIOGRAPHY. Bibliographies on Proust may be found in RENE DE CHANTAL, *Marcel Proust, critique littéraire*, 2 vol. (1967); in Proust's *Textes retrouvés*, ed. by PHILIP KOLB and LARKIN B. PRICE (1968), and *Lettres à la N.R.F.* (1932); in D.W. ALDEN, *Marcel Proust and His French Critics* (1940), listing books and articles in French, and continued for the period after 1940 and for all languages in his *Bibliography of Critical and Biographical References for the Study of Contemporary French Literature* (1949–53; as *French VII Bibliography*, 1954–).

Manuscript collections: The Bibliothèque Nationale, Paris, possesses the major Proust archive, including manuscripts and workbooks of A *la recherche*, manuscripts of *Jean Santeuil, Conire Sainte-Beuve*, and minor pieces and letters. The University of Illinois, Urbana, Illinois, has a further extensive archive. The Société des Amis de Marcel Proust et des Amis de Combray, Illiers, France, issues an annual *Bulletin* (1950–), including new texts and letters of Proust.

Letters: Correspondance (1970–), ed. by PHILIP KOLB; *Correspondance générale*, 6 vol. (1930–36); letters to Antoine Bibesco (1949; Eng. trans. 1953), Robert de Billy (1930), Lucien Daudet (1929), André Gide (1949), Reynaldo Hahn (1956), Georges de Lauris (1948; Eng. trans. 1949), Paul Morand (1949), Marie Nordlinger (1942), Mme Proust (1953; Eng. trans. 1956), and Jacques Rivière (1955); selected letters in *Letters of Marcel Proust*, trans. and ed. by MINA CURTISS (1950); *Choix de lettres* (1965) and *Lettres retrouvies* (1966), both ed. by PHILIP KOLB; bibliography, chronology, and index of letters in PHILIP KOLB, *Correspondance de Marcel Proust* (1949).

Biography: G.D. PAINTER, *Marcel Proust*, 2 vol. (U.S. titles, *Proust: The Early Years* and *Proust: The Later Years;* 1959–65), a full-scale biography; shorter biographies include ANDRE MAUROIS, A *la recherche de Marcel Proust* (1949; Eng. trans., *The Quest for Proust*, 1950); RICHARD H. BARKER, *Marcel Proust* (1958); P.L. LARCHER, *Le Parfum de Combray* (1945), on Proust at Illiers; MARTHE BIBESCO, *Au bal avec Marcel Proust* (1928; Eng. trans., *Marcel Proust at the Ball*, 1956), a friend's memories.

Criticism: LEO BERSANI, *Marcel Proust: The Fictions of Life and Art* (1965); GERMAINE BREE, *Marcel Proust and Deliverance from Time*, 2nd ed. (1969); HOWARD MOSS, *The Magic Lantern of Marcel Proust* (1962); ROGER SHATTUCK, *Proust's Binoculars: A Study of Memory, Time, and Recognition in A la recherche du temps perdu* (1963)—the above are creative studies of complementary insight and importance; P. HANSFORD JOHNSON, *Six Proust Reconstructions* (1958), radio plays of critical value; P.A. SPALDING, *A Reader's Handbook to Proust* (1952); GERMAINE BREE, *The World of Marcel Proust* (1966), a general study.

(G.D.P.)

Providence, Religious Doctrines and Myths of

Providence is the quality in divinity on which man bases his belief in a benevolent divine intervention in human affairs and the affairs of the world he inhabits. The forms that this belief takes differ, depending on the context of the religion and the culture in which they function.

In one view the concept of Providence, divine care of man and the universe, can be called the religious answer to man's need to know that he matters, that he is cared for, or even that he is threatened, for in this view all religions are centred on man, and man is individually and collectively in constant need of reassurance that he is not an unimportant item in an indifferent world; if he cannot be comforted, to be threatened is better than to be alone in an empty void of nothingness. According to J. van Baal, a Dutch anthropologist,

> Man experiences his universe as a universe full of intentions, a universe which holds a claim on him, addressing him with something undefined, urging him to act or to be in some way or another. The experience is strongest in moments of crisis, when events turn up with such an overwhelming force that it is as if they address their victim, delivering a message to him.

In answer to such a universe, religions must offer a coherent view of God or gods, world, and mankind and must give man and his physical or psychical well-being, or both, a prominent place within this world view. Thus, in all religions Divine Providence or its equivalent is an element of some importance.

NATURE AND SIGNIFICANCE

Basic forms of Providence. Basically, there are two possible forms of belief in Providence. In the first, man believes in more or less divine beings that are responsible for the world generally and for the welfare of man specifically. Although omnipotence as an attribute of gods is rare, it is true that, as a rule, gods and other divine beings have considerable power not only over man but also over nature. The gods take care of the world and of mankind, and their intentions toward mankind are normally positive. The capricious and arbitrary gods of paganism exist for the most part only in the imagination of those Christian theologians who attempt to denigrate the pagan religions. Gods and men are generally connected into one community by reciprocal duties and privileges. The belief in evil spirits does not contradict this belief in Providence but, on the contrary, strengthens it, just as in Christianity the belief in the devil might serve to strengthen the belief in God.

Belief in a cosmic order

In the second form, man believes in a cosmic order in which the welfare of man has its appointed place. This cosmic order is usually conceived as a divine order that is well intentioned toward man and is working for man's well-being as long as he is willing to insert himself into this order, to follow it willingly, and not to upset it by perversion or rebellion; the firmness of the order, however, may become inexorable and thus lead to fatalism, the belief in an impersonal destiny against which man is powerless. In that case a clash between the concepts of Providence and fatalism is inevitable. In most religions, however, both views are combined in some way.

Etymological history of the term Providence. The English word Providence is derived from the Latin term ***providentia,*** which primarily means foresight or foreknowledge but also forethought and Providence in the religious sense; thus, Cicero used the phrase the "Providence of the gods" ***(deorum providentia).*** The Stoic philosophers thoroughly discussed the significance of the term Providence, and some of them wrote treatises on the subject. A hymn to Zeus written about 300 BC by Cleanthes, a Greek poet and philosopher, is a glorification of the god as a benevolent and foreseeing ruler of the world and of mankind. God has planned the world in accordance with this Providence:

> For thee this whole vast cosmos, wheeling round
> The earth, obeys, and where thou leadest
> It follows, ruled willingly by thee.

The author asserts that "naught upon Earth is wrought in thy despite, O God" and that in Zeus all things are harmonized. Seneca, a Roman Stoic philosopher, formulates the belief in Providence in one of his dialogues as follows: man should believe "that Providence rules the world and that God cares for us." The Stoic school disagreed with those who believed that the world was ruled by blind fate; they did not deny that a controlling power exists, but, as everything happens according to a benevolent divine plan, they preferred to call this power Providence. According to the Stoic emperor Marcus Aurelius, God wills everything that happens to man, and for that reason nothing that occurs can be considered evil. Stoic ideas about Providence influenced Christianity.

In later Latin after the emperor Augustus, the word Providence was used as a designation of the deity. Seneca, for example, wrote that it is proper to apply the term Providence to God. Finally, Providence was personified as a proper goddess in her own right by Macrobius, a Neoplatonic Roman author, who wrote in defense of paganism about 400.

Epicurus, a 4th–3rd-century-BC Greek philosopher, contested the Stoic belief in Divine Providence, but the objections of his followers could not change the spiritual climate of the Greco-Roman world. More eloquent, perhaps, than the dissertations of the learned Stoic philosophers were the many stories found in a work by Aelian, an early-3rd-century-AD Roman rhetorician, about strange events and miraculous occurrences ascribed to Providence. Aelian, however, was more interested in sensational stories than in historic accuracy.

Latin meanings of the word

The several meanings of the Latin word ***providentia*** exactly mirror those of its Greek equivalent, ***pronoia.*** Herodotus, the historian of the 5th century BC, was the first Greek author to use the word in a religious sense when he mentioned Divine Providence as the source of the wisdom that keeps nature in balance and prevents one kind of creature from prevailing over all others. Writers such as the historian Xenophon and the biographer Plutarch used the word for the watchful care of the gods over mankind and the world.

The belief in the existence of a blind and inexorable fate can lead to a conflict with the belief in a benevolent Providence. In the Greco-Roman world, where fatalistic belief was strong and where it found a popular expression in astrology, the belief that the whole world, but particularly man, is governed by the stars was contested by Judaism and Christianity. The Talmud, the authoritative collection of Jewish tradition, teaches that Israel is subject to no star but only to God. An example of this conflict is also found in the novel ***The Golden Ass*** by Apuleius, a 2nd-century-AD philosopher and rhetorician deeply interested in Hellenistic mystery cults, which taught a faith that liberated man from the power of the stars. In the novel the hero is converted to the goddess Isis; then, the priest of the goddess addresses him:

> "Lucius, my friend," he said, "you have endured and performed many labours and withstood the buffetings of all the winds of ill luck. Now at last you have put into the harbour of peace and stand before the altar of loving-kindness. Neither your noble blood and rank nor your education sufficed to keep you from falling a slave to pleasure; youthful follies ran away with you. Your luckless curiosity earned you a sinister punishment. But blind Fortune, after tossing you maliciously about from peril to peril has somehow, without thinking what she was doing, landed you here in religious felicity. Let her begone now and fume furiously wherever she pleases, let her find some other plaything for her cruel hands. She has no power to hurt those who devote their lives to the honour and service of our Goddess's majesty."

Christian use of the term

The Christian use of the term Providence, besides being profoundly influenced by Greek and Roman thought, is based on the Old Testament story of the patriarch Abraham's sacrifice of his son Isaac, which is found in the book of Genesis. Abraham tells Isaac, "God will provide himself with a young beast for a sacrifice, my son." The Hebrew language lacks a proper word to express the notion of Providence, but the concept is well known in the Old Testament.

In the New Testament the word pronoia and related words are used rarely, but in no case are they used in the later Christian sense of Providence. This is of interest because the idea of Providence as such is far from foreign to the religious thinking of the New Testament. In the Gospel According to Matthew, for example, Jesus says:

> Are not two sparrows sold for a penny? And not one of them will fall to the ground without your Father's will. But even the hairs of your head are numbered. Fear not, therefore; you are of more value than many sparrows.

Providence as used in Christianity is thus a dogmatic term rather than a biblical term; it indicates that God not only created the world but also governs it and cares for its welfare. A well-known German reference work, Religion in Geschichte und Gegenwart ("Religion in History and the Present"), gives a more elaborate and more theological definition of Providence that, freely translated, is as follows:

> God keeps the world in existence by his care, he rules and leads the world and mankind deliberately according to his purpose, and he does this in his omnipotence as God the Creator, in his goodness and love as revealed by his son Jesus Christ, and to further the salvation of mankind through the Holy Spirit.

BASIC CONCEPTS AND SCOPE

Qualities of **the** divinity. The concept of Providence is rooted in the belief in the existence of a benevolent, wise, and powerful deity or a number of beings that are benevolent and that are either fully divine or, at least, appreciably wiser and more powerful than man (*e.g.*, ancestors in many religions). Benevolence is the primary requirement. In northern Malawi, death in later life is usually ascribed to the will of the ancestors, but a miscarriage or the death of a very young child is not considered to be their work because such an act would be in contradiction with their benevolent and helpful attitude toward their offspring. The three attributes, however, are all essential for the concept of Providence: the divine being or beings must be well intentioned toward man, must have the necessary wisdom to know what is good for mankind, and must have the power to act on this intention and insight. Benevolence does not exclude the possibility of punishment of men in cases of transgression. There is probably no god in existence who only rewards and helps and never punishes his believers.

Providence, however, need not operate in a direct way; it may operate through many intermediary beings—*e.g.*, the ancestors and various kinds of spirits in several nonliterate religions or the angels in Christian and Muslim belief—or the concept may be implicit in and expressed by a fixed world order, a cosmic order that makes human life possible biologically, socially, and spiritually and that guarantees its existence in the future. Thus, Providence may become a more or less impersonal principle of cosmic order as instituted and maintained by a divine being, but, if the starting point of a benevolent and just divine being is completely lost sight of or if it is consciously denied, then Providence becomes fate.

Cosmic order. ***Notion*** of cosmic order. Although the introduction of intermediary beings brings no essential change in the idea of Providence as the divine watchful care for the benefit of mankind, the notion of a cosmic order changes the picture profoundly. Even if the cosmic order is conceived as a benevolent order in which man is able to feel safe and whose very existence reassures him, such an order is different from the personal relationship between man and his god or gods. The concept of an unchangeable world order requires a different reaction. A persona1 god may, perhaps, be moved by prayer and sacrifice to give or to prevent events; when the order of the world is fixed, however, the course of events cannot be changed by these or any other means. There is probably no religion that acknowledges an all-embracing world order without any exceptions at all. Generally, man has such an important function in the order of the world that he also has a certain opportunity to manipulate this order, at least to a certain extent, for instance by sacrifice or other ritual acts. One opening is presented by the fact that the cosmic order is valid for everything of a more general character, but as a rule the divine will or the free will of man or chance operates on the level of the common occurrences and daily life of the individual. Though in theory the order may govern everything, a large field is left open for different concepts to function. In some cases even uncertainty and chance have their proper place within a determined order. In Yoruba religion (Nigeria), for example, the god Eshu represents the principle of chance and uncertainty and of all that cannot be foreseen. He is one of the gods of the pantheon and has his own sanctuaries and priests.

Manipulation of order and predestination

Another possibility for combining the idea of a personal divine will with a fixed course of events is the concept of predestination best known from Islām and some forms of Calvinism (derived from the thought of John Calvin, a 16th-century French Protestant Reformer) and also important in the theology of Augustine of Hippo, a 4th–5th-century Church Father. Although predestination essentially is concerned with salvation—the question of whether a certain individual will be saved or damned—it is a concept that easily lends itself to a more general application. In a few religions the idea that the individual chooses his own destiny before birth is encountered; *e.g.*, the Batak of Sumatra and some West African tribes. In this conception free will and predestination merge.

In all religions that acknowledge the existence of a more or less impersonal cosmic order, man is expected to work with the cosmos, to insert himself into the cosmic order. Man's behaviour in all fields is governed by a set of rules that are all based on the same principle: to act and to be in harmony with the order of the world, which is natural and divine at the same time.

The cosmic order is given with the creation of the world, but it is possible to question the relation of the Creator to the world after creation. On one hand, there is the belief that God will not abandon the world he has created; on the other, the belief that God created the world and the cosmic order in such a manner that to a great extent the course of the world is fixed from the first beginning and he is no longer involved in it. The latter was, in fact, the thesis of the 17th- and 18th-century Deists in Europe (see DEISM). The fact of creation helps man to believe in Providence because it would be inconsistent for the creator god or gods not to care for the further existence of the created world. Only persistent disobedience and open rebellion can then furnish **a** reason for the Creator to abandon or destroy the world. This situation is expressed in the myths of a great flood or some other form of destruction sent as a punishment. There is, however, never a total destruction of the world in these myths, although this final solution may be threatened for the eschatological (ultimate end) future. It may also be promised, if the eschatological events are construed as the definitive institution of a world order that is perfect for all eternity and will never deteriorate.

Cosmic order and ethical principles

The cosmic order is often clearly contrasted with the disorder of chaos. The cosmic order is a total order; it comprises not only all natural things but also social and ethical rules. This does not mean that cultures and religions centred on a cosmic order have no clear idea of distinctive ethical principles but that ethics is considered as one function of the total cosmic order and as such can never be quite independent. The rules of ethics depend on and are derived from the more general rules that govern the cosmos in its totality; they are no more than special manifestations of these general rules. An example of this attitude can be found in the Greek hymns in praise of the goddess Isis. She is honoured as the queen of heavens; she divided the earth from the heaven, showed the stars their paths, and ordered the course of the sun and the moon. But the same hymn says that she ordained that children should love their parents, that she taught men to honour the images of the gods, and that she made justice stronger than gold and silver. She established penalties for the people practicing injustice and taught that men should have mercy with suppliants. She is also praised because she invented writing, devised marriage contracts, invented navigation, and watches over all men who sail on the sea.

Personal and impersonal forms. The cosmic order can appear in a personalized form, as, for example, the Egyptian goddess Maat; but this personification of the cosmic order is not general: the Iranian Asha, the Indian *ṛta,* and the Chinese Tao are all to a high degree impersonal. Maat represents truth and order; her domain includes not only the order of the nature, but also the social and ethical orders. She plays an important role in the judgment of the dead: the heart of the deceased is weighed against the truth of Maat. She is often called the daughter of Re. In this case, Re is the creator god who not only created the world but also founded the cosmic order as represented by Maat. Her importance is also apparent in the conception of the Maat sacrifice. In Egypt sacrifice is not so much a gift of men to the gods as a sacral technique that enables man to contribute to the maintenance and, if necessary, the restoration of harmony and order in the world. Not only must man live according to Maat but also the gods must live by her truth and order; according to Egyptian texts, the goddess Maat is the food by which the gods live.

Asha, *ṛta,* and Tao

The idea of a determined cosmic order that is natural as well as ethical is an important concept in the Persian religion of Zoroastrianism (also called Mazdaism and, in India, Parsiism) founded during the late 7th and early 6th centuries BC by Zoroaster (Zarathustra). This idea is called Asha and is the counterpart of Drug, which represents evil and deceit and the disorder connected with these. Asha is connected with the sacred element fire. The Indian concept of *yta* forms the Indian counterpart of Asha. The gods, especially the Adityas, protect the world against chaos and ignorance and maintain the world order, which, however, exists independently from the gods. Although the power of *ṛta* operates according to its own principles and laws, man is able, provided he knows the right methods, to manipulate this power to some extent for his own benefit. The proper means for this manipulation is found especially in older Hindu sacrifice. The gods are generally benevolent and friendly toward men who follow *ṛta,* and they punish their own enemies and those of the world order, which in India, too, embraces the social ethical rules.

The concept of Tao is of great importance in Chinese religion, especially in Taoism, founded by Lao-tzu according to tradition in the 6th century BC. Lao-tzu is the author of the *Tao-te Ching* ("Classic of the Way and Its Power") in which he expounds this concept in a manner that is more mystical than philosophical. Tao, literally translated "road," is a difficult and complex concept. It certainly represents the cosmic order, but in Taoism it is even more than that. It is also the concept that gives existence meaning; it is the primeval power that forms the foundation of all that is; and, in some cases, it is even used to designate some kind of high god. Taoism is a mystic religion, and the ***Tao-te Ching*** is a mystic treatise in which the essence of the Tao is expounded in many parables and metaphors because it cannot be expressed rationally.

Manv related concepts exist. The Greek Moira, for instance: is comparable to Asha and *ṛta*; it lacks, however, the mystic overtones of Tao. The Moira in classical Greek religion is not yet fate as this idea was found in Greco-Roman times. The concept of cosmic order may function either in a religious or in a philosophic context; *e.g.,* the pre-established harmony ***(karmonia*** *praestabilita)* in the philosophy of Gottfried Wilhelm Leibniz, a German Rationalist, is the cosmic order that holds together and unifies the innumerable individual units, called monads by Leibniz.

Particular objects of Providence. Although cosmic order is necessarily a general idea comprising the whole of the world and all that exists in it, the concept of Providence may be more particular: the benevolent aspect of Providence may be confined to a special group of people or at least be specially related to that group; or a number of patron gods or saints may watch over some specific activity or smaller group. This accounts for the idea of a chosen people watched over and led by a just and loving God. The ancient people of Israel is, perhaps, the best known example; the concept, however, is widespread. Patron gods and patron saints who are particularly charged with caring for some small group, craft, or activity or who operate in special circumstances, such as during illness or war, occur in most religions and are popular in many.

Although Providence in most religions operates primarily for the welfare and the salvation of the community as a whole, it may also be experienced as personal guidance. This latter phenomenon is common in some diverse cultures—*e.g.,* that of the Plains Indians of North America and in some forms of Protestantism in which generally each person is expected to have a private experience of divine guidance. In other cultures and religions, personal guidance is often a prerogative of some person or persons singled out for some reason by God or the gods.

CRITICAL PROBLEMS

It is clear that the concept of Providence by its central position in many religions is connected with numerous other aspects of religion. In monotheistic religions Providence is a quality of the one divinity; in polytheistic religions it may be either a quality of one or more gods or it may be conceived as an impersonal world order on which the gods, too, more or less depend. In the latter case, Providence may lose its aspect of benevolence and become inexorable fate or fickle chance. Most religions show a certain ambivalence; for fate and Providence do not always form a clear-cut contradiction.

Still another form of ambivalence occurs between fate or divine will and the will of man when the latter is conceived as free, or at least free to a certain degree. In some religions the benevolent aspect of Providence appears as grace, and a discussion may arise about the relationship between free will and grace. Perhaps the most difficult problem connected with the notion of Providence is the existence of evil; men have perennially coped with the question of how to reconcile the idea of a provident God or gods with the evident existence of evil in the world.

The problem of evil

BIBLIOGRAPHY. No general introduction to the subject written from the point of view of the science of religion exists, but useful articles are found in some specialized encyclopaedias, such as ***Hustings' Encyclopaedia of Religion and Ethics*** (1919). Further information has to be gathered from monographs about specific problems related to Providence; *e.g.,* JOHN BOWKER, ***Problems of Sufferingin the Religions of the World*** (1970). Much information on cosmic order is found in MIRCEA ELIADE, ***Traité d'histoire des religions,*** new ed. (1964; Eng. trans., ***Patterns in Comparative Religion,*** 1963). *A* great amount of literature on ancient philosophy is available: REINOUT BAKKER, ***Lot en daad, geluk en rede in het Griekse denken von Solon tot Marcus Aurelius*** (1957); *c.* PARMA, ***Pronoia und Providentia, der Vorsehungsbegriff Plotins und Augustins*** (1972); MAX POHLENZ, ***Die Stoa, 2*** vol. (1948–49); ROBERT M. WENLEY, ***Stoicism and Its Influence*** (1924).

(T.P.v.B.)

Psilopsida

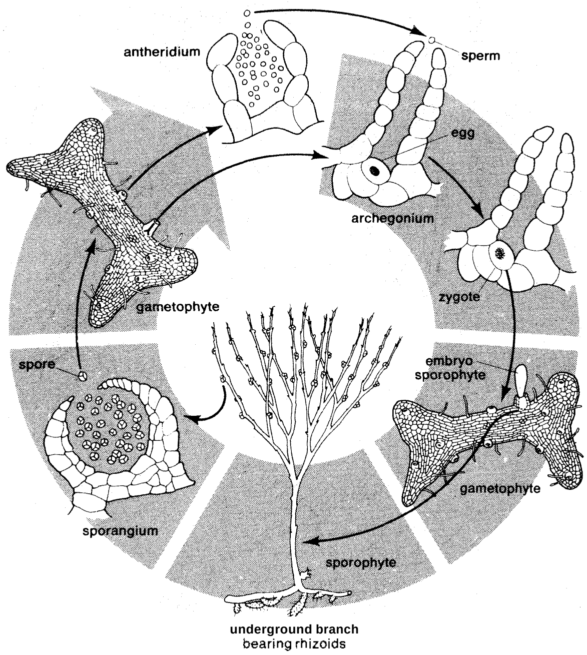
The Psilopsida is a class of primitive vascular plants (division Tracheophyta) with two living genera and several extinct members, present as early as the Silurian Period (430,000,000 years ago). Psilophytales, the extinct order of the Psilopsida, is academically interesting as the apparent ancestor of the living order Psilotales and is further considered by many botanists to be ancestral to all other vascular plants—*i.e.,* plants with specialized cells for conducting food and water.

General features. Early psilopsids ranged from plants a few centimetres tall, and Rhynia-like plants 25 to 40 centimetres (ten to 15 inches) tall, to ***Asteroxylon*** and others, more than one metre (about 40 inches) high. Unlike the leafy shoot systems of present-day flowering plants, psilopsids had spinelike leaves instead of true leaves along the stem, and the stems were capable of photosynthesis (based on the presence of holes, called stomates, and air spaces).

The living genera, ***Psiloturn*** (whisk ferns) and ***Tmesipteris,*** are terrestrial or epiphytic (living on other plant surfaces). Psiloturn, an upright, green plant that looks like a leafless shrub about 30 centimetres high, is tropical and subtropical in distribution, reaching as far north as Florida and Hawaii; Tmesipteris, a hanging green epiphyte, is found in Australia, New Caledonia, New Zealand, the Philippines, and other islands of the South Pacific area. The extinct genera grew in lowlands or were aquatic. *Psilotum* is sometimes grown in greenhouses.

The extant genera

Certain features are common to both the living and extinct psilopsids. The conspicuous green plant, the sporophyte, consists of an aerial system and an underground stem (rhizome) system, both of which repeatedly fork dichotomously—*i.e.*, into two equal branches. No roots are present, the rhizome performing the functions of a root. In Psiloturn the "leaves" are very small without vascular tissue. In Tmesipteris the "leaves" are larger, flattened structures, each with one unbranched midvein. (It is thought that the "leaves" of the psilopsids may not have had the same evolutionary development as the true leaves of ferns and seed plants.)



Life cycle of a psilopsid.

Life cycle. Spores germinate to form gamete-bearing plants (gametophytes), or prothallia, as they are commonly known when they are newly developed. These plants are very small, measuring about one millimetre in diameter and several millimetres in length. The gametophytes may grow on trunks of trees or underground. Like the sporophyte, the gametophyte branches repeatedly. It is devoid of chlorophyll, however, and lives a saprophytic existence (*i.e.*, on decaying organic matter), aided presumably by a fungus living within it. These plants are so similar to the underground rhizomes that they can be identified only if gamete-producing structures (gametangia) are present on the gametophyte. Two types of gametangia are scattered over the surface and are intermingled. The egg-producing structure, the archegonium, consists of a sterile jacket of four rows of cells enclosing another row of cells, the lowest one of which is the egg. The sperm-producing structure, the antheridium, is globose and emergent on the surface of the gametophyte; it consists of a jacket of sterile cells enclosing many spermatocytes, which upon release become swimming multiflagellated sperm. To effect fertilization a sperm must swim to the archegonium and down a canal-like passage to the egg—the passage being created by the disintegration of the cells adjacent to the nonmotile egg. The first division of the zygote (fertilized egg) is transverse (perpendicular to the long axis of the archegonium). The outer cell continues to divide and forms the axis of the developing sporophyte. The inner cell gives rise to a multicellular foot, which is in close contact with the gametophyte and presumably functions in the transfer of nutrients from the gametophyte to the young sporophyte. Frequently the young sporophyte axis branches very early during its existence; one branch may become a green aerial shoot; the other becomes a rhizome. The rhizome continues to branch, but any of the underground branches may turn up and develop into a green aerial shoot and form leaves and sporangia.

Form and function. All psilopsids have a simple internal organization. The fossil members had smooth stems or stems with spines or small "leaves." The spore case (sporangium) is three-lobed in Psiloturn and two-lobed in Tmesipteris. The sporangia in *Psilotum* appear generally to be axillary in position (in the upper angles of the "leaves") but are actually terminal on short branches; the leaves associated with the sporangia are appendages on the short branch. The presence of vascular tissue at the base of a sporangium, or even in partitions separating compartments in a sporangium, supports the concept of terminality of the sporangium.

The protostele form of vascular tissue

The vascular tissue is in the form of a slender cylinder occupying the centre of the stem (protostele) in the rhizomes of both living genera. The protostelic condition is true of the upper branches in Psiloturn, whereas in the lower branches of *Psilotum* and in the stems of *Tmesipteris* the vascular tissue is not central but forms a siphonostele, a cylinder of strands surrounding nonvascular cells. The cells of the outer layers of the stem contain chloroplasts, and in *Psilotum* this region accounts for most of the photosynthesis. One interesting feature of stem anatomy in Psiloturn is the presence of an endodermis—a layer of cells surrounding the vascular cylinder in which each cell has a substance (lignin) deposited in the form of a band in the cell wall. An endodermis is a characteristic feature of roots in all vascular plants but occurs only rarely in stems of seed plants.

Spores formed in the sporangia have nuclei with half the number of chromosomes found in nuclei elsewhere in the plant. Only one type of spore is formed; consequently these plants are said to be homosporous. Spores are released by the splitting of sporangia along longitudinal slits.

Evolution and classification. Unquestionably the extinct order Psilophytales is an ancient and primitive group of vascular plants. The Psilotales also are ancient, but some botanists question the assumption that the two orders have a close linear relationship. The extinct order takes its name from Psilophyton, a fossil from Quebec, Canada, described in 1859 by Sir John William Dawson. It was almost 60 years later before the real significance of this plant was understood. At that time some extremely well-preserved ancient vascular plants (Rhynia and *Asteroxylon*) from deposits of the Devonian Period (about 395,000,000 years ago) in Scotland were found to resemble Psilophyton, and the order Psilophytales was established. Some botanists believe that there is enough variation in the extinct Psilophytales to warrant the establishment of at least three orders or even classes. Future systems of classification may well reflect this change. Groups indicated with a † (dagger) in the classification below are extinct and known only from fossils.

CLASS PSILOPSIDA

Primitive seedless vascular plants, lacking roots and leaves, the upright stem serving as photosynthetic organ and the horizontal stem serving to anchor and to absorb nutrients. Only 2 living genera but many extinct forms.

†Order Psilophytales

Wholly extinct group, whose members were especially abundant in the Devonian Period (345,000,000–395,000,000 years ago). Rhynia, Asteroxylon, and Psilophyton are well-known examples.

Order Psilotales

Two living genera: *Psilotum*, like a leafless shrub, in the tropics and subtropics; and Trnesipteris, a hanging epiphyte, with flattened leaflike structures, in Oceania and the South Pacific area.

BIBLIOGRAPHY. The following general textbooks have sections dealing with the psilopsids: T.E. WEIER, C.R. STOCK-

ING, and M.G. BARBOUR, Botany: An Introduction *to Plant* Biology, 4th ed. (1970); R.F. SCAGEL et al., An Evolutionary Survey of the Plant Kingdom (1965); H.N. ANDREWS, Studies in Paleobotany (1961); and THEODORE DELEVORYAS, Morphology and *Evolution* of Fossil Plants (1962), both of which give detailed accounts of fossil forms and their relationships with living plants; A.S. FOSTER and E.M. GIFFORD, *Comparative* Morphology of Vascular Plants (1959); and D.W. BIERHORST, Morphology of Vascular Plants (1971), both of which provide detailed treatments of vascular plants together with theory and interpretation; and H.P. BANKS, Evolution and Plants of *the* Past (1970), a modern and readable account of the earliest evidence of plant life and evolution. Journals that regularly publish articles on vascular plant morphology include the *American* Journal of Botany, the Botanical Gazette, Phytomorphology, the Annals of Botany, and *Palaeontographica*.

(E.M.G.)

Psittaciformes

The avian order Psittaciformes contains more than 300 species of generally brightly coloured, noisy, tropical birds, to which the general name parrot may be applied. Various species are known as keas, cockatoos, cockatiels, lories, lorikeets, parrotlets (or parrolets), parakeets, budgerigars, rosellas, conures, lovebirds, amazons, and macaws. Although the first accurate written reference to a parrot is frequently credited to the Greek historian Ctesias, of the 5th century BC, who described clearly what is now called the blossom-headed parakeet (*Psittacula* cyanocephala) of India, there is no doubt that parrots were associated with man much earlier, for aborigines on all continents had parrots as pets when first visited by explorers. Parrots of many kinds have been long transported to Europe for zoos and private collections. Affluent citizens of early Rome often kept parrots in their homes and even esteemed them as delicacies of the dinner table.

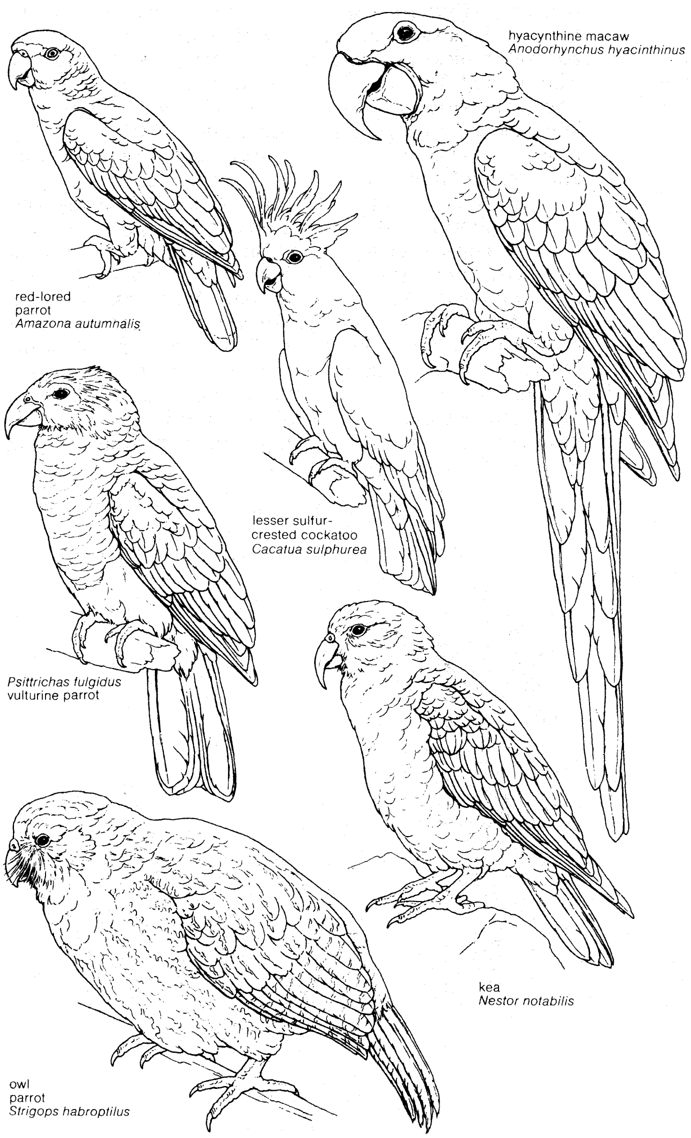


Figure 1: Body plans of representative larger Psittaciformes.
Drawing by G. Tudor

GENERAL FEATURES

Appearance. Parrots vary in total length from eight to 100 centimetres (three to nearly 40 inches), the latter in longtailed forms. The short neck and sturdy body, along with the stout feet and thick bill, give them a bulky appearance. The broad wings are often pointed; the tail is highly variable in both length and shape. In some species the tail is short and rounded or square; in others, such as the macaws (Ara), it is long and pointed. In numerous species the central tail feathers are very long, surpassing the body in total length. In the five species of racket-tailed parrots (*Prioniturus*) the central tail feathers are longer than the others and are spatulate, the middle part of the feather shaft being bare. No parrot has a forked tail. Pointed wings and a long tail usually are found in species that fly great distances; rounded wings and blunt tails typify the more adept climbers. Most parrots are swift on the wing, although they normally fatigue quickly.

Distribution. Parrots are primarily birds of the tropics. Their distribution encompasses the tropical and south temperate regions of the world, including Madagascar, New Zealand, and the West Indies. In Asia they occur throughout almost all of India but extend northward only to the Himalayas and southern China. They are absent from Europe. In the early 1970s in North America they ranged north only to the extreme southwestern United States (one species, the thick-billed parrot, Rhynchopsitta pachyrhyncha). Prior to the early 1900s, however, the Carolina parakeet (Conuropsis carolinensis) inhabited most of the eastern United States; it was brought to extinction by human persecution. The last captive died in the Cincinnati Zoological Garden in 1914, but the last generally accepted observation in the wild was a flock seen in Florida in 1904, although it has been claimed that they existed in South Carolina until 1938. In the Southern Hemisphere a number of parrots range to Tasmania and New Zealand, and in South America one species is found on Tierra del Fuego, but none are found on the southern tip of Africa.

Although parrots are found in most parts of the three southern continents (excluding the Sahara), they are not evenly distributed. Of the 81 genera recognized in a 1937 revision of the taxonomy of parrots, the Neotropical region (South and Central America) has 28, not one of which is found elsewhere. The Nearctic region (temperate and arctic North America) has had only the now-extinct genus Conuropsis. The Australo-Papuan region, which encompasses Australia, New Zealand, New Guinea, Celebes, and many of the Pacific Ocean islands, has 44 genera, three of which are shared with the Oriental region. The Oriental region, which, in addition to Asia, includes the Philippines and most of Malaysia, has nine genera, including the three shared with the Australo-Papuan region and one shared with the Ethiopian region. The Ethiopian region, comprising Africa, Madagascar, and nearby islands, has only six genera, one of which is the extinct Mascarinus from Reunion Island, 650 kilometres (400 miles) east of Madagascar. The Palearctic region (Europe and northern Asia) has none. Most parrot genera contain only a few species; only six include more than ten species, four of which occur in the Neotropics.

Importance *to* man. The qualities of parrots, especially the ability of many species to imitate human sounds, make them popular as pets. The African gray parrot (Psittacus erithacus) and some species of amazons (Amazona) from the New World tropics are particularly good mimics. There is no evidence to suggest, however, that talking parrots realize what they are saying.

Parrots as pets

Another appealing attribute of parrots is their display of affection, not only to others of their own species but also to man. Pairs of many species, especially the lovebirds (Agapornis), are together almost constantly, nibbling each other's feathers with seeming affection; if one bird disappears its mate sometimes dies, apparently of loneliness. Many parrots seem to delight in being petted and scratched, which is rare among birds. Parrots have extremely powerful jaws, however, and an indiscriminate attempt to pet them can result in a severe bite. The use of the toes for climbing and food handling, in much the same manner as man uses his hands, also makes parrots appealing. Their longevity, bright colours, intent gaze, ability to learn tricks, and willingness to remain on a perch instead of fluttering about contribute to man's fondness for various kinds of parrots as pets. Finally, most species are vegetarians and thrive on a varied diet. This circumstance, as well as the fact that their droppings typically are dry and compact, means that parrots require little care.

Most species of parrots have been kept in captivity at one time or another, and most have been bred, with the exception of the pygmy parrots (Micropsitta). A large zoological garden may have more than 100 species on display at one time. No parrot has been domesticated in the sense of gallinaceous birds and waterfowl, although in recent decades breeders have produced a variety of colour strains of the budgerigar (Melopsittacus *undula*tus), commonly called shell parakeet. In the mid-1950s "budgies" became popular household pets in the United States; within a decade more than 5,500,000 people had at least one in their homes, Captive parrots, especially the larger species, are long-lived. Claims of 80 or even 100 years are frequent and perhaps true, although thus far impossible to document. A convincing record of a 56-year-old greater sulfur-crested cockatoo (Cacatua galcrita) exists, however.

In the early 1930s the importation and sale of parrots in the United States was drastically curtailed by quarantine laws designed to combat psittacosis, or parrot fever (better called ornithosis, as the disease by no means is restricted to psittacine birds), a respiratory virus that can infect humans. Antibiotics now available reduce the severity of the disease, and most of the restrictions on the parrot trade have been relaxed.

The primary economic importance of parrots derives from their popularity with aviculturists. So popular are some species that the Australian government passed laws forbidding export because wild populations were being decimated. Unfortunately, only a few of the many individuals captured ever reach the comparative safety of a comfortable cage, because of mishaps en route. Some parrots, especially certain of the Australian seed-eating species, damage crops and therefore are hunted and killed.

NATURAL HISTORY

Habitat and food choice. Most parrots inhabit forests, although a few live in grasslands. Of the forest-inhabiting species many forage along the forest edge and on the ground. Some parrots live in the mountains, especially in the Himalayas and Andes; the New Zealand kea (*Nestor* notabilis) is a mountain inhabitant but obtains much of its food in the forested valleys; it nests either in high elevation forests or near the forest edge. Many Australian parrots, such as members of the genera *Neophema* (grass parakeets) and Psephotus, are found in dry, open grasslands, although typically where trees are scattered through the habitat. The budgerigar and the rare night parrot (Geopsittacus occidentalis) also are Australian grassland birds.

Parrots feed almost entirely on plant materials. The smaller species tend to utilize grass seeds, berries, fruits, and the juices of blossoms; the larger forms obtain fruits and nuts from trees, and bulbs, tubers, and roots from the ground. When digging, many parrots also capture larval and adult insects, and raven, or black, cockatoos (Calyptorhynchus) gnaw through bark to obtain wood-boring beetles. Many kinds of nectar-eating birds suck juices through tubelike tongues, but brush-tongued parrots feed on nectar by crushing flowers and licking the juices. The tiny pygmy, or woodpecker, parrots feed on fruit, arboreal termites, and fungi. The kea feeds on dead sheep and carrion and will attack sick, injured, or trapped individuals, but rarely will it harm healthy sheep.

Aggregations of parrots

Social behaviour. Typically, parrots are gregarious and noisy, often forming small groups—sometimes huge flocks—flying rapidly high overhead and screeching. Their seemingly conspicuous bright colours are somewhat misleading, for a group of parrots in foliage is difficult to discern. The grassland-inhabiting parrots are nomadic and often occur in flocks of tens or even hundreds of thousands. The development of agriculture in the interior of Australia, particularly the increased availability of water. has resulted in larger populations of several species, such as the corella (Cacatua *sanguinea*) and budgerigar.

The vocalizations of most parrots are loud, raucous screeches; generally the larger the species the more ear-splitting the calls. The voices of some of the smaller ones include chattering and twittering notes pleasant to the human ear. About 12 different calls, each announcing a different mood, have been identified for the greater sulfur-crested cockatoo. The amazing mimetic abilities of many parrots mentioned above are expressed only in captivity.

Reproduction. Parrots are monogamous. Some species breed colonially; others space themselves through the nesting habitat. Based on the fewer than ten species that have been studied extensively, courtship and behaviour to maintain the pair bond may include vocalizations, bill caressing, mutual preening, bowing, wing-raising, tail-spreading, and feeding the mate.

With few exceptions, parrots nest in holes in trees. Some species add nest material such as leaves, fibres, and bark strips; others lay their eggs on the floor of the cavity. Some lovebirds cut leaves into strips, which are then tucked into the feathers of the back for transportation to the nest. Several parrots, including the pygmy parrots and the orange-fronted parakeet (*Aratinga* canicularis), hollow out cavities in termite nests. Exceptional in the family is the monk parakeet (Myiopsitta *monachus*) of South America, which builds a communal stick nest in trees. Several species nest in rock crevices or earthen caves; examples include the burrowing parrot (*Cyanoli*seus patagonus), kea, night parrot, and the flightless owl parrot (Strigops habroptilus). The ground parrot (*Pezoporus wallicus*) lays its eggs in a shallow cup on the ground.

Parrot eggs are white and usually nearly spherical. Generally the larger species lay only two eggs and produce one brood per year; the smaller species lay up to six or even eight or nine eggs and may breed two or three times per year. Incubation time, which generally varies directly with size, ranges from 16 to **30** days in the few species for which there is documentation. Either both parents or else only the female may incubate the eggs. The young hatch naked or with very sparse down. They are altricial—that is, they are helpless and require complete parental care—and they are also nidicolous—that is, they remain in the nest for some time after hatching. The young are fed by regurgitation, typically by both parents. Care of the young may continue for several weeks after they have left the nest.

FORM AND FUNCTION

The yoke-toed foot

Foot structure. Parrots can be distinguished from other birds by the structure of the feet and bill. Most birds have the four toes arranged with three directed forward—the inner (11), middle (111), and outer (IV) —and one backward, the hallux (I). This condition, called anisodactyl, literally means without equal toes, referring to the unequal arrangement. Parrots have two toes (the inner and middle) directed forward, and two directed backward; this arrangement is called zygodactyl, which literally means yoke-toed and refers to the occurrence of toes in pairs. Zygodactyl also occurs in

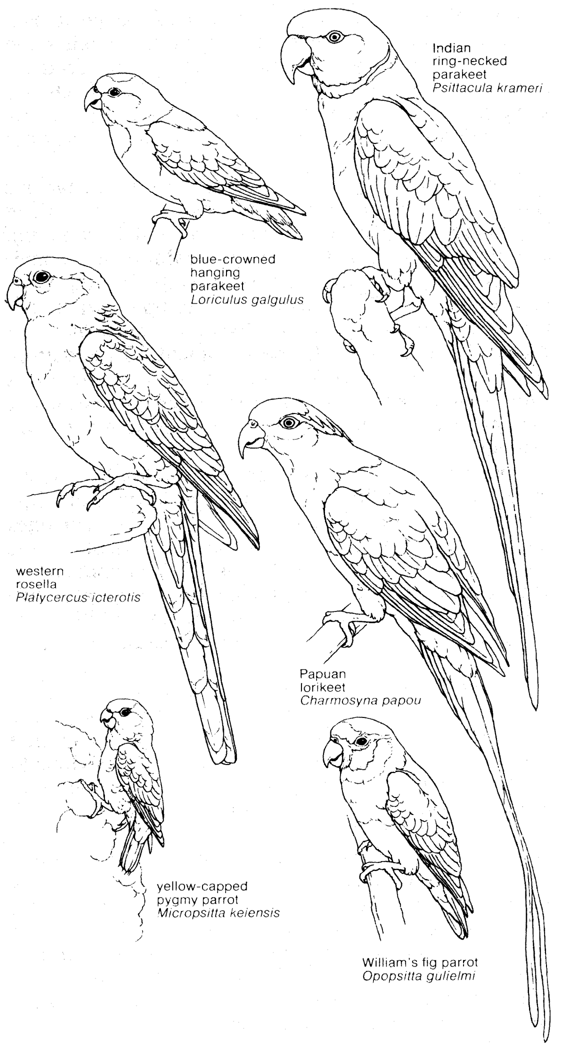

Figure 2: Body plans of representative smaller Psittaciformes.
Drawing by G. Tudor

woodpeckers and their allies (Piciformes), cuckoos (Cuculiformes), and some other birds. The proximal (upper) bone of a bird's foot, the tarsometatarsus (commonly considered the lower leg), lies between the elevated heel joint and the toes. In parrots it is short and stout, and at least one toe is always longer. It is the characteristic short, thick tarsometatarsus—or tarsus, as the entire region is called—and the zygodactylous, long, strong toes that enable parrots to climb and manipulate objects so ably. The entire foot is encased in tough skin covered with small scales.

Bill and skull. The most distinctive morphological trait of parrots is the strongly hooked, powerful bill. Superficially the bill resembles that of the hawks and owls, but the upper and lower mandibles of parrots normally have a stronger and more uniform curve. Often the anterior edge of the lower jaw is broad and truncate. The under surface of the upper bill usually possesses transverse or oblique file-like corrugations where the lower jaw occludes. These file-like ridges, along with the highly manipulative tongue, assist in holding seeds as the bird uses the chisel-shaped cutting edge of the lower bill to peel away a seed cover.

The use of the bill for manipulating objects, cracking hard nuts, and as a third "foot" in climbing are all possible because of a highly kinetic (movable) upper jaw. Most living birds have such a kinetic upper jaw, which is connected to the skull dorsally by a hinge, and is able to be moved independently by swinging on this hinge, but nowhere among birds is this kinesis better expressed than in parrots. The raising of the upper jaw can be described as follows: all movement of the upper jaw originates at the point of attachment between the skull and the quadrate bone, which forms the hinge between the skull and the lower jaw. Two series of bones (the quadratojugal-jugal series and the pterygoid-palatine series), both of which lie in the roof of the mouth, are situated between the quadrate and the upper jaw. Wnen the quadrate is swung forward, the two series of bones slide forward, causing the upper jaw to swing upward on its hinge with the skull.

The short, thick, and fleshy tongue of parrots shows a variety of specializations at the tip; one found in several groups is a brushlike fringe. Primarily, the tongue functions to manipulate and hold food. Those parrots with brushlike terminal papillae (nipple-like projections) on the tongue use them to hold juices, as a brush holds paint.

All parrots possess a cere, an area of soft skin surrounding the nostrils; it may be naked or covered with small, soft feathers. In adult budgerigars the cere is blue in males and tan in females.

The orbits (eye sockets) of some, but not all, parrots are ringed with bone. Other features of the parrot skeleton include a prominent keel on the sternum (breastbone), except in the flightless owl parrot of New Zealand, and a highly variable furcula (wishbone), which may be normal, weak, unfused medially, or absent.

Plumage coloration

Skin and plumage. Parrots have relatively few feathers, which are hard in texture and normally gaudy in colour. Many species are bright green with patches of red, orange, yellow, blue, or white; the plumage of others is predominated by the latter colours. A few parrots are brown or all green. Sexes are alike or nearly so, with a few notable exceptions. One, the eclectus parrot (Lorius roratus), was for many years thought to be two separate species until it was noted that only males were known for the predominantly green "species" and only females for the wine-red "species." The head is crested in a few parrots, especially among the cockatoos (Cacatuinae).

Powder downs, which occur in a variety of birds including some parrots, are specialized feathers, usually found in well-defined patches, that produce a powdery substance used to clean and waterproof the other feathers. They are well developed in cockatoos, in which they occur primarily as a pair of lateral rump patches.

Skin glands, which are abundant in mammals, are almost entirely lacking in birds, with the exception of the oil gland. The oil produced in this gland—also known as the uropygial gland because of its location at the base of the tail and as the preen gland because of its function—is used, like the powder down, to clean and waterproof the feathers. Oil is squeezed from the gland, and birds either use the bill to apply it to the feathers or rub their heads directly over the gland. The nipple of the gland, which protrudes through the skin at the base of the tail dorsally, is surrounded by a tuft of feathers in parrots. Not all parrots have an oil gland; for example, it is absent from the *Amazona,* Brotogeris, and *Pionus* parrots and greatly reduced in some others.

EVOLUTION AND CLASSIFICATION

The extinction of island species

Evolution. Dispersed on a multitude of small islands, parrots have always been vulnerable to extinction, and in recent times the group has suffered increasingly in this regard. From 1680 to the early 1960s at least 16 species disappeared entirely, and another 14 became endangered. Most of the extinct species lived on small islands or on large islands in the West Indies; only the Carolina parakeet had an extensive continental range.

The place of evolutionary origin of the parrot family is not known. The greatest structural diversity is exhibited by parrots from the Australo-Papuan region, but the greatest number of species occur in the Neotropical region. Some authorities doubt that either was the original home of this ancient and distinct group, although it probably did arise somewhere in the Old World. The scanty fossil record is of no assistance in determining the original home of parrots, but it does provide an indication that the group is very old. Typical parrots are known from fossils from the Miocene epoch (about 20,000,000 years ago) of France and from North America. The fact that the Old and New World share no genera and that five of the six Ethiopian genera are not found elsewhere supports the antiquity of the group. An American biologist, Philip J. Darlington, has suggested that parrots and pigeons (Columbiformes), which show similar characteristics of distribution, may have been dominant everywhere before the rise of passerine, or perching, birds (Passeriformes), which may now be replacing them.

Annotated classification. The following classification follows the scheme proposed in 1959 by the German ornithologist Hans von Boetticher. He treated the parrots, as did most of his predecessors, as one family, with seven subfamilies, the two largest of which are further subdivided into tribes. Boetticher reduced the 81 genera recognized by U.S. ornithologist James Lee Peters in 1937 to 75, a figure that reflects the modern view of broader genera.

ORDER PSITTACIFORMES (parrots and allies)

Chunky, primarily tropical birds, with short necks, tarsi, and wings. Distinctive bill, short and strongly hooked, the upper mandible extending down over the tip of the up-curved lower mandible. Feet zygodactyl. Most brightly coloured; often gregarious: highly vocal, About 75 genera, 310–320 species; length 8 to 100 cm; found in the tropics and subtropics of the world and the temperate regions of the Southern Hemisphere.

Family Psittacidae

Characteristics of the order.

Subfamily Nestorinae (kea and kaka)

Bill rather long, narrow, less curved than in other parrots. Plumage greenish-brown. Two species: kea (*Nestor notabilis*) and kaka (N. meridionalis); length about 45 cm; New Zealand and adjacent islands.

Subfamily Psittrichasinae (vulturine parrot, or bristlehead)

Bill rather elongated, but more curved than in Nestorinae; face largely devoid of feathers, those present stiff and narrow. Plumage dark brown to black, with large patches of red. One species, Psittrichas fulgidus; length about 45 cm; New Guinea and adjacent islands.

Subfamily Cacatuinae (cockatoos)

Bill strongly curved (and massive in the palm cockatoo, Probosciger aterrimus); lower mandible wider than upper. Plumage black, gray, pink, or white, sometimes tinged with yellow or pink; often a prominent erectile crest, sometimes yellow or red. Four (or 5) genera, about 16 species; length about 30–80 cm; Australo-Papuan region and Philippine Islands.

Subfamily Micropsittinae (pygmy parrots)

Tiny parrots. Tail feathers short, with stiff shafts and pointed tips. One genus, 6 species; length about 8 cm; New Guinea and adjacent islands.

Subfamily Trichoglossinae (lories and lorikeets)

Bill relatively small; tongue brush-tipped. Mostly brightly coloured and gregarious. Feed on fruit, buds, pollen, and nectar; may be important pollinators of trees. Two tribes, Psittaculirastrini and Trichoglossini, about 14 genera, 62 species; length 11–32 cm; Australo-Papua, Polynesia, Indonesia, and the Philippines.

Subfamily *Strigopinae* (owl parrot or kakapo)

Large, flightless parrot with soft greenish plumage and an owl-like facial disk. Nocturnal and vegetarian. One species, Strigops *habroptilus*; length about 60 cm; New Zealand.

Subfamily Psittacinae (all other parrots)

Range of characteristics encompasses that of order. About 52 genera, 234 species.

Tribe Platycercini (rosellas and allies). Most with long tails, many with bright plumage colours. Twelve genera, 31 species; length about 17–40 cm; Australo-Papua, especially in interior of Australia. Tribe includes budgerigar (*Melopsittacus*), grass parakeets (*Neophema*), rosellas (*Platycercus*), night parrot (Geopsittacus), and ground parrot (Pezoporus).

Tribe Loriini (wax-billed parrots). Bill typically smooth and waxlike. Many species with bright plumage, sexes often differing. About 14 genera, 47 species; length about 14–45 cm; Australia and southern Asia to Africa and Madagascar. Tribe includes racket-tailed parrots (Prioniturus), ring-necked parakeets (Psittacula), the eclectus parrot (Lorius), and lovebirds (Agapornis).

Tribe Loriculini (bat parrolets or hanging parakeets). Small, short-tailed, green parrots. Rest hanging upside down. One genus (Loriculus), 9 species; length about 12 cm; India to Philippines and New Guinea.

Tribe Psittacini (blunt-tailed parrots). Medium-sized parrots; many brightly coloured, especially in green. Many are good mimics, especially in genera Psittacus and Amazona. Twelve genera, 66 species; length about 16–65 cm; New World tropics (majority), Africa and Madagascar.

Tribe Araini (wedge-tailed parrots). Tail usually graduated (*i.e.,* centre feathers longest, side feathers progressively shorter), often long and pointed. Some, especially the macaws (Ara) and blue macaws (Anodorhynchus), brilliantly coloured in red, yellow, and green, or blue. Many species with bare skin around eyes. Thirteen genera, 81 species; length about 12–100 cm; New World tropics. Three genera collectively include 54 species: Pyrrhura and Aratinga (conures and parakeets) and Ara (macaws).

Critical **appraisal.** With the present paucity of knowledge about the evolution of the orders of birds, supposed relationships of the Psittaciformes, which are highly specialized, are purely hypothetical. Various authors have suggested, with little supporting evidence, relationships to the hawks (Falconiformes), owls (Strigiformes), game birds (Galliformes), pigeons (Columbiformes), woodpeckers (Piciformes), and cuckoos (Cuculiiormes), especially the turacos (Musophagidae).

Relationships within the parrot order have proved just as perplexing. In the 1890s British ornithologist Alfred Newton commented on the state of knowledge of parrot classification in A Dictionary of Birds by writing:

> It is a reproach to ornithologists that so little satisfactory progress has been made in this direction, and the result is all the more disheartening seeing that there is no group of exotic birds that affords equal opportunities for anatomical examination, since almost every genus extant, and more than two-thirds of the species, have within recent times been kept in confinement in one or another of our zoological gardens, and at their death have furnished subjects for dissection.

Since Newton's time at least six classifications of the order have been proposed, many of which show basic similarities, but his statement was still basically true as of the early 1970s.

BLBLIOGRAPHY

Popular accounts: J.M. FORSHAW, Australian Parrots (1969); and W.R. EASTMAN, JR. and A.C. HUNT, ***Parrots of*** Australia (1966), are large, lavish books describing and depicting in colour all Australian parrots. H. BATES and R. BUSENBARK, Parrots and Related Birds (1959); and the DUKE OF BEDFORD, Parrots and Parrot-like Birds (1954), treat all of the parrots, with particular reference to aviculture. H.S. ZIM, Parakeets (1953), is devoted to the aviculture of the budgerigar. W.C. DILGER, "The Behavior of Lovebirds," *Scient.* Am., 206:88–98 (1962), is an excellent summary of the author's research into the behaviour and evolution of *Agapornis.*

Technical accounts: H. VON BOETTICHER, Papageien (1959), is a 116-page booklet, in German, containing ten pages of introductory information, followed by a new classification based on external morphology, especially of the cere, with all species described briefly. A. NEWTON, A Dictionary of Birds (1893–96), contains a seven-page summary of parrot biology, as known at the end of the last century. J.L. PETERS, Check-List of Birds of the World, vol. 3 (1937), presents a classification of all parrots down to subspecies, with information on geographic ranges and scientific names. A. REICHENOW, *Vogelbilder* aus *fernen* Zonen-Papageien, 2nd ed. (1955), includes colour paintings and brief descriptions, in German, of almost all parrots.

(G.E.W.)

Psychiatric Treatment, Concepts of

Basic goals of treatment in psychiatry are the same as those sought from healers of all kinds since the earliest recorded time—simply, the means to relieve distress. When the results of injury or illness are felt in the body, the distress may be called pain or discomfort; or it may have less apparently palpable origins or manifestations and be known by less tangible names such as depression, anxiety, or schizophrenia. The ultimate threat posed by distress or suffering of any kind due to illness or injury is death.

In so-called primitive societies the role of the medicine man, or healer, is often identified or overlapping with that of religious leaders, such terms as witch doctor (or shaman) exemplifying this natural–supernatural duality. No comparable duality persists in modem medicine, which is nevertheless not exclusively scientific (since much remains to be explained through science). The place of psychiatry in modern medicine rests upon the assumption that the treatment of what seems to be intangible (but excluding what metaphysics and religion refer to as the spirit, or supernatural soul) can be carried out through natural means.

Psychiatry is a branch of medicine primarily concerned with disorders of thought, feeling, and behaviour. To extend this definition to efforts to solve moral and religious issues is to take psychiatry out of its depth. In just the same way, to expect psychiatry to provide the ultimate answer to the human predicament in terms of its sum of suffering is to ask a part of medicine to become a parcel of magic. The temptation to demand magic, or to deny the limitations of psychiatry, is bound up with the difficulty of assuming mind and matter as aspects of the same reality; but, unless they are so regarded, the physician cannot begin to fathom or treat them.

Primitive approaches

Modern psychiatry has discarded many of the theories of primitive medicine on the grounds that they have been tried and found wanting. Efforts to treat psychiatric symptoms by letting demons escape through holes (trephines) gouged in the skull, by seeking to restore the sufferer's wandering soul, by sorcery, or by propitiating the gods represent some of these disease theories. Overall, the evidence is that, when it is successful, much of primitive medicine as still practiced among some tribal groups owes its power to belief in magic and the normal suggestibility of people. By contrast, this article will from here on be concerned essentially with the efforts of modern medicine to mitigate distress by techniques openly taught and carefully verified by observation. It is essentially by this openness and constant exploration and validation, as distinct from mere polishing of technical skills, that modern medicine deserves its name.

In one sense all illness or injury, indeed suffering of any kind, involves disorder of feeling; thus, the primary concerns of psychiatry with disorders of feeling, thought, and behaviour are vital to a proper understanding of medicine and surgery in general. But the special province of psychiatry is the understanding of those disorders of subjective (inner, private) experience or of objective (observable, public) behaviour that are themselves a cause of disability. A great deal more has been written about the nature of modern psychiatry. Suffice it to observe that the discipline remains subject to misunderstanding, even among those who consider themselves reasonably well educated; hopefully, a consideration of the concepts of psychiatric treatment will serve to promote fuller understanding.

For as long as psychiatric disturbance has been recognized, it has been treated either by attempts at transformation of the more or less passive sufferer or by efforts to communicate with him.

Treatment by transformation. With a history as long as that of any form of medical treatment, transformation has the underlying aim of changing the sufferer by some means that either does not depend at all or depends only in the most concrete and limited sense upon his own cooperation, understanding, and interest. Under this heading come all the various forms of physical treatment that have been employed to relieve or cure psychiatric disorders. Such techniques often are identified as somatotherapy (that is, bodily treatment).

The history of psychiatry repeatedly records the past practice of inflicting some kind of physical unpleasantness or pain, almost as though the person had to be made to expiate the crime or sin of being mentally distressed. This shadow lingers in occasional theories offered to account for the effectiveness of such forms of physical treatment as the use of drugs, electric currents to induce convulsions, and brain surgery. But none of these methods has anything in common with the whips and chains to which disturbed people were subjected in former times, nor is the production of fear any part of the rationale of their use. There are instances of behavioral treatment in which the deliberate production of discomfort, with the individual's full knowledge and consent, leads to successful retraining, but terror plays no part in the experience. Yet, with a history of almost 2,000 years of continuous violence in the treatment of the mentally disturbed, it is not surprising that even today some refer to such methods collectively as "shock" treatments, implying an emotionally shocking experience rather than any beneficial physiological changes in the body.

Electric- shock treatment

Electric-shock treatment was so named originally by theorists who assumed that the passage of electricity through the brain produces emotional shock or dread. Yet modern treatment of this kind, successfully carried out under general anesthesia, is neither shocking nor unpleasant. Once widely used, insulin shock is a technical term covering the physiological response to large doses of insulin, also being produced during a period when the patient was unconscious and knew nothing about it. Indeed, a major aspect of the doctor's task in discussing these forms of treatment with a patient is to disabuse him of the idea that fear or pain or horror play any part in them whatsoever.

Treatment by communication. Covering all forms of exchange of ideas, discussion, reasoning, and emotional response, treatment by communication is an effort to make the individual's world comprehensible to him, even to help him learn to see it with new insight, and to modify his disturbed behaviour along lines governed by his changed understanding and by his increased confidence. Conimunication is the basis of all varieties of psychotherapy, whether they rest on psychodynamic (insightful) changes or on behavioral retraining. The term psychotherapy means literally the treatment of the mind; by such a definition, however, it might even be applied to surgical methods of treatment for mental illness. Nevertheless, use of the term in practice is restricted to those methods that rely for their effect upon exchange between patient and doctor through sensory avenues of communication.

BIOLOGICAL APPROACHES (SOMATOTHERAPY, TREATMENT BY DIRECT PHYSIOLOGICAL METHODS)

General methods of bodily treatment in psychiatry include rest, diet, and protective, reassuring hospital observation leading to whatever symptomatic measures seem likely to be helpful (*e.g.*, warm, relaxing baths to relieve symptoms of tension). More specific techniques depend on drugs (chemotherapy), other neurophysiological approaches, and, still occasionally, neurosurgery.

Chemotherapeutic, or pharmacological, treatment. *Sedation.* The use of sedative drugs by day has the aim of reducing subjective distress (*e.g.*, anxiety and objectively disturbed behaviour); by night it can combat insomnia, an otherwise constant and distressing feature of many forms of psychiatric disorder. Generally speaking, a class of drugs called barbiturates (*e.g.*, phenobarbital) still includes the most efficient sedatives; when properly used, some are possibly the safest and least complicated to use. Popular apprehension and medical division of opinion about them are based largely on their misuse, as when they are taken in excessive quantities and without sufficient medical supervision (see also DRUG PROBLEMS). No effective drug, however, is free of harmful effects if misused; under proper control, barbiturates continue to be widely used when sedation is required.

Chloral hydrate

As a possible alternative to barbiturates, a drug called chloral hydrate is a safe and reliable sedative. When taken by some people, however, it produces irritation of the lining of the stomach (gastritis). As a precaution, it should be taken with some palatable vehicle such as fruit juice or milk or in dilution with sugar and water.

The regularity with which overdoses of sedatives are used for suicidal attempts has prompted a number of drug manufacturers to produce combinations, such as barbiturates mixed with emetics (to induce vomiting when overdosed) or with antidotes (such as Megimide).

The day of bromides and paraldehyde for sedation in psychiatry is past. Bromide preparations have cumulative toxic effects and readily lead to confusion and disturbance of sleep rather than to its improvement. Paraldehyde, while less pernicious than the bromides, is a malodorous and nauseating drink; in intramuscular injection it carries a significant risk of abscess formation.

Sedatives are sometimes employed to maintain continuous sleep for up to 12 hours a day for two to five days or longer. This special technique occasionally is used in the treatment of severe anxiety and tension, acutely agitated chases of depression, and other states of abnormal excitement. Prolonged sedation of this sort carries considerable risks of secondary complication unless nursing care is extremely efficient and physicians who have employed the method are readily available (see also SEDATIVE–HYPNOTIC DRUGS).

Tranquillization. Tranquillizing drugs act primarily to reduce anxiety and tension, as opposed to the major sleep-inducing effects of the sedatives. The great value of a tranquillizer is to produce calmness and relaxation while maintaining a degree of alertness during waking hours. Thus, such drugs are widely used to control symptoms of anxiety that otherwise might hamper an individual in his daily work or other activities. These drugs can also relieve some of the symptoms of tension and agitation associated with depression or obsessive-compulsive disorder (see PSYCHONEUROSES). There is a wide range of them in current clinical use, of which three groups are central examples: (1) meprobamate, (2) chlordiazepoxide and diazepam, and (3) phenothiazine compounds (see also TRANQUILLIZER). In addition to providing a basic chemical structure from which many other psychotropic drugs (those acting on mental function) are derived, phenothiazines are of particular value in the treatment of many severe psychiatric disorders that have psychotic characteristics (see below; see also PSYCHOSES).

Types of tranquillizers in clinical use

Stimulation. Stimulant drugs, besides combatting sluggishness, have rapid symptomatic antidepressant action; they may be distinguished from a newer group of specific antidepressant compounds (see below) that tend to reverse depressive disorder without producing immediate relief. Symptomatic antidepressants include a class of chemical compounds called amphetamines, which have fallen into a phase of distinct unpopularity, owing to their undoubted risk of addiction and the ease with which they are misused by potential addicts. This group includes amphetamine, dextroamphetamine, methamphetamine, and other derivatives of dl-amphetamine. While their use as symptomatic antidepressants has been largely discarded, they occasionally may be prescribed for varieties of epilepsy in which abrupt fits of compulsive sleep are prominent features. Another amphetamine-related stimulant that may still be used, particularly in the treatment of old people with chronic lethargy, is methylphenidate. Although it has relatively fewer disadvantages in terms of addiction or misuse, like all other psychotropic drugs it should never be entrusted to the unsupervised self-administration of the patient. Careful monitoring and supervision are indispensable to its proper use (see also STIMULANT).

Antidepressants. Various newer, nonstimulant preparations have been found to produce specific reversal of depressive symptoms in about 60 percent of patients treated. These include so-called tricyclic compounds, such as amitriptyline and imipramine, and another group of drugs classed as monoamine oxidase (MAO) inhibitors, such as nialamide. The exact mode of action of these preparations is not yet entirely understood, but it seems probable that they enhance or prolong the action of substances normally produced in the body, such as adrenaline and serotonin (see also DRUG AND DRUG ACTION).

As a general rule the tricyclic antidepressants are safer to use but less spectacular in their effect than are the MAO inhibitors; the latter act powerfully on a number of normal physiological systems in the body, affecting many amines (protein constituents) in the metabolic cycle. Careful restrictions therefore are placed upon the diet and intake of any other drug by patients who are using monoamine oxidase inhibitors.

Restrictions with the use of MAO inhibitors

Anti-excitement and *antihallucinatory* preparations. Haloperidol is a relatively new preparation that has proved valuable in controlling excitement (mania or less intense hypomania). Abnormal excitement and overconfidence also have been controlled with a simple chemical compound (lithium carbonate) in appropriate doses monitored by weekly blood tests.

The specific roles within the body of magnesium compounds other than haloperidol are recognized in the treatment of toxic confusional states and other forms of delirium. The exhausted brain is frequently depleted of vitamins B and C, and, by saturating the circulation with them through injection, as well as by restoring blood fluids and salts, immediate benefit can be obtained for the delirious patient.

Many phenothiazine derivatives, in addition to their action as tranquillizers, share varying potentials for reducing the general level of excitement, disorientation, confusion, and thought disorder. Some of these drugs appear to have a specifically tranquillizing and antihallucinatory effect in schizophrenia, making communication possible with otherwise inaccessible patients; they also may be combined profitably with electrical treatment (see also TRANQUILLIZER).

Antirepressive ("mind-releasing") drugs. Such drugs as mescaline, cannabis (*i.e.*, marijuana), and lysergic acid diethylamide (LSD) have not fulfilled hopes once placed in them for psychiatric treatment, and they would appear to have no supportable medical uses. The hypothesis was that their action on the brain might facilitate nerve pathways and thereby effect the release of partly forgotten (repressed) memories or the loosening of obsessive-compulsive rituals. This hypothesis has not proved valid; disturbing, long-term side effects and undesirable direct consequences (*e.g.*, so-called bad trips) of some of these drugs have contraindicated their use in psychiatric treatment. Immediate release and subsequent exploration of emotionally charged memories remain feasible by the use of injectable barbiturates of proved safety. This overall process of explosive recall and subsequent emotional disinhibition is called abreaction and can form part of psychotherapy in appropriate cases (see also HALLUCINOGEN).

Physiological methods. Physiological techniques of psychiatric treatment (that is, those that produce a suspension of consciousness) demand for their administration the attention of a team of professional experts. Special physiological methods have radically altered the outlook for some types of mental disorder previously beyond the power of psychological medicine to relieve, cure, or control. These empirically useful techniques share a capacity to change the function of the nervous system and ductless glands by the use of electricity, substances such as insulin, and surgery.

Electroconvulsive therapy. The history of electroconvulsive treatment can be said to have begun with the discovery that the function of the brain can be altered immediately or over a period of time by the effects of electrical energy introduced from outside. Initially, hypotheses for the immediate use of electricity to induce seizures were based on evidence that some convulsion-producing drugs, such as pentylenetetrazol, also had beneficial psychiatric effects. Subsequent years of research and refinement have shown that, even without convulsions, induced alterations in the electrical and biochemical activity of the brain over a limited period of time can relieve symptoms of depression, delirium, stupor, and schizophrenia. Limits also have been established within which electrical current can be safely used without damage to the brain or harm to the patient.

Induced seizures

Electroconvulsive therapy (ECT) depends on the passage through the brain of a small electrical current, on the order of 200 to 500 milliamperes, for less than one second at a level not exceeding 150 volts. The current is now usually administered to only one side of the brain

—the nondominant side. Typically, this is the right half of the brain, most people showing signs of dominance (*e.g.*, location of speech centres) in the left brain hemisphere. The advantage of such unilateral ECT is simply that it diminishes undesirable side effects formerly frequent when the bilateral form of this treatment was common. Included among these side effects are loss of immediate memory, an element of confusion, and a sense of dislocation in time and awareness; all tend to be temporary, but they are relatively disagreeable.

Although bilateral ECT is still used occasionally, future methods of electrical treatment will probably be increasingly confined to the nondominant hemisphere of the brain, and the advantages to be sought from it will be increased and the side effects diminished. The appropriate indications and detailed techniques for this treatment are still a matter for continuing relearch. Usually administered at a frequency of two to four times per week, the treatment is given while the patient is under a combination of anesthesia and muscle relaxant so that no convulsions ensue.

The way in which this remarkable treatment works is still incompletely understood, but recent research into the electrophysiological and biochemical changes accompanying it suggests that its effects involve several parts of the brain (*e.g.*, cortex, midbrain, hypothalamus), the pituitary gland, and other autonomic parts of the nervous system (see also NERVOUS SYSTEM, HUMAN; ENDOCRINE SYSTEM, HUMAN). It can further be postulated that the convulsion originally associated with the treatment was always merely incidental, a by-product of the stimulation required to trigger off other, more directly therapeutic, physical processes. Although it is clear that spontaneous fits among sufferers of epilepsy produce no comparable benefit, the administration of ECT to carefully selected patients can yield spectacular and highly satisfactory results.

Whatever the indication for the treatment, it is routinely combined with direct explanation and communication with the patient. As improvement progresses, the degree to which personal problems remain to be dealt with will vary among individual patients and will affect the nature of any psychotherapy then undertaken.

Electrically induced sleep

Electronarcosis. This form of treatment is given more frequently in Britain and in the Soviet Union than anywhere else. It was pioneered as much in Australia as in the United Kingdom and has rarely found much clinical support in the United States. Essentially, the immediate aim in electronarcosis is to produce an artificial state of electrically induced sleep, which may be initiated under an anesthetic. Such sleep has been subsequently maintained for periods varying from a few minutes up to 15 to 20 minutes or longer, depending on previous experience. The eventual routine use of this induced-sleep therapy will rest on the outcome of research into its effectiveness and its appropriate indications.

Insulin treatment. Injections of insulin lower the level of sugar in the blood, the low-level state being called hypoglycemia. In so-called deep-insulin treatment, sugar is depleted to the point that the patient loses consciousness. This treatment, with its hypoglycemic coma (reversed by injections of sugar), played a historical and epochal part in transforming the outlook for sufferers of some varieties of mental disorder (particularly schizophrenia) who hitherto could be offered, at best, only protracted custodial care; it is now, however, obsolete in the treatment of schizophrenia.

Modified insulin treatment (in which the induced hypoglycemia is mild enough to avoid deep coma) continues to be a useful, practical method of treatment for conditions characterized by chronic anxiety, anorexia (loss of appetite), loss of weight, profound tension, and exhaustion or by restless, irritable resistance to treatment and management of any kind. Modified insulin treatment requires that the patient be nursed in bed, at least for the first half of every day; this provides a foundation for a regular regime of nursing care and attention, with specific concern for quiet, rest, and progress. As such it has undoubted benefit in certain cases by reducing physiological signs of disturbances and by improving the patient's sense of well-being.

In the modified method, the patient begins with a minimal test dosage of insulin every morning; the dose then is increased to an arbitrary maximum that usually does not exceed *50* units of soluble insulin. A balancing meal (containing sugar or other carbohydrate) is given within an hour of the injection, and such side effects as drowsiness, occasional faintness, and some confusion are nursed symptomatically. A favourable response is indicated by reappearance of normal appetite, gain in weight, and, most of all, a calming effect and an ability to accept other forms of treatment (*e.g.*, psychotherapy) and improvement as reasonable goals.

Neurosurgery. Brain surgery as part of the modern treatment of mental illness often is said to have begun with the speculation and experimental work of a brilliant Portuguese neurologist, António Egas Moniz. Moniz, however, had an international tradition of clinical observation and perceptive hypothesis in neurophysiology on which to build. He was familiar with the observations of the great English neurologist John Hughlings Jackson upon localization of function in the brain; she pioneer work of the noted American surgeon Harvey Cushing in brain surgery and its effects upon brain function; and German theories of the role of the frontal lobes of the brain. He had also considered the 19th-century medical history of a patient in the United States who showed major personality changes after his frontal lobes had been virtually destroyed by a crowbar that had been driven upward through the front of his skull and emerged from the top of his head (but without killing him).

There were also reports on the behavioral effects of experimental work with the living brain in otherwise intact, intelligent chimpanzees whose frontal lobes were removed or severed (leucotomized) from the rest of the brain. Moniz accepted the responsibility of transferring the operation to men when he was confronted with sufferers of apparently incurable mental disturbance, in some of whom emotional tension and depression were crippling. The operation was called prefrontal leucotomy (or lobotomy) because it depended for its effect upon severing the connecting nerve fibres (white matter) between the frontal lobes and the rest of the brain. These white fibres run beneath the surface of the brain (gray matter).

Prefrontal lobotomy

There can be no doubt that, in both conception and performance, the operation was in its earliest day a remarkable combination of technical brilliance and concentual crudity. Prefrontal lobotomy proved remarkably successful in certain carefully selected types of illness, but it was truly disastrous in others. Study of the first series of Moniz' cases demonstrated that the operation undoubtedly produced changes in the mental state of the patients. These differed, however, from the theoretical expectations of Moniz; for while delusions and hallucinations were unaffected, what was changed was the attitude displayed by the patients toward their symptoms and their overall state. Like lobotomized chimpanzees, they had become more placid, tranquil, and phlegmatic—too often, excessively so.

Following this initial series, clinical observation and research were stimulated, and the operation proved more enduring than the opposition that it first had provoked. The thesis that eventually emerged was that a great deal of emotional tension and the patient's conscious control over and preoccupation with behaviour that might lead to such tension are in some way of neurological origin. Specifically, the symptoms seem connected with the function of nervous pathways connecting the frontal lobes with the rest of the brain (particularly with the thalamus, a mass of nervous tissues about half the size of a golf ball situated in the lower core of the blain). The role of the thalamus appears to be that of a central reception station for incoming sensory messages of all kinds, and its special connections with the frontal lobes and with an associated structure (the hypothalamus) appear in turn to be concerned with the elaboration of conscious awareness of, and emotional response to, stimuli. In this sense the frontal connections to other parts within the brain seem to play a fundamental role in shaping the way the patient feels about present reality and past experience.

This is the basis for the subsequent extension of the use of the operation in certain cases of otherwise intractable pain, as in cancers that are not accessible to surgery. Whether the origin of the suffering seems to be primarily mental or physical, the relief appears to depend upon the patient's altered attitude to his pains, rather than upon their total disappearance. The general indication for these operations, however undertaken (whether by open surgery or by the introduction of radioactive implants in the body), can best be summed up as otherwise intractable distress in which tension and emotional stress are paramount and in which apathy and withdrawal from the environment are not major features.

The human frontal lobes (and the rest of the brain cortex) are substantially more highly developed than are those of most other animals. It seems probable that, as these structures have evolved and enlarged, so has their capacity for inhibiting more primitive types of activity in the nervous system. It has been pointed out that the great development of intelligence and flexible behaviour in man may be linked to a superior ability to inhibit immediate reflex reactions to disagreeable experience. Planning and thought (associated with the cortex) are involved in putting off actions until an opportune moment and in the deferment of short-term satisfactions for the sake of long-term goals.

Reduction of neural inhibition

Thus, one fundamental principle seems to emerge: lobotomy in psychiatry seems to be a way of reducing the abnormal or exaggerated effects of inhibition among different brain parts. This kind of brain surgery shows no promise of ever adding anything; rather, it is by subtracting or reducing brain functions that lobotomy relieves the patient's distress (see also EMOTION: The ***frontal lobes and emotion).***

TREATMENT BY COMMUNICATION (PSYCHOTHERAPY)

The theories underlying psychiatric treatment by communication are broadly classifiable as either psychodynamic or behavioral (see also PERSONALITY, THEORIES OF).

The concept of psychodynamics in psychotherapy owes its existence to the hypothetical postulate that each person has an unconscious mind. Versions of this theory have been advanced throughout history (*e.g.*, by Socrates in ancient Greece); but they were later considerably developed and expanded by Sigmund Freud. Subsequent streams of dynamic therapy evolved from and eventually separated from the Freudian school of psychoanalysis, under such names as Jungian, Adlerian, and Rogerian (nondirective) therapy; other dynamic variations are called Gestalt therapy and Existential analysis (originally called Daseinsanalyse by its founder, Binswanger).

By contrast, the fundamental concept underlying behavioral psychotherapy is that of the conditioned reflex. Ivan Pavlov, whose work with dogs pioneered the concept of the conditioned reflex (see LEARNING THEORIES), strenuously maintained that his was physiological rather than psychological research. Nevertheless, this mechanistic, neurological concept of learning (reflexology) as a basis for mental disturbance has become associated with the names of many psychologists. It would be generally agreed upon that its first formulation came from the American psychologist John Broadus Watson, who first wrote of it in the ***Encyclopædia Britannica*** in ***1913.***

All other systematic forms of psychotherapy are essentially derived from one of these two mainstreams; or they represent breakaway movements that tend to become mystical, religious, or heavily authoritarian in concept and so resist open, scientific scrutiny. Until they permit objective, experimental evaluation, such breakaways remain beyond the scope of scientific psychiatry.

Psychodynamic treatment. The principles of psychodynamics are ultimately mechanistic, using as their analogy the idea of physical forces in motion. Their hypothetical source can be traced to three basic theoretical principles or assertions:

1. Human behaviour is prompted chiefly by emotional considerations, but insight and self-understanding are necessary to modify and control such behaviour and its underlying aims.

2. A significant proportion of human emotion, together with the action to which it leads, is not normally accessible to one's personal awareness (or introspection: literally, looking into one's self), being rooted in the mind beneath the level of consciousness.

3. It follows logically (and is supported by experimental and clinical work) that any process that makes available to individual consciousness the true significance of emotional conflicts and tensions hitherto repressed (in the unconscious mind) will thereby produce both heightened awareness and increased stability and emotional control.

The application of these principles in practice hopefully can lead not only to improved psychiatric health in its widest sense but also to a more mature and developed personality. Classical dynamic psychotherapy is a relatively intensive type of talking treatment aimed at providing the person with insight into his conscious and unconscious life and into the deeper relationship of psychiatric symptoms to emotional conflict; it is often uncomfortable for the patient himself, at least in the early stages. Yet it promises the considerable advantage of enabling him to achieve an awareness of himself that may not only help to arm him against present difficulties but also make it easier for him to control at least a part of his fate in the future. The effectiveness of dynamic psychotherapy depends ultimately upon the patient's acceptance of a significant share of the responsibility for the success of the treatment, by experiencing the disagreeable effect of examining his emotionally tender spots. The process also imposes a considerable strain upon the therapist, who is not supposed to relieve his own anxiety about the patient by taking responsibility for the patient's difficulties away from him.

Factors in effectiveness

The original, classical, and most elaborate form of dynamic treatment was that developed by Freud and called by him psychoanalysis. Analytical psychotherapy, developed by the Swiss psychiatrist Carl Gustav Jung, and individual psychotherapy, by the Austrian psychiatrist Alfred Adler, are two further specialized psychotherapeutic techniques worked out by these former pupils of Freud who later diverged from him to create their own approaches to the goal of self-awareness. Extremes of subsequent psychodynamic theories are exemplified by the nondirective therapy of Carl Rogers, at one pole, and Existential analysis, or Daseinsanalyse, as expounded originally by Binswanger, at the other (see below).

The advantage claimed exclusively for these traditional methods of analytic treatment by their proponents is that when completed they accomplish radical and exhaustive personality change. What has been spent in time is held to be repaid in depth and degree of awareness and consequent personal stability. In practice a full, classical analysis demands not less than three to five interviews a week for anything from two to four years, excluding only the inevitable breaks caused by absence of doctor or patient. Any procedure that demands so much expenditure of skilled time is inevitably costly. Moreover, such procedures are suitable only for patients whose intelligence, determination, and resources of time or money are sufficient to enable them to complete and profit from so intensive a course of treatment. Indeed, on these grounds alone, failures in analytic treatment are quite common.

Problems of older analytic methods

These older analytic methods of psychotherapy are thus highly selective and self-limiting forms of treatment; their practice, moreover, is entrusted only to those few therapists whose training has fulfilled particularly rigorous conditions. But, despite these limitations, they are important procedures. Their importance today derives less from their practical results (gained in individually suitable patients, who probably make up not more than 5 percent of all patients with psychiatric problems of any kind) than from the body of understanding that these methods have contributed to what is called psychopathology (the study of psychiatric symptoms). Most important of all are modifications of these deep, intensive analytic techniques that have led to the evolution of various briefer varieties of dynamic psychotherapy devoted to the attainment of insight within a matter of weeks or months.

Psychoanalysis: the rnethod* of *Freud. The initial interviews in psychoanalysis follow the same general pattern as those of any other psychotherapeutic procedure. As far as possible, the history of the patient's life is obtained and noted in an orderly and comprehensible way. Thereafter it is the task of the patient to produce, out loud and absolutely without suppression or censorship of any kind, all his thoughts and feelings about whatever is uppermost in his mind. Such a talking procedure is called free association. This may sound difficult, but in practice it is even more challenging than it sounds, at least in the early stages of treatment. To speak of one's innermost (often socially unacceptable) thoughts can be most trying after years of practice in selecting what one will say to others.

In response to the hitherto inconceivable opportunity of acknowledgment and expression without fear of social disapproval, many of the ideas that rise into the patient's mind are thrust down almost before he has had time to become aware of them; such readily available ideas are said to be preconscious rather than truly unconscious. More difficult still is the patient's eventual acknowledgment of underlying unconscious sources of such preconscious ideas, which can only be achieved with time, practice, and, above all, a confidence that at the outset no patient can be expected to have.

The psychoanalytic procedure

The one essential rule of psychoanalytic procedure, that nothing shall be suppressed and nothing selected, demands the adoption of every possible measure that helps the patient to do his part of the work. It is for this reason alone that the patient is encouraged to lie down, to relax completely, to look at nothing more exciting than the ceiling, and to talk without the visible presence of another person to distract him. The analyst sits out of the range of the patient's vision and, while still able to do the therapist's part of the job, may have no cause for intervention of any kind. All the time the analyst is recording, sorting, and studying what the patient says, bearing in mind its possible interpretations and its correlation with what has been said before. As the analysis proceeds, he strives to accumulate deeper sources of understanding of the patient, but he does not obtrude into the process unless, without his help, the patient cannot go further.

The study of dreams forms an important part of psychoanalysis, being based upon theory as well as experimental evidence that dreams have a latent (hidden or disguised) content different from the manifest (literal) content by which they are remembered. This conclusion emerges from studies in which manifest dream content is subjected to analysis of the dreamer's free association about it. Thus, the ogre in one's dream may be found to be a disguised representation of a hostile, punishing parent. The production of the manifest content from the latent content is an unconscious process that Freud called the dream work, and it is the reversal of this process that constitutes the analysis of the dream.

Many of the experiences the patient resists remembering are those of personal relationships (in the recent or more remote past) that have been connected with intense and conflicting emotion and that have never been finally resolved or settled. The release of such emotion in the course of treatment, before its unconscious source has reached awareness or been understood and accepted, is in itself intensely disturbing. The patient often seeks to rationalize or to project (attribute to something other than himself) the emotion he feels. Under the conditions of treatment, the person who almost invariably is selected for such rationalization or projection is the analyst; that is, the patient is likely to blame his own emotional distress on the analyst.

In this way, during the course of treatment the patient comes to feel love and hatred, dependence and rebellion, and rivalry or rejection toward the analyst. These are the same attitudes he has felt but never fully acknowledged for other people in his life whose earlier impact has been inescapably close; they may have been his parents, his first love, or the friends, enemies, heroes, and villains of his childhood. The patient's uncritical and barely understood shift of earlier emotional attitudes to the therapist is called the transference. Control of this transference and regulation of its depth and intensity are to a great extent in the hands of the analyst, who strives to have its underlying interpretation available for use as the occasion demands. To interpret or interfere with the transference too early is to deprive it of the strength necessary to enable the patient to carry on with his already difficult contribution to the treatment. Any tendency by the analyst to escape prematurely from his obligations in transference may spring from his own anxiety or insecurity, especially if this has not been adequately dealt with in the course of his training. To interpret transference inadequately or too late or to fail to deal with the transference situation at all is to risk the development of a patient who is heavily dependent on the therapist. This may be a more serious complication than the symptoms that first brought him to seek treatment; at this point the patient is said to sufferan interminable transference neurosis.

Expression of emotions during analysis: transference

The handling of the transference situation is thus of vital importance in the course of psychoanalysis or, indeed, in the course of any form or psychotherapy. It is through transference that the patient discovers the nature of his underlying feelings and then becomes able to acknowledge them. Once this has been done, he often finds himself able to regard them in a far more tolerant and dispassionate light and to be liberated from their influence upon his future behaviour.

Jungian analysis: analytical psychology. The technique of analytical psychology as formulated by Jung differs from the original Freudian technique of psychoanalysis in that far less emphasis is placed upon free association. Much more importance is attached to an analysis and interpretation of certain aspects of the patient's fantasies and dreams. These aspects are handled in a way quite different from that propounded by Freud in his approach to the analysis of dreams by association. Perhaps the essential difference is between Jung's and Freud's concepts of unconscious mental life. The Freudian view maintains that the unconscious mind contains essentially only instinctual drives and repressed conflictive complexes. The Jungian thesis, however, is that there is an enormous reservoir of shared unconscious wisdom and ancestral experience transmitted throughout the generations to the whole of humanity. This so-called collective unconscious is said to permeate each individual unconscious mind and to enter consciousness only in symbolic form to influence thought and behaviour in powerful but indirect ways. The symbolic forms taken by these powerful archaic mental processes, regarded as common to the entire human race, are called archetypes; and it is in the archetypal nature of myths, stories, and dreams that the Jungian analyst seeks clues to his patient's problems and their interpretation.

Adlerian analysis: individual psychology. Adler's special contribution to individual psychotherapy was to stress the importance of the drive toward power, which lies at the heart of so much human endeavour.

He observed that for many people the achievement of power, status, and prestige was at least as important as the search for sexual gratification and could produce great impact upon the individual's life and emotional development. It was Adler who was responsible for the now-common phrase "inferiority complex," meaning not a conscious feeling of inferiority but, rather, an unconscious constellation of ideas of personal worthlessness. These ideas generate an intolerable sense of insecurity and inadequacy, the origins of which the sufferer is largely unaware. The effect of such unconscious feelings of inferiority upon behaviour is (by compensation) to produce a somewhat assertive attitude and to drive the individual into challenging situations within which he strives to prove his deeper misgivings about himself to be false.

The "inferiority complex"

Adlerian analysis concentrates attention upon the patient's idealized, partly conscious concept of himself and upon the goals that he has set himself. The therapist seeks to relate self-concept and goals to the patient's actual personality and to the practical circamstances, opportunities, and limitations of his life. In the inevitable conflicts and frustrations implicit in the gulf between aspiration and achievement, Adlerians perceive the foundations either of pathological emotion and behaviour or of renewed and constructive endeavour. Through the therapist's and patient's interpretations and insight, Adlerian analysis aims at enabling the individuai to become aware of the true springs of his own needs, drives, and impulses. When these urges are compensatory, in reaction to some real or imagined weakness in himself, the patient is helped to evaluate their implications consciously and, by discriminating between feasible and impractical goals, to free himself to pursue the one and discard the other.

The content of an Adlerian analysis is therefore essentially concerned with the relationship of the patient's personal aspirations and goals of achievement, both conscious and unconscious, to his social setting and total life situation. Less emphasis is placed on the more instinctual need for sexual fulfillment, which Freud saw as the ultimate driving force in human experience, or on the integration of the personality, which remains the Jungian concept of human fulfillment.

Rogers and Binswanger. In 1942 Carl R. Rogers in the United States and Ludwig Binswanger in Switzerland published two fuither (and in many ways polar opposite) contributions to psychodynamic psychotherapy: Rogerian, or nondirective psychotherapeutic counselling, and Daseinsanalyse, or existential analysis. The former relied entirely upon the inner resources of "the client" for its outcome. In Rogers' own words,

> Effective counselling consists of a definitely structured permissive relationship which allows the client to gain an understanding of himself to a degree which enables him to take positive steps in the light of his new orientation.

Binswanger's thesis was essentially inspired by Heidegger's Daseinsanalytik, a philosophical approach to the structure of human existence in general. Binswanger published it as a 726-page book, *Grundformen und Erkenntnis menschlichen Daseins* ("Basic Forms and Knowledge of Human Existence"), in essence an attempt to analyze every aspect of being-in-the-world for every human individual, embracing both shared or outwardly real experiences and the hallucinatory experiences of psychotic patients.

Gestalt therapy, a further development, can be seen in one way as an attempt to combine the best of all these various approaches by at first comprehending and then as far as possible reconstructing the whole of the subject's total inner and environmental predicament.

Brief methods of interpretive (or insight) therapy. The short summary, given above, of the analytical techniques does not present all details of the psychodynamic theories underlying them. But the highly complicated nature of this kind of treatment should be clear. Thus, it is most misleading to apply the term psychoanalysis or even analysis to psychiatric interviews that may have as their goals nothing more profound than the clarification of some immediate personal problem or domestic situation. Indeed, the vast majority of psychiatric interviews are of this relatively limited nature, and treatment by psychoanalysis, Jnngian analysis, Adlerian analysis, or any of the other varieties is suitable for only a small proportion of patients who may require psychotherapy in some form or another. For the remaining bulk of such patients, however, the practical possibilities of brief methods of dynamic treatment are most encouraging and appropriate.

Elements of psycho-analysis

All brief methods of insight therapy depend for their brevity upon reduction of elements that normally comprise a considerable part of psychoanalytic procedure and absorb much of the time involved. These elements include the repetition involved in working through problems against the patient's resistance, as heavy reliance is placed upon the patient's free associations to bring these problems back into the field of exploration every time they are evaded or shelved. In addition, much analytic time and effort is consumed in dealing with comparatively irrelevant patient comments until he finally begins to make associations that seem unquestionably important but that were formerly too emotionally charged for him to handle.

Brief psychotherapy selects those aspects of the patient's life that are most relevant to the specific problems he faces and the symptoms he displays, and thereafter it centres the entire procedure upon dealing with them.

All such methods have in common the aim of paring down the time and effort of analytical procedures by dealing almost exclusively with immediate or feasibly alterable sources of patient complaint. The criticism is sometimes offered that such brief methods tend to patch rather than to re-create analytically the personality of the patient. One practical rebuttal is that the limited resources of medicine as a whole inexorably compel the practitioner to do just so much and no more for as many people as possible. Moreover, the bright promise implicit in full-scale orthodox analysis cannot claim support by observable results in any but a minute pioportion even of those few patients for whom it is deemed practicable.

In practice, a useful framework for brief psychotherapy can be constructed by planning eight to 12 interviews at weekiy intervals, each of 30 to 45 minutes' duration, for which are set the following targets:

1. Establishment of rapport (effective doctor–patient relationship of trust and confidence) and collection of an adequate patient history (first two interviews);
2. Selection of goals; formulation of overall plan of treatment; and exploration of goals (subsequent three or four interviews);
3. Interpretation of information developed (begun at appropriate stages of exploratory interviews but completed within context of overall treatment); integration of these interpretations with the patient's own concept of his life situation and its implications; recognition and acceptance by the patient; support and reassurance by the doctor (final three or four interviews).

The phases, methods, and special techniques involved are indicated in the Table.

Outline of Brief Insight Therapy

phase of treatment	methods		special techniques
	patient	doctor	
Ventilation	describes symptoms; discharges emotions	listens; accepts; encourages	abreactive
Exploration	recalls traumas; discovers connections	questions; interprets	analytic
Guidance	listens, comments	reassures; explains	counselling; suggestion; social aid

As a general rule, it is reasonable to devote about 70 percent of the time to ventilation, 20 percent to exploration. and 10 percent to guidance in the total course of treatment. The initial interviews should consist essentially in the acceptance by the doctor of the patient's need to communicate and to be understood. In the early interviews it is not what the doctor tells the patient but what the doctor permits the patient to tell him that is likely to be decisive in the success or failure of this kind of brief treatment.

Supportive and interpretive psychotherapy compared

Supportive psychotherapy. When patients are encountered for whom a more ambitious approach is judged impracticable or unproductive, supportive psychotherapy may be employed. Supportive psychotherapy differs from interpretive psychotherapy only in that its goals are usually more modest and less ambitious; often, however, it is more difficult in execution. Supportive psychotherapy plays a great part in the relatively informal management of nonhospitalized patients who might otherwise receive no psychiatric help at all from their doctor. It can include direct, simple, and sympathetic advice and sheer reassurance and encouragement. This kind of supportive treatment may be combined with practical intervention in the social circumstances of the patient. Emotional complications of his homelife or his work, for example, may be constructively modified by making personal contact with the family or employer, usually through a trained psychiatric social worker under the supervision of the psychiatrist concerned.

The foundation for supportive psychotherapy of this kind, which may be combined with appropriate medicinal symptomatic treatment, is a thoroughgoing history of the patient. After such a history has been gathered (as early as possible), the doctor should be able to gain an understanding of the patient in some ways more objective and comprehensive than that perhaps ever gained by any other single person, including the patient himself. At this early stage, a comprehensive picture of the patient and the general direction and significance of the tendencies revealed in his life should help the doctor form a sound idea of the genesis of the patient's symptoms and the ways in which the stresses to which he is subjected may be lightened or relieved. Thereafter, such advice or explanation as a doctor has to offer can be based not upon his own personal feelings but on the objective desirability of any particular solution as revealed by the history. His advice will depend still less upon a projection on his part of what he would do if he were in the patient's shoes. Thus, a carefully reconstructed case history is a safeguard against the shortcomings from which much well-intentioned lay advice so often suffers.

Psvchotherapy of this limited but invaluable supportive kind is within the capacity of every practicing psychiatrist and other trained physicians. The otherwise unavailable help provided by expenditure of a limited amount of time in this way is not only humane, but economical. By the skilled use of a few hours spread out over weeks or months, the trained physician may avert the chronic invalidism and demoralization of the neurotic patient. He may also spare himself the bitterness and frustration that assail a medical practitioner who is continually confronted with psychiatric aspects of human suffering but has never acquired the interest or understanding necessary to deal with it effectively.

Group therapy. This technique is based on the capacity of groups of individuals to recognize and then learn to understand patterns of feeling and behaviour in each other that either resemble similar feelings in themselves or evoke reactions for which they have not previously had insight. Membership in such a group can increase the individual's sense of support and his readiness to accept others and to be accepted by them, factors that form an important part of the process of treatment.

Groups of various sizes have been treated, but probably the best size is about eight to 12 people. Such people meet together with a doctor as a member but not as the leader of the group to talk about their feelings and their problems. As their confidence increases, they attempt to offer and to accept among themselves awareness, courage, and compassion and to contribute to this experience as well as to gain from it. The doctor's role in the group is largely that of observer and occasionally interpreter. His interpretations should be confined to the meaning of the emotional interaction that is taking place and to the ways in which everyone concerned can accept and learn from it. He neither seeks nor assumes formal leadership, because this would interfere with his capacity to reflect an awareness of the struggle for power within the group or the fear or anticipation of rejection by it—both among the powerful emotional responses that arise.

Psycho-drama

Other extensions of group dynamics include various specialized types of groups in which role playing or specific social support form the goals. So-called sensitivity groups have become popular in the United States, one object being to make an individual aware of differences between the image he has of himself and how he is perceived by others. Psychodrama is the name given to a type of group activity in which the group members act out roles relevant to the problems of each of them in turn. An example of specific supportive group therapy is provided by Alcoholics Anonymous (see ALCOHOL CONSUMPTION).

Behavioral therapy. The basic principle of the modern technique of behavioral therapy rests upon the assumption that many neurotic disorders (particularly states of phobia and anxiety) can be regarded as learned responses that have been built up into conditioned reflexes. The treatment is, therefore, one of retraining by deconditioning; in one variety, the conditioned response (*e.g.*, fear) is replaced by a learned pattern of inner calmness, confidence, control, and well-being. Such feelings, for example, may be induced by hypnosis or by methods of relaxation that the patient readily learns from the therapist. Thus, the sufferer from a phobia for spiders is trained to respond to them with pleasant feelings rather than with his earlier fright.

An alternative approach to behaviour modification is the deliberate conditioning of negative responses to established but unwelcome patterns of behaviour; for example, an alcoholic may be conditioned to experience nausea when he tastes whiskey. Or, the tendency of transvestites to don clothing of the opposite sex may be extinguished with mild electric shocks to the hand. This is generally termed negative conditioning or aversion therapy.

The role of hypnosis in deconditioning has been recognized to a growing degree. There are a number of techniques available for the production of profound muscular relaxation, which may lead to hypnosis of varying depth. These hypnotic techniques vary from one practitioner to another, but the essential preliminary phase is one of suggestion of relaxation, drowsiness, comfort, and well-being. This is followed by more specific suggestions of hypnotic trance phenomena. Sometimes tests of the depth of hypnosis obtained at various stages are introduced, partly to inform the hypnotist and partly to reinforce the hypnotic suggestion in the mind of the subject. Tests of this kind tend, however, to introduce a gratuitous challenge in the proceedings that may increase any conscious or unconscious apprehension on the part of the patient that hypnosis involves some kind of battle of wills between him and the hypnotist (for an evaluation of this common attitude, see HYPNOSIS).

Use of hypnosis

Experience with patients who have attempted behavioral therapy with specialists in medical hypnosis suggests that failures to pass tests can impair confidence in the hypnotist and his methods. Confidence can very often be restored, however, by an approach to relaxation during normal wakefulness in which hypnosis itself may not even be mentioned. The ultimate role of hypnosis should be as an aid rather than as a requirement for successful reconditioning in psychiatric practice.

Whenever any alterations in human relationships are brought about by communication, individually or through groups, psychodynamic or behavioral, evidence of unconscious motives and of transference can only be neglected at the peril of all concerned. No form of psychiatric treatment is free of hazard. As in all forms of medicine and, indeed, in all human transactions, the higher the level of professional competence, integrity, and compassion, the better is the outlook for individual and society alike.

BIBLIOGRAPHY. Key theoretical works concerned with concepts that underlie psychiatric treatment include D.O. HEBB, "On the Meaning of Objective Psychology," *Trans. R. Soc. Can.*, Series 3, 55:81–86 (1961); GILBERT RYLE, *The Concept of Mind* (1949); HENRI F. ELLENBERGER, *The Discovery of the Unconscious* (1970); C.G. JUNG, *Collected Papers on Analytical Psychology* (1916); ALFRED ADLER, *The Practice and Theory of Individual Psychology*, trans. by P. RADIN (1924); R.D. LAING, *The Divided Self* (1960); and D.H. MALAN, *A Study of Brief Psychotherapy* (1963). Works that deal with pharmacological or physical methods of treatment include THOMAS A. BAN, *Psychopharmacology* (1969); and WILLIAM SARGANT and ELIOT SLATER, *An Introduction to Physical Methods of Treatment in Psychiatry*, 4th ed. (1963). For discussions of the underlying psychodynamics of group interaction, see DAVID STAFFORD-CLARK, "Supportive Psychotherapy," in *Modern Trends in Psychological Medicine*, 2nd Series (1970); ERIC BERNE, *Games People Play* (1964); and G. SEABORN JONES, *Treatment or Torture: The Philosophy, Techniques and Future of Psychodynamics* (1968). Elaborations of the concept of psychiatry as a whole are found in DAVID STAFFORD-CLARK, *Psychiatry for Students*, 3rd ed. (1969); *Psychiatry Today*, 2nd ed. (1963); and *What Freud Really Said* (1965). See also JOSEPH WOLPE and A.A. LAZARUS, *Behavior Therapy Techniques* (1966).

Psychology

On the walls of the Temple of Delphi, built by Phoebus Apollo on the jagged cliffs of Mount Parnassus, was inscribed the most famous of all Greek precepts—"Know thyself!" Man has been preoccupied with such admonitions, and his partially successful response is reflected in the discipline of contemporary psychology.

In the process of knowing themselves, some Western men from the times of the ancient Greek philosophers have divided each person into elements of "mind" (or "soul") and "body." About 1594–96, Otho Casmannus formalized this doctrine by coining words from Greek roots: anthropoiogy (the study of man), psychology (the study of mind), and somatology (the study of body). Casmannus discussed psvchology in his work Psychologia anfhropologica, sive animae humanae doctrina . . . and somatology in his *Secunda* pars anthropologiae, *hoc* est, *Fabrica humani* corporis methodice descripta . . . . This distinction between mind and body, so apparently manifest to such writers, seems capricious and unnecessary to many modern scholars.

The term mind has been eliminated gradually from scientific scrutiny, most present-day psychologists using it only with intentional vagueness. In the 17th century, influential philosophers were emphasizing views that rejected concepts of souls exercising free will and that regarded organisms as automatic machines whose actions were fully determined by internal or external stimuli. Psychology has come to mean the study of those actions and their origins, generally defined as the science of behaviour in man and other animals.

SUBJECT MATTER OF MODERN PSYCHOLOGY

Several basic topics constitute the subject matter of modem psychology: sensation–perception, motivation, emotion, innate patterns, learning, thinking, intelligence, personality, group dynamics, and behaviour pathology.

Sensation–perception. Sensations may be understood as simple experienced correlates of physical stimulation of sensory receptors, with perceptions being defined as meaningful interpretations of sensations. Subtopics include vision (mediated by such structures as the eyes and occipital lobes of the brain), audition (involving the ears and temporal lobes of the brain), olfaction (smell) and gustation (taste), somesthesis and kinesthesis (*e.g.*, experiences of temperature, pressure, and position arising from the skin and muscles), and vestibular proprioception (sensations of position and movement arising from structures of the inner ear; see SENSORY RECEPTION, HUMAN; PERCEPTION).

Motivation. Older ideas, such as "striving faculties" (the "push" behind behaviour), yielded to the more contemporary language of motives. So-called primary motives (those necessary for the preservation of the individual) include hunger, thirst, need for sleep, and avoidance of pain. Other posited primary motives are seen to be necessary for continuing the species (*e.g.*, sex and maternal behaviour). All primary motives are defined as physiological and innate. Secondary personal or social motives (those held not to be necessary for individual or species survival) include acquisitiveness, gregariousness, aggressiveness, and achievement seeking. Many so-called motives substantially depend on social groups and concern social dominance, conformity to societal norms (fads, fashions, customs, and mores), and obedience to authority. Among human beings, secondary motives seem almost always to be acquired (usually by learning), but are believed to be usually innate among other animals. The same superficially identical secondary motive (*e.g.*, social dominance) often is held to be acquired by people but to be innate in such animals as baboons (see MOTIVATION).

Emotion. Affective or emotional processes are identified with exciting or inhibiting states generated by mechanisms within the organism and that coexist with other behaviours. Weak emotions, enduring over long time periods, have been called feelings. Emotions traditionally have been classified according to such subjective, hedonistic states as pleasant, neutral, and unpleasant. Their study includes experimental aesthetics (*e.g.*, the effects of music or odours on them), their facial and postural expression, and their physiological aspects. Emotions clearly may play a motivational role (see EMOTION).

Innate patterns. Behaviour deriving directly from biological heritage potentially is exhibited by all living beings. A relatively new term in behavioral science is ethology, a discipline (with strong roots in Europe) that emphasizes these inborn sequences.

Biological bases of behaviour

Innate patterns have been classified as a form of taxis, or a simple orientation movement such as upward righting of the body in reaction to gravity; as reflexes or brief responses of limited scope, such as pupillary change to light; and as instincts or complicated, enduring patterns—*e.g.*, nest building. Animals low on the evolutionary scale characteristically exhibit innate patterns, depend little on learning, and tend to make inflexible responses to their environments; animals high on the scale also show some innate patterns, but their greater ability to learn produces a much more flexible repertoire of responses to stimulation (see HUMAN BEHAVIOUR, INNATE FACTORS IN).

Learning. Behavioral changes wrought by prior experience are used to define learning (excluding temporary changes such as in fatigue and enduring alterations as those resulting from growth). Learning may be classified as conditioned or complex.

In classical conditioning, a reflex that normally is activated by one stimulus is paired with a nonactivating stimulus that ultimately comes to initiate the response. The salivary reflex of an inexperienced dog, for example, normally is elicited by food on the tongue but not by the sight of food. If sight-of-food precedes food-on-tongue several times, however, the visual stimulus by itself begins to elicit the salivary response. In operant conditioning, responses seem to be modified by reward or punishment. **A** response that is rewarded tends to be repeated; when followed by punishment, the response tends not to be repeated. A dog, for example, normally is not likely to press a lever or bar that he sees. When, however, he presses the bar by chance and receives a food reward, subsequent sight of the bar tends to evoke the act of pressing. Many parental efforts to manipulate the behaviour of their children rest on operant conditioning (*e.g.*, spanking or rewards of candy).

Complex learning is a process in which diverse responses are integrated into a relatively smooth sequence, as in maze learning by laboratory animals and in perceptual motor learning and verbal memorizing by human beings. The features of complex learning are not adequately explained in terms of chains or combinations of classical or operant conditioned responses (see LEARNING THEORIES).

Thinking. Beyond sensing and perceiving, cognitive processes include such ideational activities as concept formation, inductive and deductive logical thinking, productive thinking (judging, comparing, and problem solving), novel thinking (originality and creativity), and chimerical thinking (phantasy and dreams; see THOUGHT PROCESSES, TYPES OF).

Intelligence. The term intelligence is used in attempts to evaluate and measure actual or potential ability to perform selected tasks by complex learning and thinking. Intelligence is not defined easily; operationally it is considered to comprise the ability to perform whatever tasks are arbitrarily included in intelligence tests. Some abilities ordinarily are poorly represented in such tests (*e.g.*, mechanical, artistic, or social intelligence). Intelligence-test content tends to reflect the theoretical approach of the person who constructed the test. Some theorists conceive of intelligence as an amalgamated, conglomerate entity and speak of intelligence as a generalized cognitive function. Others factor intelligence into "independent" dimensions, holding for a separation of several fundamental components of intelligence (see INTELLIGENCE, THEORIES OF).

Psycho-analytic theory

Personality. The dynamics of personality refer to the processes of adjustment by which each individual copes with the exigencies of environment. Psychoanalytic theorists propose a model of subjective activity at three levels of awareness: conscious, preconscious, and unconscious.

Metaphoric character actors play their drama in this psychoanalytic version of personality: the tempest-tossed ego is depicted as seeking to reconcile the requirements of the carnal id (physiological motives) and the puritanical superego (social motives) with practical considerations of the empirical world. In this framework, the ego often is said to fail because of behavioral conflicts and frustrations and to experience the terrible emotion of anxiety. It is held that the ego dispels anxiety by many defense mechanisms; for example, dreams, parapraxia (Freudian slips), humour, regression, withdrawal, and rationalization (see PERSONALITY, THEORIES OF).

Personality assessment is concerned with traits and clusters of behavioral traits. Words such as abject, Machiavellian, and lesbian describe personality traits peculiar to the individual. Personality traits often are clustered; *e.g.*, introversion–extroversion, dominance-submission. These traits and clusters may be appraised with techniques that include paper-and-pencil self-description inventories and projective tests (*e.g.*, those in which the individual describes what ambiguous inkblots remind him of, or in which he creates stories about test pictures).

Personality also is assessed through judgmental ratings, by direct interview, and via study of life histories. Despite the extraordinary number of words used to describe personality traits, investigators using factor analysis (a statistical technique designed to disclose independent, basic variables) have suggested that there are about 16 fundamental dimensions of personality (see PERSONALITY, MEASUREMENT OF).

Other topics. The study of group dynamics is concerned with the behaviour of social groups and the interactions of individuals within them. Special topics of investigation include social movements, group attitudes, leadership, networks of communication, cooperative problem solving, propaganda, and rumour (see PSYCHOLOGY, SOCIAL).

Behaviour pathology refers to such deviations as abnormal personality and disorders of speech, of hearing, and of reading (*e.g.*, see PSYCHOSES; PSYCHONEUROSES).

Major specialties. The special fields of applied psychology selectively draw on all the basic subject matter or topics of modern psychology. Thus, child psychology considers the topics that apply to children, genetic psychology concentrates on those concerning origin and development, physiological psychology stresses the neurological and anatomical bases of behaviour, and comparative psychology deals with such behaviour as it differs from one species of animal to another.

Some specialties of psychology emphasize particular basic topics. Thus, social psychology concentrates on secondary motives and group dynamics, and differential psychology compares measures of intelligence and personality as they vary with such characteristics as age, sex, and socio-economic status.

Other specialties apply the results of basic research to practical needs. Thus, industrial psychology applies them to employee selection and other problems of business, school psychology to questions surrounding educational instruction, and military psychology to such efforts as psychological warfare. Military purposes also are served by engineering psychology in the design of man-machine systems (*e.g.*, aircraft controls). Clinical psychology is concerned with personal adjustment and embraces such fields as counselling and psychotherapy, including behaviour modification (*e.g.*, see PSYCHIATRIC TREATMENT, CONCEPTS OF).

METHODS OF PSYCHOLOGICAL RESEARCH

Psychological research, as in other sciences, is experimental or at least observational and can be conducted in the laboratory or in the field. All subdisciplines rely on experimental techniques for their progress.

Modern psychological laboratories stock a variety of hardware: one-way mirrors, tape recorders, motion-picture cameras, electric timers, tachistoscopes (visual short-exposure devices), spectroscopes and colorimeters, sound-wave generators and amplifiers, mazes, electroencephalographs, surgeries for brain extirpation, anechoic (soundproof) rooms, and high-speed computers. And these represent only a fraction of such equipment.

Laboratory work with human beings is highly limited since it must be done with substantial ethical and legal constraint. Experimentation with other animals is less restricted, often at the sacrifice of the lives of healthy subjects (*e.g.*, monkeys or cats). Considerable empirical work is done without laboratory restraints to ensure normal spontaneity. Typical observations of this sort include those of human behaviour at traffic lights and of the political activity of social groups. Habitat observations of animals reveal territorial behaviour and migratory habits.

Suitable only for human beings, an extensively used method employs questionnaires on such topics as food preferences, racial attitudes, childhood experiences, and political sympathies.

Statistical methods

Psychologists analyze their quantitative data by statistical techniques. Since most data of psychological inquiry reflect the contributions of many factors, the effects of any logically identifiable simple variable are not always apparent. For example, measured intelligence reflects both genetic and environmental variables. The independent contribution of each variable and the effects of its interaction with others may be estimated through such statistical methods as analysis of variance and by advanced correlation matrix strategies (*e.g.*, factor analysis).

Psychologists tend to be categorized according to their preferences in research methods or in clinical techniques. Extreme behaviorists, for example, argue that the sole subject matter of psychology is observable, operationally defined behaviour; all else, they insist, falls outside the domain of science. Others argue that introspective verbal reports of subjective experience are the legitimate subject of scientific psychology and that experimental data constitute the heart of the discipline. The cleavage is manifest in major differences among clinical practitioners. To those who practice so-called behaviour modification, a phobia is considered cured when the symptoms are extinguished through operant conditioning; *i.e.*, when such observable behaviour as a fearful response to heights has been modified by rewards and punishments. To other psychotherapists the phobia is considered cured when the sufferer has gained introspective insight into his unconscious conflicts.

ACADEMIC AND PROFESSIONAL ASPECTS OF PSYCHOLOGY

People who earn their livings as academic psychologists or as practitioners are to be found worldwide, many with close ties to psychiatric medicine and education. Exchange of worldwide information on psychology is effected by such organizations as the United Nations, the International Union of Psychological Sciences, and the International Association of Applied Psychology, as well as by publications (*e.g.*, International Journal of Psychology).

Professional organizations for psychologists are active in many countries, including Japan, Mexico, West Germany, Thailand, Romania, The Netherlands, Belgium, and Czechoslovakia. The growing number of journals includes Magyar *pszichológiai* szemle (Budapest, Hungary), *Nordisk psykologi* (Copenhagen, Denmark), *Przegląd* Psychologiczny (Wrocław, Poland), Psychologia *Africana* (Johannesburg, South Africa), Rivista di *psicologia* (Florence, Italy), and Indian Psychological Review (Varanasi, India). In France there are about nine major journals of psychology, almost all receiving government support. Cuba has developed a five-year university curriculum in psychology (general, developmental, clinical, social, and mathematical). In the Philippines psychologists are concentrating on descriptive studies, especially in social psychology. Meanwhile, psychology in the U.S. has become so influential internationally that some authorities describe it as approaching the status of a "colonial science."

Of approximately 35,000 psychologists in the U.S. (early 1970s) about 40% worked for colleges and universities; 20% worked for federal, state, or municipal governments (in such institutions as hospitals, military establishments, and prisons); about 20% in business and industry; 10% in public and private schools; about 10% were self-employed in private practice. Of all U.S. psychologists, about 37% were primarily interested in clinical psychology; 14% in educational and school psychology; 14% in experimental, physiological, and developmental psychology; 11% in industrial and personnel psychology; 11% in counselling psychology: 9% in social and personality psychology; and about 4% in general and engineering psychology. Their incomes averaged roughly $16,000 per year. Industrial psychologists earned the most (an average of $19,600 per year, with a range beyond $35,000) ; school psychologists were paid the least (averaging $13,000 per year and ranging to $19,000).

Psychologists were unevenly distributed in the U.S.: in numbers per 100,000 of population, there were about 99.5 in the District of Columbia (largely reflecting employment), 29.6 in New York State, 21.6 in Vermont, 17.2 in Michigan, 9.4 in North Carolina, and 5.4 in South Carolina; the average for the U.S. was 17.1.

The bulk of U.S. psychologists belong to the American Psychological Association (APA), with central offices in Washington, D.C. Members of the APA, are to be found in such countries as Egypt, Israel, Nigeria, Turkey, Venezuela, Canada, and Ethiopia. There are about 29 divisions of the APA, including: General Psychology, Teaching of Psychology, Experimental Psychology, Evaluation and Measurement, Physiological and Comparative Psychology, Developmental Psychology, Personality and Social Psychology, Society for the Psychological Study of Social Issues, Psychology and the Arts, Clinical Psychology, Consulting Psychology, Industrial Psychology, Educational Psychology, School Psychology, Counselling Psychology, Psychologists in Public Service, Military Psychology, Maturity and Old Age, Society of Engineering Psychologists, Psychological Aspects of Disability, Consumer Psychology, Philosophical Psychology, Experimental Analysis of Behaviour, History of Psychology, Community Psychology, Psychopharmacology, and Psychotherapy, Hypnosis, and State Affairs.

Ethical standards

The APA holds annual meetings for exchange of research information and fur solving professional problems. It published approximately 13 journals in 1970 including: ***American Psychologist*** (stressing broad professional aspects), ***Contemporary Psychology*** (containing critical reviews of books and films), ***Psychological Abstracts*** (nonevaluative condensations of the world's literature of interest to psychologists), and the ***Psychological Bulletin*** (offering reviews of research literature). The APA maintains liaison with many state and regional societies and with foreign organizations. It demands a strict professional code of behaviour of its members; under its ***Ethical Standards of Psychologists,*** members are expected to maintain high standards of competence, to show sensible regard for moral expectations of the community, to use modesty and caution in public statements, and to withold information obtained in confidence.

The competence of professional psychologists is self-regulated by the APA in cooperation with local associations and through certification and licensing by many states. One of its agencies, the American Board of Examiners in Professional Psychology, administers examinations in clinical, counselling, and industrial psychology; it awards diplomas to those who exhibit outstanding competence. Such diplomas (owned by about 7 percent of all U.S. psychologists) are particularly esteemed by private practitioners. Psychologists in private practice also have to meet statutory certification or licensing requirements in approximately 30 states and in four Canadian provinces. Such certification requires written and oral examination, evidence of moral character, and satisfactory education at accredited institutions.

Almost all professional psychologists in the U.S. held advanced degrees in the 1970s: 65% had doctorates; 33%, the master's; and 2% held only bachelor's degrees. Approximately 210 universities in the U.S. and Canada offer courses leading to advanced degrees in psychology. Advanced training includes concentrations in psychology, clinical, general-experimental, physiological, personality-social, industrial, and counselling. The APA provides teams of experts for evaluating doctoral programs, approximately 70 institutions having been approved for clinical training.

While the Ph.D. is the usual doctoral degree in psychology in the U.S., a new degree, the Psy.D. (doctor of psychology), is being granted by the University of Illinois and was under active consideration by several other institutions. The Psy.D. requires an internship, but no research dissertation; it was designed for practicing psychologists working in clinical settings.

Most academic instruction in psychology is conducted in colleges and universities, but some courses are taught in U.S. high schools. The general course in psychology has the largest enrollment (exclusive of freshman English) of any single course—about 500,000 students each year. Specialized courses include history of psychology, medical psychology, legal psychology, design of experiments, hypnosis, psychology of race, and psychology of religion. Almost all U.S. colleges and universities grant bachelor's degrees with a major or minor in psychology.

The teaching and practice of psychology in the United Kingdom, France, West Germany, New Zealand, and Australia shows virtually the same pattern as the U.S. and Canada. In the Soviet Union psychologists are much less concerned with psychometric investigations of individual differences, giving little attention to intelligence tests and personality inventories. Psychological research in the U.S.S.R. is under the direction of the Central Institute of Psychology, with departments of General Psychology, Child Psychology, and Pedagogical Psychology. The various laboratories of the institute consider psychophysiological problems, the behaviour of laboratory animals, industrial work, and educational problems. Soviet care of psychiatric patients has been impressive to Canadian, British, and U.S. observers.

BIBLIOGRAPHY. A. ANASTASI, ***Fields of Applied Psychology*** (1964), a detailed discussion of the numerous applications of psychology; BEHAVIORAL AND SOCIAL SCIENCES SURVEY COMMITTEE, ***The Behavioral and Social Sciences: Outlook and Needs*** (1969), a survey of the relation of psychology to other disciplines; J. COHEN, "Eyewitness Series in Psychology" (1969–71), a collection of 20 paperback separates, historically oriented and richly illustrated, covering important areas of psychology; N. FRIEDMAN, ***The Social Nature of Psychological Research*** (1967), descriptions of psychological experiments that are unique to behavioral science; B. LUBIN and E.E. LEVITT, (eds.), ***The Clinical Psychologist: Background, Roles and Functions*** (1967), an analysis of the clinical psychologist in modern society; W.~SAHAKIAN (ed.), ***History of Psychology*** (1968), carefully selected excerpts from the literature upon which contemporary psychology is based; J.B. SIDOWSKI (ed.), ***Experimental Methods and Instrumentation in Psychology*** (1966), descriptions of laboratory techniques used by psychologists; E.B. WEBB (ed.), ***The Profession of Psychology*** (1962), discussion of the antecedents of contemporary psychology, its role as an academic and applied discipline, and its relations with other professions and the public.

(J.C.)

Psychology, History of

From its beginnings in supernatural beliefs, magic, and taboo, psychology has matured to a science of such broad proportions that professional psychologists today must specialize on narrow fragments of the broader discipline. Specialties are identified by such adjectival terms as physiological, comparative, developmental, personality, social, clinical, consulting, industrial, educational, counselling, military, engineering or human factors, consumer, philosophical, experimental, psychotherapy, psychopathology, and psychopharmacology. Hundreds of professional journals are devoted to psychology, and their numbers are augmented by more than a thousand journals for such allied fields as psychiatry. The world's first psychological laboratory appears to have been established by Wilhelm Wundt in 1879 at Leipzig University, Germany, marking what has been called the birth of psychology as a science. Two years later Wundt founded the first journal of experimental psychology. G. Stanley Hall (1844–1924) is thought to have founded the first laboratory of psychology in North America (1883); the first journal in English, still being published, the ***American Journal of Psychology***

First psychology laboratory

(1887); and (with other psychologists meeting at Clark University in Worcester, Massachusetts, on July 8, 1892), the American Psychological Association, Hall serving as first president. The first International Congress of Psychology met in Paris, France, in 1889 with psychiatrist Jean-Martin Charcot (1825–93) presiding over an attendance of 203. In the 1970s the American Psychological Association alone comprised 30,592 members; according to the International Directory of Psychologisfs (1966), of 20,000 questionnaires sent to psychologists outside the U.S., only 8,000 responded (the People's Republic of China declining; see also PSYCHOLOGY).

Contemporary psychology developed from a confluence of diverse streams: these include religions of the Orient and the classical Greek and Roman philosophies; Jewish, Christian, and Islāmic medieval thinking; philosophical psychologies of the Renaissance and modern periods; psychiatric and biological influences of every age; British physicists of the 17th to 19th centuries; 19th-century German and Russian physiologists, British-American evolutionists and statisticians; continental European psychiatry of the first half of the 20th century; German and North American experimentalists and theorists of the last and present centuries.

Philosophical-religious roots

NON-WESTERN INFLUENCES

Psychology had inchoate beginnings in animism, the view that objects such as trees have an indwelling vital principle, or "soul," and in hylozoism (or hylopsychism), the belief that matter has life or sensation. An epic poem of ancient India, the Mahdbhdrata, disclosed five senses, and an intermediary faculty (*manas*) for receiving sense impressions that were transmitted to *buddhi* (intuitive discernment, intellect) before reaching "soul" or self (*ātman*). A group of Theravada Buddhist realists (Vaibhāṣikas) held that "mind observes, manas deliberates, and consciousness (*vijñāna*) discriminates. In China, Buddhist philosophers of the school known as Ch'an (Zen in Japan) emphasized meditation as a way to enlightenment. Morita therapy, a form of Japanese psychotherapy drawing upon Zen, developed (1930s) by Shoma Morita, rests on efforts to diminish excessive self-consciousness. The Chinese humanism of the philosopher Confucius (551–479 BC) held for the perfectibility of man, emphasizing moderation, balance, and harmony. A Chinese philosopher, Mencius (371–289? BC), espoused a form of Confucianism that assumed original goodness in human nature. According to the ancient Chinese book Lao-tzu and its doctrine of Taoism, a desirable life was one of tranquility, spontaneity, and humility or weakness.

Morita therapy

By 525 BC, when the Egyptian physician Imhotep (c. 2850 BC) was pronounced god of medicine, sleep was employed in psychotherapy, as were dancing, drawing, music, and similar occupational measures. Later, the cult of Asclepius, Greek god of medicine, used sleep, dreams, and suggestion in treatment (see DREAMS). Ancient Mesopotamians seemed aware of psychosomatic medicine, relying on the suggestive power of incantations by priests. Babylonians, and Israelites and Christians at the time of Jesus, invoked demons as the cause of psychiatric disorder, holding that they could be driven from the sufferer in a ritual called exorcism.

THE CLASSICAL WORLD

Among the ancients, Greek philosophers, led by Aristotle (384–322 BC), were pre-eminent in advancing psychology. Heracleitus of Ephesus (c. 540–c. 480 BC) reasoned that "soul" in man was fire and that inner serenity was attained through reason. Anaxagoras of Clazomenae invested all of the functions of fire in nous ("mind"). A precursor of modern behaviorists, Empedocles of Agrigentum (c. 490-430 BC), identified thinking with perceiving and believed that it is dependent on bodily change. He offered what amounted to the modern doctrine that no matter how it is stimulated each sense organ responds specifically; for example, one has visual experiences whether his eyes are stimulated by light or by pressure on the closed lids. Refining Empedocles' theory of specific energy of sense organs, Democritus of Abdera (460?–357 BC) explained sensory experiences by asserting that atoms are emitted from objects and transported through air to produce images by stimulating sense organs; this early variation of physiological psychology reduced psychological activity to the motion of fire atoms.

During what is called the period of the Greek Enlightenment, the Sophist philosopher Protagoras of Abdera (c. 481–411 BC) enunciated a doctrine of sensationalism that attributed all psychological activity to sensory function alone. Sensationalism later was adopted by French philosopher Etienne Bonnot de Condillac (1715–80), who tried to imagine what human personality would be like if limited to the sense of smell.

The first Western thinker to suggest the existence of unconscious mental activities seems to have been Socrates (469–399 BC), who, in anticipation of modern psychoanalysis, called for self-analysis. Holding that knowledge can remain dormant in the "soul," he employed a so-called maieutic technique that (like contemporary psychoanalysis) was supposed to bring to consciousness that which had been forgotten. Taking the lead from Socrates, Plato (428–348/347 BC) discussed interpretation of dreams and unconscious motivation, as well as association of "ideas." Plato's was a biological psychology that localized "mind" in the brain, "will" in the heart, and appetites and desires in the liver or stomach. His pupil Aristotle (384–322 BC) has been called the founder of functional psychology and apparently originated the concept of emotional catharsis, a kind of "purging" of pent-up emotion through such acts as weeping. Attributing a double aspect to human "soul," Aristotle cited the first as passive "mind," analogous to a blank writing tablet (tabula rasa) on which sensory experience was imposed; the second he held to be actively rational and motivational. Aristotle elaborated on the traditional five senses, also considering memory, dreams, and sensory afterimages (*e.g.*, the effect of staring at a bright light). He claimed that there also is a "common sense" for unifying sensory experience and serving as a basis for memory.

Unconscious activities

The so-called Stoic philosophers held to a dualistic notion that flesh and "soul" are in opposition. Seneca (c. 4 BC–AD 65) propounded this doctrine, and Marcus Aurelius Antoninus (121–180) sharpened the distinction. The Stoic theory of perception compared sensations to impressions on wax (Cleanthes, 331/330–232/231 BC) and viewed the "soul" as originally devoid of impression (again, tabula rasa). In addition, "soul" was said to embrace five senses and numerous other faculties. Stoic psychology, practically applied by Epictetus (c. 55–c. 135), emphasized the role of "the will," one's attitude, indifference to pain, calling tranquillity the ideal of psychological adjustment and passion a disease. Lucretius (c. 95–55 BC) reduced "mind" or "spirit" to physical terms, explaining sensation as did his materialistic predecessor, Democritus (460?–357 BC), to hold emotion to emanate from animus, or physical "mind." Lucretius followed the lead of Epicurus (341–279 BC), according to whose atomic theory life, consciousness, and experience were equally as real as the atomic movements from which they sprang.

EARLY CHRISTIAN–MEDIEVAL PERIOD

The Hebrew term for "soul" (nefesh, that which breathes) was used by Moses (*c.* 13th century BC), signifying an "animated being" and applicable equally to nonhuman beings. The Hebrews used the term to apply to the entire personality but reserved the concept *ruaḥ* ("spirit") to denote a principle of life, "mind," and occasionally "heart." Nefesh was often used as if it were the seat of appetite, emotion, and passion and, conjoined with "heart," was held to encompass intellect, will, and feeling. New Testament usage of *psychē* ("soul") was comparable to nefesh. Jesus' complete dualistic demarcation between flesh and "spirit" was quite evident, and St. Paul (died AD 64) exceeded the dualism of Jesus to invent a triune man, regarding "spirit" (pneuma) as a divinely inspired life principle, "soul" (psychd) as man's life in which "spirit" manifests itself, and body (*sōma*) as the physical mechanism animated by "soul." In New Testament usage, man variously was regarded as having "free" will (*thelēsis*); as a rational being with faculties and "mind" (*nous*); as a contemplating, understanding, intelligent being with "mind"(*phronēma*); as a sublime being or "spirit" (*pneuma*); and as a being with predispositions and attitudes, or "heart" (*kardia*).

Plotinus and the "higher soul"

The duality of man as "soul" (defined as a vital force of the physical body), and man as a higher "spiritual" self (pneuma) was enunciated by Philo of Alexandria (c. 30/*c.* 20 BC–after AD 40). Plutarch (c. AD 48–c. 119) also distinguished rational "spirit" (*nous*) from psych.? ("soul"), conceived as the seat of man's emotional, sensuous, and animate nature. St. Irenaeus (c. 120/140–200/203) likewise separated a "psychic" breath of life (a perishable characteristic of man tied to body) from a kind of eternal, animating "spirit." Stressing "will" or "freedom" of choice, Origen (*c.* 185–254) differentiated between so-called rational and animal souls. Credited as founder of Neoplatonism, Plotinus (205–270) seems first to have developed an empirical (objective) psychology, though it was introspectively (subjectively) oriented. He held that conscious activity (cognition) by "higher soul" depended on data from the senses. Physical sensations, passions, and feelings were seen as passive states of "lower soul" and conscions perception or reflection as functions of "higher soul," and Plotinus was led to the experience of self-consciousness. The culmination of Patristic (by the Fathers of the Christian Church) and of Neoplatonic psychology was found in the psychology of St. Augusine (354–430), who constructed his system on Origen's hypothesis of will and Plotinus' theory of self-consciousness. Augustine saw the fundamental aspects of psychological experience as being memory, understanding, and will. His belief that experience represents external physical (phenomenological) truth was an early basis for a branch of philosophy now called phenomenology.

Seizing on Aristotle's threefold concept of "soul" (vegetative, sensitive, intellective), the Arabic philosopher Avicenna (980–1037) constructed a psychology entailing external and internal senses, the former utilized to perceive external objects. He traced psychiatric disorder to disorders of the brain. Another Aristotelian Muslim, Averroës (1126–98), postulated "soul" as a corporeal form connected with body, its supreme powers said to consist of "passive intellect" or imagination. The Jewish philosopher Maimonides (1135–1204) followed the same line, especially in regarding "agent intellect" (invented by Aristotle) as the source of intellectual knowledge; and a Christian philosopher, St. Thomas Aquinas (1225–74), in following the Aristotelian tradition, accepted a threefold division of "soul" and a belief in human freedom, while emphasizing instinctual aspects of psychological function. Whereas Aquinas placed intellect above will, John Duns Scotus (c. 1265–1308) was more voluntarist than intellectualist, assigning priority to will. Splitting conscious "soul" into the intellective and the sensitive, English schoolman William of Ockham (*c.* 1285–1349) ascribed numerous individual faculties or powers to "soul." Another British Scholastic (in the Aristotelian tradition), Roger Bacon (*c.* 1220–c. 1292), distinguished between external and internal experience, the former said to be related to sense experience, the latter to internal activities.

RENAISSANCE TO THE MODERN PERIOD

A Spanish humanist and precursor of modern psychology, Juan Luis Vives (1492–1540) inclined toward an empirical approach to psychology and invoked direct experience as a basis for knowing "things themselves," as is done by contemporary phenomenologists. The French skeptic Michel de Montaigne (1533–92) shared Vive's views of an empirical psychology. During this period the term psychology already was being used by the German theologian Philipp Melanchthon (1497–1560), and Niccolò Machiavelli (1469–1527) was declaring the domination of man by his passions.

On the continent of Europe, so-called rationalists sought to resolve what they called the "mind-body problem," which originated as a strict dualism in the system of French philosopher René Descartes (1596–1650), who wrote that the interaction of mind and body occurred in the brain's pineal gland. This view terminated in a psychophysical parallelism (the notion that mind and body do not interact but exist "side by side") in treatments by Dutch philosopher Benedict de Spinoza (1632–77) and German philosopher Gottfried Wilhelm Leibniz (1646–1716). Some give Descartes the distinction of founding physiological psychology, for it was he who explained the behaviour of nonhuman animals entirely on the basis of mechanistic functions in the nervous system, denying "souls" to such creatures. He also advanced a theory that accounted for visual perception of distance, shape, and size in terms of secondary sensory cues. A French materialist, Julien Offrey de La Mettrie (1709–51), taking his lead from Descartes, purported to explain the psychology of man in terms of the functions of a machine. Spinoza, asserting that the "order and connection of ideas is the same as the order and connection of things," laid the foundation of modern holistic psychologies; *i.e.*, those that consider man as a unified whole rather than as an arrangement of separate physical parts. Also attributable to him was the view that a rational cause accounts for every human action, a view that Sigmund Freud later also offered. Leibniz resolved the "mind-body problem" by asserting both to be in pre-established harmony and was credited with the notion of "petites perceptions" (unconscious representations), a theory of unconscious function.

Man as a machine

While rationalists on the continent occupied themselves with the "mind-body" dispute and concluded that "ideas" are inborn, British empiricist philosophers, prompted by John Locke (1632–1704), postulated "mind" as a "white paper" (again tabula rasa) on which all sensations were imprinted. Locke agreed with Aristotle that there was nothing in "mind" that was not first in the senses. Leibniz appended to this assertion "except the mind itself," a concept that Immanuel Kant later used to construct his a priori theory of time and space as pure forms of sensibility. According to Locke, man's knowledge and the development of his personality were accounted for by "ideas" experienced together with their associations. He held that "ideas" sprang from two sources, sensation and reflection, the latter being an inner sense. Although Locke coined the phrase association of ideas, British association psychology really dates back to Locke's compatriot, Thomas Hobbes (1588–1679), who claimed that sense impressions supplied consciousness with its content and that by their associations "thought" was produced and memory or forgetfulness was explained in their gradual decay. The wide use of the term association and the founding of associationism has been imputed to David Hartley (1705–57), though it seems to have stemmed from Aristotle. In preference to association, Thomas Brown (1778–1820) used the term suggestion and developed a neurological theory of memory, association, and learning. An Irish empiricist in the British tradition, George Berkeley (1685–1753), constructed a theory of visual perception of distance in which cues came from the surroundings (context) in which objects are seen. Berkeley's idealism as reflected in the assertion "to be is to be perceived," terminated in psychologism, a view that equated "reality" with experience. A Scot, David Hume (1711–76). carried the concept of association into a denial of the principle of causality, theorizing that so-called cause-and-effect relations represent mere sequence rather than necessarily consequential relationships. Hume also reduced human "soul" to "a bundle of perceptions." Taking his cue from Hume, James Mill (1773–1836) constructed a psychology of association based solely on sensory proximity in time and space, allowing no creative function to "mind." In an effort to correct what he considered his father's deficiencies, John Stuart Mill (1806–73) ascribed an active role to "mind" and accorded new qualities to complex "ideas" instead of regarding them as merely a summation of simple "ideas." While the father represenled the simple "mental compounding of ideas," the son held that "ideas" actually could be changed through "mental chemistry."

Mental chemistry

Contributions of the German idealists to psychology during the 18th and 19th centuries were essentially philosophical. Christian Wolff (1679–1754) distinguished between empirical and rational psychology as early as 1732. Immanuel Kant (1724–1804) contributed the notion of an a priori intuition of time and space, and Johann Gottlieb Fichte (1762–1814) agreed, while Johann Friedrich Herbart (1776–1841), credited by some with being author of the first textbook of psychology, opened the way to mathematical approaches to psychology. Rudolf Hermann Lotze (1817–81) endorsed the inborn-intuition-of-space hypothesis and advanced a theory of local signs (or local sensory cues to space). Arthur Schopenhauer's (1788–1860) "psychology of will" anticipated Freudian instinct theory, plus later movements in psychology th [illegible] rratic ism and pessimism; but Friedrich Ni [illegible] (1844–1900) optimistically turned his attention to a psychology of power, the base on which the psychology of Alfred Adler (1870–1937) later was founded. Nietzsche's pronouncements on repression, conscience, and defense mechanisms found their way into Freudian theory. German philosophical psychologists of the 20th century, though influenced by these idealistic philosophers, moved into what are now called phenomenology and existential psychology. The act psychology of Franz Brentano (1838–1917) set the stage for phenomenological psychology; he sought to ascertain the precise contents of consciousness about a given object by an analysis of specific human acts; *i.e.*, what people said about their immediate conscious experience. His student Edmund Husserl (1859–1938) virtually defined phenomenology as this kind of descriptive analysis of subjective processes or acts. Max Scheler's (1874–1928) application of phenomenology to values, especially to moral and religious experience, was to become the foundation of Viktor E. Frankl's (1905–) logotherapy, a form of psychotherapy based on meaning. Scheler conceived of phenomenology as the a priori knowledge of untutored experience. Within this phenomenological movement, Martin Heidegger (1889–) set the stage for existential psychiatry by his notion of dasein (man as a human being, operating within this world; *i.e.*, being-in-the-world). The existential psychology of the French philosopher Jean-Paul Sartre (1905–) is in the phenomenological tradition, but like Heidegger's thinking, it was heavily influenced by Søren Kierkegaard (1813–55), a Dane who sired such existential concepts as the phenomenology of anxiety and an emphasis on choice. While phenomenology was effectively applied to psychiatry by Frankl's logotherapy (or will to meaning) and by the U.S. psychologist Carl R. Rogers (1902–) to personality theory and psychotherapy, it was the Swiss thinkers Ludwig Binswanger (1881–1966) and Medard Boss (1903–) who were most successful in the application of existentialism to psychiatry. German existentialist Karl Jaspers (1883–1969), author of General Psychopathology (1913), was more active in applying existentialism to philosophy.

Origins in biology and psychiatry

ADVANCES IN BIOLOGY AND PHYSIOLOGY

The Pythagorean physician Alcmaeon of Croton (flourished 6th century BC) had identified thinking or consciousness as the distinguishing feature of man and localized these functions in the brain; he traced perceiving to specific sense organs and emotions to the heart. Britain saw Thomas Young's (1773–1829) publication of a three-component theory of colour and an undulatory (wave) theory of light. The former theory, verified by Hermann von Helmholtz (1821–94), came to be known as the Young-Helmholtz three-colour theory of vision. In 1811 Sir Charles Bell (1774–1842) noted distinct functions of sensory and motor nerves, independently suggested by the Frenchman François Magendie (1783–1855) a decade later; it is currently called the Bell-Magendie law of spinal nerve roots and forecasts the doctrine of specific nerve energy. Bell is also credited with discovery of a sixth sense, muscular sensation, although Aristotle seems to have been aware of the same function, having called it kinesthetic. Another Frenchman, Edme Mariotte (1620–84), earlier (1668) discovered the blind spot in the retina of the eye. Sir Isaac Newton (1642–1727) demonstrated that the experience of white is the composite awareness of all colours in light. In 1838 another Britisher, Sir Charles Wheatstone (1802–75), contributed the concept that the perception of depth depends on disparate images in each eye. In 1861 in France, Paul Broca (1824–80) identified the physical basis of articulate speech in a localized portion of human brain tissue, said to be the first direct evidence that "mind does not function as a single, unitary, homogeneous thing. By 1870 the Germans Gustav Fritsch (1838–1927) and Eduard Hitzig (1838–1907), by electrical stimulation of laboratory animals, had localized centres for voluntary movement in the brain. In 1889 a Spaniard, Santiago Ramón y Cajal (1852–1934), identified neurons as the functional cells of the brain. A British physiologist, Sir Charles Sherrington (1857–1952), coined the term synapse to describe the gaps between neurons and is known for his dictum that "behaviour is rooted in integration" of the nervous system. Others contributing to neurophysiology were Britain's John Hughlings Jackson (1835–1911), distinguished for work relating epilepsy and the brain, and John Langley (1852–1925), who studied the role of the autonomic nervous system in automatically regulating such functions as breathing and emotional expression.

Specific energy of nerves

The British also were stimulated by Charles Darwin (1809–82) and his theory of the evolutionary origin of species and his doctrine of the survival of the fittest. Darwin held that emotions in man were inherited in an evolutionary sense, reflecting emotional behaviour that served the survival of lower animal species. Darwin's friend George Romanes (1848–94) ushered in and coined the term comparative psychology with his book Animal Intelligence (1882). In this evolutionary tradition C. Lloyd Morgan (1852–1936) offered a psychological version of the law of parsimony in 1894, known as Morgan's cannon, by which he urged explanations of behaviour in the simplest, most parsimonious terms feasible. During the same year the evolutionist Herbert Spencer (1820–1903) defined life as a "continuous adjustment of internal relations to external relations." By 1908 William McDougall (1871–1938) had explored social psychology from the standpoint of evolution and of comparative psychology. He and Edward A. Ross (1866–1951) seem to have been the first to publish books with "Social Psychology" in their titles. An American, Christine Ladd-Franklin (1847–1930), offered an evolutionary account of the development of human colour vision.

Evolution

The founding of experimental psychology and experimental aesthetics is associated with Gustav Theodor Fechner (1801–87), a German who wrote *Elemente* der Psychophysik (Elements of Psychophysics) in 1860. The book marked the founding of psychophysics, experimental psychology, and the formulation of Fechner's law or the Weber-Fechner law: "The magnitude of the sensation . . . is proportional to the logarithm of the fundamental stimulus value." According to Ernst Heinrich Weber (1795–1878), "equal relative increments of stimuli are proportional to equal increments of sensation." Major accomplishments by Fechner include what are called psychophysical methods, techniques for measuring the intensity of subjective experience~.

The doctrine of the specific energy of nerves was enunciated in detail in 1838 by Johannes Müller (1801–58), a German who maintained that awareness is of one's nerves rather than of external objects and that "the same internal cause excites in the different senses different sensations; —in each sense the sensations peculiar to it. . . . External agencies can give rise to no kind of sensation which cannot also be produced by internal causes."

Hermann von Helmholtz (1821–94), a German, accelerated progress in experimental psychology with major advances in sense physiology, including an influential theory of hearing, the Young-Helmholtz three-colour theory of vision, an empirical theory of perception, a theory of unconscious inference, and the application of the theory of specific energies to experiences of the distinctive qualities of sense (*e.g.*, colour, loudness). In opposition to Helmholtz, Ewald Hering (1834–1918) espoused a theory that the power of visual space perception is inborn and offered a six-colour theory of vision. In 1904 Max von Frey (1852–1932) offered a theory of four skin senses: warmth, cold, pressure, and pain, challenging the traditional notion of a single sense of touch. A German, Adolph Jost, is known for Jost's law (1897); *i.e.*, for two associations learned equally well, the older one will be better retained.

DEVELOPMENT OF PSYCHIATRY

The beginnings of psychiatry may be traced to the Code of Hammurabi (c. 1950 BC), which recommended opium and olive oil be used as cures for psychiatric disorders held to be produced by demonic possession. The Greek physician and "father of medicine," Hippocrates (flourished c. 400 BC), developed a theory of personality based on bodily fluids (humours), reasoning that psychiatric disorder was attributable to natural causes rather than to demons. During the period 25 BC to AD 50, Aulus Cornelius Celsus published De rnedicina, a work in which the term insanity seems first to have appeared. During the 2nd century AD the Greek physician Galen of Pergamon (c. AD 130–c. 200) developed a humoral theory of psychopathology. The Arabian physician Avicenna later traced psychopathology to disorders of the brain. In the 12th century, an Italian, Roger Frugardi, recommended a form of brain surgery (trephining) in dealing with psychiatric problems, a practice that can be traced at least to ancient Greece and Rome, perhaps even to prehistoric men, By 1891 the Swiss psychiatrist Gottlieb Burckhardt performed a related kind of psychosurgery, removing a portion of the b: ain surface to make patients docile. A Portuguese psychiatrist, António Egas Moniz (1874–1955), helped develop the operation, and in the U.S. Walter Freeman (1895–   ) with his associate James W. Watts (1904–   ) performed psychosurgery by entering the skull through the eye sockets. Other techniques of neuropsychiatric treatment included giving sufferers of brain syphilis cases of malaria (1917); the use of insulin to induce shock in treating schizophrenia, electroshock therapy (used particularly in depression), and the use of chemical (metrazol) shock therapy.

Demonic possession

The 15th century saw the establishment of the first psychiatric asylum in Valencia, Spain, in 1410. A book called Malleus *maleficarum (The* Witches' Hammer), written in that century by two German Dominicans, Johann Sprenger and Heinrich Kraemer, treated witchcraft, psychopathology, and sexuality. The following century saw the Belgian physician Johann Weyer (1515–88), the "father of modern psychiatry," become one of the first to condemn belief in witchcraft as superstition; it also saw the establishment of Bethlehem Royal Hospital (nicknamed Bedlam) in London for disturbed people. The beginnings of electrotherapy were made by an English physician, William Gilbert (1540–1603), and of "animal magnetism" (mesmerism or hypnosis) by William Maxwell (1581–1641) a century before the Viennese physician Franz Mesmer (1734–1815). Autosuggestion ("I am becoming better and better") was developed by Émile Coué (1857–1926) about 1910.

The birth of modern psychiatry may be traced to the appointment in 1792 at Paris of Phillippe Pinel (1745–1826) as physician in chief of Bicêtre Hospital for the Insane, where he proceeded to remove chains from the inmates. An emotional basis for psychiatric disturbance was endorsed by Pinel's student Jean Esquirol (1772–1840), the reputed founder of French psychiatry. Several years later the first U.S. textbook of psychiatry was authored by a professor of chemistry, Benjamin Rush (1745–1813). What is now called schizophrenia, Bénédict-Augusten Morel (1809–73) labelled (1860) *démence précoce* (dementia praecox). He believed it to be a premature form of dementia. Ewald Hecker (1843–1909) identified a form of the disturbance as "hebephrenia," and Karl Kahlbaum (1828–99) called another "catatonia." They opened the way for Emil Kraepelin (1856–1926) to formulate an elaborate system of psychiatric classification that still is in use. The term schizophrenia itself was introduced by a Swiss psychiatrist, Eugen Bleuler (1857–1939).

During the 19th century, psychiatrists (especially Pinel and Kraepelin) tended to view all psychiatric disturbances as being related to physical disease, but a shift to psychological (functional) explanations was precipitated when hypnosis gained recognition. The term hypnosis, introduced in Britain by James Braid (1795–1860), was a topic of controversy in psychiatric circles, gaining reception only gradually and with difficulty. Othei Britishers who employed hypnotism with remarkable therapeutic success were John Elliotson (1791–1868), who used it to diminish pain during surgery, and James Esdaile (1808–59), who performed more than 250 painless operations on hypnotized people. In the U.S. Phineas Parkhurst Quimby (1802–66) used hypnosis to cure the founder of Christian Science, Mary Baker Eddy (1821–1910), of hysterical paralysis in 1862. Hypnotism was vigorously debated in France where it was employed in psychiatric treatment. Jean-Martin Charcot (1825–93) at the University of Paris and Ambroise-Auguste Liébeault (1823–1903) and Hippolyte Bernheim (1840–1919) argued about whether hypnosis was a normal state characterized by suggestion or a pathological symptom exhibited only by hysterics. The Nancy school subscribed to the former position, and at Paris the latter was endorsed. Supporting Charcot, Pierre Janet (1859–1947) theorized that the hysteric individual suffers from psychological weakness (what he called "psychasthenia").

It may be said that psychoanalysis was born when Sigmund Freud (1856–1939) learned about posthypnotic suggestion from Charcot and about the "talking cure" (free association), transference, and catharsis from Joseph Breuer (1842–1925). The birth was marked by Freud's publication of Studies in Hysteria in 1895. With Freudian psychoanalysis the transition from pkysiological to psychogenic (functional) explanations was enhanced. Although evidence for unconscious activities extended from the writings of Plato to those of Leibniz, Schopenhauer, and Karl von Hartmann (1842–1906), Freud made special contributions, resulting in what has been called depth psychology.

Depth psychology

De-emphasizing Freud's stress on sexual motivation, Carl Jung (1875–1961), a Swiss, founded a school of "analytical psychology," highlighting what he called "the will to live" (rather than sex), yet with a more-than-Freudian stress on unconscious function, dividing "mind" into what he called the "personal" and "collective" unconscious. He also coined and developed a technique (the word-association test) for uncovering "complexes"—related words that evoked signs of disturbance. Jung was also the inventor of the terms introvert and extrovert. Freud's Viennese associate, Alfred Adler (1870–1937), founder of the school of "individual psychologv," emphasized a "drive for superiority" or a reaction to the inferiority "complex," rather than sex. German-born Erich Fromm (1900–   ) shifted the attention of psychoanalysts from Darwinian notions of man as one of many animals to man as a unique creature. The cultural school of psychoanalysis drew influence with the development in the U.S. of Harry Stack Sullivan's (1892–1949) "interpersonal theory of psychiatry."

Development of psychology as a scientific discipline

GERMANY AND AUSTRIA

Recognized by many as the founder of scientific psychology, Wilhelm Wundt (1832–1920) saw the object of psychology as the introspective analysis of the contents of immediate experience, with elements called sensations and feelings. He regarded "mind" as activity and psychological causality, the sum of inner experiences. His work included studies of association, psychophysics, reaction time, and folk psychology, representing an elementistic and associationistic system. Two of his students, Oswald Kiilpe (1862–1915) and Edward Bradford Titchener (1867–1927), developed further the "structural psychology" (or content psychology) of their mentor. Husserl and Brentano influenced Kiilpe sufficiently to include function in his content psychology. Since Hermann Ebbinghaus (1850–1909) had successfully investigated the "higher mental processes" of memory by experimental

Structural psychology

methods, it was asked: Should it not be possible to do the same with thinking? Hence the development by Külpe and his colleagues at the University of Würzburg of a new method, "systematic experimental introspection," and a new finding, "imageless thought," suggested that thinking can proceed without sensory images. Ebbinghaus' experimental measurements of memory yielded evidence that forgetting is related to the passage of time (curve of retention) and endorsed the value of repetition in learning. Members of the Wiirzburg school stressed higher-mental process or function; Karl Marbe (1869–1953) studied conscious attitudes and judgment; Henry J. Watt (1879–1925) experimented with thinking itself, finding the free flow of thinking to depend upon one's preparation to undertake a "mental" task; Narziss Ach (1871–1946) investigated awareness, willing, and thinking through systematic experimental introspection, concluding that awareness (an imageless component) is the determiner of thinking; Karl Buhler (1879–1963) studied imageless thoughts, concluding that, though at times accompanied by images, they were devoid of sensory qualities.

In his Analysis of Sensations (1886), Ernst Mach (1838–1916) noted sensations of "space form" and "time form" as being independent of sensory elements; *e.g.*, a circle conceptually remains a circle despite change in size or colour. In 1890 at Vienna, Christian von Ehrenfels (1859–1932), introducing the concept of "form quality" (Gestaltqualitat), claimed that appreciation of form in space and time is a quality that arises from the perceiver's own activity rather than being directly given to the senses. Gestalt psychology as a movement is attributable to Max Wertheimer (1880–1943) and two associates from the Frankfurt Psychological Institute, Kurt Koffka (1886–1941) and Wolfgang Kohler (1887–1967). Their experimental findings proved antagonistic to Wundt's notions of elements of consciousness. When Wertheimer reported the phi phenomenon (*e.g.*, apparent visual movement as in the stationary lights on a theatre marquee), it marked the birth of Gestalt psychology. The Gestalt view is that perceptual qualities exist in the whole that are absent in the individual parts; *e.g.*, no single light bulb moves, but each light seems to move when seen as part of a whole. Other contributions by the gestaltists pertained to insightful learning, brain structure and function, creative thinking, discrimination learning, the physical basis of memory, and laws of gestalt (or perceptual organization). Efforts to apply gestalt principles to child psychology, learning, and personality were made by Kurt Lewin (1890–1947), who invented a "topological psychology" and "field theory" of personality. In the field of psychopathology, Kurt Goldstein (1878–1965) tried to apply gestalt notions in what he called a holistic or organismic approach aimed at helping people to come to terms with themselves and their environment. So-called gestalt psychotherapy is most notably associated with Frederick Perls (1893–1970). The Zeigarnik effect (interrupted tasks are more readily remembered than those that are completed) was contributed by Bluma Zeigarnik (1900–). With the exception of the Russian-born Zeigarnik, the founding members of the gestalt movement were German-born migrants to the U.S. during the rise of Nazism.

Gestalt psychology

ELSEWHERE IN EUROPE

In French-speaking countries, therapeutic success in using suggestibility and hypnosis to treat hysterics led Gabriel Tarde (1843–1904), Gustave Le Bon (1841–1931), and the Italian Scipio Sighele (1868–1913) to apply the notion of suggestibility to social psychology. In 1890 Tarde pointed to imitation and invention as being responsible for the formation, development, and nature of society. A few years later, Le Bon saw crowds and mobs as susceptible to the suggestions of leaders in a manner comparable to an individual's response to a hypnotist. In France and Switzerland, interest in psychology also had turned to the study of children. By 1908 Alfred Binet (1857–1911) had, with Theodore Simon (1873–1962), developed a test of general intelligence; Lewis Terman (1877–1956) at Stanford University revised it in 1916 to produce the Stanford–Binet Intelligence Scale. The concept of I.Q. (intelligence quotient) was contributed in 1912 by the German psychologist William Stern (1871–1938). A group of U.S. psychologists, headed by Robert M. Yerkes (1876–1956), administered about 2,000,000 (Army Alpha) tests to literate soldiers and another 100,000 (Army Beta) tests to illiterates during World War I and discovered the average mental age of the servicemen to be about 13.

Psychology in Switzerland centred at the University of Geneva where Theodore Flournoy (1854–1920), after studying with Wundt, established a laboratory in 1892. With his cousin and former student, Édouard Clapari.de (1873–1940), he founded the journal Archives de *Psy*chologie in 1901. On succeeding to Flournoy's professorship in 1920, Clapari.de founded the Institut Rousseau for child study. Successor to Claparède as professor at the University of Geneva and director of the Institut Rousseau, Jean Piaget (1896–) investigated the development in children of moral, abstract, logical, and concrete modes of thinking.

The Russian school of psychology, permeated with objectivity and physiology, effectively began with work by Ivan M. Sechenov (1829–1905), founder of Russian physiology and scientific psychology, who discovered evidence of localized inhibitory function in the brain (Sechenov's centre) in 1863. According to Sechenov, "all acts of conscious or unconscions life are reflexes." This school's most distinguished member, Ivan Petrovich Pavlov (1849–1936), is principally known for demonstrating conditioned reflexes; he showed that neurotic behaviour may be learned and provided the basis on which much of modern learning theory rests. Vladimir M. Bekhterev (1867–1927) founded Russia's first laboratory of experimental psychology in Kazan. The "reflexological period" of Soviet psychology lasted from 1917 to 1923, followed by the "reactology" of Konstantin Kornilov (1879–1957) until 1931; interested in child psychology, Kornilov sought to structure psychology in terms of Marxist dialectical materialism. A student of his, Aleksandr Luria (1902–), concerned with "defectology" (disorders of the handicapped), made efforts to investigate pathophysiology (psychiatric disorder) through rigorous scientific methods. Many other Soviet researchers were interested in child study, including L.V. Zanov (1901–), Leo Vigotsky (1896–1934), and Aleksey Leontiev (1903–), the latter two being involved in developmental psychology. Since 1931 Soviets have shown interest in a Marxist version of cognitive psychology; *i.e.*, the study of man as controlled by his goals, will, purposes, needs, thinking, and the like. On the basis of a resolution jointly issued in 1950 by the Soviet Academy of Sciences and the Soviet Academy of Medical Sciences, psychology in that country has been reconstructed along Pavlovian lines, characterized by a major emphasis on the neurophysiology of behaviour. The decade of the '50s saw the establishment in the U.S.S.R. of the Society of Psychologists, with A.A. Smirnov (1894–) as president.

Russian psychology

The beginnings of serious study in psychometrics and biometrics were in Great Britain, personified by Sir Francis Galton (1822–1911), Karl Pearson (1857–1936), and others at University College, London. Credited with being the first to investigate the psychology of individual differences and to develop the technique of statistical correlation, Galton was as well an active anthropologist, contributing to such fields as eugenics, the inheritance of behavioral traits, and fingerprint identification. Pearson developed a technique for computing correlation coefficients known as the Pearson r. Two mathematician-astronomers, a German, Carl Friedrich Gauss (1777–1855), and a Belgian, Adolphe Quetelet (1796–1874), also contributed to statistics, the former providing equations for the normal probability (Gaussian) curve and the latter providing applications of probability to social and life sciences. Charles Spearman (1863–1945), a British psychologist who immigrated to the U.S., advanced the method of correlation in identifying so-called factors of intelligence. At University College, London, James Sully (1842–1923), after writing the first English-language text for psychology, Outlines of Psychology (1884), established a laboratory of psychology in 1897. British experi-

Instinct

mental psychologist W.H.R. Rivers (1864–1922) directed that country's first psychological laboratory (1897) at Cambridge and headed another at University College, London. Cambridge University's psychologist, James Ward (1843–1925), in the tradition of Brentano and act psychology (see above), wrote a most influential article "Psychology" in the 9th edition (1886; and in revised form in the 11th) of *Encyclopædia Britannica* Ward's influence was carried on by his student George Frederick Stout (1860–1944), whose textbook written from the standpoint of act psychology, *A Manual of Psychology* (1899), became a standard work for a quarter of a century. First to define psychology as the study of behaviour (in 1905), William McDougall (1871–1938) founded in England his own school of "hormic" or "purposive" psychology based on the notion of instinct, McDougall later coming to Harvard College in the U.S.

Correlation

THE UNITED STATES

Recognized as the foremost U.S. psychologist of his time and a pioneer in the new scientific psychology, William James (1842–1910) taught physiological psychology with informal demonstration laboratories as early as 1875. He is known best for his *Ptinciples* of *Psychology* (1890). which offered views on personality types habits, stream of consciousness, and the James–Lange theory of emotions (see EMOTION). While James was at Harvard College, G Stanley Hall (1844–1924), who is believed to have earned the first U.S. Ph.D. in the "new psychology" under James, was at Clark University. Hall helped found the first U.S. psychological laboratory (1881), the *Amei ican Journal of Psychology* (1887), *Journal of Genetic Psychology* (1891), *Journal of Religious Psychology* (1904), and *Journal of Applied* P~chology(191.5)he was first president (and a founder) of the American Psychological Association. Hail, a genetic (evolutionary) psychologist deeply interested in human development and known best for his *Adolescence* (1904), is credited with writing the first text on the psychology of aging. *Senescence* (1922). Under the influence of Wundt, George Trumbull Ladd (1842–1921), a functionalist, published *Elements of Physiological Psychology* (1887), a standard text for many decades.

The next generation of "new" psychologists in the U.S. included James McKeen Cattell (1860–1944), James Mark Baldwin (1861–1934), Joseph Jastrow (1863–1944), British-born Edward Bradford Titchener, Eduard Wheeler Scripture (1864–1945), and German-born Hugo Munsterberg (1863–1916). Jastrow, a student of Hall's at Johns Hopkins University, seems to have been first in the world to receive a Ph.D. in psychology (1886). Another student of Wundt's, psychologist-philosopher Baldwin, founded a Canadian laboratory at Toronto (1889) and another at Princeton University (1893) and helped found the *Psychological Review* in-1894. He edited the first *Dictionaly of Philosoplzy and Psychology* (1901–05). Miinsterberg, another student of Wundt's, was brought to Harvard by James to teach experimental psychology, but his interests in law and business diverted him to become the first applied psychologist. Before settling at Columbia University, where he founded a laboratory, Cattell studied with Hall and Wundt and lectured at Cambridge University, where he became associated with Galton. In addition to being a founder (1921) of the Psychological Corporation for the promotion of professional psycholog ical services to industry and of such publications as *American Men of Science, The Directory of American Scholars,* and *Popular Science Monthly* (1900), Cattell became professor in the first independent department of psychology at the University of Pennsylvania in 1877; previously psychology had been the responsibility of philosophy departments. Interested in "mental tests" (a term he coined), he also investigated reaction time, association, perception, reading, psychophysics, and individual differences The leader of the structuralist school of psychology, Titchener promoted Wundt's tradition in the U.S., taking a post at Cornell University in 1892. Holding consciousness to be the only legitimate subject for psychology, he defended introspective psychology, concerned with the content of consciousness and the structure of subjective life. Titchener's influence, however, perished with his death.

Applied psychology

Functionalism as a school or movement sprang from the efforts of John Dewey (1859–1952) and of James Rowland Angell (1869–1949) at the University of Chicago and reached its height in the early 20th century. Dewey attacked the reflex-arc concept as an effort to reduce behaviour to "mere" neural events. By 1907 Dewey's student at the University of Michigan, Angell, propounded the functionalist's position in an influential article in 1907, "'The Province of Functional Psvchology." Functionalists focussed on the operations or functions of conscious activity (*e.g.*, thinking, learning), while structuralists studied so-called elements (*e.g.*, "ideas." "sensations") of consciousness. The successor of Angell as department chairman at Chicago and spokesman for functionalism was his student Harvey A. Carr (1873–1954), who introduced motivational topics (*e.g.*, striving) into functionalism. By the 1930s, interest in the functional-structural controversy had subsided, and a functionalist Robert S. Woodworth (1869–1962), spent 40 years at Columbia University developing "dynamic psychology." defined as the "study of cause and effect. motives and processes, or in the questions 'Why?' and 'How?' focussed on human activites and ach~eveinents.'Woodworth's work was a repudiation of Titchener and a reaction against McDougall and Watson. This "dean of American psychology" contributed the S–O–R formula (stimulus–organism–response), asserting that the older S–R formula (stimulus–response) failed to consider the responding organism itself: he observed that a given stimulus can produce a variety of responses, depending on the state of the organism. Edward L. Thorndike (1874–1949), Woodworth's colleague at Columbia. was a functionaiist interested in learning theory. He developed a psychology of learning called "connectionism," grounded on British associationism and on his own work with intelligent behaviour among laboratory acimals. Thorndike can be said to have established educational psychology as an autonomous discipline. A Johns Hopkins professor who had studied at Chicago under Angell, John B. Watson (1878–1958) launched U.S. "behaviourism" with his 1913 article, "Psychology as the Behaviorist Views It." Watson discarded consciousness. rejected introspection as a legitimate method of observation, replaced "mental" events with the study of behaviour, and regarded the only valid psychology as being physiological. Though Watson's behaviourism had major impact in the early 1920s in the U.S., it failed to gain wide acceptance elsewhere. Later forms of "neobehaviourism," especially the systems of Clark L. Hull (1884–1952) and B.F. Skinner (1904–), enjoyed wider popularity.

Educational psychology

Contemporary trends

DECLINING INFLUFNCE OF SCHOOLS OF PSYCHOLOGY

By World War II, schools of psychology (with few exceptions) had faded. Contributions to the common pool of psychological understanding were coming from many sources, no one school offering a sufficiently comprehensive account of the available evidence. As schools receded, their function passed to what may be termed miniature systems, models, limited theories, the three terms often being used interchangeabiy. Contemporary psychology is characterized by interest in theory, research, and experimentation. University courses specifically concentrate on personality theory, learning theory, theories of psychotherapy, and so on. While psychology in the 19th century gravitated toward Germany, by the 20th century, two-thirds of the world's psychologists were living in the U.S., with Canada and Britain playing important roles.

Contemporary learning theories still embrace older notions (functionalism, reflexology, gestalt, connectionism. and psychoanalysis; see LEARNING THEORIES). Personality theories commanding the attention of the psychological community include several based on learning. theories (see PERSONALITY, THEORIES OF),

GROWING STRESS OF QUANTIFICATION

The application of mathematics to psychology dates at least to Herbart in the early 19th century. In 1940 Clark

L. Hull applied mathematics to behaviour theory in a mathematico-deductive theory of rote learning, and there has since been a growing tendency to develop quantitative hypotheses accounting for human behaviour, beginning in 1950 with William K. Estes' (1919–) development of a statistical theory of learning based on stimulus sampling. The following year Robert R. Bush and Frederick Mosteller offered a mathematical or stochastic model for learning predicated on probability theory. Four years later, Frank Restle constructed a similar model for discrimination learning, and another, by Richard C. Atkinson, appeared in 1958. By 1963 R. Duncan Luce, Robert R. Bush, and Eugene H. Galanter had collaborated in assembling a three-volume handbook of mathematical psychology. In the same year, David Zeaman and Betty J. House developed a mathematical theory of attention based on studies of retarded individuals.

COOPERATION WITH ENGINEERING SCIENCE

Man–machine systems

Since the early 1940s human engineering (human factors psychology) has been applied to man–machine systems, the goal being to design equipment compatible with human structure and function. In 1948, with the publication of Norbert Wiener's ***Cybernetics: or Control and Communication in the Animal and the Machine*** and Claude E. Shannon's "Mathematical Theory of Communication," engineers and computers came to the service of psychology. Cybernetics, a term used by the Frenchman André-Marie Ampère (1775–1836) in 1834, was defined by Wiener as "the entire field of control and communication theory, whether in the machine or the animal." In addition to Wiener's views regarding the brain and computers and Shannon's information theory, computer technology grew, the electronic digital computer first being developed in 1946. The computer opened the way to machine simulation of complex psychological processes such as problem solving and perceiving. Information-processing (machine) theories of behaviour have been developed and applied to the interpretation of such human activities as learning, among the most influential being those of Herbert A. Simon (1916–) and his colleague A. Newell (1927–).

BURGEONING OF BIOPSYCHOLOGY

Behaviour genetics ("psychogenetics") treats behaviour as affected by heredity. In psychology there has been a growing interest in human genetic factors as they affect retardation and psychiatric disorder. Phenylketonuria (an inborn metabolic defect that can produce retardation) was discovered in 1934 in Oslo, Norway, by A. Fölling, stimulating efforts to advance biochemical genetics and to develop tests for carriers of the abnormal gene. In 1959 the French researchers Jérôme Lejeune, Gautier, and Turpin discovered the presence of 47 chromosomes (instead of the normal 46) in defective children with Down's syndrome (mongolism). Studying another form of retardation (Klinefelter's syndrome) in Britain, Patricia A. Jacobs and John A. Strong in 1959 reported an abnormal chromosomal count of 47. During the same year, Charles E. Ford and his associates discovered that in another variety of retardation (Turner's syndrome), bone-marrow cells contained only 45 chromosomes in the female sufferer studied.

Drugs

The so-called psychopharmacological revolution, beginning in the 1950s, ushered in the use of tranquillizers, antidepressives, nonbarbiturate sedatives, and nonhypnotic muscle relaxants. The term psychosomimetic refers to a drugged state mimicking a psychosis; hallucinogenic, psychedelic, and psycholvtic are more recent terms describing the effects of such-drugs as LSD and mescaline. Chlorpromazine (a phenothiazine chemical) and Rauwolfia alkaloid (reserpine) were among the first tranquillizers to come into general use in the early 1950s; the former, a French discovery in 1952, was used by Jean Delay of the University of Paris in treating psychotics. Reserpine, developed by Swiss researchers in 1952, has been used as a treatment in psychiatric disorders as well as in reducing high blood pressure. Drugs called monoamine oxidase inhibitors were introduced in 1951 for the treatment of severe depression and were followed by a number of other chemical compounds. Meprobamate, a minor tranquillizer used to treat anxiety, appeared in the early 1950s, followed by others such as chlordiazepoxide. The discovery of the effects of LSD (lysergic acid diethylamide) by Albert Hofmann (1906–) in 1943 in Switzerland occurred when he inadvertently swallowed the merest bit of it, with resultant hallucinations and confusion.

RISE OF PROFESSIONALISM

The multifarious nature of psychology in the world today has resulted from the rise of professional psychology since World War II. Academic psychologists, who once predominated, currently constitute a small minority. Most psychologists are distributed over many specialties, serving as industrial and personnel psychologists, school and guidance psychologists, clinical psychologists and psychotherapists, engineering and space psychologists, military psychologists, and social psychologists. They are employed in government agencies, business and industry, hospitals and clinics, private practice, prisons, and schools (see PSYCHOLOGY). By the 1970s, psychology had become a well-established discipline, respectably ranked among such other professions as the law and medicine.

BIBLIOGRAPHY. E.G. BORING, *A History of Experimental Psychology*, 2nd ed. (1950), and G. MURPHY, *Historical Introduction to Modern Psychology*, rev. ed. (1972), are two excellent histories to the mid-20th century. Current textbooks include: R. THOMSON, *The Pelican History of Psychology* (1968); D.P. SCHULTZ, *A History of Modern Psychology* (1969), a concise treatment limited to the period subsequent to Descartes; H. MISIAK and V.M. STAUDT, *History of Psychology: An Overview* (1966), another readable text similarly limited; R.I. WATSON, *The Great Psychologists: From Aristotle to Freud*, 3rd ed. (1971); and J.R. KANTOR, *The Scientific Evolution of Psychology*, 2 vol. (1963–69). W.S. SAHAKIAN (ed.), *History of Psychology: A Source Book in Systematic Psychology* (1968), outlines the historical landmarks. R.J. HERRNSTEIN and E.G. BORING (eds.), *A Source Book in the History of Psychology* (1965), is topically oriented but limited to experimental and quantitative psychology. F. ALEXANDER and S.T. SELESNICK, *The History of Psychiatry* (1966), and G. ZILBOORG and G.W. HENRY, *A History of Medical Psychology* (1941, reprinted 1967), are single-volume treatments of the history of psychiatry currently available in paperback. Other histories, limited in scope but well written, include: L.S. HEARNSHAW, *A Short History of British Psychology* (1964); A.A. ROBACK, *A History of American Psychology*, rev. ed. (1964); and J.C. FLUGEL, *A Hundred Years of Psychology, 1833–1963*, 3rd ed. rev. by D.J. WEST (1964).

Psychology, Physiological

Introduction and historical background

Physiological psychology is the study of the physical basis of behaviour. Primarily it is concerned with how the brain and the rest of the nervous system function in activities (*e.g.*, thinking and perceiving) recognized as characteristic of man and other vertebrate animals. Since the nervous system critically depends on additional organs of the body for its normal function, physiological psychology is also concerned with mechanisms of metabolism, the production of hormones by endocrine (ductless) glands, and other regulatory effects on the internal bodily environment. Furthermore, the structural and functional characteristics of the nervous system, as well as of other organs, are mediated by mechanisms of heredity and are affected by diet, drugs, and disease. Thus, among all sufficiently evolved animals, behaviour may be influenced by all of these factors, since the nervous system for them is the major immediate (proximate) agent producing behaviour.

Although ancient philosophers poorly understood the nervous system, they usually wrote that psychological activities were in some way related to the body and its functions. Indeed, the historic roots of physiological psychology lie in classical mind–body notions of philosophy. Aristotle's view of this dispute, known as the double-aspect theory, defined mind and body as two aspects of the same thing, body serving as structure and mind being simply one of its functions. This surprisingly modern view failed to attract endorsement from many others, however. French philosopher Rent Descartes (1596–1650), for example, reserved soul as the realm of mind among human beings. He denied that mind existed for other animals and viewed their behaviour as being completely mechanistic, ascribing it entirely to the functioning brain and nerves. While he argued that basic reflexes in man were mechanistically determined, he depicted mind as a separate, spiritual (immaterial), uniquely human entity. To explain how two presumably distinct things called mind and body could influence each other, he proposed an interaction theory, holding that the physical site at which mind and body interacted was a structure in the brain called the pineal body (or gland).

The mind–body dispute

Even more independence of mind from body was envisaged by German philosopher Gottfried Wilhelm Leibniz (1646–1716) in his theory of psychophysical parallelism. Leibniz maintained that mental events and bodily changes occurred quite separately, holding them to be entirely independent but nevertheless paralleling each other perfectly, as though in accordance with a predetermined plan.

In modern history such behaviorists as U.S. psychologist John B. Watson (1878–1958) tried to carry the question one step beyond Descartes by saying that human beings were essentially the same as all other animals and by embracing another ancient philosophy that denied the existence of anything spiritual. They tried to strike all mentalistic terms—mind, consciousness, and feelings—from scientific use and directed attention only to observable behaviour, which they held to be the biologically determined outcome of the activity of the nervous system.

Although the term mind is more abstract than is readily observable overt behaviour, it remains a convenient word in ordinary conversation for designating the inner (private, subjective) aspects of human experience. Scientifically, however, mind cannot be used to refer to the nonphysical (since science is limited to phenomena; *i.e.*, to the physical), despite the great emphasis that philosophical and cultural heritage has placed upon the spiritual. Physiological psychology begins, then, with the basic understanding that if the word mind is to be used, it is to be conceived in such terms as the activities of the nervous system or other parts of the living body.

Basic properties of the nervous system. The anatomy and physiology of man's nervous system are given in detail in the article NERVOUS SYSTEM, HUMAN. Only a brief review will be given here.

Grossly, a normal vertebrate nervous system consists of the brain and spinal cord and their nerves. Stimuli from the environment prompt sensory nerves to deliver impulses to the spinal cord; motor nerves direct them from the cord to the muscles and glands. This provides the basis for such reflexes as the automatic withdrawal of a limb from a painful stimulus. In addition, incoming sensory impulses travel up to the brain, which in turn sends motor impulses down to the segments of the spinal cord. At various levels in the brain, incoming sensory nerves are linked by multitudinous connections to the outgoing motor nerves, making up a remarkably complex mechanism for integrating behavioral functions, similar in principle to the reflex mechanism.

The brain: structure and funcrions

To understand these connections and their importance in man's behaviour requires an appreciation of the gross structure of the human brain and its function (see Figures 1 and 2). The continuation of the spinal cord into the brain is called the medulla; in addition to major sensory and motor pathways and their integrating mechanisms, it contains many groupings of nerve cells that mediate such functions as breathing and the circulation of blood. Above the medulla is the midbrain, serving in many simple visual and auditory reflexes (*e.g.*, the pupillary reflex of the eye).

From K.L. Munn, Psychology (1951); Houghton Mifflin Company

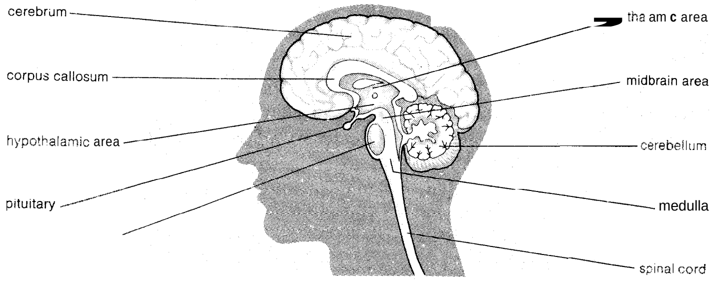

Figure 1: Internal structure of the human brain.

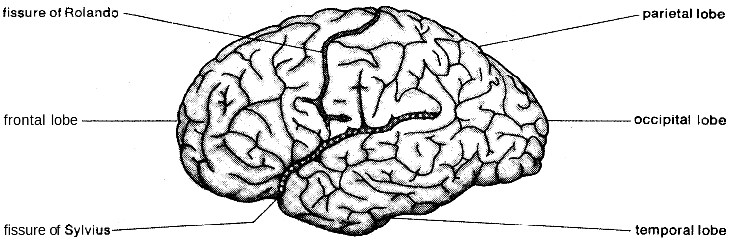

Figure 2: Major lobes and external surface of cortex in the human brain.

Behind the medulla and midbrain lies the cerebellum, acting primarily in the coordination of posture and in locomotion. The thalamus, situated above the midbrain, functions to integrate incoming sensory nerve impulses and relays sensory impulses to the cerebral cortex (the outer mantle of the brain). Below the ihalamus is a brain structure called the hypothalamus, concerned with control of the pituitary gland and with such complex functions as water balance in the body, thirst, sleep, food ingestion, reproduction, and emotional expression. Above the thalamus are the two cerebral hemispheres so prominent in man. The main mass of these hemispheres in humans consists of white matter entering and leaving outer layers of gray matter known as the cerebral cortex. Deeper parts of the cortex (the so-called old cortex) are parts of that structure that apparently evolved first and may be seen in many other animals as well as in man; it seems primarily concerned with vegetative (body regulating) and emotional functions. The new cortex, which evolved later, participates in sensory, motor, and such associative functions as learning. The new cortex includes occipital lobes (one at the back of each hemisphere) concerned with visual function, temporal lobes (at the lower sides of the brain) concerned with suditory and language functions, parietal lobes (behind the fissure of Rolando on each side) that integrate sensory information coming from the skin and muscles, and frontal lobes (in front of each fissure of Rolando) with motor areas that control discrete movements and postural adjustments; the remainder of each frontal lobe is presumed to serve complex associative functions still poorly understood.

In this greatly simplified picture of the human nervous system, sensory stimulation typically results in activation of integrative mechanisms at all levels, from the spinal cord to the cortex. The major sensory pathways described so far serve quite discrete functions; *e.g.*, some are specific for painful stimuli while others are specialized for tasting, still others selectively serve other parts of the body. This gives the nervous system considerable discriminative power. In addition, all sensory pathways send branches to a network of nerve cells (the reticular formation) lying in the centre of the hindbrain or brain stem (medulla and midbrain). The reticular formation relays nerve impulses to all parts of the brain and serves to activate or arouse the brain generally. It is held that this arousal function is crucial to wakefulness, attention, and emotion; reticular mechanisms may be thought of as preparing the brain for receiving impulses arising from stimuli.

Nerve cells

Much of the nervous system just described consists of billions of individual nerve cells (neurons), some of which are quite long, their tiny filaments extending all the way from the big toe to the spinal cord; others are not much longer than they are wide. These individual neurons connect with each other across tiny gaps between them (synapses). Connections may be such that the activity in one neuron will arouse a number of connecting cells, or activity in many cells may converge on a small number of others, or there may be reverberatory loops in which activity traverses a chain of neurons until the first cell is aroused again and again by the process it initiated.

The activity of neurons is detected as a nerve impulse: an electrochemical disturbance that may be propagated as rapidly as 120 metres (about 395 feet) per second. When these disturbances are recorded electrically with suitable amplification devices, the results show that if a nerve cell is to be activated at all, it must be stimulated at least at a minimal intensity (threshold energy). Once a nerve cell is activated, it discharges its electrical impulse fully; it responds in an all-or-none fashion.

Major integrative mechanisms of the nervous system depend on excitation (the arousal of activity) and on inhibition, in which the activity of a group of cells is arrested. Excitation and inhibition can be illustrated in spinal reflexes; touching a hot object with one's hand, for example, leads to excitation of nerves serving flexor muscles (that pull the limb away) and to simultaneous inhibition of nerves leading to opposing extensor muscles.

Sensing and perceiving. One of the oldest goals of physiological psychology is to explain how information (*e.g.,* a visual stimulus) is received from outside the body or from within the body itself (*e.g.*, as in a stomach ache). The aim is to specify physical bases for sensing and perceiving.

An early result of the endeavour was the doctrine of specific nerve energies offered by German physiologist Johannes Peter Miiller in 1826. While the anatomical and physiological details he specified were inaccurate, the basic notion still seems valid. The doctrine states that what is sensed (one's immediate awareness of stimulation) is determined by structures and events in the nervous system rather than by the quality of the stimulus itself. Thus a finger pressed on a closed eyelid mechanically produces visual experiences in the absence of the proper visual stimulus, light. Müller argued that people would see thunder and hear lightning if the nerves from the eye and the ear could be interchanged. Many phenomena support Muller's doctrine, and its general validity can be demonstrated most easily: an electrical stimulus will produce experiences appropriate to the sensory structure it stimulates, whether it be the eye, the skin, the tongue, or some point within the brain to which impulses from these organs go. Thus the experience one reports or the discriminative response he makes is specifically related to the part of the nervous system that is activated.

Hearing

To illustrate more fully: in hearing, the experience of pitch is determined largely by the frequency at which a sound source (*e.g.,* a tuning fork) vibrates—the faster the rate of vibration, the higher the pitch. Vibrations are transmitted through the air to the eardrum. The eardrum passes this vibration through tiny bones in the middle ear to vibrate the membrane of the oval window of the cochlea, a bony structure resembling a snail shell in the inner ear (see EAR AND HEARING, HUMAN for illustrations of these structures). This vibrates a fluid in the cochlea that, in turn, sets up a wave of vibration in the basilar membrane, which extends throughout the coiled length of the cochlea. The wave has its maximum effect on the basilar membrane at different places, depending on the frequency of vibration introduced. Low frequencies (relatively slow vibrations) affect the basilar membrane near the apex of the cochlea, while higher frequencies have their effect near the base. The basilar membrane is lined with the hair cells of the organ of Corti (crudely equivalent to the soft body of a snail coiled up in its shell), and as the membrane is moved, the shape of the hairs is distorted. Like crystals in an old-fashioned radio set that are distorted mechanically, the hairs initiate tiny electrical currents to stimulate the fibres of the auditory nerve .that arise from the vicinity of the hairs. In this way, different fibres of the auditory nerve are activated by vibrations produced by sound waves of different frequencies.

More than that, the different auditory nerve fibres are distinct (insulated) from each other in their course into the brain, at each of the neural relay centres through which they pass, and at the auditory region of the temporal lobe of the brain's cerebral cortex where they end. Hence investigators are able to record electrical activity from different parts of the auditory cortex, representing the different tonal frequencies that stimulate different parts of the basilar membrane in the inner ear. It is even feasible (in a cat, for example) to stimulate different parts of the basilar membrane directly with electrical current and to find the same arrangement of locations activated in the cerebral cortex. It would seem that the experience of pitch depends upon the place in the auditory nervous system that is activated by the stimulus.

Aside from pitch, other attributes of auditory experience are mediated by somewhat different mechanisms. Loudness depends on the intensity (*i.e.,* amplitude) of vibration, and it is held that the experience of loudness is a function of the density (or number per second) of nerve impulses conducted over the nerve fibres serving the specific frequencies associated with pitch experience. Density can be increased by discharging individual fibres more rapidly and by activating additional fibres of high threshold (*i.e.*, fibres that require a great deal of energy before they will discharge).

The temporal (time) pattern of pitches and loudnesses of sounds presumably is given by the temporal pattern of arousal of nerve fibres activated by a frequency- or intensity-patterned external stimulus. Finally, one's ability to localize sources of sound in space depends mainly on slight differences from one ear to another in the sound wave's time of arrival and on the intensity of vibration from a single source. These differences appear in electrical recordings from the auditory cortex to appropriately reflect differences in time of arrival and amplitude of nerve impulses on the two sides of the brain.

The same general principles apply to the other senses. Thus there are separate fibres and pathways in the spinal cord for carrying nerve impulses produced by stimuli that give rise to experiences of pain, temperature, and pressure in the skin. Different parts of the tongue are activated by sweet, sour, bitter, and salty stimuli; when the tongue is stimulated more intensely, the density of the patterns of nerve impulses increases proportionally. In vision different parts of the retina, the receptor surface of the eye, are sensitive to specific wavelengths of light and induce the experience of different colours. There appear to be different combinations of receptor cells in the retina that are maximally sensitive to different wavelengths in the visible spectrum (*i.e.*, the full range of the rainbow). The study of vision illustrates another property of sensory systems, for certain neurons may be found in the visual system that qualify as feature detectors. That is to say, they respond to some complex feature of the visual environment such as a line that tilts 45° to the left (but not the right or vertical or horizontal), or such as an edge or curve. Thus, some of our complex perceptions may be determined by the action of such feature detectors.

Vision

Physiological approaches to relatively complex perceptual problems can be illustrated with such visual examples as the awareness of real and apparent movement and ability to perceive depth and the location of objects in space. The visual localization of anything in view, for example, depends on the part of the retina stimulated and the manner in which that localization is represented in the brain. Philosophical interest in this problem arose when it was learned that the lens of the eye inverts the image of objects on the retina. It seemed difficult to understand how it was that people did not see the world upside down. Investigations were inspired into the role of learning early in life as related to the inversion of the visual field.

If the eye of a salamander is surgically rotated 180°, the animal will snap upward at a lure held below it and to the left at a lure held to its right. Even if the salamander's optic nerve is cut and allowed to grow back, the animal will not reorganize its visual behaviour in accordance with its experience and still will behave 180" out of phase upon recovery. The visual field of man can be rotated experimentally with special lenses. Although there are individual difference~some people seem to adapt to such visually reversed experiences and after a time will say that things look upright again. Thus, although visual localization is largely a function of the central (brain) connections of the retina, it seems also to be modified by experience (see LEARNING, PERCEPTUAL; PERCEPTION OF MOVEMENT).

The perceptual role of the brain has been studied in many experiments with laboratory animals and is shown through complex effects of human brain injury on visual processes. A man with damage to the region of the visual cortex may fail to recognize familiar objects for what they ale, although he may clearly be able to see them, to describe their appearance, or trace them with a finger. In other cases, such a brain-injured man may seem totally to ignore all events in a specific part of his visual field, although it can be shown by careful tests that he can indeed see in that part of the field; sometimes he may experience gross distortions of objects in the affected part of the field. The human brain (particularly the cerebral cortex) seems concerned with interpreting (perceiving) rensory information.

Motivated behaviour and the emotions. Problems of historic interest to physiological psychology concern the physical bases of feelings, urges, and emotions—a most difficult area of scientific inquiry (see EMOTION; MOTIVATION).

Drive (sometimes called instinct) has been defined as the arousal of the organism, observable as an increase in general activity or as the appearance of highly specific behaviour. Thus a hungry animal tends to become generally restless and hyperactive. Typically, however, any drive has a highly specific goal (such as food or a mate), or it might be expressed bodily as in sleep or flight or rage. Once the activity has been executed, the organism tends to become satiated; drive is reduced, hyperactivity ceases, and behaviour no longer is directed strongly toward the goal. The case of a three-year-old boy with an abnormal craving for salt is illustrative. This boy's history showed that his general appetite was poor and that he was restless and upset in his first years when fed an ordinary diet. He strongly preferred salty foods such as bacon or smoked fish, and these seemed to appease him a great deal; but this great craving did not become apparent until he discovered the saltshaker at the age of 18 months and ate salt by the spoonful. Belatedly taken to a hospital for observation, the child was mistakenly placed on a standard diet with only a normal amount of salt, and within seven days he died. Autopsy revealed extensive damage to his adrenal glands, leading to a disorder in which the body cannot retain salt normally. Apparently the boy had a deficiency that strongly drove him toward the specific goal of salt; when he gorged on salt, the drive was reduced; it was only through repeated cycles of drive and satiation that the boy managed to stay alive as long as he did.

Hypothalamic mechanisms

There seem to be interrelated brain functions centring in the hypothalamus: an excitatory process for the arousal of drive and an inhibitory mechanism for its reduction or for satiation. For example, experimental destruction on both sides of the brain of small areas in part of the hypothalamus of a rat. cat, or monkey results in a doubling or tripling of food intake, leading to great obesity; on the other hand, similar destruction of nearby regions of the hypothalamus results in refusal to eat and starvation in the presence of customary food supplies. That some parts of the hypothalamus are inhibitory is shown by experiments in which electrodes are surgically implanted into those regions of the brain. Electrical stimulation through the electrodes in a waking, hungry animal results in inhibition or depression of feeding. Conversely, the excitatory nature of other hypothalamic regions is shown when their electrical stimulation increases feeding activity.

Similar control mechanisms can be found in the hypothalamus in the cases of thirst, sexual behaviour, and sleep. It is clear that the hypothalamus also is directly influenced by sex hormones; mating behaviour may be aroused in animals by introducing small quantities of hormones directly into the brain. The cerebral cortex also contributes to the arousal of sexual behaviour, particularly among males; extensive damage to the cortex may eliminate the ability to show sexual arousal. That the animal is still capable of mating, however, quite clearly emerges when a massive dose of sex hormones distributed by the bloodstream throughout the body restores the mating response lost through injury to the brain cortex. Sexual behaviour does not seem to depend on any particular sensory stimulation, including impulses arising from the genitals (external sex organs); cutting the nerves from the genital region or surgical elimination of any one of the other sensory systems (*e.g.,* the visual apparatus) does not by itself block sexual behaviour. Among naïve rats, it takes elimination of no more than two sensory avenues at once to preclude sexual arousal; among more experienced animals, however, sexual behaviour may survive the elimination of three sensory systems, illustrating the role of learning and experience in the physiological control of sexual behaviour. It would seem that the mechanism of sexual behaviour must have gone through marked changes in evolution. In comparing animals from rat to man, it is found that the role played by sex hormones diminishes as dependence increases on sensory stimuli, on learning, and on the cerebral cortex.

Sexual behaviour

Much of the same physiological mechanisms that serve sexual function also operate in emotional expression. Cats surgically deprived of their cerebral cortex are easily aroused to apparent rage by almost any mild stimulus, but their response is short lived and poorly directed. If only the new cortex is removed, cats tend to become placid; if the old cortex is removed alone, they almost invariably become fierce. Monkeys, on the other hand, become strangely placid in the absence of selected portions of the old cortex, particularly those portions called the hippocampus and amygdala (see EMOTION for anatomic illustrations). In addition to placidity, the monkeys display exaggerated sexuality and markedly increased and indiscriminate oral activity, even to the point that some have been observed to put a snake or a lighted match into the mouth. Damage to different parts of the hypothalamus also can produce profound changes in emotional expression. Appropriate electrical stimulation of the hypothalamus in people will lead to such emotional responses as apparently unmotivated weeping and laughter.

Electrical stimulation of the hypothalamus and related brain structures under somewhat-different circumstances further illustrates physiological mechanisms that underlie motivation and emotion. For example, an animal may be allowed to press a lever that serves to electrically stimulate its own brain through appropriately implanted electrodes. Such animals have been observed to operate the lever as often as 5,000 times in one hour; under some conditions, pressing the lever seems to provide greater reward than do sexual activity or food; and it has been shown that the animals will readily walk across a painfully electrified grid repeatedly, apparently just to press the lever. When electrodes are placed in other parts of the brain, animals behave as if this kind of self-stimulation produces intense punishment rather than reward. Such experiments demonstrate the probable existence of selective brain mechanisms that serve all aspects of emotion and motivation, including the experiences called pleasure and anguish.

In general, such animals as men and rats seem to be aroused to strongly motivated behaviour and emotion as a result of physiological activity in an excitatory neurological mechanism centring in the hypothalamus. Contributing to this are major influences from sensory stimuli, often as modified by learning, and such internal factors as hormones, blood temperature, and levels of salt and other dietary substances.

Learning and intelligence. While many remarkable adaptations are accomplished through instinctive (or built-in) physiological mechanisms, a major factor in the adaptation of mammals (especially man) is an ability to learn. While they remain poorly understood, the mechanisms of learning and remembering seem to depend on relatively enduring changes in the nervous system. Physiological psychologists are especially concerned with discovering which structures in the body mediate learning, and they seek to understand the nature of neurological changes produced by learning.

In all kinds of learning the organism (from one-celled amoeba to man) makes new responses to some stimulus or general situation. Thus a dog can learn to salivate consistently in response to a bell, cats will learn to press a pedal that opens a door to a cage in which they are locked, and the English-speaking student of German learns to say "almond tree" when presented with the German term Mandelbaum. Aspects of the process of learning and remembering are described by so-called laws of association, some formulated by Aristotle himself: the laws of contiguity (in time and place) and repetition. (For example, one learns to associate ham with eggs; both tend to be contiguous in that they are apt to occur together at the same time and place.) Other such laws formulated later include those of effect (or reinforcement) and interference (leading to forgetting or extinction). In training dogs, for example, it has been found effective to present a bell together with meat (a normal stimulus for salivation); with this pairing, if repeated many times, the bell alone will begin to elicit salivation. The meat functions as a reinforcer for learning (in the sense that salivation tends to lessen when the bell is presented without the meat and to increase when the meat is included). The waning of salivation in response to the bell alone is called extinction and is similar to forgetting. Both extinction and forgetting appear to result from responses that interfere with those that have been learned; these interfering responses are favoured when reinforcement is omitted. The evidence is that the effects of most learning are stored over the lifetime of the individual and that forgetting ordinarily is a temporary failure to retrieve stored information through interference or competitive learning.

Some have held that even simple learning such as conditioning depends on the cerebral cortex, but it has been amply shown that animals still may be conditioned after the whole cortex has been removed from the brain by experimental surgery. In a complex learning situation, like a maze, however, an animal like a rat is heavily dependent upon its cerebral cortex for learning and remembering. In his classical studies, U.S. psychologist Karl S. Lashley showed that the larger the amount of cortex destroyed, the larger the impairment (principle of mass action). Since the same degree of impairment occurred regardless of the locus of the lesion, Lashley concluded that all parts of the cortex are equipotential for learning.

It once was held that the frontal lobes of the brain were critical in memory processes involved in problem solving. Indeed, monkeys without their frontal lobes tend to fail what is called the delayed-reaction test; for example, they are shown food placed under one of two identical cups and then made to wait several seconds to a minute or so before being allowed to uncover the food if they are able. Yet, some function other than memory seems to be involved in this defect, since monkeys without frontal lobes turn out to be quite distractible. If their attention is fixed firmly on the baited cup before the delay, monkeys with frontal lobes removed do succeed; if distractions are reduced by putting the animals into the dark during the delay period or by giving them sedatives, they also tend to perform successfully. The frontal cortex probably contributes more in the way of perceptual-attentive function than in storing the specific effects of learning.

The concept of mass action seems to have arisen from studies designed only to assess the effects of experimentally damaging brain tissue. By contrast, when the temporal lobes (at the sides of the cortex) of human beings are exposed for surgery while the individual remains awake on the operating table, it is found that specifically localized electrical stimulation can evoke in him dreamlike or hallucinatory experiences of familiar episodes from the past. (Mass action does not seem to apply.) When the temporal lobes are damaged in otherwise normal people, curious memory defects appear. While these people are able to recall past events very well, they typically are unable to remember what they have learned or experienced a few hours earlier. Study shows that they remember a definite event for about 15 minutes afterward; beyond that period, memory seems to fade and is lost. It is as though two memory processes have been separated by the temporal lobe damage: a temporary (short-term) memory process of very short retention seems to be spared by the injury, while more enduring storage of new information (long-term memory function) is impaired.

Short-term and long-term memory function

Support for a distinction between long-term and short-term memory comes from experiments with nonhuman animals, too. In one study, an octopus exposed to a crab that was dangled in the far end of its tank every two hours, six times a day, quickly learned to venture out of its shelter and to eat the bait. After a white card (that signalled an impending electric shock) was lowered from time to time with the crab, the octopus learned not to take the food when this cue was presented. Following removal of the vertical lobe of its brain, the octopus no longer could make the discrimination learned earlier; it kept emerging when the warning card was dangled. Even repeated retraining attempts every two hours with the card and electric shock proved ineffective. (This seems to contradict the notion of full equipotentiality.) But if training trials were closer together, the octopus was able to perform much better; within 15 minutes to an hour after the octopus was shocked on approaching the crab and the card, it stayed away from them. The animal's ability to retain information over the long term seemed to be impaired, even though short-term memory remained.

Rats subjected to electric shocks that produced convulsions after each daily learning trial also gave evidence of at least two kinds of memory. There were few signs of learning when shocks were administered within an hour after any trial, but if shocks came more than an hour later, the usual evidence of learning was observed. It seems to take some time for the effects of a learning experience to consolidate in the brain with some stability. For about the first hour afterward the storing of information can be disrupted by convulsive shock; after that the function is not easily disturbed.

Apparently the effects of learning first are retained in the brain by some reversible process, after which some more permanent neural change takes place. It has been suggested, therefore, that learning is mediated neurologically by at least two types of process as time passes. Perhaps the short-term function, temporary and reversible, reflects a physiological mechanism (*e.g.*, synaptic electrical or chemical change) that maintains a reverberatory loop (described above in discussing nerve cells) over a limited period to keep the memory trace alive. The ensuing, more permanent (long-term) storage may depend on an anatomical process in which nerve endings grow larger or increase in number so that synapses have enriched connections; perhaps new synapses are formed. Another speculative possibility is that long-term learning depends on changes in the chemical structure of neurons through alterations of peptides or complex protein substances such as ribonucleic acid (RNA) contained in the cells. Support for the inference comes from evidence that hereditary information is carried by chromosomes, coded in the structural arrangements of a related, protein-like molecule called deoxyribonucleic acid (DNA). While it has not been shown that learning and memory are similarly coded in RNA, the observation that memory in mice can be obliterated by injecting into the brain a drug (puromycin) that inhibits protein synthesis tends to endorse such a conclusion.

Since, however, other drugs (acetoxycycloheximide) can block protein synthesis in mice without impairing memory, it appears that some other aspect of puromycin is important in blocking memory. This is all the more impelling, for it turns out that the effect of puromycin can be reversed by subsequently injecting saline into the same regions of the brain as received puromycin. That is, memory lost through puromycin injection into the brain may be recovered by saline injection into the brain. The evidence is that a puromycin-peptide stays in the brain for long periods after intracranial injection and serves to inhibit the expression of memory rather than destroy it.

Since the neurophysiological reactions necessary for learning and memory seem to occur at the synapse, the chemistry of memory is apt to be the chemistry of synapses. It is here that we should look for the effects of drugs like puromycin.

Akin to the problem of learning are such relatively complex activities as reasoning, problem solving, and intelligent and linguistic behaviour. These have been studied

Reasoning, intelligence, and language

primarily in cases of brain damage, particularly in man, but to some extent also in other animals. Large amounts of human brain tissue may be destroyed without measurable impairment of these complex processes. For example, although removal of one entire cerebral hemisphere from a human being results in specific sensory and motor defects within the limits imposed by such impairments, intelligence may be effectively unaltered. On the other hand, damage to specific, restricted regions of the brain (particularly the cortex) may have devastating effects on intelligent behaviour. Following injury to the lateral surface of the frontal cerebral cortex, human-intelligence testing and delayed-reaction studies with monkeys may reveal severe impairment. In man a region fairly specific for speech functions is found on the side of the cortex (in almost all cases only on the left hemisphere). Damage there results in varying degrees of aphasia, an inability to name objects properly or to point to objects named by an examiner, even when the brain-injured person can see the object and may be able to say what it is used for. When parts of the temporal, parietal, or occipital cortex are damaged, there may be other language difficulties such as trouble in reading (dyslexia) or writing (dysgraphia).

Lesions in limited portions of the occipital cortex produce visual agnosia: once-familiar objects are no longer recognized when they are seen. With parietal-lobe lesions a man may have difficulty in recognizing parts of the environment, including his own body (to produce so-called distortions of the body image). In people with these injuries such skilled acts as putting on clothes cannot be coordinated, even though individual movements can be made normally; the disorder is called dyspraxia. In some cases of frontal-lobe damage a person may not be able to go through the motions of drinking from an empty glass, although he can easily oblige a request to drink from a glass with water in it. While such disorders are incompletely understood, it is clear that relatively small lesions of the brain can lead to major psychological impairment.

Personality and its disorders. While normal personality, as well as such disorders as neurosis and psychosis are to some degree the functional products of wholesome or stressful experiences, they also reflect physiological processes, some of which may be determined by heredity. In the 5th century BC, the Greek physician Hippocrates wrote that human temperament is largely determined by body fluids (humours). While his view was inaccurate in detail, many everyday examples emphasize the potent role of body chemistry in personality; consider the effects of alcohol, marihuana, and tranquillizers on behaviour.

These drugs affect the nervous system, as do vitamins in foods and hormones and enzymes produced in the body. The production of chemicals in the body that influence the function of the nervous system often is traceable to hereditary factors. For example, a striking variety of retardation in intelligence known as phenylketonuria (or phenylpyruvic oligophrenia) is transmitted through a gene that produces a defective enzyme in the body. The resultant inability of the sufferer properly to use specific kinds of protein from his diet in some way impairs brain function. A number of studies of the major psychoses implicate heredity as an important factor. When the psychosis called schizophrenia, for example, is diagnosed in one identical twin, it is most apt to occur in the other, even if the two have been reared apart; fraternal twins (those with no more similar heredity than ordinary brothers or sisters) are much less likely to exhibit symptoms of schizophrenia in common. Quite clearly heredity factors predispose the individual to some forms of psychosis; life experience, stress, disease, or other factors apparently contribute to precipitate the symptoms. It is suggested that the genetic predisposition is represented as a biochemical defect that affects the nervous system; the expectation that psychiatric symptoms may be controlled with substances that inhibit or excite brain chemistry is increasingly being fulfilled.

Genetic factors are less clear-cut in neuroses, and the disturbance usually is not so severe nor so incapacitating as in psychoses. Considerable experimental evidence, however, indicates that psychological stress and anxiety are characterized by widespread correlates in bodily activity; neurosis thus may be understood to involve altered physiological function. Indeed, presumably "mental" symptoms such as anxiety are physiologically controlled with tranquillizers. Experiments have shown that stress activates the pituitary gland, in part through the regulatory activity of the brain's hypothalamus. The pituitary, in turn, releases hormones that activate other endocrine structures of the body, particularly the adrenal cortex (see ENDOCRINE SYSTEM, HUMAN). Once stressed, this system may become increasingly sensitive, resulting in an oversecretion of the hormone adrenaline that seems to generate such psychosomatic symptoms as high blood pressure. Chronic overactivity of adrenal tissue may lead to exhaustion of its ability to secrete, perhaps contributing to psychosomatic symptoms of rheumatism and arthritis. It appears that prolonged psychological stress may affect the physiology of the organism and sensitize it to further emotional disturbances.

FIELD (gen. ed.), *Handbook of Physiology,* sect. 1, *Neurophysiology,* 3 vol. (1959–68), an authoritative and extensive handbook covering the broad reaches of physiological psychology; E. STELLAR and J.M. SPRAGUE (eds.), *Progress in Physiological Psychology* (1966–), a continuing handbook of physiological psychology, up-to-date and authoritative, covering the full range of the field in the series.

(El.S.)

Psychology, Social

Social psychology is the scientific study of the behaviour of individuals in their social and cultural setting. Though the term may be taken to include the social activity of laboratory animals or those in the wild (see SOCIAL BEHAVIOUR, ANIMAL), the emphasis here will be on human social behaviour. The discipline of social psychology overlaps with other fields of study such as PERSONALITY, THEORIES OF, as well as with other disciplines such as COMMUNICATION; LINGUISTICS; SOCIOLOGY; and ANTHROPOLOGY.

Once a relatively speculative, intuitive enterprise, social psychology has become an active form of empirical investigation, the volume of research literature having risen rapidly after about 1925. Social psychologists now have a substantial volume of observation data covering a range of topics; the evidence remains loosely coordinated, however, and the field is beset by many different theories and conceptual schemes.

Early impetus in research came from the United States, and much work in other countries has followed U.S. tradition, though independent research efforts are being made elsewhere in the world. Social psychology is being actively pursued in the United Kingdom, Canada, Australia, Germany, The Netherlands, France, Belgium, Scandinavia, Japan, and the Soviet Union. Most social psychologists are members of university departments of psychology; others are in departments of sociology or work in such applied settings as industry and government. In the 1970s there were several thousand people employed as social psychologists in the U.S., about 200 in the U.K., and smaller numbers in other countries.

Scope of social psychology

Much research in social psychology has consisted of laboratory experiments on social behaviour, but this approach has been criticized in recent years as being too stultifying, artificial, and unrealistic. Much of the conceptual background of research in social psychology derives from other fields of psychology. While learning theory and psychoanalysis were once most influential, cognitive and linguistic approaches to research have become more popular; sociological contributions have also been influential.

Social psychologists are employed, or used as consultants, in setting up the social organization of businesses and psychiatric communities; some work to reduce racial conflict, to design mass communications (*e.g.*, advertising), and to advise on child rearing. They have helped in the treatment of mental patients and in the rehabilitation of convicts. Fundamental research in social psychology has been brought to the attention of the public through popular books and in the periodical press.

AKEAS OF STUDY

Research methods. Laboratory experiments, often using volunteer students as subjects, omit many features of daily social life. Such experiments also have been criticized as being subject to bias, since the experimenters themselves may influence the results. Research workers who are concerned with more realistic settings than with rigour tend to leave the laboratory to perform field studies, as do those who come from sociological traditions. Field research, however, also can be experimental, and the effectiveness of each approach may be enhanced by the use of the methods of the other.

Many colleges and universities have a social-psychology laboratory equipped with observation rooms permitting one-way vision of subjects. Sound and video recorders and other devices record ongoing social interaction; computing equipment and other paraphernalia may be employed for specific studies.

Social behaviour is understood to be the product of innate biological factors resulting from evolution and of cultural factors that have emerged in the course of history. Early writers (*e.g.*, William McDougall, a psychologist) emphasized instinctive roots of social behaviour (see INSTINCT). Later research and writing that tended to stress learning theory emphasized the influence of environmental factors in social behaviour. In the 1960s and 1970s field studies of nonhuman primates (such as baboons) drew attention to a number of similarities with human social behaviour, while research in cultural anthropology has shown that many features of human social behaviour are the same regardless of the culture studied. Human social behaviour now seems to have a biological basis and to reflect the operation of evolution as in the case of patterns of emotional expression and other nonverbal communication, the structure of language, and aspects of group behaviour.

Much research has been done on socialization (the process of learning from a culture), and learning has been found to interact with innate factors. An innate capacity for language, for example, makes it possible to learn a local language. Culture consists of patterns of behaviour and ways of organizing experience; it develops over the course of history as leaders and innovators introduce new elements, only some of which are retained. Many aspects of social behaviour can be partly accounted for in terms of their history.

Social perception. In some laboratory experiments, subjects watch stills or moving pictures, listen to tape recordings, or directly observe or interact with another person. Subjects may be asked to reveal their social perception of such persons on rating scales, to give free descriptions of them, or to respond evaluatively in other ways. Although such studies can produce results that do not correspond to those in real-life settings, they can provide useful information on the perception of personality, social role, emotions, and interpersonal attitudes or responses during ongoing social interaction.

The effect of cultural stereotypes

Research has been directed to how social perception is affected by cultural stereotypes (*e.g.*, racial prejudice), by inferences from different verbal and nonverbal cues, by the pattern of perceptual activity during social interaction, and by the general personality structure of the perceiver. The work has found practical application in the assessment of employees and of candidates for positions.

There has also been research on the ways in which perception of objects and people is affected by social factors such as culture and group membership. It has been shown, for example, how coins, colours, and other physical cues are categorized differently by people as a result of their group membership and of the categories provided by language. Other studies have shown the effect of group pressures on perception.

Interaction processes. The different verbal and nonverbal signals used in conversation have been studied, and the functions of such factors as gaze, gesture, and tone of voice are analyzed in social-interaction studies. Social interaction is thus seen to consist of closely related sequences of nonverbal signals and verbal utterances. Gaze has been found to perform several important functions. Laboratory and field studies have examined helping behaviour, imitation, friendship formation, and social interaction in psychotherapy.

Among the theoretical models developed to describe the nature of social behaviour, the stimulus–response model (in which every social act is seen as a response to the preceding act of another individual) has been generally found helpful but incomplete. Linguistic models that view social behaviour as being governed by principles analogous to the rules of a game or specifically to the grammar of a language have also attracted adherents. Others see social behaviour as a kind of motor skill that is goal-directed and modified by feedback (or learning), while other models have been based on the theory of games, which emphasizes the pursuit and exchange of rewards and has led to experiments based on laboratory games.

Small social groups. All small social groups do not function according to the same principles, and, indeed, modes of social activity vary for particular kinds of groups; *e.g.*, for families, groups of friends, work groups, and committees.

Early research on social groups

Earlier research was concerned with whether small groups did better than individuals at various tasks (*e.g.*, factory work), while later research has been directed more toward the study of interaction patterns among members of such groups. In the method known as sociometry, members nominate others (*e.g.*, as best friends) to yield measures of preference and rejection in groups. Others have studied the effects of democratic and aathoritarian leadership in groups and have greatly extended this work in industrial settings. In research on how people respond to group norms (*e.g.*, of morality or of behaviour), most conformity has been found to the norms of reference groups; *i.e.*, to such groups as families or close friends that are most important for people. The emergence and functioning of informal group hierarchies, the playing of social roles (*e.g.*, leader, follower, scapegoat), and cohesiveness (the level of attraction of members to the group) have all been extensively studied. Experiments have been done on processes of group problem solving and decision making, the social conditions that produce the best results, and the tendency for groups to make risky decisions (see ATTITUDES; PERSUASION). Statistical field studies of industrial work groups have sought the conditions for greatest production effectiveness and job satisfaction.

Social organizations. Such organizations as businesses and armies have been studied by social surveys, statistical field studies, field experiments, and laboratory experiments on replicas of their social hierarchies and communication networks. Although they yield the most direct evidence, field experiments present difficulties, since the leaders and members of such organizations may effectively resist the intervention of experimenters. Clearly, efforts to try out democratic methods in a dictatorship are likely to be severely punished. Investigators can study the effects of role conflict resulting from conflicting demands (*e.g.*, those from above and below) and topics such as communication patterns in social organizations. Researchers also have studied the sources of power and how it can be used and resisted. They consider the effectiveness of different organizational structures, studying variations in size, span of control, and the amount of power delegation and consultation. In factories, social psychologists study the effects of technology and the design of alternative work-flow systems. They investigate methods of bringing about organizational change; *e.g.*, in the direction of improving the social skills of people and introducing industrial democracy.

Changes in approach since **1900**

Ways of looking at working organizations have changed considerably since **1900.** Classical organization theory was criticized for its emphasis on social hierarchy, economic motivation, division of labour, and rigid and impersonal social relations. Later investigators emphasized the importance of flexibly organized groups, leadership skills, and job satisfaction based on less tangible rewards than salary alone. There has been a rather uneasy balance in the industrial social psychologist's concern with production and concern with people.

Personality. It is evident that there are individual differences in social behaviour; thus, people traditionally have been distinguished in terms of such personality traits as extroversion or dominance (see PERSONALITY, THEORIES OF). Some personality tests are used to predict how an individual is likely to behave in laboratory discussion groups, but usually the predictive efficiency is very small (see PERSONALITY, MEASUREMENT OF). Whether or not an individual becomes a leader of a group, for example, is found to depend very little on what such personality tests measure and more on his skills in handling the group task compared with the skills of others. Indeed, the same person may be a leader in some groups and a follower in others. Similar considerations apply to other aspects of social behaviour, such as conformity, persuasibility, and dependency. Although people usually perceive others as being consistent in exhibiting personality traits, the evidence indicates that each individual may behave very differently, depending on the social circumstances.

Socialization. The process by which personality is formed as the result of social influences is called socialization. Early research methods employed case studies of individuals and of individual societies (*e.g.*, primitive tribes). Later research has made statistical comparisons of numbers of persons or of different societies; differences in child-rearing methods from one society to another, for example, have been shown to be related to the subsequent behaviour of the infants when they become adults. Such statistical approaches are limited, since they fail to discern whether both the personality of the child and the child-rearing methods used by the parents are the result of inherited factors or whether the parents are affected by the behaviour of their children.

Problems in the process of socialization that have been studied by experimental methods include the analysis of mother–child interaction in infancy; the effects of parental patterns of behaviour on the development of intelligence, moral behaviour, mental health, delinquency, self-image, and other aspects of the personality of the child; the effects of birth order (*e.g.*, being the firstborn or second-born child) on the individual; and changes of personality during adolescence. Investigators have also studied the origins and functioning of achievement motivation and other social drives (*e.g.*, as measured with personality tests; see MOTIVATION).

Several theories have stimulated research into socialization; Freudian theory led to some of the earliest studies on such activities as oral and anal behaviour (*e.g.*, the effect of the toilet training of children on obsessional and other "anal" behaviour). Learning theory led to the study of the effects of rewards and punishments on simple social behaviour and was extended to more complex processes such as imitation and morality (*e.g.*, the analysis of conscience).

The self. Such concepts as self-esteem, self-image, and ego-involvement have been regarded by some social psychologists as useful, while others have regarded them as superfluous. There is a considerable amount of research on such topics as embarrassment and behaviour in front of audiences, in which self-image and self-esteem have been assessed by various self-rating methods. The origin of awareness of self has been studied in relation to the reactions of others and to the child's comparisons of himself with other children. Particular attention has been paid to the so-called identity crisis that is observed at various stages of life (*e.g.*, in adolescence) as the person struggles to discern the social role that best fits his self-concept.

Attitudes and beliefs. Research into the origins, dynamics, and changes of attitudes and beliefs has been carried out by laboratory experiments (studying relatively minor effects), by social surveys and other statistical field studies, by psychometric studies, and occasionally by field experiments. The origins of these socially important predispositions have been sought in the study of parental attitudes, group norms, social influence and propaganda, and in various aspects of personality. The influence of personality has been studied by correlating measured attitudes with individual personality traits and by clinical studies of cognitive and motivational processes; so-called authoritarian behaviour, for example, has been found to be deeply embedded in the personality of the individual. Early research based on statistical analyses of social attitudes revealed correlations with such factors as radicalism-conservatism. Later research on consistency provided extensive laboratory evidence of consistency but little evidence of it in actual political behaviour (*e.g.*, in attitudes on different political issues).

Factors in the origin of predispositionsof individuals

Research on attitude change has studied the effects of the mass media, the optimum design of persuasive messages, the effects of motivational arousal, and the role of opinion leaders (*e.g.*, teachers and ministers). Research has been carried out into the origins, functioning, and change of particular attitudes (*e.g.*, racial, international, political, and religious), each of which is affected by special factors. Attitudes toward racial minority groups, for example, are affected by social conditions, such as the local housing, employment, and the political situation; political attitudes are affected by social class and age; and religious attitudes and beliefs strongly reflect such factors as inner personality conflict.

EDUCATION IN SOCIAL PSYCHOLOGY

Undergraduate courses. Most social psychologists first take a bachelor's degree in psychology or in psychology and sociology. As a branch of psychology, social psychology typically constitutes between **10** and 25 percent of the course of studies (see PSYCHOLOGY). Other course titles that are particularly relevant to social psychology include personality, developmental psychology, animal behaviour, cognition, and psycholinguistics. Practical classwork includes a number of experiments carried out under supervision; students may also carry out an individual project, usually experimental, and on a modest scale. A smaller number of social-psychology students work toward degrees in sociology. Such students receive training in methods of field research rather than in laboratory work.

Graduate courses. Commonly, the graduate student is directed toward a Ph.D. There is often course work of a more advanced character than that for undergraduates; emphasis may be placed on studying journal articles, research monographs, and advanced handbooks, for example, instead of the less specialized undergraduate textbooks. There is an emphasis on the mastery of research techniques and the advanced use of statistics. A primary part of the training (for the Ph.D. especially) typically consists of writing a thesis or dissertation based on a series of original experimental or other studies. This work is done under the guidance of an experienced social psychologist and usually with the additional advice and evaluation of other senior members of the department.

THE PRACTICE OF SOCIAL PSYCHOLOGY

Teaching. Many social psychologists earn their living by teaching in psychology departments of universities and colleges. A smaller number teach in departments of sociology, social science, education, and management. Within psychology departments there may be subgroups or divisions; one division may embrace social psychologists (as well as those in related fields such as the study of personality), and there may be other groups of psychologists concerned with such fields as clinical, experimental, physiological, and comparative psychology. A number of universities have separate departments of social psychology. Social psychologists in psychology departments often maintain strong links with sociologists, as evidenced by the joint degrees offered by some schools.

Research. Most research is done by social psychologists working in university departments; *i.e.*, by university teachers and their graduate students, research assistants, and research workers on fellowships financed by the university or by outside grants from government research councils or from private foundations. There are also research institutes, often connected with universities, whose members do no teaching; well-known examples are the Institute for Social Research at the University of Michigan and the Tavistock Institute of Human Relations in London. These institutes are financed partly by grants from the government and foundations; partly they earn their way by acting as consultants for such clients as industrial firms.

Industry and commerce. A number of social psychologists work for research institutes or firms of industrial consultants who advise companies on organizational problems; *e.g.*, on the organizational or work-flow structure, incentive schemes, or personnel selection and training. Sometimes this service includes social-skills training (*e.g.*, in supervision and in personnel interviewing). One form of training offered (so-called T-group, or sensitivity, training) has aroused some controversy over its effectiveness. While many T-group trainees seem to improve their social skills, others have become emotionally disturbed. A number of social psychologists work in mass communication for advertising, market research, and similar organizations. They make use of research on attitude change and use techniques for ascertaining consumer "images" of products, services, and even people (*e.g.*, politicians) being presented to the public.

Sensitivity, or T-group, training

Government and military. An increasing number of governments throughout the world are employing social psychologists. They work in employment (selection, vocational guidance, training), social surveying, mass persuasion, criminology, mental health, and in the selection and training of civil servants. The military of many countries use social psychologists for officer selection and training and for research on leadership styles, reactions to the stress of combat, and the organization of crews of vessels and aircraft.

SPECIALTIES AND SUBSPECIALTIES

Propaganda and public opinion. Social psychologists are concerned with such aspects of public opinion (social survey) research as the design of standardized interviews and questionnaires. Forms of questions have been devised to compensate for errors that arise from the efforts to respond in a socially approved manner; some are designed to detect lying. Mass communications have been devised on the basis of research into persuasion (*q.v.*). Use is also still made of Freudian symbolism and theory.

Social prychiatry. Research into the causes of mental disorders has shown the importance of social factors in the family and elsewhere. Mental patients often show deficiencies in social performance that may be the cause of other symptoms. Many social psychologists hold that social factors may also apply to such disorders as schizophrenia, which also seem to have hereditary and chemical bases. There has been a corresponding growth in the use of various kinds of social therapy in psychiatry (*e.g.*, group therapy, therapeutic communities, and social-skills training; see also PSYCHIATRIC TREATMENT, CONCEPTS OF).

Industrial social psychology. Considerable research has been devoted to industrial productivity, absenteeism, labour turnover, accidents, and job satisfaction. Factors that have been found to be important include the style of supervision and management, the size and composition of working groups, the technology and the work-flow systems, the span of control, and other features of the organizational structure. Research results point strongly toward the advantages of a less rigid hierarchical structure of authority, with more delegation of authority and consultation, training in supervisory skills, small and cooperative work teams, and interesting and varied work.

Social-skills training. A major application of research in social interaction and group behaviour is in training in social skills, as in the T-groups, or sensitivity training, noted above. Role playing with video-tape playback and training in the imitation of other persons who serve as behavioral models are used in teaching people new skills. Actual training on the job has the advantage that there is no gap between the training and the work itself. All of these methods have been shown to be effective, depending on the job and the teacher. Social-skills training has been given successfully to industrial managers and supervisors, social workers and clergymen, interviewers, public speakers, mental patients, and juvenile delinquents.

Other fields. A great deal of research has been done on factors underlying racial prejudice, but the understanding thus obtained has not had much effect upon the social problems involved. Similarly, the causes of delinquency and crime have been extensively studied, but it is not feasible to manipulate the factors influencing crime, such as genetic factors, methods of upbringing, and inequalities of opportunity. Social psychology has made some contribution to education; sociometry is quite widely practiced as a means of grouping children, and evidence is growing about the optimum styles of teacher behaviour (see MENTAL HEALTH AND HYGIENE).

PROFESSIONAL ORGANIZATIONS

International organizations. Papers and symposia on social psychology are presented at meetings of the International Congress of Psychology and the International Congress of Applied Psychology, both of which meet in different countries every three years. The European Association for Experimental Social Psychology holds conferences every two or three years and arranges a number of smaller working parties and summer schools. Social psychologists from eastern Europe and Israel attend some of these meetings.

National organizations. A number of countries have social psychology sections or divisions of their national psychological associations. In the U.S. there is also the Society of Experimental Social Psychology and the Society for the Psychological Study of Social Issues.

Journals. Major English-language journals covering the field include the *Journal of Experimental Social Psychology* (U.S.), the *Journal of Personality and Social Psychology* (U.S.), *Sociometry* (U.S.), *Human Relations* (Great Britain), the *British Journal of Social and Clinical Psychology* (Great Britain), and the *European Journal of Social Psychology.*

BIBLIOGRAPHY. Excellent general textbooks include EDWIN P. HOLLANDER, *Principles and Methods of Social Psychology*, 2nd ed. (1971); and ROGER W. BROWN, *Social Psychology* (1965). A comprehensive account of research is G. LINDZEY and E. ARONSON (eds.), *Handbook of Social Psychology*, 2nd ed., 5 vol. (1968–69). A useful account of theories in social psychology is MARVIN E. SHAW and PHILIP R. CONSTANZA, *Theories of Social Psychology* (1970). Social psychology approached through detailed analysis of social interaction is described in MICHAEL ARGYLE, *Social Interaction* (1969). A. PAUL HARE, EDGAR F. BORGATTA, and ROBERT F. BALES (eds.), *Small Groups* (1965), is a most useful collection of papers. Research on social psychology in industry is described in BERNARD M. BASS, *Organizational Psychology* (1965). Social behaviour in relation to personality is dealt with in EDGAR F. BORGATTA and WILLIAM W. LAMBERT (eds.), *Handbook of Personality Theory and Research* (1968). *A* so-called symbolic interactionist approach is represented by a large volume of readings: GREGORY P. STONE and HARVEY A. FARBERMAN, *Social Psychology Through Symbolic Interaction* (19'70); and by ERVING GOFFMAN, *Relations in Public* (1971).

(M.Ar.)

Psychoneuroses

Psychoneuroses are patterns of behaviour classed as a major category of psychiatric disturbance; often preferably called neuroses or neurotic reactions. In general, neurotic behaviour is characterized first by its apparently defensive intent (of which the sufferer seems unaware) and by its commonly self-defeating consequences. The diagnosis of neurosis is made on the basis of any of a variety of symptoms, including exaggerated character traits, changes in mood, preoccupations, or untoward fears. Usually, neurotic people suffer from the loss of ordinary feelings of equanimity, happiness, satisfaction, and personal-social effectiveness. Neurotic needs nevertheless can contribute to achievement, and anxiety may serve socially constructive purposes. Indeed, such neurotic symptoms as depressive reactions or compulsive behaviour often are associated with superior intelligence.

Neurotic manifestations are widespread if not universal; the concern they arouse depends on their degree and quality rather than on their mere presence or absence. It is distinctive and critical that neurotic symptoms, such as an exaggerated fear of heights, cannot be banished by the sufferer's immediate effort.

General considerations

The term neurosis came into use at about mid-19th century when psychiatrists commonly held that the symptoms had their origins in neural (nervous-system) disturbances.

Neurosis and psychoneurosis

The prefix psycho- was added toward the end of that century to suggest that some neurotic symptoms had nonphysical, psychic ("mental"), or emotional origins. Over several decades it became popularly accepted that all neurotic patterns were based on psychic phenomena, and efforts to find gross physical (organic) bases in the nervous system were gradually abandoned. Distinctions between neurosis and psychoneuroses blurred, and the terms are now used interchangeably by most psychiatrists.

As compared with psychoses (*q.v.*), neuroses are characterized by minimal loss of contact with popularly accepted views of reality. The neurotic person generally recognizes that his feelings and reactions are inappropriate. He may not be able to recognize, however, that such physiological symptoms of neurosis as skin rashes have so-called mental bases; indeed, he may reject that possibility and seek to prove that they have organic origins.

Neurosis is regarded by most theorists as a form of maladaptation that reflects unconscious conflict (*e.g.*, between one's needs and the restrictions of society). Ordinarily less severe than psychosis, neurotic behaviour can lead to psychotic reactions; with sufficient improvement, neurotic symptoms may return.

GENERAL THEORIES OF THE ORIGINS OF NEUROSES

Anxiety and conflict

Nearly all modern authorities relate neurotic symptoms to anxiety, to attempts to avoid anxiety, and to internal (intrapsychic) conflict. Fear is a response to external danger (*e.g.*, a poisonous spider) and roughly reflects the degree of threat one perceives. While anxiety is a similar apprehensive feeling, it occurs in response to unknown, or at least unclear, hazard; *e.g.*, one is uneasy without knowing why. Anxiety is an experience common to mankind; being a terribly uncomfortable feeling, anxiety is generally avoided in every way possible, often through the development of neurotic manifestations.

While conflict may be conscious or unconscious, most theories of neurosis stress the latter. Conflict is said to occur between instinctual forces (which make up what is called id by psychoanalysts) and the inhibiting pressures of conscience (superego in psychoanalytic language) and the constraints of the environment.

According to psychoanalytic theory, the resolution of conflicts is sought through pressures brought to bear on the id and superego by the reality-oriented part of the personality called the ego, which tends to reconcile and compromise the opposing forces. Ego is said unconsciously to utilize so-called defense mechanisms in attempts to cope with conflict. Well-known ego-defense mechanisms have become part of ordinary language and include rationalization and compensation. The latter, for instance, is the process through which, many believe, one unwittingly attempts to make up for his perceived inadequacy by developing other attributes. Thus, in an aggressive person, aggressiveness may be a compensation for feelings of inferiority about his height or attractiveness or intelligence. There is a consensus that when ego defenses prove to be insufficient, so-called neurotic symptoms evolve as a further defensive endeavour by the person in conflict. Such dynamic or analytic views have been espoused by many psychiatric workers in the United States, with varying but lesser support in the United Kingdom, western Europe, and in most other parts of the world (where physiologic interpretations also enjoy support). In the Soviet Union the principles of learning or conditioning are widely invoked to account for psychiatric disorders including the neuroses. These stress the role of the nervous system in reflex conditioning. In this context, it is denied that neuroses constitute any form of "mental" illness; neurotic persons are not held to be "sick." Instead, they are said to have "learned" self-defeating habits that may be broken (rather than "cured") through retraining. Such theories explain the development of neurosis as direct responses to stress or as the result of a sensitization process in dealing with life problems. In general, these two theories, the psychoanalytic and the reflex-learning, are the dominant views in this field, with the former considerably more widely held in Western countries.

Neuroses as learned patterns of behaviour

PREVALENCE

Symptoms of neuroses appear to be universal or nearly so; most people at some time are likely to develop one form of neurotic manifestation or another. Symptoms warranting medical-psychiatric treatment, however, can be expected sooner or later in one out of every three or four persons.

Specific ethnic or national backgrounds do not seem to be strongly predisposing factors; neither is one's sex. A person's age, however, does seem to be related to neurotic tendencies since during one's life cycle there are specific times of added stress. Some of these in childhood include the death of a parent or other close associate, changing residence or school, puberty and the onset of menstruation, and such frightening events as sexual assaults. Emotional hazards later in life may stem from marriage, divorce, menopause, vocational and military experience, and senescence. The intensity of stress or conflict generally is increased at such times, and one's vulnerability to neurosis becomes accordingly greater.

GENERAL APPROACHES TO TREATMENT

In psychoanalytically oriented psychotherapeutic efforts to treat neuroses, the sufferer is expected to gain understanding (insight) into the psychic origins of his symptoms through talking and thinking about himself with the help of a therapist. Sufficient insight is expected to lead to enduring relief, when the patient finds that his symptoms are no longer necessary to defend against conflict and that he can surrender them in favour of more constructive activity. Psychotherapy more superficially also may include suggestion, advice, or hypnosis. A growingly popular approach to neurotic disorder is through retraining or reconditioning (sometimes called behaviour modification). A considerable number of physicians use drugs and other physical methods (occasionally electroshock) in managing a wide variety of neurotic symptoms, including anxiety and depression. Less technical efforts may be inspirational or religious, variously based on admonishment, encouragement, or even punishment.

Neurotic reactions

ANXIETY REACTIONS

Anxiety reactions are estimated to comprise 12 to 15 percent of the psychoneuroses seen in medical practice and may be conveniently distinguished as acute anxiety attack, anxiety-tension state, and anxiety neurosis. These distinctions are made to describe the extent, intensity, and duration (chronicity) of the sufferer's distress. In advanced countries, about 1 in every 400 people suffers significant disability from anxiety reactions.

Acute anxiety attack

The acute anxiety attack is a dramatic and intense episode in which the victim may show panic and be temporarily incapacitated. Typically appearing abruptly and without obvious warning, the attack is marked by signs of extreme apprehension or dread and by bodily symptoms such as sweating, pallor, and changes in heart rate. It is usually short-lived, the most intense manifestations continuing less than an hour. An acute anxiety attack may be an isolated event or, for particularly vulnerable peopie, a series of them can occur at varying intervals. Because of its dramatic nature and the briefly severe disability exhibited, it is not infrequently mistaken for a serious organic disorder such as a heart attack. Physical bases for such episodes may be presumed and actively sought, although psychiatric workers may hold the precipitating events to be psychic and unconscious and to be susceptible only to psychotherapy. The victim comes to fear such episodes and may even avoid places where he has experienced prior attacks. Acute anxiety attacks of some severity may be experienced by 1 to 3 percent or more of the general population at some time in their lives. While dread of subsequent attacks can be substantial, the predicted outcome (prognosis) is generally good; attacks will abate with no formal treatment.

By comparison, the anxiety-tension state is a less intense (subacute), more continuous anxiety reaction, although still considered to be limited in duration. Signs of anxiety, tension, and accompanying bodily changes seem to be precipitated by situational (environmental) stress and to be eased by reduction in stress; for example, anxiety-tension states are likely to be observed among soldiers in combat. When it is possible to remove the individual from battle or other environmental stress, the symptoms will not subside all at once; improvement may occur over several weeks or longer. As long as tension and anxiety continue, bodily functions may be disturbed (*e* g., digestive upsets, increased perspiration, headaches, pounding heart). 'There are wide differences among individuals; the same environmental stress that brings on subacute anxiety in one person may leave another relatively undisturbed and disable still another.

Anxiety neurosis

The anxiety neurosis is distinguished from other anxiety reactions by its relatively chronic nature. Otherwise. the sufferer reports the usual subjective experiences of anxiety and exhibits an array of typical bodily signs. Such secondary physical effects tend also to be subacute and prolonged (*e.g.*, chronic indigestion or high blood pressure). These can seem so dominant that the sufferer and the diagnostician may fail to recognize them as neurotic signs. The neurotic person himself, often unwittingly, directs attention away from any underlying anxiety.

Indeed, the clinical manifestations of anxiety neurosis are almost legion. Psychomotor symptoms include lestlessness, muscular tension, and a tendency to jump or be startled at the slightest unexpected stimulus. Perceptual-rational functions, particularly the ability to concentrate and to solve problems in logic, tend to be impaired. Physiologic signs include palpitation of the heart, weakness, headaches, and sexual impotence or frigidity; there may be evidence of emotional changes such as heightened irritability and decreased ability to show love or affection. Alterations in appetite can lead to obesity or underweight; insomnia is not infrequent. The person may describe what he calls feelings of fear, dread, panic, nervousness, apprehension, anxiety. or uneasiness; nevertheless, he cannot explain the real bases for these.

Anxiety reactions may be interpreted as arising through mechanisms of learning and reinforcement. In the more elaborate psychoanalytic interpretation of the anxiety reactions, psychic defenses are said to be mobilized against the experience of anxiety but to be poorly organized and relatively ineffective. It is suggested that the resulting symptoms may represent unconscious compromise, that while symbolism influences symptom "selection," its role is less prominent than in other types of neurosis. In general it is theorized that when some unwanted, forgotten (repressed) experience "buried in the unconscious" threatens to emerge into awareness, feelings of anxiety signal the hazard.

The prognosis in anxiety reaction is moderate to good; controlled studies reveal that roughly 70 percent of sufferers can improve even without treatment. When tranquillizers are used, more than 95 percent of these people secure some relief. The effectiveness of psychoanalysis or other forms of insight psychotherapy is endorsed by many authorities and challenged by others.

DISSOCIATIVE REACTIONS

Dissociative reactions comprise a large group of disorders that are generally classified with the neuroses. Dissociation generally may be understood as a process in which a limited aspect of human function becomes split off (dissociated) from the mainstream of activity. The concept of dissociation includes several reactions in which a portion of the personality seems to operate more or less independently; the consequences may include amnesia (in which certain aspects of the function of memory are said to have become dissociated).

The process of dissociation is widespread, and evidence for it seems to be uncovered in studying many neurotic people. Instances in which a dissociative process constitutes the most prominent feature of a neurosis are relatively rare, however; 2 to 4 percent of all cases of neuroses are estimated to be of this kind.

Sleep-walking

Normal dreaming can be considered dissociative since it occurs outside of ordinary consciousness, beyond voluntary control, and since it comprises activities that clearly are split off from one's usual awareness. Dreams can be disturbing or can indicate psychiatric disturbance. Somnambulism (sleepwalking) can be similarly viewed since it involves movements that are dissociated from the mainstream of consciousness.

Depersonalization (in some classifications considered to be a separate category of neurosis) is experienced as feelings of dissociation or unreality; the victim may report that his own experiences of the environment around him seem unreal. Such feelings are not uncommon and have long been recognized, but the term depersonalization came into widespread use only in the latter part of the 19th century. A related experience is that of déjà vu, in which one inaccurately feels that he has earlier had the same experience. One theory is that depersonalization reflects one's desire to escape from reality. This symptom complex may be induced with such drugs as mescaline and LSD.

Fainting is a temporary loss of consciousness; in some cases it map be interpreted as an unwitting neurotic dissociation from otherwise intolerable circumstances. Fainting of course has its physical basis, as in reduced blood circulation in the brain. There are different origins for amnesia; some forms can be induced by suggestion under hypnosis and others from gross injury such as brain concussion. Psychologic-emotional amnesia reflects the involuntary banishment of otherwise intolerably painful memories or experiences (see MEMORY, ABNORMALITIES OF).

Fugue

The fugue state is a major dissociative activity characterized by loss of memory and by flight from one's usual environment. The fugue may have physical origins (*e.g.*, in epilepsy) or may represent a drastic and involuntary neurotic escape from intolerable conflict. The victim may wander about, perhaps in a strange city or in other unfamiliar surroundings, sometimes in an aimless or confused fashion for days, weeks, or longer. On occasion he may carry on fairly well, unsuspected by others in his new role or identity. On recovery, memory for events of the fugue period is generally poor.

Rare instances of alternating or multiple personality occur in which one portion of the "mind" or "psyche" becomes dissociated and takes over to function independently, producing what seems to be a behaviorally different person. This can continue for months or years; instances of this extremely rare disorder have led to such literary classics as ***The*** Strange Case of Dr. *Jekyll* and *Mr. Hyde* (1886). Automatic writing, in which one's hand seems to write independently of his thoughts, can be induced through suggestion; in hypnosis of sufficiently suggestible people, any part of the "self" may be made to dissociate, take over, and act under the direction of the hypnotist.

PHOBIC REACTIONS

The word phobia comes from the Greek phobos, meaning dread, panic, or fear; among neuroses, phobias are specific fears out of proportion to the apparent stimulus. According to psychoanalytic theory, the painful feelings have become displaced from their internal and unconscious bases to become attached to a specific external situation or object. At any rate, a phobia is an obsessively persistent kind of unrealistic fear that seems inappropriate and unreasoning. It has become traditional to give phobic reactions names that indicate the object or situation feared. Theoretically the list of phobias could be endless; since some people fear specific numbers (*e.g.*, 3 or 7), the potential for specific number phobias (numerophobias) might be infinite. Some commonly encountered phobic reactions are listed in the accompanying Table, according to their technical names, objects, and derivations.

Common Phobic Reactions

Acrophobia	height (Greek *akra*, heights or summits)
Agoraphobia	open spaces (Greek *agora*, market place, the place of assembly)
Ailurophobia	cats (Greek *ailouros*, cat)
Anthophobia	flowers (Greek *anthos*, flower)
Anthropophobia	people (Greek *anthropos*, man, generically)
Aquaphobia	water (Latin *aqua*, water)
Astraphobia	lightning (Greek *asteropē*, lightning)
Bacteriophobia	bacteria (Greek *bactēria*, small rod)
Brontophobia	thunder (Greek *brontē*, thunder)
Claustrophobia	closed spaces (Latin *claustrum*, bar, bolt or lock)
Cynophobia	dogs (Greek *kynas*, dog)
Demonophobia	demons (Latin *daemon*, demon)
Equinophobia	horses (Latin *equinus*, horse, adj.)
Herpetophobia	lizards or reptiles (Greek *herpetos*, a creeping or crawling thing)
Mysophobia	dirt, germs, contamination (Greek *mysos*, uncleanliness of body or mind; abomination or defilement)
Numerophobia	a number or numbers (Latin *numeri*, numbers)
Nycotophobia	darkness or night (Greek *nyx*, night)
Ophidiophobia	snakes (Greek *ophidion*, snake or serpent)
Pyrophobia	fire (Greek *pyr*, fire)
Spatiophobia	self-confining phobia; phobically imposed area or spatial restrictions; often gradually, occasionally rapidly, progressive (English space)
Zoophobia	animals (Greek *zoos*, animal)

A psychiatric diagnosis of phobic reaction is likely to be made when one shows specific handicapping or self-defeating fear that is out of keeping with the danger as assessed by the diagnostician. While phobic attacks are not uncommon in childhood, many of these tend to subside spontaneously. Phobias can develop at any age, and the ease with which they respond to therapeutic efforts varies widely with their complexity and with the method of treatment used.

There is some support for the hypothesis that phobic behaviour can be learned. Encouraging reports of therapeutic success in eliminating phobias have come from practitioners and researchers who seek to help the sufferer unlearn his apparently illogical fears. It is not necessarily valuable for a claustrophobic, for example, to recall after months or years of effort, in analysis, that he once accidentally was locked in a closet when he was two years old and for him to say that he understands this traumatic event to have produced his phobia. Usually the phobia is lost following significant recall—abstraction along with real insight. In some cases, the chances of relieving his symptoms within a few weeks seem to be substantially enhanced if methods of behaviour modification (retraining, reconditioning) are used. In this particular case, the technique may be to have him relax comfortably in a large room at first and then to move him through a series of smaller and smaller rooms until he has learned to associate his feelings of relaxation with the same kinds of small spaces that once evoked feelings of panic.

Psychoanalytic theorists consider the phobic object as an external representation of unconscious bases for fear and that one's "selection" of a phobic object is an unwitting process determined through symbolism or circumstantial influences. Thus, a child who has attacks of fear when he sees white horses may eventually learn through analysis that the horses symbolize his father, for whom he holds an unconscious (but unacceptable) fear.

OBSESSIVE-COMPULSIVE REACTIONS

Obsessive-compulsive reactions are a group of neuroses marked by the repetitive intrusion of ideas, impulses, or behaviour that the sufferer finds consciously unwelcome. The subjective activity is called obsessive; the objective behaviour is compulsive. Freudian theorists write that these intrusions evolve unwittingly and with defensive intent in one's attempts to allay or to prevent anxiety, to which the obsessive person is very vulnerable. Psychoanalytically, the aim of the obsessive intrusion also can be viewed as that of maintaining or reinforcing repression. By contrast, behaviour theorists maintain that the reactions are undesirable habits that developed from unfortunate learning experience.

Kleptomania

Often included with the obsessive-compulsive reactions are socially undesirable manifestations referred to as impulsions, including exhibitionism (extreme attention seeking), kleptomania (compulsive stealing, for other reasons than the intrinsic value of that which is taken), pyromania (the compulsive setting of fires on neurotic bases), and voyeurism (peeping-tom behaviour).

Examples of obsessive disorders are common, comprising about 10 percent of the neuroses encountered by therapists. Some of these are so severe as substantially to cripple the person, but less serious obsessive-compulsive symptoms are widely observable throughout the world (*e.g.*, minor mannerisms such as ear pulling, eyebrow raising, and finicky cleanliness or dress).

Obsessively oriented people are more likely to be reserved, finicky, and conforming, exhibiting inhibition, indecision, control of hostility, and exaggerated feelings of guilt and responsibility; sexual maladjustments are frequent.

Obsessive activity can run the gamut from intrusive and unwelcome thinking about harming someone (*e.g.*, urges to injure a child or spouse) to preoccupation with musical themes or prayers or recurrent ideation (*e.g.*, profanity) that the neurotic individual finds to be personally repugnant. Compulsive behaviour can include repetitive hand washing and so-called compulsive security rituals ("making-sure" routines) such as repeated list making, door locking, switch checking, making amends, or counting supplies of money. What are called attitude-symptoms include perfectionism, obsessive interest at cleanliness, supermoralism, obsessively pervasive criticism of others, social withdrawal, and general inhibition of emotional expression. In seeking to protect himself from threat, the neurotic may become obsessed with keeping people at arm's length. Such a person is likely to have a low level of self-esteem and may manifest a preoccupation with the smallest details of his work.

Compulsive rituals

Obsessive predispositions of adults seem to originate in infancy and childhood and to stem from the vicissitudes of personal relationships with others. Frequently there is evidence of early parental overemphasis on control of expressions of anger and hostility, the child's behaviour being manipulated through his fears of rejection. Compulsive rituals among such individuals tend to become more complex than their antecedents (*e.g.*, the usual childhood rites of avoiding pavement cracks or touching every third fence post). The subsequent behaviour may include hair-brushings far beyond the number needed, repetitive telephoning, and compulsive talking that effectively keeps others from saying any words that might provoke anxiety; it is as though the obsessive-compulsive person can never really feel secure.

When obsessive-compulsive symptoms are generalized and complex, response to any form of psychotherapy (*e.g.*, behaviour modification or psychoanalytic insight) can be slow and difficult. While the persistence, concern with detail, and conscientiousness of such persons are assets in any therapeutic endeavour, their inhibitions, restrictions of emotionality, and continuing security rituals delay and slow the process.

DEPRESSIVE REACTIONS

Depression as a major symptom of neurosis refers to lowered spirits, undue sadness, dejection, or melancholy.

The depressed mood appears out of proportion to any loss or injury as objectively evaluated (see EMOTION).

Suicide

Frequently observed in some degree in many psychotic disorders, depression also can appear in neurotic syndromes as the most prominent symptom. There is a relatively high frequency of neurotic depression among the more sophisticated, educated, mature, and intellectually favocred groups of people, the disturbance tending to be most common in middle age. One consequence is that the rate of suicide in Western countries is greatest between the ages of 35 and 75 years, with a peak at about 55. Depressive reactions are estimated to comprise about 14 to 18 percent of instances of neuroses observed in psychiatric practice

Symptoms include lack of ambition, withdrawal, decrease in interests, restricted social activity and interests, a pessimistic or even hopeless outlook, and bodily accompaniments of low spirits; the latter can include fatigue, aches and pains, constipation, and appetite and weight loss. Coldness of the hands and feet is not infrequent, as are difficulties with sleep (especially dawn insomnia, so termed because of a difficulty in -remaining asleep as dawn approaches). All types of emotional, intellectual, motor and physiologic activity tend to be slowed as the severity of depressive reaction increases.

Some theorists interpret neurotic depression as arising from an inabiiity consciously to cope with hostility, sometimes describing it as a "frozen state of rage." The dynamics of such depression are held not to be simple or superficial matters, and their working out during insight therapy is seen to require a great deal of patience and determination on the part of sufferer and therapist alike.

Some forms of depressive reaction are seemingly paradoxical; one type can follow the achievement of a long-sought goal and has accordingly been named the depression of success; the so-called promotion depression occasionally follows a long-awaited advancement. There are also situational or reactive depressions that follow clear-cut disappointment or loss. Anxious depression apparently arises when the defensively evolved and unwitting symptom of melancholy is not sufficient protection against anxiety.

intensive psychotherapy in neurotic depressions often is followed by improvement, although the process is slow. Suicide is a hazard in severe depressive reactions. More rapid response is sometimes produced with mood-elevating drugs and in some instances of psychotic depressions with electroshock therapy.

CHARACTER REACTIONS

Character neurosis is a reaction in which normal personality traits known as character defenses become exaggerated to the point of personal handicap and self-defeat. Their evolvement is an unwitting defensive process each person undergoes in his personality growth. When such normal character traits become overdeveloped, they may not be readily apparent but are considered roughly equivalent to the overt symptoms (*e.g.*, obsessive or depressive) evolved in other types of neurosis (sometimes termed symptom neuroses because the symptoms are the clinically prominent manifestations).

Manifestations of the overdevelopment of any character trait are often largely subjective and may become apparent only through therapeutic study. Major categories of character neurosis (constellations of exaggerated personality traits) include the obsessive personality, the conversion personality, and the depressive personality.

The obsessive personality is characterized by such traits as orderliness, restricted emotionality, resistance to change, meticulousness, ovirconscientiousness, tendency to worry over responsibilities, self-doubts and feelings of inadequacy, overconcern with detail, intellectualization, pessimism, and sexual inhibitions. His intelligence is likely to be high, and he well may have superior capabilities for a particular business, artistic, or professional pursuit.

Needs for attention

The conversion personality is marked by strong, shifting emotional activity, susceptibility to suggestion, tendencies toward dependency and helplessness, and strong needs for attention. Mature sexual adjustment rarely is achieved, but such a person is likely to be responsive, appealing, warm, imaginative, and flexible. While his mood may swing rapidly, he is in good spirits frequently; he is likely to be more buoyant than are persons with other types of character neurosis.

The depressive personality is marked by overseriousness. by a restricted sense of humour, and often by low spirits. He tends to be studious, overconscientious, and has unusual vulnerability to disappointment, frustration. or loss. He tends to be highly dependable, responds poorly to hostility, but has an excellent capacity for work, application, and long-term endeavour. Readily assuming responsibility, he tends to be overly straitlaced, and his levels of intelligence, ability, and potential for achievement typically are high.

Efforts to treat character reactions psychoanalytically may involve so-called character analysis, in which inquiry and study of the individual's personality traits or defenses are undertaken. The therapist and the neurotic person together seek to elucidate and resolve the sufferer's conflicts that contribute to his elaborate character defenses. This comprises a personal educational process of some depth that some authorities feel can be useful for nearly anyone. The personality traits of the individual are enlisted in treatment; his persistence, application, and conscientiousness are applied to his work and his collaboration in the therapeutic process.

Estimates are that character reactions comprise from 16 to 20 percent of all neuroses. Their recognition is hampered by the relative absence of obvious symptoms as encountered in symptom neuroses. Their pervasiveness and their profound effects on the life, satisfactions, and happiness of the individual concerned nevertheless make their recognition and therapy of considerable moment.

FATIGUE REACTIONS: NEURASTHENIA

Emotional fatigue refers to weariness produced by psychic factors rather than from such activities as muscular exertion. It arises from continued emotional stress and tension that stem from inner conflicts. Evidence for emotional fatigue is to be found in a discrepancy between how tired a person feels and how much effort he has been exerting. If one is in good health, has been getting enough rest, and still complains of marked weariness, this provides presumptive evidence of the fatigue reaction. Such neurotic reactions, in which the most prominent feature is emotional fatigue, once often were associated with the term neurasthenia.

Neurasthenia, as described in the latter half of the 19th century, was a widely inclusive syndrome: since then its popularity as a diagnostic term has fluctuated widely. For decades neurasthenia was a catchall for many neurotic and even psychotic manifestations. Nearly abandoned in most quarters, this term was again gaining a more specific definition and growing currency by the 1970s.

Features of neurasthenia include dependency, self-absorption, preoccupation with physical problems, a tendency toward regression, and attenuated interaction with others. Emotional features include difficulty in concentration, irritability and tension, problems with memory, detachment, feelings of inferiority, and lowered spirits. Impairment of sexual function is prominent. Physical features of neurasthenia are especially likely to include fatigue, feelings of weakness, headache, and insomnia; shifting bodily symptoms can be indigestion, heartburn, loss of appetite, rapid heart rate, and varicus aches.

Sexual origins

Neurasthenia once was attributed to sexual origins (*e.g.*, frustration and masturbation), views held by many psychiatrists into the 20th century. It is now wideiy agreed that these manifestations have many other bases as well. The consensus is that sexual difficulties often are secondary to otherwise hidden conflicts that also underlie such symptoms as weakness and fatigue. Mood-elevating drugs are widely employed in managing neurotic disorders of this kind. Psychotherapeutic measures include efforts to help the person cope with feelings of hostility, to deal with unconscious dependency needs, and to selectively maintain repression of conflicts.

While chemical therapies are useful, the effectiveness of psychotherapy in neurasthenia or fatigue reaction depends on hcw chronic the symptoms have been and on the person's motivation and ability to cooperate. Emotional fatigue is frequently encountered in ordinary medical practice and may yield to drug therapy; at any rate, any psychologic basis often goes unrecognized. Instances of major neurotic disordei in which emotional fatigue is the outstanding feature are far less freouent, an estimated 3 to 4 pcrcent of neuroses being called fatigue reaction; the figure is somewhat higher when use of the older and broader category of neurasthenia is included.

HYPOCHONDRIACAL REACTIONS

The term hypochondriasis is derived from a Greek word meaning under or below the rib cage, a frequent site for symptoms of the disorder. The reaction is marked by a persistent overconcern with health, in an obsessive kind of preoccupation with bodily functions. Uncomfortable feelings may appear anywhere in the body and may shift from one part to another. Observable signs of physiologic disorder or disease are insufficient to account for the person's reports of pain and discomfort or for the !eve! of his concern. An alternative term, hygeiaphrontis (hygeia, "health," and *phrontis*, "anxious concern about," both from the Greek), more accurately describes the symptoms.

Reactions that fit well into the category of hypochondriasis (or hygeiaphrontis) include about 3 to 5 percent of the major neurotic complaints encountered. Preoccupation with health can become so neurotically pervasive in hypochondriasis that the person suffers considerable pain or other discomforts. Unfortunately he not infrequently is certain that organic disease is present (although these is none), an often troubling barrier to initiating psychotherapy. A wide variety of discomforts can occur on a hygeiaphrontic basis, sometimes simply representing an increased awareness of normal function. At other times, functional change (*e.g.*, indigestion) car occur through stress or conflict, sometimes with implications of symbolism. Thus, "I am sick" can have figurative meanings; one may feel "sick" of his work situation, of his marriage, or of another relationship. At times the figurative csn carry over into the literal expression of illness. This is reflected in many other common figures of speech, such as "He gives me a pain in the neck," "That situation was a headache," or "I can't stomach that professor "

Hygeiaphrontic manifestations are rarely seen in conjunction with serious organic disease, but accompany many instances of emotional disturbance. The diagnosis is best made on positive evidence of psychic origins rather than by exclusion of organic illness. The prognosis for treatment is most variable; results are sometimes very good. In many other cases, despite the best efforts of experienced therapists, hypochondriacal symptoms may persist until the sufferer's last days.

CONVERSION REACTIONS: HYSTERIA

In conversion reactions or hysteria, elements of an inner, emotional conflict and its consequences are converted into external expression through bodily, physiologic mechanisms in the form of many eymptoms the most severe of which con include blrndness and paralysis. Since symptoms of this sort can serionsly hamper daily activities, conversion reactions were among the earliest neurotic disorders to be so recognized and enjoy a position of historical precedence.

Ancient Greek medical writings state that such symptoms derive from the wanderings of the uterus (womb) within the body; their word for this female organ (*hystera*) provides the root for the term hysteria. Widely held contemporary accounts of the origins of hysteria are apt to draw on psychoanalytic theory and on modern understanding of how brain function affects activities in other parts of the body. Psychoanalysts posit that an ego-defense mechanism (an unconscious process they call conversion) acts to produce the signs of hysteria as disguised expressions of intrapsychic conflicts that otherwise would give rise to anxiety. Consciously disowned ideas and associated emotions, plus the psychologic defenses against them, are said to be transmuted or converted so as to secure a measure of outward expression in bodily or sensory symptoms. Psychoanalytically, the conversion reaction is understood generally to symbolize factors involved in repression and to exact a certain toll of self-punishment (to atone for the repressed. unacceptable needs or drives). Theorists of a more heavily neurologic orientation are likely to replace such terms as intrapsychic conflict and repression with the more mechanistic language of biochemistry and physiology, attributing hysteria to physical changes within the brain. Neither the neurologic nor the psychoanalytic view excludes the other, however: indeed, they may prove to be different ways of talking about the same set of phenomena.

Conversion reactions may be divided into those that are somatic (bodily) and those that are functional or physiologic, the latter including or overlapping with psychosomatic and somatization reactions. With the two grouped together, conversion accounts for an estimated 15 percent or more of neurotic reactions encountered, physiologic conversions far outnumbering the somatic. Younger and less sophisticated people are most subject to conversion reactions; indeed, perhaps gross somatic conversions are less frequent than they once were because their underlying emotional bases have become more clearly understood by ordinary people.

Neurotic deafness

Symptoms in hysteria or conversion reactions can simulate those of almost any kind of organic illness. Conversion pain is not infrequent and can affect any part or region of the body; major symptoms also can include deafness, spasms, cramps, tics, losses of tactual sensation, and othei behavioral disturbances. Despite the severe disabilities and limitations that conversion symptoms can produce, the attitude of persons so afflicted can seem paradoxically indifferent. Almost characteristic of somatic conversion, this feature is called in French *la* belle *indifférence* ("the beautiful indifference"); it is as if the symptom is protecting the person from experiencing anxiety. He is quite indifferent to its extent, limitations, the sacrifices entailed, and handicap.

It is most distinctive of hysteria that such symptoms as blindness and paralysis can be at least temporarily abolished by suggestion while the sufferer is under hypnosis (*q.v.*). The prognosis with educationally oriented psychotherapy is generally good in young people whose conversion symptoms are less fixed and chronic and when they are not the sole neurotic manifestation. Encouraging reports have been published concerning the effectiveness of behaviour modification or re-education (*e.g.*, with rewards or punishments such as electric shocks). Additional more superficial treatment methods that have been used with varying efficacy include various types of direct suggestion without hypnosis, reassurance, threats or trrckery, and supportive measures.

RELATED DISORDERS

Neuroses following trauma (or harmful experience). Alternatively termed traumatic reactions or traumatic neuroses, these are disorders that show a distinct relationship to such trauma as a bodily injury or an emotionally stressful experience.

Responses to a given harmful experience vary widely from person to person; subsequent emotional effects are often unpredictable. Sometimes, limping may persist years after a broken ankle has mended. If the disability is functionally disproportionate to the structural impairment, it represents a distinguishing feature of traumatic neurosis. In a broad sense all emotional disorders might be regarded as ultimately traumatic in origin. Symptoms follow the pattern of other neurotic reactions, the most frequent being those of the anxiety, conversion, and hypochondriacal patterns. A distinguishing feature is the sharpness of the precipitating event (trauma), without which it is believed the neurotic reaction would not have occurred. It is widely held that pre-existing psychic factors influence the form and character of symptoms in the traumatic reactions as in any type of neurosis.

Typically in such cases an injury is followed within a period of days or months by the onset of a variety of symptoms that are out of proportion to what one might ordinarily expect from the injury alone. The neurotic victim himself is usually certain that a direct cause-and-effect relationship exists between the injury and his symptoms. Since such behaviour is even more frequently encountered among victims of industrial accidents, the potential economic gains for the victim may lead some to confuse neuroses with malingering (feigned illness).

The prognosis in traumatic reactions varies widely and is related to the chronicity, fixation, and duration of the symptoms, as well as to their meaning to the individual who suffers them. Psychotherapy is not invariably beneficial, especially when the sufferer fails to cooperate actively.

Soterial reactions. Essentially the converse of phobic reactions, in soterial behaviour an external object, situation, or person becomes the source of feelings of comfort, security, and well-being that seem objectively out of proportion. An adult, for example, may habitually go to sleep clutching the teddy bear he first owned as a child. The soterial object (from the Greek *soter,* "saviour") counters fear and anxiety by stimulating feelings of salvation, solace, preservation, and safety.

Since soterial objects help to abort experiences of dread or threat, they are rarely a basis for complaint; soterial persons seldom seek assistance and are apt to come to the therapist's attention only when their behaviour is a source of distress to others.

The "choice" of a soterial object is practically unlimited; examples include money, special foods, people, locales (*e.g.*, the physician's office), rituals and procedures, prayers, religious objects, talismans, and drugs. Compensation pensions and even symptoms of disability or illness can secure soterial significance. Deprivation of a soterial object provokes resistance and anxiety; the neurotic individual who uses milk as a security food, for example, may become frantic without it.

In the treatment of soterial reactions, symptom resolution is readily obtained through reconditioning and other forms of behaviour modification. Therapists of a psychoanalytic bent interpret remission of symptoms as a limited goal and seek to trace the unconscious antecedents of the symptoms.

Military reactions. While various types of neurotic reactions are evolved under the stresses of military conditions, the term military reactions delineates those that develop during operational (*e.g.*, combat) situations. Alternative designations include combat fatigue, combat exhaustion, effort syndrome, acute situational reaction, and operational fatigue. In World War I, shell shock was a prominent diagnosis, based on the assumption that the shock of exploding ammunition affected the nervous system.

Shell
shock

What one man tolerates well under military stress can prove overwhelming for another. In acute combat reactions, prominent symptoms include psychomotor expressions of anxiety (*e.g.*, tremors), sleep disturbances, restlessness, exaggerated tendency to startle, and such bodily manifestations as heart palpitation and increased perspiration. Conversion symptoms such as headache, fatigue, backaches, and functional cardiovascular and gastrointestinal symptoms are frequent. There may also be signs of depression, guilt feelings, withdrawal, apathy, and scattered amnesia. The battle dream is a frequent and outstanding feature; irritability is quite common and sometimes leads to destructive behaviour.

Manifestations of military reactions gradually subside following the victim's removal from stress. If stress has been particularly intense or prolonged, remission of symptoms can be long delayed. Factors that influence susceptibility to combat stress include the individual's prior adjustment and emotional stability, the adequacy of his military training and his leaders, the level of his morale, and the degree to which he and his comrades suffer exhaustion or defeat. Treatment in acute combat and military reactions above all demands removal from the stress of war. Beyond this, the provision of adequate rest, reassurance, food, sleep, shelter, supportive psychotherapy, and judicious sedation can be quite beneficial.

Additional terms and concepts. ***Psychophysiologic disorder.*** A more recent term, psychophysiologic disorder describes reactions marked by the morbid bodily expression of emotions. It is akin to psychosomatic illness, somatization reaction, and physiologic conversion, all of which label significant overlapping concepts that stress the wide potential for bodily and visceral expression of psychological disturbance.

Somatization reactions. This term also covers functional and physiological symptoms held to evolve as expressions of emotional conflict. The concept of somatization stresses the principle that any type of functional disorder of the body can be based upon or contributed to by emotional stress and tension. Subtle, progressive functional changes stemming from emotional factors can produce structural alternations such as skin rashes, as in hives. This inimical sequence can progress to organic pathology sufficient to require medical intervention (*e.g.*, skin lesions that may be managed with hormone salves or creams).

Psychosomatic illness. This related diagnostic label emphasizes the interaction of physical (somatic) and emotional (psychologic) aspects in generating serious physical illness; noteworthy examples include asthma and allergic disorders, gastric ulcers, forms of high blood pressure, some heart attacks, endocrine gland disorders, inflammation and ulceration of the colon, and arthritis.

Asthma

Impulsive reactions. This diagnostic term is akin to the character or personality disorders, patterns of responses that are in varying degree socially disapproved and that are accompanied by minimal evidence of anxiety. The more common impulsions include exhibitionism, kleptomania, pyromania, and voyeurism. At times impulsive gambling, drug addictions, and dipsomania (craving for alcohol) are so included.

Impulsions are characterized by repetitive efforts to carry out socially disapproved or unlawful actions and as such often are considered a subtype of the obsessive-compulsive reactions. More or less characteristic are evidences of minimal discomfort, unconscious satisfaction, resistance to therapy, concealed hostility, and defiance toward society.

Psycho-
pathic
personality

Psychopathic personality sometimes is used to refer to a type of antisocial reaction characterized by impulsive and irresponsible behaviour that is accompanied by unstable emotional and social adavtation. Psychoyathic individuals seem poorly to anticipate the social consequences of their acts, appear to lack conscience, are undeterred by the prospect of punishment, and seem to learn little through experience.

Transient reactions and special syndromes. ***Grief state.*** Intense reaction to loss, particularly following the death of someone close, is normally called grief. Exaggeration and prolongation of normal grief constitutes the grief state, which can lead to the more severe symptoms of emotional depression or depressive reaction.

Stress reaction. Individual responses to emotional or situational stress are influenced by prior adjustment. Stress reactions can include acute manifestations typical of almost any of the psychoneuroses; fatigue state and anxiety-tension state may be so generated. The stress reaction is also commonly encountered in military situations.

Anorexia nervosa. This is a severe neurotic reaction in which appetite and weight loss on emotional bases are the prominent features. The anorexia (loss of appetite) can result in such an active aversion to food that it may lead to death. Anorexia nervosa in the 1970s was likely to be regarded as a symptom of some other neurosis rather than as a distinct clinical entity.

Ganser syndrome. Regarded by some as a variety of conversion reaction, this disorder is one in which objects are misnamed, questions elicit senseless answers, and the sufferer displays an abrupt loss of general competence. Especially described among prison inmates, the term Ganser syndrome has been utilized to include a broad spectrum of neurotic and psychotic manifestations (see also PSYCHOSES). In view of its locale and symptoms, the disturbance also has been called prison psychosis and nonsense syndrome.

Nail-biting and thumb-sucking

Conflict indicators. A significant group of attitudinal and behavioral manifestations serve to indicate emotional tension and conflict. They include somnambulism, enuresis, nail-biting, stuttering, nightmares. tics, various mannerisms, persistent insomnia. thumb-sucking, teeth clenching. hair pulling, head banging, and ceriain rhythmic movements. While these attitudinal and behavioral manifestations are often developmental and transient, they may persist, recur under later adult stresses, and accompany or indicate the potential for the progression of further emotional difficulties.

GENERALLY USEFUL CONCEPTIONS ABOUT NEUROTIC BEHAVIOUR

Many concepts evolved in relation to the dynamics, cause, prevention, and therapy of psychoneuroses have applicability in the general study of human reactions and behaviour.

One such concept is that an individual's earlier experience tends to take emotional precedence over subsequent impressions. According to this impression-priority rule, impressions resulting from a first visit, initial meeting, original experience in a sport or activity, learning to drive a car, first day at a new school, or initial contact with one's employer all tend to have special significance. Subsequent events, attitudes, and reactions henceforth can be profoundly influenced.

A number of advantages are consciously or unconsciously derived through emotional defenses or neurotic symptoms. The so-called primary gain refers to what are held to be the deeply buried, hidden needs, basis, and purpose of the neurotic activity. These defensively intended gains are said to comprise its raison d'être; included is a need to avoid conflict and consequent anxiety. The primary gain is said to be basic to the genesis of every neurotic disorder. Secondary gains refer to situational advantages that derive from an established symptom or illness. Thus a soldier who develops hysterical blindness becomes eligible for the secondary gain of being removed from the scene of battle. The indicted criminal who suddenly finds himself unable to tie his own shoelaces (as in Ganser's syndrome) may reap the secondary gain of avoiding prosecution on grounds of legal insanity.

A kind of neurotic status quo sometimes is achieved when the symptoms efficiently serve their defensive intent in allaying anxiety and in holding repressed conflict in abeyance. When such a balanced neurotic position is secured, the psychopathology tends to become more or less stable. The individual's freedom from anxiety and his inability to recognize any self-defeat or handicap can comprise an almost iron-clad defense against so-called therapeutic intervention. Indeed, many social associations (for example, choice of a marital partner) seem to be based on complementary neurotic symptoms. Neurotic interdependency of people in large measure is responsible for the development of social relationships and their long-range vicissitudes (for example, chronic discontent in marriage).

Psychoses

Psychosis is the term commonly used to designate a severe or major psychiatric disorder. In practice, the concept is more difficult to define. since severity is not an inflexible sign and a relatively small number of cases diagnosed as psychosis may in fact be less serious to the sufferer or to society than are some of those assigned to other psychiatric categories. The term psychosis is at times indistinctly equated with insanity: the latter term, when used legally or in popular language, suggests a person who is so incompetent that he may require special control or supervision. Difficulty in definition also arises from the inclusion in the psychotic category of many disturbances of different origin, course. and symptoms.

Insanity

According to some authorities, the term psychosis indicates not only actual or potential severity but also connotes that the disturbed state is accepted by the sufferer as a normal way of living. Most people who are labelled psychotic seem not to know that there is anything wrong with them. No matter what unusual behaviour the psychotic exhibits (*e.g.*, severe withdrawal from ordinary life or major emotional changes, or defect in memory or perception), ihat behaviour represents the routine way of responding to the environment around him. By contrast, people who are placed in another psychiatric category, psychoneurosis (or neurosis), generally appear to know they suffer some disorder and typically strive to get rid of the symptoms. 'Thus a psychoneurotic who is panicked by cats, or who tries to wash his hands every five minutes, almost invariably seeks relief from the symptoms; he is said to have insight into his abnormal state (see PSYCHONEUROSES).

A psychotic European who says that he is the emperor of China may insist on being recognized as Chinese royalty even though there is no observable evidence for such a belief. That the psychotic seems to accept his abnormality as normal often sharply distinguishes him from most of those around him. Although philosophers argue about the nature of "reality" (see METAPHYSICS), observers soon discover that psychotic ways of perceiving what most people call reality follow distinct patterns that cannot be validated logicaily by others in the individual's culture. Such characteristics common to psychotic people are not enough to specify a single biological category, as in classifying animal and plant species. The term psychosis is effectively limited to practical use, suggesting that one is suffering major psychiatric disorder of which he has no insight and that he probably requires hospitalization.

Since no collective biological category for psychosis is defined, causes, symptoms, and treatment vary considerably, each type of disturbance requiring separate examination.

Psychoses once were called mental alienations; psychiatrists dealt almost exclusively with them and were therefore called alienists. Nowadays psychiatrists have expanded their concerns to many additional problems, including minor personality disorders, questions of child rearing, and mental hygiene. Psychoses nevertheless continue to attract substantial attention as serious problems that require so much care that the great majority of inmates of psychiatric hospitals are drawn from ranks of psychotics.

Benign and pernicious psychoses

Psychoses once were classified as benign if recovery was satisfactory and prompt, and as pernicious if symptoms were protracted or became worse. Benign cases often were labelled as manic-depressive, while those with poor signs of recovery were diagnosed as suffering "dementia praecox." The practice was not dissimilar to that prevailing in general medicine before bacteria were well understood: when a child with a sore throat recovered, he had "tonsillitis," and if not, he was said to have died of "diphtheria." While many other classifications for psychoses have been proposed, one that has been generally adopted distinguishes between so-called organic and functional psychoses.

A psychosis is called organic if it seems to result from some demonstrable physical abnormality, such as a brain tumour, or some chemical derangement in the body. When the individual behaves abnormally, and no chemical or anatomical basis for that behaviour is found, the psychosis is said to be functional; for example, many psychotic signs of emotional maladaptation appear at least partially to be provoked by how one perceives the stresses of daily life.

Major controversy centres on the concept of functional disorder. Many authorities caution that although no organic bases are observed, even with the most refined techniques available, it is unwise to conclude that none exists. New, more sensitive methods indeed might permit detailed exploration of the nervous system with enough precision to disclose physical abnormalities. Additional debate concerns biochemical alterations detected in the bodies of some sufferers of functional psychoses, the question being whether the chemicals produce the disordered behaviour or result from it.

In many European countries the term endogenous (produced within the individual) is preferred to the term functional. The term endogenous directs attention away from environmental factors in psychosis to emphasize abnormality that may exist within the sufferer himself and that predisposes him to develop signs of disorder. The American (U.S.) Psychiatric Association has officially distinguished psychoses associated with organic brain dysfunction from those not yet demonstrably based on physical disorder. This avoids taking a stand on whether functional psychoses have organic origins; thus psychiatrists who speak of functional disturbance do not necessarily deny organic or physical predisposition.

FUNCTIONAL PSYCHOSES

Functional psychoses have been defined as those in which an organic basis has not yet been generally established nor widely accepted.

Schizophrenia. Schizophrenia is the most frequently made diagnosis among the major psychoses, schizophrenics constituting 20 to 25 percent of first admissions to public psychiatric hospitals. Since the symptoms tend to appear relatively early in life and tend to result in long periods of hospitalization, schizophrenics make up about 55 percent of the disturbed population at such hospitals. The prevalence rate (the total number of schizophrenics living at a given time) can only be estimated and has been calculated variously from about 170 to 950 per 100,000 of all living people. No known society or culture seems to be immune; in so-called developed lands schizophrenia tends to be more frequent among the unmarried, immigrants, those of low social status, people who belong to ethnic minorities, and those living in large cities. Assuming the lowest prevalence value (170 per 100,000), and a world human population of 4,000,000,000, a modest estimate of the total number of schizophrenic people is 6,800,000.

Schizophrenia (Greek: "split mind"), a term coined by Swiss psychiatrist Eugen Bleuler (1857–1939) to replace the older designation dementia praecox, indicates a *group* of disturbances with symptoms occurring in different combinations and intensity but generally having in common disturbances of feeling and thinking—a kind of withdrawal ("splitting") from the outside world. Neither dementia praecox nor schizophrenia is satisfactory as a term to cover all syndromes (combinations of symptoms) usually included in the group. During the 20th century there have been alternating trends to consider the term schizophrenia as denoting a single "disease" process or as a number of similar patterns of psychological reaction to the stresses of life.

Symptoms

All major types of schizophrenia now generally differentiated exhibit signs of withdrawal from the environment. (1) The simple type is differentiated by insidious and gradual reduction in external relationships and interests. Emotional expression is shallow, thinking tends to be simple and to refer to concrete things rather than to abstractions. The sufferer's general level of activity diminishes; he shows progressively less and less use of his inner resources and retreats to less demanding or stereotyped forms of behaviour. For example, a skilled industrial designer who develops simple schizophrenia may retreat to routine factory work. (2) The hebephrenic type is characterized mainly by shallow, inappropriate emotional reactions, silly or bizarre behaviour, false (delusional) beliefs and perceptions in the absence of the usual stimuli (hallucinatory activity). (3) The catatonic type is characterized by striking changes in bodily movement; sufferers may become almost completely immobile, often assuming statuesque positions. Mutism, extreme compliance, and loss of almost all voluntary activity are also common. Such inactivity may be preceded or interrupted by episodes of excessive movement and excitement, generally unpredictable and apparently impulsive. (4) The paranoid type, usually appearing later in life than the others, is characterized by unrealistic, illogical, hallucinatory thinking and by bizarre delusions of being persecuted or of being a great person (*e.g.*, of being Jesus Christ or the "emperor of the Pacific Ocean").

Beyond the four major types, many authorities also describe: (5) schizo-affective schizophrenia, distinguished from other types by moods of elation and depression; (6) undifferentiated schizophrenia, characterized by disturbed, but not sufficiently distinctive, behaviour and thinking; (7) pseudoneurotic schizophrenia, with predominantly neurotic behaviour, psychotic episodes being brief.

Although not consistently found, hallucinatory signs are perhaps most conspicuous in the hebephrenic and paranoid types. The most common are auditory, the individual reporting "voices" that no one else seems to hear, but the "reality" of which he accepts. Visual hallucinating also is relatively common, especially during acute episodes; less often there are signs of hallucinatory smelling and tasting and of abnormal bodily perceptions (*e.g.*, a depersonalized feeling that one's arm does not belong to him). The symptoms of withdrawal that are common to all types may be minimal and difficult to detect but are reflected as withdrawal into concrete ways of thinking and impaired abstract reasoning.

These "textbook" types of schizophrenia are by no means mutually exclusive; mixed syndromes are found especially in early acute cases as well as in some later chronic phases. As the disorder continues, some sufferers show few of their original symptoms, these having yielded to a mixed set of others.

The course of schizophrenia is extremely variable; a 48-hour schizophrenia has been described, yet people who never recover sufficiently to leave the hospital also constitute a significant percentage. Most improve to make at least a social recovery that permits them to live more or less adequately in society.

The course of schizophrenia

The classical course of schizophrenia sometimes is said to begin with a prodromal phase, characterized by hypochondriacal symptoms, introversion, restlessness, depersonalization, and abnormal preoccupation. The change in personality can be slow or abrupt and is followed by overt signs of psychosis in which the intensity and quality of symptoms become manifestly abnormal. Symptoms next tend to diminish in intensity and may finally disappear (go into remission). In chronic cases the abnormal signs tend to become less acute, but with increasing duration there is gradual deterioration.

Theories about the origin of schizophrenia include hypotheses that are anatomical, biochemical, psychological, hereditary, and environmental. In some countries (*e.g.*, Great Britain and Germany) biological or organic theories have been prevalent; in others (Switzerland and the U.S.) psychological or functional theories have attracted more adherents, although the number of authorities in all lands who endorse at least a partial organic basis grows steadily larger. Many theories cannot be considered *exclusively* psychological or biological; however, one extreme or another tends to predominate in each.

Predominantly psychological theories. German psychiatrist Emil Kraepelin (1856–1926) seems to have been first to distinguish what is now called schizophrenia from other psychiatric disorders and to describe it in detail. He gave it the name dementia praecox, a term that had been used by others earlier and in a more restricted sense. Kraepelin held that its varied manifestations all result from the same underlying physical disorder, suggesting either degenerative brain disease or metabolic self-poisoning (auto-intoxication), and pessimistically pronounced that all cases end in deteriorated intelligence (dementia). Bleuler, however, early influenced by Freudian theory, emphasized psychological roots (impairment of thinking) as the primary source of schizophrenic symptoms, although he did not deny the possibility of a coexisting toxic basis as well.

A Swiss-American, Adolf Meyer (1866–1950), attributed schizophrenic reactions to maladaptive learning (habit disorganization), emphasizing the anatomic and chemical integrity of the sufferer while affirming that such functions as learning were not to be separated from physical structures, a view called psychobiological.

Psychoanalyst Sigmund Freud (1856–1939) showed more interest in psychoneuroses than in psychoses, but his theories and investigations have nevertheless been widely applied in efforts to account for schizophrenia. Schizophrenic symptoms have been interpreted psychoanalytically as symbolic manifestations similar in form, content, and motivation to ordinary dreaming (see DREAMS). The psychoanalytic view interprets regressive schizophrenic symptoms (*e.g.*, soiling oneself) as a retreat or withdrawal to less mature levels of development. Such restitutive symptoms as hallucinating, delusional activity, phantasizing, or peculiarity of language are viewed as attempts to replace the world from which the person has withdrawn.

Swiss psychiatrist Carl Gustav Jung (1875–1961) asserted that schizophrenia is caused by unusually intense regressive activity and by an abnormal resurgence of primitive tendencies, evolutionary throwbacks from what he called the person's "collective unconscious." He imagined the latter to be an inherited repository of primordial images (archetypes) that accumulate from the experiences of each individual's ancestors.

An American psychiatrist, Harry Stack Sullivan (1892–1949), blamed schizophrenia on the sufferer's faulty interaction with others, especially on poor parent-child relationships. One's anxiety and lack of self-esteem, originating in these early relationships, he held, lead to peculiar ways of coping with life (parataxic distortions), to lack of consensual validation (decreasing agreement with others in perceiving the world), and finally to what Sullivan called schizophrenic panic.

An Italian-American psychiatrist, Silvano Arieti (1914–), has attributed major, but not exclusive, importance to psychological factors. He believes that the psychological life history of the schizophrenic, from birth to the onset of the disorder, can be divided into four stages, of which only the last can be considered psychotic. In the first three stages the future patient responds to an unhealthy environment in specific ways that distort and magnify the environmental abnormality. Consequently, it will be more difficult for him to integrate psychologically. When, under the stress of psychological problems with which he cannot cope, the patient decompensates and becomes psychotic, he adopts a special way of thinking, which makes him delusional so that he deals with reality in an individualistic and inappropriate way. The patient follows a particular way of thinking, called paleologic, which is not reconcilable with Aristotelian logic. Arieti feels that the schizophrenic process also may be interpreted psychosomatically, inasmuch as intensely disturbing emotional factors may bring about the resurgence of obsolete functional and neuronal patterns.

Predominantly biological theories. Many authors have interpreted schizophrenia as a hereditary disease. A detailed discussion of these efforts is given in HUMAN BEHAVIOUR, INNATE FACTORS IN: Personality. In general, these genetic theories of schizophrenia are based on the observation that the disorder seems to run in families.

Heredity and metabolic disorder

Many other investigators agree that schizophrenia is more frequent in some families than in others but that what is transmitted by heredity is only a predisposition for the disorder. Whether or not actual symptoms develop is said to depend on environmental factors (presumably psychological) to change this potentiality into clinical actuality. It is evident that the available data do not permit an explanation of schizophrenia solely on the basis of the laws of heredity, as has been done for such inherited medical disorders as hemophilia and muscular dystrophy.

Biochemical interpretations of schizophrenia based on the notion of pathological metabolic activity have also been advanced. According to one view, the body produces a substance similar to mescaline, a chemical obtained from a cactus, which produces hallucinatory behaviour when swallowed. Some data have confirmed this hypothesis while many other studies have failed to do so. Other investigators have reported isolating from the blood of schizophrenics a substance called taraxein that is said to be responsible for the disorder. Others have theorized that a deficiency of serotonin, another chemical produced in the body, is responsible for the psychosis, although actual studies have yielded contradictory results.

Gross and microscopic examinations of the nervous systems of deceased schizophrenics have failed to reveal distinctive anatomical alterations. If such alterations exist, they must be so subtle that they escape detection with available methods.

Treatment. Earlier pessimism about the outlook for recovery in schizophrenic cases has changed markedly. Even orthodox psychoanalytic therapy, about which Freud himself was skeptical in the treatment of psychoses, has been modified for use with schizophrenics. These modifications include dispensing with the couch, direct intervention by the therapist in changing the symbolic language of the sufferer, and much less reliance on free association. Other individual psychological techniques in Europe and North America include the treatment of non-hospitalized (ambulatory) schizophrenics during periodic visits to the therapist's office.

By far the majority of sufferers are treated with physical methods. Drug therapy consists in the administration of large doses of tranquillizers, particularly one called chlorpromazine. Other techniques include electroconvulsive therapy in which electric current is passed through the individual's head; insulin therapy, in which enough of that hormone is administered to produce coma; and psychosurgery, in which connections between different parts of the brain are severed. The latter technique (sometimes called lobotomy) underwent a great decline of interest by the mid-1950s; psychosurgery now is applied quite rarely and only in the most recalcitrant cases of schizophrenia.

An increasing number of schizophrenics are treated outside hospitals, but most continue to be hospitalized, especially during acute episodes. Almost all psychiatric hospitals are equipped to provide physical treatments and occupational therapy, and an increasing percentage provide psychotherapy. In many cases, what seems most helpful is to provide the individual with an environment in which he is protected and in which, away from the demands of ordinary life, he can gradually work his way through his periods of confusion and disturbance.

Success of treatment appears to vary with the stage of the disorder at which it is started. If the symptoms have been present for a long time, successful results are relatively difficult to attain. Good outcome is related to: acute, sudden onset of a confused, excited kind of disturbance; absence of schizophrenic family history; presence of additional emotional symptoms usually found in manic-depressive psychosis (see below Affectivepsychoses); and evidence of some fairly clear psychological conflict that seems to have precipitated the disturbance. Statistical studies indicate that shock treatment (insulin and electroconvulsive) produces a greater number of improvements among schizophrenics than do other methods; however, shock seems to work even better for psychoses primarily characterized by emotional symptoms (*e.g.*, depression).

Prevention. Without clear-cut understanding of the origins of schizophrenia, specific and reliable preventive measures remain to be established. A number of authorities, influenced largely by psychoanalytic points of view, hold that one's relationship in the early years of life with his family, particularly with his mother, plays a considerable role in the development of schizophrenia. Their recommendations for prevention therefore centre largely in the provision of security for the child through warm, understanding relationships in the family.

There are also indications that urban areas, very large cities in particular, tend to promote the development of this disorder and industrial societies seem to spawn the disturbance more than do agricultural settings. On these grounds some have looked to wider dispersion of the population as hopefully reducing the prevalence of schizophrenia, although the disorder is found in all cultures and societies.

Affective psychoses. Affective (emotional) psychoses include what are called manic-depressive psychosis and psychotic depression; it is debated whether the latter is an incomplete form of the manic-depressive psychosis or an independent disorder. While schizophrenia was not recognized as an entity until the 19th century, forms of manic-depressive psychosis have been well described since ancient times. People who today would be classified as manic-depressive are discussed in the writings of the Greek physicians Hippocrates (flourished 400 BC) and Aretaeus of Cappadocia (2nd century AD). Kraepelin conceived of manic-depressive psychosis as one syndrome that includes many varieties.

Manic-depressive psychosis manifests itself with recurring, sometimes cyclic, attacks of depression and of manic (excited) behaviour, often elated. Attacks of depression are characterized by signs that the person has deep feelings of melancholia (sadness); onset may be acute and dramatic, or slow and insidious. The sufferer typically looks unhappy, says he feels hopeless and worthless, that he considers his life a torment. He seems to experience a desire to punish himself by self-destruction; evidence of suicidal thinking is observed in about 75 percent of these people, and actual suicide attempts are found to be made by at least 10 to 15 percent. In fact, suicide constitutes the greatest risk in manic-depressive psychosis, although some sufferers (especially females) kill their small children, whom they seem to consider parts of themselves, immediately prior to their suicidal attempts. Generally, however, the depressed person is dangerous to himself rather than to others.

Suicide

The individual apparently convinces himself that his depression and suffering are justified, saying that he is unhappy because he is sick, is destitute, has lost all his money, has sinned, is guilty, is worthless, is a failure, and so on. Hypochondriacal thinking, as an almost full-blown delusion of being ill, is not uncommon. Evidence of depression is also seen in retardation of motor activity; bodily movements are reduced in number and are carried out at a slow pace. The depressed person is neglectful of his appearance and manifests limited ability to work or to take care of household and family duties. Depression may become so profound as to reach the state of stupor; the individual seems unable to talk or to move and may be mistaken for an immobile catatonic schizophrenic. Insomnia, decrease in appetite, loss in weight, and marked decrease in sexual desire are common symptoms.

In classical cases of the manic-depressive psychosis, periods of depression are followed by manic attacks in which the person becomes excited; while the excitement may be unpleasant for the sufferer, the mood often is one of elation (euphoria). The manic individual typically shows unrestrained good humour; however, he may change to sarcasm, irritation, and hostility when he comes into conflict with the environment. He may consider himself rich, strong, and very healthy and make grandiose plans; he may dissipate large amounts of money in a few days. His thinking seems flighty, he cannot concentrate on any topic more than briefly, and his speech is rapid. In this flight of ideas the manic individual is ineffective in self-criticism and manifests poor judgment. Motor activity may be so excessive that the sufferer becomes exhausted; in other cases the attack is of mild intensity (hypomanic) and continues without fatigue.

During depression or mania the psychotic patient shows no insight into the abnormal nature of his mood. He seems to accept his behaviour as an appropriate and justifiable way of living and feeling. The most typical form of the psychosis is circular, being characterized by an alternation of manic and depressed episodes. The first attack may occur any time between adolescence and the age of 45. Depressive attacks are much more common than are manic, especially as the disorder progresses. There are, however, numerous variations; in one (agitated depression), motor restlessness, more typical of manic excitement, is superimposed on a set of markedly depressive symptoms.

The disorder is likely to be called psychotic depression when there is no history of repeated episodes of depression or of circular attacks of depression and mania (as in classical manic-depressive psychosis), and when the depression is intense and not perceived as abnormal by the sufferer (as it would be in neurotic depression). When environmental precipitating factors (*e.g.*, loss of a loved one) are easily recognized, the diagnosis of psychotic depression is more likely to be given as a separate clinical entity; nevertheless, some authorities still consider it a partial form of manic-depressive psychosis.

The psychological symptoms of all such psychoses have been classified by Arieti as either "self-blaming" or "claiming." In self-blaming depression the focus is on self-accusation, self-deprecation, and guilt feelings that lead one to feel he does not deserve help. This type of depression is traditionally described in textbooks of psychiatry. In claiming depression, a term that has begun to attract more diagnostic use, the symptoms of the individual seem to reflect a gigantic claim on the attention and sympathy of others. All the symptoms seem to have a message: "Help me; pity me; it is in your power to relieve me. If I suffer, it is because you don't relieve me of this suffering."

Some psychiatrists have reported a decline in the incidence of the disorder; for instance, in one study of hospitals over a period of 20 years (from 1928 to 1947), manic-depressive psychosis declined from 13.5 percent of all first admissions to 3.8 percent. After the mid-1960s, however, psychiatrists detected what seemed to be an increase in the number of depressed people though their symptoms are not typically manic-depressive.

Theories. Some authorities have stressed hereditary factors in the etiology (causation) of manic-depressive psychosis, one view attributing it to a single dominant gene. A German psychiatrist, Ernst Kretschmer (1888–1964), noticed a large number of short, heavy people (so-called pyknic body type) among those suffering from manic-depressive psychosis, and other investigators have found what seem to be distinctive fluctuations in the levels of certain chemicals (17-hydroxycorticosteroids) in the urine of depressed patients.

Psychoanalysts have compared psychiatric depression to normal grief, suggesting that it is normal to feel sad through concern about a lost dear one, while the depressed psychiatric patient is disturbed by guilt feelings. Unconscious hostility that he had for the lost person is now said to be directed toward himself; in a sense, the personality of the lost person is thought to have been introjected (incorporated) into the unconscious life of the depressed person.

Arieti believes that the depressed patient has sustained a trauma in early childhood, when from an environment characterized by great parental care and devotion he found himself carried into an atmosphere of great expectation. To recapture what he had lost, he becomes dependent and claiming, or he becomes duty bound, compliant, and hard working. Later in life, any loss is experienced as a reactivation of the early loss. Arieti has also tried to illustrate the importance of the cultural environment in facilitating those psychodynamic mechanisms that lead to manic-depressive psychosis. The psychosis occurs more frequently in those cultures that have been called inner-directed and tends to disappear where this culture is disappearing. This hypothesis receives some validation from research on Hutterites, an ethnic minority of German ancestry who settled in the Dakotas and Montana. They are held to constitute a typical inner-directed culture; among them manic-depressive psychosis occurs 4.33 times more frequently than schizophrenia, contrary to the comparative incidence of these two psychoses elsewhere.

Treatment. While psychoanalytic treatment has been attempted, electric-shock treatment seems to cure practically all episodes of depression but does not prevent their recurrence and is less effective in manic attacks. Drugs are commonly used to control attacks of depression, especially so-called antidepressants, like the drug imipramine. In manic attacks the use of compounds of lithium has given good results, but not invariably. The poor judgment of manics and the possibility of suicide among depressed people make hospitalization advisable in many cases.

Involutional psychoses. Involutional psychoses are generally classified as involutional melancholia, and as involutional paranoid state (in Europe often called paraphrenia). Several authorities have denied the existence of these conditions as separate clinical entities, being inclined to hold that involutional melancholia is a variety of affective psychosis and that involutional paranoid state is a variety of schizophrenia. Some official diagnostic publications nevertheless retain the category.

Involutional melancholia

These disorders are observed during the so-called involutional period of life; that is, between about 48 and 60 years of age when signs of aging become apparent. Observed three times more frequently in women than in men, involutional melancholia may occur at the time of menopause (cessation of menstruation) but in most cases appears from two to seven years after menopause. Among men, the symptoms generally appear even later; these include anxiety, insomnia, restlessness, and loss of appetite and of sexual desire. In many cases there is a marked loss of weight; the person worries about his health and consults a physician, hoping to find a medically treatable reason for his distress. Soon the mood of melancholia becomes predominant and covers all the other symptoms; agitation is more common than motor retardation, this serving as a distinguishing characteristic from other types of depression. Expressions of feelings of worthlessness, self-condemnation, and guilt are prominent in involutional melancholia.

Biological, especially glandular, factors have been considered responsible; yet, treatment with hormones generally seems ineffective in involutional melancholia. Electric-shock treatment and drugs (especially antidepressants) are most profitably used, as they are in other types of depression. Many psychiatrists see in the psychosis the culmination of a life of disappointment, an inability to face the future, and a sense of regret for that part of life unsuccessfully spent.

The involutional paranoid state is characterized by suspiciousness and hostility, changing into delusions of persecution and ideas of reference. Often it is difficult to differentiate this disturbance from paranoid schizophrenia. Mixed cases occur with symptoms of melancholia and paranoid thinking.

Paranoia. The existence of paranoia as a separate entity is doubted by many psychiatrists, who consider it a variety of schizophrenia. As described in old textbooks of psychiatry, paranoia is a condition characterized by apparently logical systems of delusions (false beliefs). The person nourishes beliefs that appear to be absurd to others; nevertheless, he gives convincing and apparently plausible arguments to support them.

The paranoiac does not resort to primitive ways of thinking to demonstrate the validity of his delusions (as schizophrenics do); rather, his thinking is generally logical once the false premises are accepted. Often, mere possibilities and coincidences are considered as conclusive evidence; the paranoiac feels persecuted or imagines plots and conspiracies organized against him or against parts of society with which he identifies. At times the person sees himself as a saviour of society whose mission it is to unmask the obscure plotting of clandestine agencies. The paranoiac becomes so sure of the validity of his beliefs that he may go to the extent of killing the alleged persecutors; more often he becomes the plaintiff in almost endless legal suits.

Incidence of paranoia

Paranoia is most likely to be diagnosed among unmarried men in their 40s and 50s who have made a poor sexual adjustment, and who always have tended to experience difficulties in relating to people. Paranoiacs as described in classic books of psychiatry are rarely encountered and seem most unlikely to respond to treatment. They may require forced hospitalization when authorities judge them to endanger the safety of others. Some authors have described what they call mild cases of paranoia that may be of short duration and that are said to respond to psychotherapy.

Rare functional psychoses. Other types of functional psychoses have been described, but their occurrence is rare; a few of them are mentioned below.

Ganscr syndrome. This occurs especially among prisoners who are facing trial, occasionally among people confronted with other unpleasant conditions. Together with partial amnesia, the sufferer shows an abrupt loss in his ability to reason, giving absurd answers or making unbelievable statements; for instance, he map say that 3 plus 3 is 7 or that a horse has five legs. The syndrome often is confused with voluntary malingering (faking) by prisoners who want to escape indictment. Some interpret the Ganser syndrome as an involuntary escape from rationality in an unconscious effort to avoid responsibility for past actions.

Capgras' syndrome. This diagnosis has received considerable attention by European psychiatrists since the original description in 1923. On meeting someone he knows very well, a sufferer will claim that the person is a double or an imposter; for example, he may claim that his mother is another person who has tried to assume her appearance to deceive him. The phenomenon is more characteristic and specific than the usual misidentifications occurring in schizophrenia, but some question whether this is a distinct clinical entity or a schizophrenic syndrome.

Latnh syndrome. An extremely rare psychosis in Western countries, latah syndrome is fairly common in the Fast East, especially in Malaya. The patient acquires the habit of repeating the words or sentences of other people, especially persons in authority. The patient, in pantomime fashion, repeats or imitates the gestures and acts of others. The same kind of behaviour is observed among schizophrenics.

Paranoid behaviour in pairs

Folie à deux. A rare syndrome characterized by the simultaneous occurrence of psychosis in two persons who have a close relationship (*e.g.*, live together) is called folie à deux. In such cases, one of the two (the inductor) is usually suffering from paranoia or some other paranoid disorder. The inductee (generally a woman or a passive male) seems to accept the delusional attitudes of the dominant person and often is his spouse or child. When the passive person is separated from the domination of the inductor, his psychosis is likely to disappear, while the inductor retains his abnormal symptoms.

ORGANIC PSYCHOSES

Psychoses for which a definite anatomical or chemical basis has been definitely established are called organic.

Senile psychosis. After about the age of 60, mild impairment in such functions as remembering and learning is so common as to be considered statistically normal. The term senile psychosis is used when such defects are so pronounced as to deprive the person of insight into his condition and to impair his ability to take care of himself. In a large-scale study, about 15 percent of all patients admitted to psychiatric hospitals were diagnosed as suffering from senile psychosis. Differences from one society to another in attitudes toward the shortcomings of old age understandably affect the number of admissions; for example, the number of hospitalized senile people is reduced to the extent that they are cared for at home.

Paranoid thinking, as of being robbed or victimized, often occurs in senile psychosis. Even more pronounced are defects in orientation as to time, place, and occasionally about personal identity. Memory may be impaired only in relation to recent happenings, but in advanced cases the loss may extend to long past events (see MEMORY, ABNORMALITIES OF). Ability to learn new skills, to adapt to new environments, to calculate, and to use logic may be severely impaired; and mood tends to change rapidly from laughter to tears and vice versa.

Among sufferers of senile psychosis the brain is markedly reduced in size; while normal adult brain weight is about 1,300 grams, that of senile psychotics has been observed to range from 1,100 to 900 grams. The reduction in volume is particularly pronounced in the front and middle parts of the brain surface (cortex). Microscopic studies of nerve cells reveal that the parts of the cortex believed to have evolved earliest are least affected. Often there is a marked reduction in the number of nerve cells in all the layers of the cortex and selective shrinkage or coalescence of parts of the cells that remain. The brains of senile psychotics also are likely to show many senile plaques—*i.e.*, small roundish areas of tissue degeneration scattered throughout the cortex, but particularly numerous in the frontal lobes and the hippocampal cortex.

Varieties of the disorder, generally labelled presenile psychoses, occur between about 40 and 60 years of age. Alzheimer's disease is fundamentally similar to senile psychosis but appears earlier in life and involves more severe behavioral and neural change. Pick's disease, again with similar symptoms, is characterized anatomically by circumscribed regions of atrophy (wasting away) in localized parts of the brain.

Psychoses with cerebral **arteriosclerosis.** In senile psychosis the nervous tissue is directly involved and degenerating, but in psychoses with cerebral arteriosclerosis brain deterioration results from changes in the circulatory system. Arteriosclerosis (hardening of the arteries) may be present throughout the body or may be restricted to the brain; in any case, the blood supply of the brain is disturbed. Large blood vessels become thickened and tortuous, their inner walls becoming coated with a fatty material that reduces the volume of blood they can carry; smaller blood vessels are even more likely to become occluded (plugged). As a consequence undernourished bits of brain tend to soften, nerve cells degenerate, and blood vessels in the head may burst and bleed. Psychologically the symptoms of cerebral arteriosclerosis resemble those of senile psychosis; disorientation, memory defects, and inability to learn and calculate are similar. Generally, however, the symptoms fluctuate, at least in the beginning of the illness, and the progression of the disorder is less uniform than in senile psychosis. A change of personality, with decay in judgment and loss of ethical behaviour, is observed in some cases; confusion with apprehension and panic, childish and impulsive behaviour also occur.

In both senile and arteriosclerotic psychosis, psychiatric management consists of offering the sufferer an environment adapted to his limitations. Efforts to use chemicals related to ribonucleic acid (RNA) in treating arteriosclerotic and senile patients have shown some success, but results have been inconsistent. The most commonly used medical treatment is symptomatic in nature, aiming at ameliorating the symptoms; for example, drugs that dilate blood vessels and similar techniques for nourishing oxygen-starved brain tissue are used.

General paresis. Although this disease once was thought by most authorities to be functional, in 1913 paresis was shown to be the result of syphilis of the brain. The illness typically develops several years after the original syphilitic infection (see REPRODUCTIVE-SYSTEM DISEASES). The infectious organism (***Treponema*** pallidurn) produces clearly discernible alterations in the microscopic structure and circulation of the cerebral cortex.

At the behavioral level the psychosis assumes different patterns, at times resembling that of schizophrenia, at others that of cerebral arteriosclerosis. Most typical, however, is the expansive paretic, a grandiose, euphoric psychotic who may claim to be a millionaire, a great inventor, or a genius. He lacks insight, his judgment is very poor, and his behaviour is impulsive and capricious. Once very common, the problem of general paresis has faded wherever medical care and public health education are adequate. When they were considered to be suffering from a functional psychosis, paretics were doomed to hopeless, wasted months or years of psychotherapy; standard therapy today consists of giving large quantities of penicillin or other antibiotics. Since early infections of syphilis are so readily treatable, the complication of general paresis has become rare in enlightened communities. Some psychiatrists have not seen even a single case for years.

Alcoholic psychoses. Alcoholic psychoses are psychiatric disorders produced by withdrawal from or by abuse of alcohol. Delirium tremens is the most common alcoholic psychosis; after prolonged and excessive use of alcohol, if a person abstains from drinking he tends to become restless, tremulous, fearful, unable to sleep or rest. Increasing tremulousness ("the shakes") is followed commonly by visual and auditory hallucinating. Most characteristic are visions of small animals, especially insects, crawling around the sufferer's body. Optical illusions, with external objects appearing to change size and form, are common. The major part of modern treatment consists of massive doses of vitamin B.

Delirium tremens

Alcoholic hallucinosis seems related to schizophrenia and to delirium tremens; alcoholics who abstain after heavy drinking tend to become hallucinated and deluded like schizophrenics. The trembling of delirium tremens is lacking, and visual hallucinating occurs more frequently than in schizophrenia.

Psychoses produced by continuous abuse of alcohol include Wernicke's encephalopathy, in which damage to structures deep within the brain is found. Confusion and excitement, followed by somnolence and stupor, are the main symptoms. In a similar disorder called chronic alcoholic deterioration, there is a gradual decline of sensory, rational, and ethical behaviour, the sufferer becoming inconsiderate, quarrelsome, crude, and often obscene.

Korsakoff's psychosis is another of the typical disturbances that develop after the prolonged use of alcohol. The individual suffers severe memory defect that he somehow may succeed in hiding by fabricating all kinds of fanciful tales. In about 50 percent of the cases, polyneuritis (painful nerve inflammation) accompanies the psychiatric syndrome.

Psychosis with Huntington's chorea. Often cited as the only clear example of a hereditary psychosis, Huntington's chorea is transmitted by a dominant gene, and most cases in North America can be traced to three men who went there in 1630 with John Winthrop, the first governor of the Massachusetts Bay Colony. Brain pathology consists of atrophy of the caudate and lenticular nuclei, parts deep within that organ. The illness is characterized by choreiform (twisting) movements of the neck, trunk and limbs, and grimacing of the face. The psychiatric picture consists of progressive intellectual deterioration, with occasional paranoid or depressive features; the illness in the 1970s was irreversible and incurable.

Psychosis with epilepsy. Epilepsy is a neurological disorder characterized by convulsions and by distinctive electroencephalographic changes. In a minority of cases epilepsy produces some symptoms that may be considered psychotic. Among these are so-called psychic seizures in which the epileptic feels forced to think or to act in ways that are in disagreement with his conscious determination. Hallucinations, delusions, and illusions occur; a characteristic symptom is the déjà vu feeling that what one is experiencing now has already occurred in his past life.

Another typical symptom associated with epilepsy is the so-called fugue; the sufferer may leave home, travel for several days or weeks without seeming to have full realization of what he is doing. He may suddenly come to himself and interrupt the fugue without appearing to remember what he has done. Although he apparently is not fully conscious during the fugue, he is able to abide by the rules of society; for instance, respecting traffic regulations.

In some cases of epilepsy (especially those involving temporal-lobe brain function) there are symptoms resembling schizophrenia, depression, or organic deterioration. The main treatment is directed toward the underlying epilepsy, while symptomatic therapy is applied to the concomitant psychiatric signs.

Other organic psychoses. Psychoses may occur in a large number of organic conditions; these are best studied and managed by neurologists. Among them are postencephalitic conditions, conditions following head injury, brain tumours, and various chronic neurologic disorders. A wide range of symptoms is observable, including memory defect, disorientation, poor judgment, inability to learn, and emotional instability. Depressive features and paranoid thinking may complicate the clinical picture. Toxic psychoses are the result of taking poisonous materials (*e.g.*, bromides, mescaline) into the body.

Disorders that some consider organic, that others call functional, and that still others deny as separate clinical entities are the so-called postpartum (after childbirth) psychoses. Some authorities, focussing on the symptoms, consider them as cases of schizophrenia or depression precipitated in the mother by the stresses of giving birth. Some attribute them to endocrine or other chemical changes engendered by labour and the termination of pregnancy. Others stress the psychological aspects of giving birth. The woman who is unprepared for motherhood is said to be presented with a challenge with which she cannot cope. She is seen to have doubts about fulfilling her maternal role and to have mixed feelings toward her child and her marriage. Whatever the causes, there is generally an interval of a day or two between the birth of the child and the appearance of postpartum psychosis.

Such differences in authoritative opinion eventually may be expected to yield to careful research as the subtler bases of human behaviour and experience become more fully understood.

Ptolemy

Although Ptolemy (Claudius Ptolemaeus) was a celebrated astronomer, geographer, and mathematician whose work had a profound influence on subsequent generations, virtually nothing is known about his life. The period during which he flourished (2nd century AD) is known from the dates of certain of his astronomical observations. It was from these observations and from the work of previous astronomers that Ptolemy evolved his detailed description of an Earth-centred (geocentric) universe, a revolutionary but erroneous idea that governed astronomical thinking for over 1,300 years. His influence in geography was equally long-lasting.

According to Theodorus Meliteniota of Byzantium, Ptolemy was born in the Hellenistic city of Ptolemais Hermii. He did his major work at Alexandria between 127 and 145 and may have been active as late as 151.

Astronomical work

Ptolemy's astronomical work was enshrined in his great book HE; *mathēmatikē syntaxis* ("The Mathematical Collection"), which eventually became known as *Ho megas astronomos* ("The Great Astronomer"). During the 9th century, however, Arab astronomers used the Greek superlative *Megistē* to refer to the book. When the definite article *al* was prefixed to the term, its title then became known as the *Almagest,* the name still used today.

The *Almagest* is divided into 13 books, each of which deals with certain astronomical concepts pertaining to stars and to objects in the solar system (the Earth and all other celestial bodies that revolve around the Sun). It was, no doubt, the encyclopaedic nature of the work that made the *Almagest* so useful to later astronomers and that gave the views contained in it so profound an influence. In essence, it is a synthesis of the results obtained by Greek astronomy; it is also the major source of knowledge about the work of Hipparchus, most probably the greatest astronomer of antiquity. Although it is often difficult to determine which findings in the book are those of Ptolemy and which are those of Hipparchus, Ptolemy did extend some of the work of Hipparchus through his own observations, apparently using somewhat similar instruments. For example, whereas Hipparchus had compiled a star catalog (the first of its kind) containing 850 stars, Ptolemy expanded the number in his own catalog to 1,022 stars.

On the motions of the Sun, Moon, and planets, Ptolemy again extended the observations and conclusions of Hipparchus—this time to formulate his geocentric theory, which is popularly known as the Ptolemaic system. In the first book of the *Almagest,* Ptolemy describes his geocentric system and gives various arguments to prove that, in its position at the centre of the universe, the Earth must be immovable. Not least, he showed that if the Earth moved, as some earlier philosophers had suggested, then certain phenomena should in consequence be observed. In particular, Ptolemy argued that since all bodies fall to the centre of the universe, the Earth must be fixed there at the centre, otherwise falling objects would not be seen to drop towards the centre of the Earth. Again, if the Earth rotated once every 24 hours, a body thrown vertically upwards should not fall back to the same place, as it was seen to do. Ptolemy was able to demonstrate, however, that no contrary observations had ever been obtained. As a result of such arguments, the geocentric system became dogmatically asserted in Western Christendom until the 15th century, by which time detailed observations had made the system so complex that its validity had lo be seriously questioned. In 1543 the geocentric system was supplanted by the heliocentric (Sun-centred) system of Nicolaus Copernicus (*q.v.*), a Polish astronomer.

Ptolemy accepted the following order for celestial objects in the solar system: Earth (centre), Moon, Mercury, Venus, Sun, Mars, Jupiter, and Saturn. He realized, as had Hipparchus, that the inequalities in the motions of these heavenly bodies necessitated either a system of deferents and epicycles or one of movable eccentrics (both systems devised by Apollonius of Perga, the Greek geometer of the third century BC) in order to account for their movements in terms of uniform circular motion. In the Ptolemaic system, deferents were large circles centred on the Earth, and epicycles small circles whose centres moved round the circumferences of the deferents. The Sun, Moon and planets moved round the circumference of their own epicycles. In the movable eccentric, there was one circle; this was centred on a point displaced from the Earth, with the planet moving round the circumference. These were mathematically equivalent schemes. Even with these, all observed planetary phenomena still could not be fully taken into account. Ptolemy therefore exhibited brilliant ingenuity by introducing still another concept. He supposed that the Earth was located a short distance from the centre of the deferent for each planet and that the centre of the planet's deferent and the epicycle described uniform circular motion around what he called the equant, which was an imaginary point that he placed on the diameter of the deferent but at a position opposite to that of the Earth from the centre of the deferent—*i.e.*, the centre of the deferent was between the Earth and the equant. He further supposed that the distance from the Earth to the centre of the deferent was equal to the distance from the centre of the deferent to the equant. With this hypothesis, Ptolemy could better account for many observed planetary phenomena.

Although Ptolemy realized that the planets were much closer to the Earth than the "fixed" stars, he seems to have believed in the physical existence of crystalline spheres, to which the heavenly bodies were said to be attached. Outside the sphere of the fixed stars, Ptolemy proposed other spheres, ending with the *primum mobile* ("prime mover"), which provided the motive power for the remaining spheres that constituted his conception of the universe.

Work in mathematics and geography

As a geometrician of the first order, Ptolemy performed important work in mathematics. He devised new geometrical proofs and theorems; and, in a book entitled *Analemma* (Greek *Peri analēmmatos*; Latin *De analemmate*), he discussed the details of the projection of points on the celestial sphere (an imaginary sphere extending outward from the Earth for an infinite distance and on whose surface the objects in space appear to be located) onto three planes at right angles (90") to each other—the horizon, the meridian, and the prime vertical. In another book, the *Planisphaerium*, Ptolemy is concerned with stereographic projection—the delineation of the forms of solid bodies on a plane—and here he used the south celestial pole as his centre of projection.

Ptolemy also prepared a calendar that gave, in addition to weather indications: the risings and settings of the stars in the morning and evening twilight. Other mathematical publications include a work, in two books, entitled *Hypotheseis ton planōmenōn* ("Planetary Hypothesis") and two separate geometrical works, one of which is concerned with proving that there cannot be more than three dimensions of space; the other contains an attempted proof for a postulate on parallel lines that had been devised by Euclid. According to one authority, Ptolemy wrote three books on mechanics; another authority, however, credits him with only one mechanical work, *Peri ropōn* ("On Balancing").

Ptolemy's work on optical phenomena appeared in *Optica*, the original edition of which consisted of five books. In the last book, he deals with a theory of refraction (the change in direction of light and other energy waves when they pass obliquely from a medium of one density into a medium of different density), and he discusses the refraction suffered by light from celestial bodies at various altitudes. This is the first recorded attempt at a solution of this observational problem. Ptolemy also wrote a three-book treatise on music known as the *Harmonica*.

As a geographer, Ptolemy's reputation rests mainly on his *Geōgraphikē hyphēgēsis* (*Guide to Geography*), which was divided into eight books; it included information on how to construct maps and lists of places in Europe, Africa, and Asia tabulated according to latitude and longitude. There were, however, many errors in the *Guide*—*e.g.*, the Equator was placed too far north, and the value used for the circumference of the Earth was nearly 30 percent less than a more accurate value that had already been determined—as well as some contradictions between the text and maps. Moreover, as a whole, the *Guide* cannot be considered "good geography"; it does not mention anything about the climate, natural products, inhabitants, or peculiar features of the countries with which it deals, and Ptolemy's treatment of the geographical importance of such factors as rivers and mountain ranges is careless and of little use.

In spite of its faults, the *Guide* is an important work from a historical point of view because, like the *Almagest,* it exerted a great influence on later generations. Christopher Columbus, for example, used it to strengthen his belief that Asia could be reached by travelling westward because Ptolemy had indicated that Asia extended much farther east than it actually does. Even as late as 1775, it was believed that the Indian Ocean was bounded by a southern continent, as Ptolemy had suggested; the return voyage from the Southern Hemisphere of Capt. James Cook in July of that year proved otherwise.

Although it is not known exactly when Ptolemy died, Arabian traditions claim that he was 78 years old at the time of his death.

BIBLIOGRAPHY. There is no biography of Ptolerny. His astronomical work is described in some detail in J.L.E. DREYER, *A History of the Planetary Systems from Thales to Kepler* (1905; republished as *A History of Astronomy,* 2nd ed., 1953). A full English text of *Almagest* which, incidentally, shows how clearly Ptolemy expressed himself, is the translation by R CATESBY TALIAFERRO published in "Great Books of the Western World," vol. 16 (1952). Ptolemy's geographical work is discussed by J.O. THOMSON in *History of Ancient Geography* (1948); and his mathematics in THOMAS L. HEATH, *A Manual of Greek Mathematics* (1931, reprinted 1963). There are no popular texts about Ptolemy or his work; those mentioned above are somewhat specialized although all are readable by the nonspecialist. Ptolemy's work is also described in the context of early astronomy as it leads to modern times in COLIN A. RONAN, *Discovering the Universe* (1971), which is a more popular text.

(C.A.R.)

Ptolemy I Soter

Ptolemy I Soter, friend and general of Alexander the Great, was a man of remarkable military, diplomatic, and organizational abilities, who rose from the lower Macedonian gentry to become king of Egypt, where he ruled from 323 (king from 305) to 285/283 BC. The Ptolemaic dynasty, which he founded, reigned longer than any other dynasty established on the soil of the Alexandrian empire and only succumbed to the Romans in 30 BC. He introduced the cult of Alexander the Great, whom he buried in Egypt, and thus inaugurated a new epoch marked by the worship of the Hellenistic kings. He also originated the cult of Sarapis, a Greco-Egyptian deity, which outlasted his heirs to the throne by centuries.

Ptolemy I Soter, portrait on a silver tetradrachrn. In the British Museum.

Early life and career

Ptolemy, born about 367/366 or 364 BC, was the son of the nobleman Lagus, a native of the Macedonian district of Eordaea whose family was undistinguished until Ptolemy's time, and of Arsinoe, who was related to the Macedonian Argead dynasty. He was probably educated as a page at the royal court of Macedonia, where he became closely associated with Alexander. He was exiled in 337, along with other companions of the crown prince. When he returned, after Alexander's accession to the throne in 336, he joined the King's bodyguard, took part in Alexander's European campaigns of 336–335, and in the fall of 330 was appointed personal bodyguard (*sōmatophylax*) to Alexander; in this capacity he captured the assassin of Darius III, the Persian emperor, in 329. He was closely associated with Alexander during the advance through the Persian highland. As a result of Ptolemy's successful military performance on the way from Bactria (in northeastern Afghanistan) to the Indus River (327–325), he became commander *(tridrarchos)* of the Macedonian fleet on the Hydaspes (modern Jhelum in India). Alexander decorated him several times for his deeds and married him to the Persian Artacama at the mass wedding at Susa, the Persian capital, which was the crowning event of Alexander's policy of merging the Macedonian and Iranian populations.

Ptolemy, who distinguished himself as a cautious and trustworthy troop commander under Alexander, also proved to be a politician of unusual diplomatic and strategic ability in the long series of struggles over the throne that broke out after Alexander's death in 323. Convinced from the outset that the 'generals could not maintain the unity of Alexander's empire, he proposed during the council at Babylon, which followed Alexander's death, that the satrapies (the provinces of the huge empire) be divided among the generals. He became satrap of Egypt, with the adjacent Libyan and Arabian regions, and methodically took advantage of the geographic isolation of the Nile territory to make it a great Hellenistic power. He took steps to improve internal administration and to acquire several external possessions in Cyrenaica (the easternmost part of Libya), Cyprus, and Syria and on the coast of Asia Minor; these, he hoped, would guarantee him miiitary security. Although he pursued a friendly policy toward Greece that secured his political influence there, be also succeeded in winning over the native Egyptian population.

Egypt of

In 322 Ptolemy, taking advantage of internal disturbances, acquired the African Hellenic towns of Cyrenaica. In 322–321, as a member of a coalition of "successors" (*diadochoi*) of Alexander, he fought against Perdiccas, the ruler (*chiliarchos*) of the Asiatic region of the empire. The coalition was victorious and Perdiccas died during the fighting. Ptolemy's diplomatic talent was put to the test during this war. When the satrapies were redistributed at Triparadisus in northern Syria, Antipater, the general of the European region, became regent of the Macedonian empire and Ptolemy was confirmed in possession of Egypt and Cyrene. He further strengthened his position by marrying Eurydice, the third daughter of Antipater.

About 317 he married Berenice I, the granddaughter of Cassander, the son of Antipater, who, at his father's death in 319, refused to accept the new regent, made war upon him, seized part of the empire, and in 305 assumed the title of king of Macedonia. In the coalition war of 315–311, Ptolemy obtained possession of Cyprus. In this war he scored his most important victory in the battle near Gaza in 312, in which the Egyptian contingents were decisive. But war broke out anew in 310, and he lost Cyprus again in 306. He temporarily lost Cyrene as well and was unable to hold the important Greek positions of Corinth and neighbouring Sicyon and Megara, which he had captured in 308. He ultimately suffered overwhelming defeat in 306 in the naval battle near Salamis on Cyprus. The victor in this battle, Antigonus I Monophthalmus, who was assisted by his son, Demetrius Poliorcetes, assumed the title of king in 306. The remaining satraps, led by Ptolemy after he successfully resisted Antigonus' attack on Egypt, also took the title of King in 305–304.

King of Egypt

After naming himself king, Ptolemy's first concern was the continuing war with Antigonus, which was now focussed on the island of Rhodes. In 304 Ptolemy aided the inhabitants of Rhodes against Antigonus and was accorded the divine title Soter (Saviour), which he was commonly called from that time. The dissolution of Alexander's empire was brought to a close with the battle near Ipsus in Asia Minor in 301. During this battle Antigonus was defeated by the other kings. This led to the attempt by the remaining successors of Alexander to define their kingdoms. For this reason a dispute arose between Ptolemy and Seleucus I Nicator of Babylon over Syria, particularly the southern Syrian ports, which served as terminal points for the caravan routes. This quarrel, however, was temporarily settled peacefully through compromise. In addition to Coele Syria (Palestine), Ptolemy apparently also occupied Pamphylia, Lycia, and part of Pisidia in southern Asia Minor.

During the last 15 years of his reign, because of the defeats he suffered between 308 and 306, Ptolemy preferred to secure and expand his empire through a policy of alliances and marriages rather than through warfare. In 300 he concluded an alliance with Lysimachus of Thrace (modern Bulgaria) and gave him his daughter Arsinoe II in marriage in 299/298. At approximately the same time he married his stepdaughter Theoxena to Agathocles, the tyrant of Syracuse (southeastern Sicily). About 296 he made peace with Demetrius Poliorcetes, to whom he betrothed his daughter Ptolemais. To Pyrrhus of Epirus, Demetrius' brother-in-law, who was at the Egyptian court as a hostage, he gave his stepdaughter Antigone. He finally brought rebellious Cyrene into subjection in 298, and in approximately 294 he gained control over Cyprus and the Phoenician coastal towns of Tyre and Sidon.

In a last coalition war in 288–286, in which Ptolemy, Seleucus, Lysimachus, and Pyrrhus opposed Demetrius, the Egyptian fleet participated decisively in the liberation of Athens from Macedonian occupation. During this war Ptolemy obtained the protectorate over the League of Islanders, which was established by Antigonus Monophthalmus in 315 and included most of the Greek islands in the Aegean. Egypt's maritime supremacy in the Mediterranean in the ensuing decades was based on this alliance.

Ptolemy was able to evaluate the chaotic international situation of this post-Alexandrian era, which was characterized by constantly renewed wars with shifting alliances and coalitions, in realistic political terms. Adhering to a basically defensive foreign policy, he secured Egypt against external enemies and expanded it by means of directly controlled foreign possessions and hegemonic administrations. He did not, however, neglect to devote attention to the internal organization of the country and to provide for a successor. In 290 he made his wife Berenice queen of Egypt and in 285 (possibly on June 26) appointed his younger son Ptolemy II Philadelphus, who was born to Berenice in 308, coregent and successor. The provision for the succession, which was based on examples from the time of the pharaohs, made possible a peaceful transition when Ptolemy died in the winter of 283–282. The early Ptolemies were occupied with the economic exploitation of Egypt, but, because of the lack of first-hand information, the details of Ptolemy's participation in the process cannot be determined. It is certain, however, that discrimination against the Egyptians took place during his reign. The only town he founded was Ptolemais in Upper Egypt. He probably placed Macedonian military commanders alongside the Egyptian provincial administrators and intervened unobtrusively in legal and financial affairs. In order to regulate the latter, he introduced coinage, which until that time was unknown in Egypt.

He found it necessary from the outset, however, to pursue a conciliatory policy toward the Egyptians, since Egyptians had to be recruited for his army, which initially numbered only 4,000 men. Ptolemy won over the Egyptians through the establishment in Memphis of the Sarapis cult, which fused the Egyptian and Greek religions; through restoration of the temples of the pharaohs, which had been destroyed by the Persians; and through gifts to the ancient Egyptian gods and patronage of the Egyptian nobility and priesthood. Finally, he founded the Museum (Mouseion), a common workplace for scholars and artists, and established the famous library at Alexandria. Besides being a patron of the arts and sciences, he was a writer himself. In the last few years of his life Ptolemy wrote a generally reliable history of Alexander's campaigns. Although it is now lost, it can be largely reconstructed through the extensive use made of it later by the historian Arrian.

Several times during his life Ptolemy was proclaimed a deity by certain classes of people. After his death he was raised to the level of a god by all the Egyptians.

Ptolemy II Philadelphus

Ptolemy 11 Philadelphus, a masterful diplomat and a famous patron of the arts, was the first king of the Macedonian dynasty of the Ptolemies in Egypt to set up the Hellenistic divine cult of the living ruler. Born on the island of Cos in the Aegean in 308 BC, Ptolemy II was king of Egypt and its foreign possessions from 285 to 246 BC. Reigning at first with his father Ptolemy I Soter, he became sole ruler in 283–282 and purged his family of possible rivals. This dynastic strife led also to the banishment of his first wife, Arsinoe I, daughter of king Lysimachus of Thrace. Ptolemy then married his sister, Arsinoe II, an event that shocked Greek public opinion but was celebrated by the Alexandrian court poets. Taking advantage of the difficulties of the rival kingdoms of the Seleucids and Antigonids, Ptolemy II extended his rule in Syria, Asia Minor, and the Aegean at their expense and asserted at the same time his influence in Ethiopia and Arabia. Egyptian embassies to Rome as well as to India reflect the wide range of Ptolemy's political and commercial interests.

Militaıy leader

While a new war with the Seleucids (from 274 to 270) did not affect the basic position of the rival kingdoms, the so-called Chremonidean War (268?–261), stirred up by Ptolemy against Antigonus II Gonatas, king of Macedonia, resulted in the weakening of Ptolemaic influence in the Aegean and brought about near disaster to Ptolemy's allies Athens and Sparta. Ptolemy was no more successful in the Second Syrian War (c. 260–253), fought against the coalition of the Seleucid king Antiochus I and Antigonus Gonatas. The unsuccessful course of the military operations was compensated for, to a certain degree, by the diplomatic skill of Ptolemy, who first managed to lure Antigonus into concluding a separate peace (255) and then brought the war with the Seleucid Empire to an end by marrying his daughter, Berenice—provided with a huge dowry—to his foe Antiochus I. The magnitude of this political masterstroke can be gauged by the fact that Antiochus, before marrying the Ptolemaic princess, had to dismiss his former wife, Laodice. Thus freed for the moment from Seleucid opposition and sustained by the considerable financial means provided by the Egyptian economy, Ptolemy 11 devoted himself again to Greece and aroused new adversaries to Antigonid Macedonia. While the Macedonian forces were bogged down in Greece, Ptolemy reasserted his influence in the Aegean, making good the setback suffered during the Chremonidean War. He further improved his position by arranging for the marriage of his son (and later successor) Ptolerny 111 Euergetes to the daughter of King Magas of Cyrene, who had proved so far a very troublesome neighbour. Not aiming at outright hegemony (even less imperialistic conquest) in the Hellenistic world of the eastern Mediterranean, Ptolemy II tried nonetheless to secure for Egypt as good a position as possible, holding at large his rivals beyond a wide buffer zone of foreign possessions. Without being completely successful, he managed to let his allies bear the brunt of the heaviest reverses, healing his own military wounds with diplomatic remedies. The influence on Ptolemy of his wife and sister Arsinoe II, particularly in foreign affairs, was certainly substantial, though not as extensive as claimed by some contemporary authors.

Domestic innovator and patron of the arts

Ptolemy II's record in domestic affairs is no less impressive. From pharaonic times onward, agriculture and the work of artisans in Egypt had been highly organized. Under Ptolemy's supervision and with the help of Greek administrators, this system developed into a kind of planned economy. The peasant masses of the Nile Valley provided cheap labour, so that the introduction of slavery on a broad basis was never considered an economic necessity in Ptolemaic Egypt. Ptolemy II became a master at the fiscal exploitation of the Egyptian countryside; the capital, Alexandria, served as the main trading and export centre. Ptolemy II displayed a vivid interest in Greek as well as in Egyptian religion, paid visits to the sanctuaries in the countryside, and spent large sums erecting temples. Anxious to secure a solid position for, and religious elevation of, his dynasty, the King insisted upon divine honours not only for his parents but also for his sister and wife Arsinoe II and himself as *theoi adelphoi* ("brother gods"). He thus became one of the most ardent promoters of the Hellenistic ruler cult, which in turn was to have a far-reaching influence on the cult of the Roman emperors.

Under Ptolemy II, Alexandria also played a leading role in arts and science. Throughout the whole Mediterranean world the King acquired a reputation for being a generous patron of poets and scholars. Surrounding himself with a host of court poets, such as Callimachus and Theocritus, he expanded the library and financed the museum, a research centre founded as a counterweight to the more antimonarchial Athenian schools. Learning there was not confined to philosophy and literature but extended also to include mathematics and natural sciences. The age of Ptolemy II coincided with the apex of Hellenistic civilization; its vigour and glamour were a result of the still fresh forces of Greek leadership in the eastern Mediterranean. Ptolemy 11 was no man of peace, but neither was he one of the warlike Hellenistic soldier-kings. A prudent and enlightened ruler, he found his strength in diplomatic ability and his satisfaction in a vast curiosity of mind.

Public Administration

Public administration, traditionally defined, comprises those activities involved in carrying out the policies and programs of governments. The term is also used today in a broader sense, for public administration is often regarded as including some responsibility—varying widely in degree among governments and departments—in determining what the policies and programs of governments should be, as well as in executing them. But public administration focusses principally on the planning, organizing, directing, coordinating, and controlling of government operations.

As an occupational field, public administration is common to all nations, whatever their system of government. Whether monarchical, totalitarian, socialist, parliamentary, or congressional-presidential, all countries require machinery to put into effect the policies of the government. Within nations public administration is practiced by the central government, by local governments, and, in federal systems, by intermediate provinces and states. The interrelationship of different levels of government within individual nations is in fact a continuing and growing problem for public administration generally.

Public administration as a profession

The professional identity of those engaged in public administration has been strengthened in European countries, and, by colonial imposition or diffusion, in most of the rest of the world, through the establishment of more or less elite administrative, executive, or directive classes in civil services. In the United States and a few other countries, the elitist class connotation was consciously abandoned or avoided, with the result that professional recognition has come slowly and only partially.

Public administration, as well as being a profession, is also a distinct field of study, and the middle decades of the 20th century have seen a considerable increase in research and in the education and training of public administrators.

Historical background. Public administration is an ancient activity. It must have existed for as long as there have been organized societies, for few group determinations in society are self-executing. The earliest records of civilization in south Asia, China, and Egypt contain references to what one would now call public administration.

Modem public administration is a by-product of the emergence of nation-states from the feudal societies of Europe (see also BUREAUCRACY). With the growth and centralization of power and responsibility in monarchical courts came the need for a full-time, stable, and qualified corps of public administrators, who became increasingly specialized in different fields of national activity. One of the earliest systematic manifestations of public administration was known as cameralism, which developed during the 17th and 18th centuries in Prussia and Austria. Cameralism was designed to provide efficient management of highly centralized, paternalistic states characterized by mercantilist economies. It required university training in such fields as public finance and its administration, police science, economics, and agriculture and forestry. The 18th century also witnessed the development in France of a high degree of emphasis and proficiency in technical and engineering activities and saw the establishment of national professional schools, primarily to provide qualified technicians for the public service.

Legalistic approach to public administration

Though some of the elements of cameralism and French technology have had significant impact on public administration in various countries down to the present time, the emphases upon them could not survive the French Revolution and the Napoleonic era. The weight given to the rights of individuals and the obligation of states to protect those rights, the introduction of laissez-faire economics, the codification of law, and other developments led to a quite different view of the state and of its administration. The essence of the latter came to be obligation and loyalty to the state through the interpretation and fair-handed application of law, legitimately enacted to express the will of the state. Such a view suggested that senior permanent officers should be trained in law. The nation-state was sovereign, centralized, and durable; and the legally oriented bureaucracy served the function of providing permanence and stability and of expressing and preserving its "will," despite changes of government and even systems of government. This legalistic view of the state and its bureaucracy persists in much of western Europe and, to a lesser degree, in parts of eastern Europe, as well as in many of the newer countries that were once colonies of continental powers.

Great Britain and the United States followed paths quite different from each other and from continental Europe in the development of their systems of public administration. Neither adopted the somewhat mystical European view of the state, and neither abandoned its common-law tradition for codification. Britain had long entrusted the administrative responsibilities of its government to representatives drawn from its aristocracy of unspecialized, often well-educated gentlemen. Until the Industrial Revolution of the late 18th and early 19th centuries, most of the aristocracy came from rural estates. Following the reform of the civil service in the 19th century, most administrators came to be drawn from the growing mercantile and business classes of the cities. For the last century, they have been selected primarily on the basis of stiff competitive examinations of university graduates, mainly from Oxford and Cambridge. These examinations tested neither administrative law, as on the continent, nor any other specialization directly related to public administration but concentrated on the classics and humanities. This method of recruitment to the British administrative class persisted, with only temporary changes during periods of crisis, into the late 1960s. It was designed to produce generalist administrators—intelligent, broad-gauged men free of parochial, professional perspectives. They would learn administration and the activities they were administering on the job. Administration was perceived more in terms of providing policy advice to ministers and less in terms of internal management than in most other countries. In general, British administrative practice was highly centralized, with controls over the system itself largely concentrated in the Treasury. In 1968 a committee of inquiry into the civil service under the chairmanship of Lord Fulton made recommendations that would result in much broader recruitment into the upper reaches of the civil service.

Through the Indian and other colonial civil services, the British concepts of administration were conveyed to the colonies, and they continue to have impact, though with varying force, in the Commonwealth.

Public administration in the American colonies and in the states and national government that succeeded them also began on the model of the mother country. Administration was by the gentry or landed aristocracy in the South, and by the increasingly commercial and industrial gentry in the North. Public administration was not perceived as a distinct and separable kind of activity or occupation, and the term was not used in the U.S. Constitution. There were three basic structural differences from the British system. One was the federal system and particularly the limited powers of the national government. Second was the separation of executive from legislative powers at the national, state, and city level of government. Third, growing out of the fear and distrust of concentrated executive powers over which the American Revolution had been fought, was the tendency to scatter executive power among a wide variety of commissions, boards, or elected or appointive officials who were either autonomous or responsible to the legislative body. Among other consequences of these structural differences are that to this day, the primary problems of American public administration are these: bridging the separation of executive and legislative powers; establishing more effective and cooperative relationships between and among the national government, the states, and a vast array of local governments; and integrating executive powers in single executives at each level.

Since the Revolution three major developments have significantly affected American public administration.

Major influences on the development of public administration

One has been the two-party political system and, especially during the middle decades of the 19th century, the invasion by political parties of the administrative offices of governments under the patronage system. This practice of rewarding political service with public office effectively thwarted the development of stable administrative systems and made the career prospects of administrators uncertain, for with each change in political control a new group of officeholders would replace the old. Party affiliation, rather than merit or ability, was the criterion for appointment. But the so-called spoils, or patronage, system had a corollary and more wholesome effect: it was a sweeping expression of egalitarianism in its weakening of the hold of the gentry on public offices and its opening of public service to the common man. This move toward egalitarianism preceded by more than a century steps in the sarne direction that were underway in many European and other countries in the 1970s. The depredations of the spoils system gave rise in the late 19th century to a second development: a fervent movement to reform the civil service on the basis of merit and without regard to political affiliation or to social class background. Civil service reform is still far from complete, but it has given rise to many of the features and developments of public administration throughout much of the 20th century. American civil service reform was originally molded on the British pattern, but its effects were entirely different, for it prevented the development of an elite administrative class.

The third development affecting the character of American public administration was the accelerating specialization, diversification, and professionalization of occupations that began about the turn of the 20th century in the United States and within its governments. This development took place all around the world, but its impact in the United States on public administration has been somewhat different. The public agencies of the United Slates had no entrenched amateur, gentlemen administrators as in Britain, nor administrative lawyers, as in continental Europe. Specialists assumed substantial control over the agencies appropriate to their skills: engineers for public works, agriculturists for agriculture, doctors for public health, lawyers for regulatory programs, and so forth.

Russia inherited some of the legal tradition associated with the Napoleonic era, acquired in its case largely thraugh international osmosis rather than occupation. The Russian Revolution of 1917 superimposed a very different set of values and institutions in public administration: subordination of the individual citizen in favour of dominance of the state; a high degree of concentration of power; the one-party system and party control not only of basic policy but of administrative and industrial agencies at every level. The goals of the state are determined by the Communist Party, and these have been primarily concerned with the expansion of political, economic, and military power. The means toward this end are seen as rapid industriaiization, high productivity, discipline, and the suppression of elements in society that might retard or endanger such development. The Soviet Union has thus moved in the direction of a technocratic administration. Its administrative leadership consists increasingly of engineers, production managers, and scientists. They are usually party members, but of a distinctly different type from the older revolutionaries. The Soviet Union may thus be regarded as providing a fourth main source of administrative thought and practice, its system of public administration contrasting strongly with the British, American, and ccntinental patterns. The importance of these four patterns of public administration has been greatly increased as a result of their impact on many other governments of the world.

An important factor in the spread of particular approaches to public administration is the education and training of future leaders in foreign countries, Many Communist political, as well as administrative, leaders around the world were trained in the Soviet Union. A good many public administrators in Africa, Latin America, and Asia were trained in Britain, the United States, and France. Finally, and related to such educational activity, is the conscious imitation of the administrative systems of other countries, often coupled with a request for assistance in establishing such a model. During the 19th century, for example, Japan imitated, and was assisted by, Germany; Thailand was aided similarly by Britain and France. Since World War II, most of the former colonies have been assisted and influenced by their erstwhile mother countries. The United States has had the largest technical assistance program, and American practices are consequently becoming increasingly prevalent. This may be due in part to the greater ability of the United States to provide such assistance and in part to a belief that the United States is most advanced in this field. Public administration is one of the major fields of technical assistance of the United Nations, and such assistance is also provided by a number of other international organizations and by some private foundations.

Factors hindering reform

Current efforts to improve public administration, which seem to be common to almost every country in the world, take different forms in different lands. Improvement is everywhere identified with greater effectiveness or productivity in responding to public needs, but particular facets of the different administrative systems retard such improvement in a variety of ways. The continental legal psychology, for example, is more conducive to stability than to innovation, and the dominance of a legal class has not encouraged the employment of other kinds of specialists and scientists. To a considerable extent the same is true of the British administrative-class generalists. Insofar as both groups are drawn principally from established upper class minorities, their domination is not coriducive to what has been called "democratization" of the public services. Ey way of contrast, a major problem of public administration in the United States is to coordinate the efforts of numerous separate departments at the federal, state, and local levels, each dominated by its particular brand of specialists. In addition, the long-standing American orientation toward business, free enterprise, and economics has discouraged the development of integrating mechanisms for social planning. And the severity and discipline of the single party in most of the Communist states has. according to many observers, provided disincentives toward either innovation or productivity.

Basic approaches. A central theme of public administration throughout the 20th century has been reform. That is, it has been assumed that current administrative processes can and should be improved. The study and practice of public administration has been essentially pragmatic and normative rather than theoretical and value free. This may explain why public administration, unlike some social sciences, developed without much concern about an encompassing theory. Not until the middle decades of the 20th century and the dissemination of the German sociologist Max Weber's theory of oureaucracy was much interest stimulated concerning a theory of public administration. Most of the recent development of bureaucratic theory, however, has been addressed to organizations in the private sector, and, with a very few exceptions, there has been little effort to relate organizational theory with political theory. The main emphasis remains upon pragmatic reform (see BUREAUCRACY).

A second theme of public administration has been economy and efficiency; that is, the provision of public services at the minimum cost, This has usually been the stated objective of administrative reform. Despite growing concern abcut other kinds of values such as responsiveness to public needs, justice and equal treatment, and citizen involvement in government decisions, efficiency continues to be a major goal.

A third feature of public administration has been its emphasis on the structure of formal organization. Most efforts at administrative reform have included as their central element the modification of organizational structures. They reflect a basic faith, held by administrators, politicians, and the educated public, that administrative ills can be at least partly corrected by reorganization guided by logical rules or "principles." Many of the principles were initially borrowed from the military, a few from private business. They include, for example: (1) organizing departments, ministries, and agencies on the basis of common or closely related purposes; (2) grouping like activities in single units; (3) equating responsibility with authority; (4) ensuring unity of command (only one supervisor for each group of employees); (5) limiting the number of subordinates reporting to a single supervisor; (6) differentiating line (operating or end-purpose) activities from staff (advisory, consultative, or support) activities; (7) employing the principle of management by exception (only the unusual problem or case is brought to the top); and (8) having a clear-cut chain of command downward and of responsibility upward.

Some critics have maintained that these and other principles of public administration are useful only as rough criteria for given organizational situations. They believe that organizational problems differ and that the applicability of rules to various situations also differs. Nonetheless, and despite much more sophisticated analyses of organizational behaviour in recent decades, such principles as those enumerated above continue to carry force.

A fourth feature of public administration has been its stress upon personnel. In most countries administrative reform has been preceded or accompanied by civil service reform. Historically, the direction of such reform has been toward what has been labelled "meritocracy"—the best individual for each job, competitive examinations for entry, and selection and promotion on the basis of merit. Attention has increasingly been given to factors other than merit, including personal attitudes, incentives, personality, personal relationships, and collective bargaining.

A fifth feature of public administration has been the development of the budget as a principal tool in planning future programs, in making decisions as to program priorities and the allocation of resources, in managing current programs, in linking executive with legislature, and in developing control and accountability. The public budget and thecontests for its control have along history, particularly in the Western world, that began with centuries of struggle between monarchs and representatives of their subjects for control over public finances. The modern executive budget system in which the executive recommends, the legislature appropriates, and the executive oversees expenditures originated in 19th-century Britain. In the United States during the 20th century, the budget became the principal vehicle for legislative surveillance of administration, for executive control of departments, and for departmental control of subordinate programs. It has been assuming a similar role in many of the developing countries of the world.

Recent developments. The classical approach to public administration described above probably reached its furthest development in the United States during the 1930s. Since that time, through educational and training programs, technical assistance, and the work of international organizations, it has become standard doctrine in many countries, although some of its elements have been resisted by governments with British or continental-legal perspectives. During the 1930s this rather simplistic, mechanistic approach was also challenged from a number of different directions. The field, in practice and in study, has since been greatly enlarged and enriched by new perspectives and insights. It has also been somewhat confused as a result of certain inconsistencies in approach.

Changes in the basic premises of public administration

The orthodox doctrine rested on the premise that administration was simply the implementation of public policies determined by others. According to this view, administrators should seek maximum efficiency but should be otherwise neutral about values and goals. During the Great Depression of the 1930s, and even more so during World War II, however, it became increasingly evident that most new policies originated within the administration; that policy and value judgments were implicit in most significant administrative decisions; that many administrative officials worked on nothing except policy; and that, insofar as public policies were controversial, such work inevitably involved administrators in politics. The presumed separation of administration from policy and politics was seen to be artificial. Since the 1930s there has thus been increasing concern in public administration about the determination of policies and the development and use of techniques to improve policy decisions. Although the concept of a value-free, neutral administration is regarded by many as a thing of the past, no fully satisfactory substitute has been offered. How to ensure that responsible and responsive policy decisions are made by career administrators, and how to coordinate their work with the policies of politically elected or appointive officials, remain vital problems, especially in democratic states.

A second challenge to the old concepts of public administration was a result of a direct response to the Depression and the accompanying responsibility of national governments to restore, stimulate, and stabilize their economies. With these responsibilities came new informational devices, including the system of national income accounting and the emergence of gross national product as a major index of economic health. The practices of fiscal and monetary policy have become established specializations of public administration. Economists occupy key posts in the administrations of most nations, and many other administrators must have at least elementary know!-edge of the economic implications of government operations. Great Britain, Sweden and other Scandinavian nations, and the United States were among the leaders in the development of tools and techniques for economic planning. Such planning has become a dominating concern of public administration in many of the developing countries.

Modem economists have introduced new methods of analyzing the costs and benefits of government programs. An extension of cost-benefit analysis known as Planning Programming Budgeting System (PPBS) was developed in the U.S. Department of Defense and was later adopted by civil agencies of the U.S. government during the 1960s. Though officially abandoned by the national government in 1971, it has been increasingly applied in U.S. states and cities. Most of the nations of western Europe, Japan, and some of the developing nations have introduced the PPBS system or some aspects of it, although sometimes under a different name.

Under a PPBS system long-range objectives are defined as specifically as possible, and alternative programs for the attainment of such objectives are analyzed and compared from the standpoint of their predicted costs and benefits. PPBS is objective, quantitative, and economic in its orientation. Whether or not it will survive as a "system" is conjectural, but its emphasis upon concrete evaluation and analysis of programs has made a significant contribution to decision making in the administrative sphere, and it seems likely that this influence will continue to grow.

PPBS has proved to be a forerunner of a more profound shift in emphasis in public administration toward systems and systems analysis and away from structures and processes. As indicated above, public administration has traditionally been concerned with the legitimacy and efficiency of the organizations and procedures by which public decisions are reached and executed. In the emerging systems approach, public problem areas—such as weapons systems, housing, employment, and education—have come to be perceived and analyzed as systems that consist of interacting parts and that are responsive in predictable ways to influences and "inputs" from outside. Public administrators require more and diierent kinds of data from those that are customarily available to governments, and new kinds of information systems providing data on the condition of society have been developed.

Most of the domestic activities of governments have been directed to the improvement of the quality of life in a society. Quantitative economic measurement has been useful to a certain extent in this respect, but the value of human life, of freedom from sickness and pain, of safety on the streets, of clean air, and of opportunity for achievement have hardly been measurable in monetary terms. Public administration has thus increasingly concerned itself with finding and developing better social indicators, quantitative and qualitative—that is, better indexes of the effects of public programs, and new techniques of social analysis.

A concurrent, but entirely different, development in public administration has been the movement known generally as human relations. Its seeds were also planted in the 1930s when research, conducted over a period of several years and involving the workers and management of an industrial plant near Chicago, was reported. The research brought out, among other things, the importance of social or informal organization, of good communications, of individual and group behaviour, and of attitudes (as distinct from aptitudes). Concurrent and subsequent studies, especially in Great Britain and the United States, explored group dynamics, the process of attitude change, and differing styles of leadership and their effects.

The human relations movement was initiated by interest among social scientists—psychologists, social psychologists, sociologists, cultural anthropologists, and psychiatrists. During the middle decades of the 20th century their views had an increasing impact upon business management and a somewhat less but still significant influence upon public administration. The human relations approach raised questions concerning many of the oldest dogmas of administration: hierarchy; directive styles of leadership; clear and set definitions of duties; treatment of employees as impersonal "units" of production; and monetary incentive systetns (see also INDUSTRIAL AND ORGANIZATIONAL RELATIONS).

By the early 1970s the human relations approach had developed into a field known as "orgznization development." Its primary goal and orientation was tcward change: change in the attitudes, values, and structures of organizations so as to better adapt them to rapid change in their environment and in the demands placed upon them. Its tools included the use of trained consultants, usually from outside the organization, intensive interviewing of managers and employees, sensitivity training, confrontation meetings, and many others. Unlike the rationalistic PPBS approach, organization development stressed the identification of personal with organizational goals, the "self-actualization" of workers and managers, effective interpersonal communication, and broad participation in decision making. Its direct use within governmental agencies has been limited and has not always been successful, but it has had considerable indirect influence upon the way administrators think and behave.

Another modern movement in public administration, which is at least philosophically related to organization development, has been directed toward the greater participation of citizens in governmental decision making and action. It was stimulated during the 1950s and 1960s by a growing feeling that governments were not responding to the needs of their citizens, particularly minority groups and the poor. This disaffection contributed to widening protests against public, agencies and institutions. A variety of experiments to involve citizens or their representatives in governmental decision processes were begun in the 1960s that involved the delegation of decision-making power from central to local offices and, at the local level, the sharing of authority with citizen groups. This challenge to governmental bureaucracy could lead to fundamental changes in the nature and style of public administration. At the least it will probably contribute to greater concern on the part of administrators about the effects of their actions on citizens.

Comparative public administration. Until World War II there was rather little cross-filtration or even communication of public administration between nations except, as noted earlier, within the confines of imperial systems. As early as 1910 a professional organization, which eventually became the International Institute of Administrative Sciences (IIAS), was established. At first, however, its membership consisted principally of scholars and practitioners of administrative law in the countiies of continental Europe. In the early 1980s the IIAS had a membership drawn from about 50 countries. Its triennial congresses have covered all aspects of the field.

The period since World War II has witnessed an extraordinary burst of interest in the administrative systems of other countries. This was precipitated by the necessity of cooperation among the allied countries during the war; by the formation of international organizations; bv the occupation of conquered nations and the administration of economic recovery programs for Europe and the Far Bast; and by aid and technical assistance programs for developing countries. One by-product of aid and assistance programs was a renewed appreciation of how crucial effective administration was to national development. Another by-product was a realizztion of how parochial and culture-bound public administration thinking and practice had often remained within individual countries.

International interest in public administration

Another effect of this international communication and sharing of experiences has been the realization that development is not exclusive to the so-called underdeveloped countries. All countries have continued to develop, and public administration has increasingly been perceived as the administration of planned change in societies that themselves have undergone rapid change. not all of it planned. Government has no longer been merely the keeper of the peace and the provider of basic services: in the postindustrial era government has become a principal innovator, a determinant of social and economic priorities, and an entrepreneur on a major scale. On virtually every significant problem or challenge—from unemployment to clean air—people have looked to the government for solutions or assistance. The tasks of planning, organizing, coordinating, managing, and evaluating modern government have likewise become awesome in both dimension and importance.

Education and training for public administration. It is probably a safe judgment that every nation in the world has suffered a shortage of well-trained public administrators. European universities have been producing administrative lawyers for their governments for more than a century and a half, but legal skills are hardly adequate for handling contemporary problems. U.S. universities more than half a century ago began graduate programs, and by the 1970s there were moie than 60 university programs in public administration. Their total output has been, however, insufficient to meet the needs of government, and very few of the scientists and other specialists who become administrators in their fields attend such programs.

Shortage of trained public administrators

There has been a burgeoning of training programs around the world since World War II, many of them set up or sponsored by national governments, and some of them attached to universities. As one of its civil service reforms of 1946–47, France established an École Nationale d'Administration, which provided an extensive course for recruits to the higher civil service. It was not until 1969 that Britain established a Civil Service College under the new Civil Service Department. In the United States, the government established a variety of educational and training programs during the 1960s, including the Federal Executive Institute and the Executive Seminar Centers. Many of the developing countries have established one or more schools or training institutes, and by 1970 centres for the training of public administrators existed in more than 100 countries.

BIBLIOGRAPHY. The most comprehensive treatment of' administration is B.M. GROSS, ***The Managing of Organizations: The Administrative Struggle,*** 2 vol. (1964). Among the classics in the field are F.W. TAYLOR, ***The Principles of Scientific Management*** (1911; reprinted in ***Scientific Manugernent.*** 1947); HENRI FAYOL, ***Administration industrielle et générale*** (1916 and 1941; Eng. trans.. ***General and Industrial Management,*** 1949); and MAX WEBER, ***Wirtschaft und Gesellschaft*** (1922: Eng. trans. of pt. 1, ***The Theory of Social and Economic Organization,*** 1947, reprinted 1964).

The traditional approach to public administration and its principles were set forth in L.H. GULICK and L. URWICK (eds.), ***Papers on the Science of Administration*** (1937); and L. URWICK, ***The Elements of Administration,*** 2nd ed. (1947). Challenges to the principles, as well as efforts to build a theory of decision making as central to administration, appeared in C.I. BARNARD, ***The Functions of the Executive*** (1938, reprinted 1958); and H.A. SIMON, ***Administrative Behaviour: A Study of Decision-Making Processes in Administration Organization*** (1947). DWIGHT WALDO provided a thoughtful review of the evolution of public administration in its relation to society in ***The Administrative Stare: A Study of the Political Theory of American Public Administration*** (1948). The challenge to the traditional dichotomy between policy and administration was

expressed cogently in various works of P.H. APPLEBY, most notably in his ***Policy and Administration*** (1949). Later developments of similar views are contained in D.B. TRUMAN, ***The Governmental Process*** (1951, 2nd ed. 1971); E.S. REDFORD, ***Democracy in the Administrative State*** (1969); and H. SEIDMAN, ***Politics, Position and Power: The Dynamics of Federal Organization*** (1970). The economic systems approach to public program decisions and PPBS are set forth by two of their principal architects: C.J. HITCH, ***Decision-Making for Defense*** (1965); and C.L. SCHULTZE, ***The Politics and Economics of Public Spending*** (1968). The prophet of the human relations movement was Mary Parker Follett, some of whose writings were published by H.C. METCALF and L. URWICK (eds.), in ***Dynamic Administration: The Collected Papers of Mary Parker Follett*** (1960). More recently, the derivative movement (now called organization development) has been treated by C. ARGYRIS, ***Integrating the Individual and the Organization*** (1964); RENSIS LIKERT, ***New Patterns of Management*** (1961); and W.G. BENNIS, ***Organization Development*** (1969). A significant and growing literature has been developed since World War II in case studies of actual administrative experience. Pioneered and led by the American Inter-University Case Program, the use of cases has spread to many other countries. An example of the use of cases in comparative analysis is F.C. MOSHER (ed.), ***Governmental Reorganizations: Cases and Commentary*** (1967).

On the administrative systems of different countries, the following are of special note: B. CHAPMAN, ***The Profession of Government*** (1959); F.F. RIDLEY (ed.), ***Specialists and Generalists: Civil Servants at Home and Abroad*** (1968); F.W. RIGGS, ***Administration in Developing Countries*** (1964); M. BERGER, ***Bureaucracy and Society in Modern Egypt*** (1957); and J.G. LaPALOMBARA (ed.), ***Bureaucracy and Political Development*** (1963).

Public Debt

Kinds of public debt

Public debt may be defined as sums owed by governments, in the form of bonds, notes, bills, etc., requiring the payment of specified amounts of money to the holders at designated times. For the most part public debt differs from private debt only in that it is an obligation of government rather than of private individuals or corporations. Public debt may be classified according to various criteria.

Internal and external debt. If the debt is held by persons outside of the issuing jurisdiction, it is called external; if it is held within the jurisdiction, it is called internal. The U.S. national debt is almost entirely internal, while the debts of many developing countries and of subordinate units of government in the United States are largely external.

Maturity period. Public debt ranges in maturity from infinity to periods of a month or even a few days. Debt instruments without a maturity date, requiring merely the payment of interest, are often called consols. The name originated in Great Britain, where the first important indeterminate-period debt issue was one that consolidated a number of separate issues.

A large portion of government debt consists of bonds with specific maturities of five to 99 years or more. Twenty- and 30-year periods are common. These are often known as long-term or funded debt.

Debt of maturity less than five years is often called short-term or floating debt and may take several forms: notes, with maturities from one to five years; treasury bills, with maturities from one month to a year and often sold at auction; and certificates of indebtedness, with similar maturities but available at a fixed interest rate.

The length of the maturity period affects what is known as the liquidity of the debt—*i.e.*, the quickness with which it can be converted into money. Securities with very short maturity periods are constantly repayable in money and thus have maximum liquidity or "moneyness." As the period maturity increases, the liquidity falls and the pure debt characteristic increases; consols have minimum liquidity because they have no date of maturity.

Type of issuer. Government debt may be directly issued by a government or by semi-autonomous governmental organizations. Examples of the latter would include railways, provincial power authorities in Canada, and various federal lending agencies in the United States. Their issues may be guaranteed by the government (general obligation bonds) or may rest solely upon the enterprises themselves, to be paid out of their revenues. In the United States this type of obligation is known as a revenue bond.

Marketability. The great bulk of all government debt consists of marketable securities. These securities are negotiable and sell freely on the market. They are usually issued in relatively large denominations, $1,000 or higher, and interest is paid periodically by check or coupon. Since they are salable, their price fluctuates from time to time, going above maturity value when the current market interest rate falls below the interest rate that they bear, and falling below the maturity value when the current rate rises or when fear about the ability of the government to pay interest develops.

Other bonds bought by the public are not marketable but can be redeemed, after a specified period, for their principal plus accrued interest. Various savings bonds, including those of the United States, are of this kind.

Other characteristics. Bondholders may receive current interest either by redemption of coupons attached to the bonds or by check from the government. Alternatively, interest may be receivable only upon maturity or redemption of the bond, as in the case of savings bonds. Interest and principal are usually payable in fixed monetary units, but they may be payable in amounts with fixed purchasing power based on changes in price levels.

THE ECONOMICS OF PUBLIC DEBT

The effects of debt financing upon the economy

Government borrowing is likely to have effects upon the economy that are substantially different from those of other methods of financing, and the existence of a sizable debt may likewise have important consequences. The effects of retiring the debt may also be significant. National government borrowing has the greatest impact, but that of subordinate units may also have some influence.

Borrowing. Government borrowing in the strict sense includes only borrowing from the private sector of the economy—from individuals, corporations, and various financial institutions, including banks. When the government obtains its funds from the central bank (the Bank of England, the Bank of Italy, the Bank of Japan, or the Federal Reserve System in the United States) it is really creating money rather than borrowing it, since the purchasing power is made by the central bank and no obligations to the public are created.

When a government borrows, funds are transferred from the lender to the government, the lender exchanging its money for government securities. The effect is to reduce the liquidity of the lender—its command over cash—to an extent dependent upon the nature of the securities. The reduction in liquidity is small with short-term securities and greatest with nonsalable, nonredeemable securities—a type seldom issued.

Funds loaned to the government almost certainly come from savings, unlike, for example, funds paid in higher taxes, which are more likely to come out of consumption. To pay higher taxes, many individuals are forced to reduce their consumption since they have no margin of savings and are unable or unwilling to go into debt; others do so as a matter of choice, in an effort to keep their savings intact. Lending, on the other hand, is entirely voluntary. People who buy government securities are not likely to increase their rate of saving in order to do so or to decrease their consumption. If government borrowing raises the market rate of interest, this may in turn encourage the diversion of additional money to saving, as may government securities that offer additional attractions—such as small denominations or redeemability—not possessed by other securities. Both effects in total, however, are not likely to be significant.

The net effect of government borrowing on total spending and thus on employment and national income will depend upon its influence on real investment—the purchase of new capital goods. In a period of unemployment, when savings will be available in greater quantity than investors will be prepared to use, government borrowing will not compete with private investment nor make it more costly. In effect, the government will be absorbing funds that would otherwise be idle.

In periods of full employment the situation is substantially different. With banks loaned up to the limit of their reserves and real investment absorbing all of savings, government borrowing will restrict private spending as much as an increase in taxation will under the same conditions.

Government borrowing is of economic significance in several other respects. First, the buying and selling of government securities provides the central bank with a means of influencing the money supply, essential for effective monetary policy. Second, borrowing avoids the adverse effects that taxes may have on incentives, particularly if the taxes are raised sharply above levels to which persons have become accustomed. Third, borrowing permits government expenditures to be higher than would otherwise be feasible, as explained in a subsequent section. Finally, the foreign borrowing of some governments gives them access to a greater quantity of foreign exchange, which enables them to finance the import of capital goods essential for economic growth. This consideration is not of concern to highly developed countries.

Effects of the debt. The existence of a government debt is of economic significance in itself, as distinct from the effects of the borrowing. In the first place, individuals who hold government securities regard them as a portion of their personal wealth and accordingly consider themselves to be wealthier than they would if they had only tax receipts. This may make them spend more on consumption and save less than they otherwise would. The additional consumption may reduce the rate of capital formation and economic growth; it may also increase the level of employment over what it would otherwise be.

Second, because government securities are more liquid than most other investments, their holders are able to increase consumption out of accumulated savings more easily than they could otherwise. This may contribute to inflationary pressures.

Third, it is often argued that a large national debt makes equity capital (stocks) somewhat cheaper. The larger amount of fixed-income securities will lead to a relatively greater willingness to invest in stocks, given investors' relative preferences between loan and equity investments.

Fourth, if investors, and particularly the business community, regard the national debt as a source of potential economic instability, their willingness to undertake real investment will be lessened. At times, particularly in the 1930s, there has been widespread fear of government debt even though there was, in reality, little basis for the fear. A similar phenomenon, with more logical foundation, may arise in the case of subordinate units of government. A large debt may discourage expansion of economic activity because of the fear of high taxes in the future and the realization that the large debt may prevent borrowing for urgently needed local improvements.

When governments borrow they must meet interest obligations, and these are usually paid out of taxes. The payment of interest on government debt thus involves a transfer of wealth from taxpayers to bondholders. The taxes may have adverse effects upon incentives while receipt of the interest will provide no offset to these adverse effects. The tax-and-interest-payment program is also likely to redistribute wealth in favour of higher income groups, since government bonds are likely to be held to a greater extent by those groups. The effect may be to increase saving and reduce consumption.

Finally, large interest obligations lessen the ability of the government to finance other governmental activities. This effect is particularly obvious at the local level, where there are limited tax potentials.

Retiring the debt. The retirement of debt has effects opposite from those of borrowing. Bondholders receive money in exchange for their bonds; though they could increase their consumption, they are more likely to put the funds into other securities and, as a consequence, security prices will rise and money capital will become more readily available for business investment. Whether it will be used for that purpose depends, of course, on the general economic situation.

The money for retirement must be obtained from some source. If it is simply created, there will be no repressive effect on consumption or investment, and total spending in the economy will rise—although by an amount relatively small compared to the total retirement. If, as is more common, the debt is retired from tax revenues, consumption will be reduced in substantial measure; the remainder of the tax will be absorbed from savings, and real investment may be reduced. The net curtailment in spending from the program of debt retirement is almost certain to reduce total spending in the economy. Elimination of the debt has one other effect: while current taxes will be increased, future taxes required to meet interest and principal obligations will be reduced.

The burden of the debt. It is often said that borrowing shifts the burden of governmental activities to future generations, since those generations will be assessed higher taxes to pay the interest and principal. Economists generally regard the argument as invalid, for future generations will inherit both the bonds and the obligations to pay them and collectively will be neither richer nor poorer than if the debt had not been incurred, except as a result of the difficulties incident to the debt and its retirement noted in preceding sections. Regardless of the methods of financing, the real cost of any governmental activity, war or otherwise, is borne in the form of reduced consumption and investment and harder work or the like during the period in which it is carried on. The only burden on the future is that arising from the depletion of natural resources or slower rates of investment, and these are not affected by methods of financing.

The effects of borrowing upon future generations

Several writers have pointed out that this reasoning ignores one significant element: if governmental activities are financed by borrowing, consumption will be reduced less and savings more than with tax financing, and also, because of the existence of the debt, persons will continue to consume more and save less. Assuming full employment, the rate of capital formation will therefore be less than with tax financing; future generations will inherit a somewhat smaller stock of capital goods, and per capita real incomes will be somewhat less than they would have been if tax financing instead of borrowing had been used.

Some writers question the doctrine that the burden, even apart from its effects on capital formation, is not shifted forward to the future. They argue that the burden can be thought of as meaningful only in terms of individual satisfaction. In the period in which the borrowing occurs, according to this view, the purchasers of government bonds obviously suffer no burden, in the sense of loss of personal satisfaction, because they bought the bonds voluntarily, and, having exchanged money for the bonds, presumably regard themselves as better off. But, in the future, when the debt is repaid, taxpayers will suffer a loss since they must pay larger amounts of taxes than they otherwise would and will therefore lose satisfaction, while the bondholders will experience no net increase in satisfaction since they will merely re-exchange the bonds for money. Thus a net decline in personal satisfaction will have occurred in the future generation and the burden will actually have been shifted to the future.

The difference between these two lines of reasoning hangs upon the definition of burden. If burden is defined as the reduction of output in the private sector of the economy when resources are transferred to the public sector, obviously the burden occurs at the time the governmental activities are undertaken. If burden is defined in terms of individual sacrifices, the burden occurs in the future. The first definition is useful in stressing the fact that resources cannot be pulled from one generation to another (except through the effect on the rate of capital formation), and that therefore borrowing does not make real income greater in the present and less in the future. The second definition is relevant if persons believe that borrowing does shift the burden to the future, for then, during the period of the borrowing, fewer private-sector goods will be available for consumption and capital formation, but individuals will experience an equivalent increase in their personal wealth in the form of government bonds. Thus as long as they disregard the future tax liabilities created by the borrowing, they do not feel a burden.

The argument of the preceding paragraphs is applicable, of course, only to domestically held national debt. Foreign-held debt gives a claim to foreigners against national output; payment of interest and principal will require the export of goods and, thus, a reduced domestic standard of living. Similar reasoning applies to state or local debts held outside the community, in which cases payment of interest and principal will constitute a decline in the real incomes of the people of the area as a whole, and the burden will thus be effectively shifted to future generations.

SHOULD GOVERNMENTS BORROW

Objections to borrowing. The desirability of government borrowing has been debated for centuries. The traditional argument against borrowing is, of course, the interest burden to which it gives rise, an argument applicable equally to private and governmental borrowing. These interest obligations require either higher levels of taxes, with possibly adverse effects on the economy, or reduced expenditures for other purposes. The payment of interest may easily result in a transfer of purchasing power to higher income groups, contrary to accepted standards of equity.

Arguments for and against government borrowing

As noted in the preceding section, the financing of expenditures by borrowing instead of taxation and the debt itself, once incurred, tend to produce higher prices and other inflationary effects in periods of full employment because they increase total spending. During periods of full employment, any increase in government expenditures not offset by an equivalent decline in private spending for consumption or business expansion will be inflationary. This is the usual argument made against the use of borrowing instead of taxation from the standpoint of the goal of economic stability. It is primarily relevant to national government borrowing because the national government must assume the primary responsibility for lessening economic instability. But state and local borrowing is, of course, equally inflationary.

Borrowing, if freely employed, can easily lead to increases in government expenditures beyond levels regarded by society as the optimum and may reduce the pressures for efficiency and elimination of waste. As governments consider expenditure levels, the adverse reaction to taxation serves as an offset against the favourable response to increased services that will have to be paid for by taxation and thus facilitates the attainment of a balance between government-produced services and privately produced services. But if borrowing replaces taxation and is generally accepted as a suitable routine method of financing, the pendulum will swing in the direction of increased governmental activity, and appropriate balancing wlll be lost. The best evidence of this danger is to be found in the history of state and local government finance in the early 19th century in the United States, when large sums of money were borrowed for purposes of limited usefulness to society. The basic trouble with borrowing is its relative painlessness as long as people disregard the future consequences.

There is, of course, the further possibility that a government may accumulate so much debt that it will lose the confidence of the people and may reach a point at which it cannot meet its obligations. Loss of confidence will make borrowing of additional funds in an emergency difficult and may check economic development by lessening optimism on the part of businessmen. If a government goes so far into debt that it cannot meet its obligations, its credit is seriously impaired. A national government, with its extensive taxing potentialities and its control over the banking system, is hardly liable to find itself in a position in which it cannot meet interest obligations or sell bonds. But if debt were to exceed certain levels, the government might be unable to sell bonds extensively to individuals and thus be forced to resort to borrowing from the central bank, the most inflationary form of financing.

These arguments are believed to constitute a significant case against general reliance on borrowing. The case is felt to be strongest in periods of full employment; for local governments, when it exceeds levels at which interest can be met easily from current sources; and in all circumstances in which governments are relatively irresponsible with regard to future problems created by present policies.

The case for borrowing. There are three primary circumstances in which government borrowing is usually regarded as justifiable:

1. In a period of unemployment or depression or both, the basic argument against the use of government borrowing—that it tends to generate inflation—is not relevant. At such times, any expansionary effect that the financing of government expenditures by borrowing instead of taxation may have will tend to bring about an increase in output rather than an increase in the general price level. Accordingly, the use of borrowing may be regarded as justifiable, in terms of the goal of lessening the severity of depressions and attaining greater economic stability. However, the other objections against borrowing may still remain and suggest the need for a restraint on the borrowing, particularly at the level of units smaller than national governments. Indeed some persons regard these objections as serious enough to overrule the justification for depression borrowing as a means of encouraging recovery. But this has now become a minority point of view. In a severe depression borrowing could be avoided only by a sharp curtailment in activities and an increase in taxes, all of which would not only aggravate the depression but would be politically intolerable. Even if the point of view that governments cannot succeed in bringing about recovery from depression by deliberate action is accepted, it must still be recognized that some national reliance on borrowing in depressions is inevitable and justifiable to avoid aggravating the depression.

An alternative to borrowing in time of depression is the creation of money through the central bank. The government borrows from the central bank, which creates the required funds and thus enlarges the money supply. Money creation offers two significant advantages: no obligations to repay debt in the future are created, and there is no direct depressing effect on private spending. The funds spent by government are merely created, rather than being taken from anyone. A secondary advantage is the increase in commercial bank reserves that results from the process; the banks are made more liquid and can expand loans, thus stimulating investment.

In practice, however, governments have been unwilling to use money creation as a means of financing deficits in periods of unemployment. The primary reason for this is the widespread belief that money creation is irresponsible and a source of inflation. This fear arises from the black memories of runaway inflations that have occurred in various countries in the past when governments resorted to excessive creation of money. But with responsible use of the technique, most economists believe that the dangers are slight.

2. The use of borrowing is regarded as inevitable in periods of major war. If taxes were increased sufficiently to finance all war costs, they could seriously impede the war effort by impairing incentives to work and by reducing the overall morale of the people. The limits of economically and politically tolerable taxation may well be below the maximum feasible allocation of resources to the war effort. Adequate tax increases would also aggravate the inequities of the tax structure; an overall level that would reduce total consumer spending to a level equal to the rate of output of consumer goods might well push some persons below subsistence levels and make it impossible for others to meet fixed commitments. While the use of borrowing as a method of war finance makes the control of inflation more difficult, there appears to be no escape from the necessity.

3. When governmental activities require capital outlays far in excess of usual expenditures and of a nonrecurrent character, then borrowing is not only virtually imperative if the outlays are to be made but is entirely justifiable. This rule is of primary concern to local governments because at higher levels the ratio of nonrecurrent expenditures to total expenditures is such that tax financing is possible without undue fluctuation in tax rates or hardships to taxpayers in particular years. But local governments must often make expenditures far in excess of usual annual income on projects that will last over a period of years. In such cases, the failure to use the loan method would tend to hold expenditures for such purposes below the optimum level because taxpayers will fight such sharp increases in taxes, particularly if the capital outlay will tend to benefit taxpayers in future years. The argument is particularly strong in the case of self-liquidating projects such as power or water system expansions and is valid even when the outlays are to be paid off out of tax revenues. It must be emphasized that the characteristic feature justifying the use of borrowing is the nonrecurrent element; the mere fact that the object of a particular expenditure will last a number of years is not in itself a justification if roughly the same amounts will be spent each year. If a city is to repave 20 blocks of streets annually, there is no need for borrowing, and a good case can be made against it, even if each particular repaved street may last 25 years.

A final justification for borrowing, relevant only to short-term loans, is a lack of exact correlation in the time when revenues are received and expenditures are made. Unless a government is to build up a surplus, it must borrow occasionally to meet expenditures at a date earlier than the receipt of the tax revenue.

Debt limitation laws. Efforts have been made in some countries to set restrictions on government borrowing through legislative acts.

Efforts to restrict government borrowing

In the United States, fear of excessive borrowing has resulted in restrictions on the amounts the executive, and even the legislative branches of government, can borrow. When many states found themselves in financial difficulties after borrowing heavily to provide funds for canals and railroads in the middle of the 19th century, public debt provisions were written into the constitutions of all but seven states. The provisions limiting borrowing differ widely. In most jurisdictions a maximum, usually expressed as an absolute dollar sum and one relatively low in terms of present-day expenditure levels, is set. Either this figure cannot be exceeded at all (except by amending the constitution) or it can be exceeded only with the approval of the voters at an election. In some places all bond issues require approval by popular vote and in some instances by more than a bare majority. The purposes for which funds may be borrowed and the duration of the issue are also frequently restricted. These constitutional restrictions have unquestionably lessened state borrowing; in so doing they have, perhaps, reduced waste, but they have also sometimes prevented urgently sought improvements. The limits have likewise greatly increased the use of revenue bonds, which are normally not subject to the restrictions. Unfortunately, the interest rate on these bonds is higher than the rate on other bonds.

Restrictions on municipal borrowing in the United States are almost universal. The restrictions, established either in the state constitutions or by state legislation, limit the total sum to be borrowed by any particular unit to a certain percentage (from 2 percent to over 20 percent) of the total assessed value of its property. The limits vary for different types of local units (city, county, school district, etc.). They usually do not apply to debts incurred for self-liquidating enterprises. In many states every bond issue must be approved by popular vote, in some instances by a two-thirds majority. In other states the limits established may be exceeded by popular vote, often with a requirement beyond a mere majority. Legislation also controls maximum interest rates that may be paid, the duration of the issues, the purposes of the borrowing, the establishment of means of retiring the bonds, etc. Several states exercise review over local bond issues, but only North Carolina requires specific state approval of all issues. Like the states, the local governments have found means of escaping the restrictions. Special taxing districts with their own debt limits are often formed when a city has reached its limit. Revenue bonds are also employed. In some states, such as Pennsylvania, there has been widespread creation of special authorities. A special school building authority, for example, is established with the power to finance the building of schools by issuing revenue bonds. In turn, the authority pays interest and principal on the bonds from rentals obtained from the school districts using the buildings.

While there are no constitutional limits on federal borrowing powers in the United States, Congress for many years has restricted borrowing by the Treasury Department. Before 1917 borrowing was permitted only upon specific authorization by Congress. After 1917 maximum figures were set at first for each type of loan and then, after 1938, as an overall total. The 1938 figure of $45,000,000,000 was gradually increased to a high of $300,000,000,000 in 1945 and reduced to $275,000,000,000 in 1946. Buttressed by a strong belief in Congress that failure to raise the limit would check growth in government spending, the limit remained at the 1946 level until 1954. Eventually, pressure on the limit became so great that various government bodies such as lending agencies were forced to borrow on their own at higher interest rates, and a series of increases was made in the 1960s. The limit was $377,000,000,000 as of Jan. 1, 1970. Experts differ in their estimates of the usefulness of the federal limit. Some believe that it curtails government waste and unjustified increases in expenditures, while others argue that it reduces flexibility in meeting emergencies, checks needed increases in various activities, could prevent quick action to stave off a depression, and leads to uneconomical forms of borrowing.

In Canada, neither the dominion nor provincial governments are subject to debt limitations. Local government limits are comparable to those in the United States, and in several provinces bond issues must receive the approval of a provincial agency. In Great Britain, borrowing by local governments is subject to control, specifically by the Ministry of Housing and Local Government, and limits are usually established in terms of a ratio of debt to total ratable value (assessed value of property). After World War II much local borrowing was channelled through the Public Works Loan Board, and thus was subject to additional control.

EVOLUTION OF GOVERNMENT BORROWING

The history of government debt in various countries

The evolution of government borrowing was very slow. The extensive use of loans by governments became possible only after the ruler had become differentiated from the state and after the fact of the continuity of the state had been separated from the persons of the rulers. Other factors were also required: the development of a regular revenue source to provide funds for repayment of loans, a monetary system, and an organized money market. The earliest loans of medieval times were either forced loans or personal borrowing by the sovereign. Government borrowing in its modern form first occurred in medieval Genoa and Venice when the city governments borrowed on a commercial basis from the newly developed banks.

France. Throughout much of French history public borrowing has been of major dimensions. Ministers of finance in the 17th and 18th centuries found the problem of managing the debt almost insuperable. During the Revolution that began in 1789, about two-thirds of the accumulated debt was repudiated, and the remainder was refunded in new securities in 1800 at a total of 926,000,000 francs. The sum increased by only 340,000,000 francs during the Napoleonic period because Napoleon's military expenditures were financed mainly by foreign levies. A large increase occurred during the Second Empire, when the debt rose from 5,516,000,000 francs in 1852 to 12,310,000,000 francs in 1870. The Franco-Prussian War, which ended in defeat for France, and the consequent imposition of an indemnity of 5,000,000,000 francs by the victorious Germans raised the French public debt to over 21,000,000,000 francs in 1873. Most of the increase was financed by four bond issues. After 1878 the debt increased further as a result of public works expenditures and France's colonial expansion until it stood at 34,204,000,000 francs at the outbreak of World War I. The war and its effects multiplied the debt, although at the same time inflation reduced the value of the franc by half.

The inflationary trend continued throughout the interwar years, and by 1960 the franc had lost more than 99 percent of its 1914 value. The increase of the public debt in this period to 8,404,000,000,000 francs has to be seen, therefore, in the context of the continuing inflation. The issuance in 1960 of a new franc equalling 100 old francs automatically reduced the nominal value of the public debt to 1 percent of its previous figure.

Great Britain. Government borrowing in Great Britain dates back to the end of the 17th century. In 1692, legislation pledged the receipts from beer and liquor taxes as security for a loan of £1,000,000. As Table 1 indicates, the trend of the debt was upward throughout the next 150 years largely because of wars; by 1802 it had reached £523,000,000 and by 1840, £827,000,000. The second half of the 19th century saw gradual reduction of the debt to £610,000,000 in 1900, while the amount of debt still remaining became less significant because of the growth of the economy in the same period. World War I brought a tremendous increase, the 1920 figure being £7,828,000,000. The 1920s showed little reduction and the figure rose slightly during the Depression years. World War II brought the level to £21,366,000,000 in 1945, and the figure rose in the postwar period—partly as a result of nationalization of industry—to over £34,000,000,000 in the late 1960s.

*Fiscal years vary between countries and over the periods covered for the same countries. †Data for 1697–1828 are from E. L. Hargreaves, *The National Debt*, p. 291 (London 1930). Data for 1836–1935 are net national debt compiled from British official "Accounts and Papers" by subtracting exchequer balances from total debt. Data for 1940 and 1945 are from the United Nations, Department of Economic Affairs, *Public Debt, 1914–1946* (1948). Data for 1950–69 are from the United Kingdom Central Statistical Office, *Annual Abstract of Statistics*. ‡Data for 1791–1850 are from U.S. Treasury Department, *Annual Report of the Secretary of the Treasury on the State of the Finances for Fiscal Year Ended June 30, 1903*, p. 63. Data for 1855–1935 are from *ibid, June 30, 1943*, pp. 562–563. Data for later years are from subsequent *Annual Reports* and *Treasury Bulletins*. §Data are from the French Institut National de la Statistique et des Études Économiques, *Annuaire Statistique de la France*. ‖Data for 1870–1935 are from the *Statistisches Jahrbuch fiir das Deutsche Reich;* for 1940, Bank for International Settlements, *Thirteenth Annual Report* (May 1944); for 1944 United Nations, Department of Economic Affairs, *Public Debt 1914–1946*. Data for 1950–68 are for the Federal Republic of Germany and are from the German Statistisches Bundesamt, *Statistisches Jahrbuch fiir die Bundesrepublik Deutschland*. ¶Data for 1870–1945 are computed from Japanese government sources, especially the Department of Finances, *Financial and Economic Annual of Japan*. Data for 1950–64 are from the United Nations, *Statistical Yearbook*. ♀Data are from the Dominion Bureau of Statistics, *The Canada Year Book*, and Canadian Tax Foundation, *The National Finances*, annual. ♂After 1965, data reported are in new francs, equal to 100 old francs. □1828. ◇1836. ▲The total gross debt of the U.S. on Jan. 1, 1835, was $33,733.05. +Sept. 30, 1944.

United States. In the United States, when the federal government was formed, it assumed the debts of the states and various other obligations incurred during the American Revolution, all of which were funded into a single debt issue of $75,000,000 in 1790. The government was highly successful in avoiding additional borrowing in the early years, except for the War of 1812, and during 1835 all federal debt was eliminated (see Table 1). The years 1835 and 1836 were the only ones in the history of the country during which there was no federal debt at all. The American Civil War, only 25 percent of which was financed by taxation, pushed the debt to a total of $2,678,000,000 in 1865. Most of this debt was retired by budget surpluses during the following decades; debt reduction proceeded so far that bonds available for security behind national bank notes became inadequate. The debt remained relatively constant in the 1890s and during the early 1900s. World War I brought an increase to $26,000,000,000, consisting in part of short-term and intermediate-term securities and in part of Liberty Loan bonds. In the 1920s the government was able to reduce the debt; the low point reached was $16,185,000,000 in 1930, primarily by budget surpluses. Interest costs were materially reduced through replacement of old issues by new ones at lower interest rates.

The 1930s brought budget deficits because of the Depression and the efforts to stimulate recovery. Despite extensive borrowing, which raised the total debt to $42,968,000,000 by 1940, interest rates fell sharply as a result of the surplus of money capital and federal reserve action. A substantial part of the borrowing was on a short-term basis, partly because the interest on such loans was extremely low. With the outbreak of World War II, borrowing rose sharply and by 1946 the debt had reached $269,000,000,000.

In the postwar period the debt fell to a low of $252,000,000,000 in 1948, then gradually rose to $371,000,000,000 in December, 1970. This increase was caused by budget deficits arising primarily from a high level of defense spending and the unwillingness of Congress to hold taxes to rates high enough to meet the expense and in some years from a desire to stimulate economic activity.

The states incurred substantial debts in the early part of the 19th century, largely for public improvements, and some found themselves in financial difficulties. As a result, borrowing came nearly to an end until after 1900; after that date there was further borrowing, particularly for highways. After 1945 the state debt increased sharply and reached a total of $39,500,000,000 by 1969. Much of this additional borrowing was for highway purposes. The local governments have traditionally borrowed more than the states, largely because of the nature of their functions. Local debt in the 20th century increased steadily and had reached $94,000,000,000 by 1969. Table 2 shows the growth of federal, state, and local debt in the United States.

Canada. Canada's debt began with $75,000,000 at the time of confederation in 1867, when certain obligations were taken over from the provinces. The figure grew slowly until 1915, largely because of government railroad financing. World War I pushed the figure to $3,042,000,000 by 1920; the total rose as the Canadian National Railways was developed, fell slightly in the late 1920s, rose to $5,000,000,000 with Depression borrowing, and reached $15,713,000,000 at the end of World War II. Some debt fluctuation then took place and the figure reached about $17,000,000,000 by 1950. By April

1969 it had risen to $35,800,000,000 as a result of deficits. The path of provincial and local borrowing in Canada was similar to that in the United States, though with a slower rate of growth.

Germany. The German Reich, founded in 1871, began as a confederation of sovereign states. Most financial powers remained with the individual states until the Weimar Republic was established in 1919. A French war indemnity of 1871 was used largely to reduce the public debts of the states. As late as 1913 the debt of the Reich (4,900,000,000 marks) was less than half that of Prussia (9,900,000,000 marks) and substantially less than the aggregate debt of all the other federal states (6,300,000,000 marks). The country's defeat in World War I led to financial chaos. In 1925, after the stabilization of the new Reichsmark, the public debt was 2,413,000,000 marks. In the 1930s the public debt rose, going to 52,060,000,000 marks by 1940. The Second World War was financed mainly by borrowing, from both the private sector and the central bank; by 1945 the debt stood at more than 300,000,000,000 marks. Most of this was wiped out by the postwar currency reform of 1948.

Japan. The rise of the modern Japanese state began in the latter part of the 19th century. The government began to issue bonds in 1870. The cost of financing the war with China in 1894–95 and a subsequent buildup of its army and navy raised Japan's public debt from 255,000,000 yen in 1890 to 506,000,000 in 1900. The war with Russia in 1904–05 cost about 1,500,000,000 yen, which was mainly raised by foreign borrowing. The financial burden of growing empire was henceforth largely covered by taxation, so that public debt did not increase substantially from 1907 until the end of World War I. Between 1918 and 1930, however, the debt doubled. In these years a large proportion of the debt was in foreign-owned bonds. In the 1930s the government adopted heavy spending policies, mainly for military purposes, and in 1940 the debt was more than three times what it had been in 1930. Since World War II the debt has risen from 150,795,000,000 yen to over 750,000,000,000.

Local governments in Japan have always been heavy borrowers. This has continued to be true in the postwar years, when prefectures, cities, towns, and villages issued bonds on a scale approaching that of the national debt. Much of the local indebtedness was used to finance large public works programs.

Comparative size and burden of government debt

Debt and **national** income. The absolute figures of growth in government debt exaggerate the actual growth in the debt relative to the economy as a whole. In the first place, the general price level has increased significantly over recent decades; since debt obligations are stated in fixed monetary terms, the relative magnitude goes down as the price level goes up. The general rise in prices over a period thus reduces the problems created by the debt for the government and the magnitude of the adverse effects of the interest payments on the economy. The gain occurs at the expense of the bondholders whose real economic position is worsened by the change.

Secondly, the rise in national income reflecting an increase in output reduces the real significance of a fixed sum of debt for the economy. The combined effects of the real and monetary influences can be illustrated by expressing the size of the debt as a ratio to gross national product over a period of years. Data for the United States are shown in Table 3. The ratio fell from 129 percent in 1946 to 38 percent in 1969. The ratio of interest payments to national income likewise fell, despite a rising interest rate level over this period. In Great Britain the ratio of national debt to gross national product fell from 221 percent in 1952 to 136 percent in 1958, although the size of the debt increased slightly over the period.

Magnitude of debt in various countries. An adequate comparison of debt burdens in various countries is difficult to make. The reported figures are by no means en-

tirely comparable because they vary in their treatment of debt incurred for various commercial enterprises, loans from foreign countries, special issues, and the like. The relative importance of the national debt and the debt of subordinate units of government also varies, and figures for the latter are not available for many countries. Any comparison of absolute figures of debt in monetary terms is of limited value and may be very misleading because of problems of conversion to a common monetary unit. The only meaningful figure is the ratio of national debt to national income, and the significance of these figures is greatly lessened by the inaccuracy of national income data for many countries. Figures of national debt and of the ratios of debt to Gross National Product are shown in Table 4.

DEBT RETIREMENT POLICY

The question whether a government should seek to pay off its debt must be considered separately for the national government and for the state and local governments.

National debt. Retirement of the national debt has the obvious advantage of eliminating the undesirable features noted in an earlier section: the adverse effects of the taxes necessary to pay interest; the redistribution of income resulting from interest payments; the inflationary effects of the debt under certain circumstances; and the confidence-disturbing effects, which are of particular importance in a depression. Furthermore, an overall program calling for a budget surplus accompanied by debt retirement aids in checking inflationary pressures. While it is true that the accumulation of a budget surplus without retirement of debt would exercise still more anti-inflationary pressure, such a policy is not usually regarded as politically feasible. Furthermore, the accumulation of surpluses without debt retirement tends to bring increases in government expenditures; it is politically difficult for a government to maintain an accumulated surplus for any length of time.

Methods and consequences of national debt retirement

Debt retirement is also likely to increase the rate of capital formation in the country; that is, investment in business expansion will increase as long as full employment of resources is maintained. The taxes necessary to finance debt retirement will tend to reduce consumption to some extent, while the sums paid out to the bondholders will be made available, in large measure, as money capital for business expansion. The net effect is to reduce the percentage of total national product used for consumption and increase the percentage used for expansion of the economy.

Retirement of national debt is not always a necessarily good policy. Maintaining a rigid program of debt retirement regardless of business conditions could easily produce a decline in business activity, which in turn would make further repayment virtually impossible for the duration of the slump. If economic stability is regarded as an important goal, then debt retirement is possible only in years of inflationary pressures. Thus, few national governments attempt to retire their debt systematically, year by year. Another objection to debt retirement is that strong popular resistance to tax increases beyond certain levels could result in a situation in which the debt retirement program is carried on at the expense of urgently needed current activities of government, rather than through higher taxes. Certain other arguments can be advanced against retirement. Most national debt is incurred for the conduct of wars; since the effects of these wars extend indefinitely into the future, it may be argued that no one generation of taxpayers should be made to shoulder the burden of debt retirement. Closely related is the argument that continued expansion in the economy will gradually reduce the significance of the debt, so that failure to retire it is no cause for alarm.

If debt retirement is carried on as part of an anti-inflationary program, the net effectiveness of the program will be influenced by the nature of the debt being retired. Maximum effect is obtained by retiring debt held by the central banking system since the repayment will create no inflationary influence at all and, by reducing reserves of the banks, will tend to check bank lending. Retiring debt held by the commercial banks will produce the next best results; although the banks' reserve positions will be improved by the retirement, they will not extend new loans to the extent of the debt retired because other investments will be less liquid than government bonds and the banks will feel obligated to hold greater reserves.

An alternative to debt retirement at the national level is monetization of the debt, that is, payment of the debt by new monetary issues. In a period of depression, business activity would be stimulated by such an act, and the burdens created by the debt would be lessened. Such a policy is rarely favoured for the same reasons that it is not favoured as a means of raising revenue in lieu of borrowing in the first place. If there were assurance that governments would not overissue money and that the policy of monetization would not cause a general loss in confidence, this alternative would be more acceptable.

Finally, national debt may be retired by direct repudiation. Since a sovereign government cannot be sued without its permission, it can, if it wishes, cancel outstanding debt without legal interference. Such a policy has usually been followed only after a government has been overthrown by revolution and the new government has disavowed the debt of the old. Under ordinary circumstances such a policy cannot be seriously contemplated because of the injustice to the bondholders that would result, the loss of prestige by the government, and the difficulty of selling bonds in the future.

The necessity of retiring local government debt

State and local debt. The question of debt retirement is a different one for units of government below the national level. Their debts are incurred primarily for the financing of capital improvements with a limited life, and if they are not retired during the period of use of the improvements, the burden will rest upon generations of taxpayers who will not enjoy the benefits of them. Furthermore, failure to retire debt will soon get a state or local government into a position in which it will be unable to borrow for new improvements because the total amount of debt will exceed the capacity of the government, at tolerable tax rates, to meet interest payments. These levels of government are not faced with the same degree of responsibility for maintaining economic stability as is the national government.

In view of these factors, state bond issues in the U.S. normally provide for a systematic program of retirement, and state law generally requires that the local governments take such action. The length of life of the bonds is limited to the expected life of the improvements. There are two systems for retirement. The older, the sinking fund system, requires that during each year of the life of the issue the government make payments into a sinking fund so that the interest on the accumulating sums, plus the original payments, will be sufficient when the bond issue matures to pay it off in full. Unfortunately, sinking funds are sometimes used for other purposes, and scheduled payments are not always made into them. As a consequence, governments have tended to shift to the serial bond system, under which the maturity dates of serial bonds are spread over a period of years, so that a certain amount will fall due each year, and the issue will thus be redeemed gradually, without the establishment of a sinking fund. Though investors were at first inclined to resist this approach, by the 1960s it had become more or less standard in many countries.

The states of the United States have the power to repudiate debts if they wish, since they have inherent sovereign powers. On some occasions, notably in the South after the ousting of the carpetbagger governments following the American Civil War, states have repudiated debts outright. Local governments, however, being technically corporations, have no sovereign powers and thus can be sued and cannot repudiate debt.

Distinct from the question of outright repudiation is that of unintended default. In the 1830s and again in the 1930s, several states of the U.S. and provinces of Canada and large numbers of municipalities were unable to meet their obligations at tax rates that were politically acceptable. As far as the states and the Canadian provinces were concerned, bondholders could not take legal action and simply had to wait until tax collections improved. At the municipal level, legal action was possible, as provided by state law; in some instances bondholders could obtain a court order requiring the levying of additional taxes. In other instances this was either impossible or futile, given the depressed conditions of the period. In four states provision was made for a state agency to assume administrative receivership of municipalities in default to straighten out their finances. In 1934 the U.S. Congress enacted a municipal bankruptcy act that provided for a revision of local government debts under court supervision and with the concurrence of various percentages of the debt holders. The original law was held unconstitutional, but a new law enacted in 1936 was upheld. Government bondholders can never foreclose on government-owned property in the event of default and normally cannot proceed against the property of taxpayers or municipal officials, except to a limited extent in the New England states. It is interesting that in Great Britain in the 1930s, where the Depression caused acute distress, no local authority defaulted.

DEBT MANAGEMENT

Government debt takes various forms, and the combination of them is the province of debt management. There are two sets of problems: new borrowing and the conversion or refunding of existing securities into new issues.

Alternative methods of financing government debt

Policies on new borrowing. Governments face a number of alternatives when undertaking new borrowing. National governments of large, developed countries seldom consider borrowing from foreign sources, since they are able to obtain desired funds within the country. For developing countries, however, the issue is a significant one. Frequently potential sources of domestic funds are limited. Savings are small and not easy to mobilize through financial institutions. Foreign borrowing also offers the important advantage of access to additional foreign exchange, thus permitting the importation of goods important for economic development. But such loans create obligations to pay interest and principal to foreign debt holders in the future; these payments may be difficult to make if the country's export potential is limited. Foreign loans often have restrictions attached that governments are reluctant to accept and may bring foreign intervention. Accordingly the governments of developing economies differ in the degree of their willingness to seek foreign funds. The development of international lending agencies such as the International Bank for Reconstruction and Development (World Bank) has increased the availability of foreign loans to developing countries without the danger of foreign interference.

The general rule for subordinate governments is that of adjusting the borrowing in such a manner as to minimize interest and other casts. National governments must strike a balance between low interest costs and attainment of the goals of economic stability. The precise policies that must be followed in the light of this objective will depend on the relative importance attached to the interest and economic stability goals, the relative effectiveness of monetary policy and other methods of attaining economic stability, and the state of business conditions. Policies appropriate for depressions are clearly different from those suitable for inflationary periods. While the principles themselves are widely accepted, there are serious problems of interpretation in specific cases.

Voluntary vs. compulsory loans. One question of concern in time of war is the choice between voluntary and compulsory loans. Canada, Great Britain, and several other countries used a compulsory lending program to some extent during World War II; the United States considered it but relied on the voluntary approach. The compulsory system is undoubtedly more anti-inflationary, per dollar obtained, since a greater amount of the money will come from persons who would otherwise spend it in consumption. But it is much less acceptable politically.

Compulsory lending offers several advantages over tax increases. Because the sums will eventually be paid back, political opposition to the program and the possible adverse effects on incentives will be less than they would be with tax increases. The program may be more equitable than with a tax increase for the lower income groups because the overall final burden may be distributed to a greater extent on the higher income levels than would be possible with the tax increase. The return of the funds may cushion a postwar depression. However, in neither Great Britain nor Canada was the World War II experience very satisfactory, because the taxpayers regarded the payments essentially as another tax rather than as savings that they would ultimately get back, and therefore the hoped-for advantages were lost.

Compulsory lending must be distinguished from a true compulsory savings program. The former method requires persons to place a certain amount of money (usually related to income) in government bonds each year. The latter method requires persons to save—*i.e.*, reduce their consumption—a certain amount during the year and place it in government bonds. A compulsory savings plan has not been attempted because of problems of enforcement. The liquidation of existing assets to offset the new saving and thus defeat the intent of the program would be very difficult to detect. But if the program could be made effective it would be much more anti-inflationary than even a compulsory lending system.

In a period in which borrowing is necessitated by war or high defense spending, the government may appeal to the public to buy bonds on patriotic grounds. During and after World War II, the U.S. government followed this program extensively, particularly to get the bonds into the hands of individuals rather than banks and thus to minimize inflationary pressures. In a severe emergency such a program may have merit, but it is difficult to maintain the "crisis" atmosphere indefinitely. If, however, persons can be induced to commit themselves to buy bonds on a payroll deduction basis, the forces of inertia are placed on the side of recurrent bond purchases, and the net effect may be to increase materially the total purchase of bonds by the lower income groups and thus to reduce consumer spending.

To a considerable degree, the national government can influence the extent to which the bonds are acquired by different types of purchasers. It may "borrow" directly from the central bank, if it wishes and the law permits, and thus create money. It may borrow from the commercial banks by direct sales of bonds to them, and it can, in fact, exert strong pressure on them to buy; it may sell to individuals, even restricting bank purchases of the issues. The choice of lender depends in large measure on the state of economic activity. In a period of depression, the goal is to obtain funds with the least possible contracting effect on individual and business spending. Thus, if money creation is ruled out, sale to commercial banks, which usually have excess reserves in depressions, is almost as good but gives rise to greater interest cost. In a period of full employment and inflationary tendencies, the goal is the reverse—to borrow in such a manner as to restrict private spending to the maximum extent. Thus during World War II, governments stressed their savings bond programs.

Short-term versus long-term borrowing. Subordinate units of government are usually unable to borrow substantial sums on a short-term basis, and they thus confine their borrowing to the issuance of bonds, usually running for 10, 20, or more years. The only exception may involve small amounts of short-term borrowing in anticipation of tax revenue. But national governments have a much greater choice between the two methods. Traditionally, short-term borrowing has been regarded as indicative of financial irresponsibility. Beginning in the 1930s, however, many national governments began to make increased use of this form of credit, primarily because of the much lower rate of interest. In depression periods, a substantial volume of loanable funds exists whose owners are willing to invest them only on a short-term basis, with maximum liquidity and minimum risk.

From the standpoint of economic stability, the primary disadvantage of the short-term loan is the greater degree of liquidity to the investor. In inflationary periods, borrowing of this sort is less effective than long-term borrowing in reducing liquidity. Short-term borrowing also creates a continuous problem of refunding the issues as they mature, increases the danger that large amounts of debt may come due in a period of financial stringency and embarrass the government, and renders the government's interest burden highly vulnerable to changes in the market interest rate. Short-term borrowing is particularly disadvantageous if interest rates are expected to rise in the near future. On the whole, short-term borrowing is most justifiable when interest rates are expected to fall—*e.g.*, at the top of an inflationary boom.

When inflation continues for a period of time, many persons become reluctant to buy any type of fixed-money-return security. Accordingly, it has been suggested that in such periods bonds might be sold with fixed purchasing power; that is, interest and principal payments would be adjusted in terms of changes in the price level so that the holder would be protected from the effects of inflation. At least one city in the United States has issued bonds of this type. But such a policy would not be without difficulties if adopted by a national government. If there were strong fear of inflation, a great shifting from existing securities to the new ones would occur and could disorganize the bond markets. The change would serve as a notice that the government expected inflation to continue, and that in itself would be a spur to increased purchasing, which would stimulate inflation. Payment of interest and principal on the basis of higher prices would feed the inflationary pressures and increase the future financial problems of the government. One more "escalator" would be added to the economy, and inflationary pressures would be increased.

Most government bonds are salable, have a market price, and therefore may be transferred on the market. On the other hand, they are not usually redeemable until maturity. In the United States, Canada, Great Britain, and some other countries, savings bonds were made nonsalable at the outbreak of World War II, primarily to insure the purchasers against any decline in market value such as occurred to similar bonds after World War I. This feature also enabled the government to control the amounts individuals purchased and prevented a mass shift from regular issues to the higher-interest-rate bonds. But since they were nonsalable it was virtually imperative to have them redeemable at will in order to make them attractive to the purchaser. Persons were given an incentive to hold them, however, because the interest rate was higher the longer the bonds were held. Use of the discount method of paying interest avoided the need for making large numbers of very small payments, delayed the receipt of interest until after the major inflationary pressures were expected to be over and facilitated the scheme of varying the rate according to the period the bonds were held in order to discourage persons from cashing them in.

Interest rate policy. Governments can borrow only at the market interest rates as determined by current demand and supply for loanable funds. A government will attempt to ascertain the rate at which a new issue can be sold by examining yields on existing issues and consulting investment banking firms. Normally an effort is made to set a rate at which the bonds will sell at par (maturity value). If the rate is set too low, the bonds will have to be sold at a discount and the effective rate will reflect the market figure; the result of selling at a discount is often a net actual rate slightly higher than otherwise.

Occasionally governments deliberately set rates higher than the market in order to attract certain classes of investors. A primary example of this was the establishment of an unnecessarily high rate on U.S. savings bonds during World War II in order to get as much of the debt as possible into the hands of individuals rather than the banks. Banks were not permitted to buy these issues.

While state and local governments are completely at the mercy of the money market insofar as interest is concerned, a national government can affect the rate of interest through its influence over the central banking system. The national government can thus reduce its interest burden if it wishes or can prevent an increase. If such a policy is followed in an inflationary period, however, it will interfere with effective anti-inflationary measures by the central banking system.

When the central banking system raises interest rates in periods of inflation, state and local borrowing is made more expensive. These governments then seek special assistance from the national government in obtaining funds more cheaply. Such aid was provided after World War II in Great Britain through the Public Works Loan Board, which made loans to local authorities. There was extensive demand for this sort of assistance in Canada after 1955. Similar difficulties arose in the U.S. in 1966–68. The problem illustrates one of the basic difficulties of general credit control, namely, the nonselective restriction on borrowing.

A government can make its bonds more acceptable to buyers, and thus obtain a lower rate of interest, by exempting the interest on its bonds from tax. This was the practice of the U.S. federal government before 1941; after that date only state and local bond interest were exempted from federal tax. Many countries do not provide such an exemption.

For a particular level of government, if tax rates are progressive, the tax loss will exceed the gain from lower interest rates unless there is sufficient market among persons in the highest tax bracket to absorb all of the bonds. In this instance the interest rate savings would more or less offset the tax loss. But this is unlikely to be the situation, and in all higher tax brackets than the one at which the two elements are in balance, the government will lose in tax more than it gains through lower interest, and persons in lower brackets will not, presumably, buy the bonds. The shift in federal policy in the United States in 1941 was therefore desirable.

But when the units of government involved are at different levels, as in the case of the exemption of state and local bond interest from federal tax in the United States, the units whose bonds are exempt experience a net gain from lower interest and thus will oppose any effort by the other government to make the interest taxable. The United States originally exempted interest on state and local bonds because the 1894 income tax law had been held invalid in part because the Supreme Court considered the inclusion of state and local bond interest to violate the constitutional division of powers between the federal and state governments. Since the attitude of the Supreme Court on this general question has changed materially (federal taxation of the salaries of state employees having been held valid in 1939), it is now thought likely that the court would accept the taxation of interest on state and local bonds. But the strong opposition of the states and local governments has prevented action by Congress, although it is obvious that these governments gain less than the federal government loses. Furthermore, the exemption provides a simple avenue of tax avoidance and encourages wealthy persons to put their money into these safe investments instead of into business expansion. The 1969 tax reform legislation did not alter the tax status of state and local bonds, although 1968 legislation did restrict somewhat the tax-exempt status of bonds issued to provide facilities for new industry.

Adjusting the structure of debt

Management of existing debt. Debt management also involves adjustment of the existing debt: replacement of short-term securities by long-term securities, refunding of maturing issues, transfer of securities from one type of investor to another (banks to individuals, for example), conversion of issues, and the like. This is a problem rarely faced by local and state governments because their debt is retired on a systematic basis and there is little opportunity to change the form before the date of maturity. About the only possibility of change is that of repayment before maturity if surplus funds are available or if replacement of an old issue by a new (as lower interest rates) is feasible. To facilitate such action without the necessity of buying the securities in the market, the issues are sometimes made callable so they can be paid off at maturity value (or with some premium) at any time beyond a certain year.

Maturity structure. **A** national government can, if it wishes, materially change the relative size of the short-term and long-term elements in the debt. Short- and intermediate-term issues, which are constantly maturing in large volume, can be replaced by long-term bonds, or long-term bonds can be replaced by short-term issues, either as they mature or through purchase or call.

Replacement of short-term by long-term issues, advocated by many persons in the period after 1945 and attempted by the U.S. government on several occasions during that period, offers several advantages in periods of inflationary tendencies. First, it reduces the overall liquidity of the debt structure, making it more difficult for investors to use wealth in government securities for spending on consumption or business expansion. Second, increased use of long-term securities lessens the nuisance and cost of constant refunding operations and makes less frequent the danger that extensive refunding may coincide with a stringency in the money market, thus necessitating central bank action to support the government's borrowing. This action may run directly counter to the interests of economic stability. Lengthening the maturity structure of government debt also tends to raise long-term interest rates relative to those on short-term loans. This should lessen inflationary pressures. But the actual magnitude of the effect is doubtful; a deflationary monetary policy pursued by the central banking system may be far more effectiveand simpler.

The primary disadvantage of increased reliance on long-term securities is the higher interest rate that must usually be paid, especially if the change occurs in periods of high rates. On rare occasions short-term rates may exceed long-term rates, but normally the reverse is true. It is this consideration that discouraged the U.S. government from continuing its program of lengthening the maturity structure of the debt in the late 1950s. Part of the difficulty lay in the reduced competitive position of long-term government bonds compared with other securities. The rapid fluctuations in government bonds, as monetary policy was used more intensively, made them less attractive investments, while private securities became more attractive while business activity remained at a high level. The increased supply of government-guaranteed mortgages also lessened interest in government bonds.

In terms of cost considerations alone, the appropriate time for a shift toward long-term issues is in a depression. While short-term funds become very cheap in such periods, it is more advantageous for the government to take advantage of the low figures on long-term issues. On the other hand, short-term borrowing keeps the lenders' investments highly liquid and facilitates their spending the sums for consumption or business expansion whenever they wish. Thus cost and stability considerations suggest opposite policies. The former requires shifting from short-term to long-term loans in depressions, while the latter dictates this shift in periods of inflation. But the liquidity considerations are probably not very important in depression periods, nor is the gain from the shift toward long-term securities in inflationary periods. The important consideration is that the overall length of issues be relatively long when inflation does arise. There is an increased trend toward a policy of relying on other policies than changes in debt maturity as a means of lessening economic instability and of lengthening debt maturities in periods when interest rates are low.

Structure of holdings. The government may at times find it advantageous to shift the relative holdings of different types of investors. In periods of inflationary pressures, increased holdings of savings bonds by the public and reduced holdings of other bonds by commercial banks would lessen spending in the economy and reduce the liquidity of individuals — the ability to increase spending sharply if they wish. It is for this reason that during the inflationary years of the postwar period the U.S. government continued to push the savings bond program even when it was not doing any net borrowing. Table 5 shows the changing ownership of the U.S. national debt between 1940 and 1970.

On the other hand, during a period of depression, the repayment of savings bonds through borrowing from the commercial banks would tend to increase total spending. Some of this effect will be attained automatically as persons cash in their savings bonds when they lose their jobs.

Government securities are held, apart from those in government trust funds and the central banking system, by three principal groups of investors — commercial banks, other financial institutions, and individual investors. In the United States, some tailoring of securities to the particular needs of various investors has been undertaken through the use of savings bonds, which have been restricted to individuals. Some authorities have suggested that much more of this should be done, in the interests of stability and reduced cost to the government. In general such a program could greatly reduce the volume of refunding and free the central bank from constant concern with this problem to the neglect of credit control policy. The direct effect of debt management on stabilization could be increased through varying redemption and volumes of issues for various classes of investors.

Distinct from the question of adjustment in the structure of the debt is that of conversion designed simply to lower interest cost, without change in the nature of the debt involved. When the interest rate has fallen sharply, conversion may be highly advantageous. It is not possible, however, unless the bonds are callable, except in the rare

instance of forced conversion. This latter type of policy is in a sense partial repudiation and is not followed by democratic governments. If the bonds involved are callable and conversion is decided upon, the government will give the bondholders notice of conversion and give them the choice of repayment in cash if they wish.

Debt management in the usual sense does not include central bank policy designed to influence the general interest rate level, which is regarded as a distinct form of stabilization policy. The two are, however, closely related. Central bank policy controls the interest rate that the government must pay; the interest costs of the national debt can always be reduced by central bank action that increases the supply of money capital through credit creation. But such a policy is not likely to be consonant with the goal of economic stabilization.

British **debt policy.** In recent years particular attention has been given to debt management by the government of Great Britain. Its debt policy in the 1960–70 decade was dominated by three influences: the theoretical and practical implications of the work of the Radcliffe Committee, the world trend in interest rates, and the problems posed by the balance of payments.

The Radcliffe Committee

The Report of the Committee on the Working of the Monetary System (1959) questioned the traditional Bank of England view that the demand for long-term government debt was perverse so that higher interest rates lowered the demand for gilt-edged securities instead of increasing it. The reasoning turned on the expectation of investors in the bond market. If interest rates rise and bond prices fall, investors may expect further declines in the bond market and delay purchases or even sell bonds, thus precipitating a further decline. The implication of this traditional view was that the monetary authorities, if they wished to sell long-term debt, had to maintain an orderly bond market; this, in turn, meant supporting prices if they were falling fast and dampening them if they were rising quickly.

The Radcliffe Committee challenged this policy, pointing out that permanent damage could be done to the market's appetite for government bonds if the authorities were continually dragging themselves up behind inexorably rising rates. Despite the Report, this happened in the 1960s when the bank rate rose from 4 percent to 8 percent. Over the decade the average bank rate was *6* percent and the average yield on 2½ percent non-redeemable bonds was 6% percent. Within this ten-year period there were three cycles. The bank rate rose to 7 percent by July 1961 and then fell to 4 percent by January 1963; it rose again to 7 percent by July 1966 and was reduced to 5% percent by August 1967; finally, with the balance of payments crisis in late 1967, it was pushed to 8 percent and by April 1970 was back to 7 percent.

During the period when rates were rising to 8 percent, the authorities were consistent sellers of bonds. At the same time they were obliged to convert gilt-edged securities maturing at a rate of about £1,500 million a year. The difficulties of the authorities as net sellers of debt in a period of rising rates forced them to rely on methods other than open-market operations to control credit. These included requests made by the central bank to the clearing banks to limit advances or even to reduce them and the requirement that the banks maintain special deposits at the Bank of England in addition to their cash reserves. By 1970 the authorities found themselves pushed toward a more active open-market policy.

As the Radcliffe Committee had suggested, serious consequences occurred in the bond market with a large reverse yield gap (an investment in bonds yielding more than it would in stocks) and the authorities often in the position of supporting a falling bond market. Late in 1968 bond prices were allowed to fall sharply. This appeared to follow the Radcliffe prescription.

Another part of the Radcliffe legacy was what has become known as the "new-orthodoxy" controversy. This gave short-term government treasury bills a central part to play in influencing the volume of banks' liquid assets, which in turn set a ceiling to the expansion of bank deposits, The central bank by selling Treasury Bills can reduce banks' cash and thereby their deposits and advances.

From 1959 to 1969 the Treasury Bill portfolio of the clearing banks and the money market fell from 22 percent of gross deposits to only 12 percent; but this fall was partially offset by a rise in commercial bills (through export credits) unexpected by the Radcliffe Report. Also Treasury Bills were replaced for the nonbank public by short-term local authority claims.

This debate over short-term debt policy was conducted against the background of a shortening of the average maturity of the debt and a substantial increase in official holdings (*i.e.*, funds held by government agencies, the Bank of England, and the Exchange Equalization Account). In 1959 about 50 percent of the total U.K. debt was held in bonds maturing in over fifteen years, and 17.5 percent in bonds maturing in under five years. By 1969 the long-term debt had dropped to **46** percent, medium debt had been further squeezed, and short-term debt had risen to 32 percent of the total. Short-term floating debt had remained at 17 percent of the total debt. Official holdings increased both as a proportion of total debt held and in their commitment to short-term bonds. Between 1959 and 1969 official holdings rose from 25 percent of marketable securities to 29 percent; but official holdings of short-term debt rose from 12 percent of total official holdings to 32 percent.

Finally, the persistent deficits on the current balance of trade and the accumulated international indebtness of the United Kingdom over the decade also affected debt policy. In 1967, after the pound was devalued, the authorities implied that they meant to exercise greater control over the money supply. This new emphasis on restricting the money supply was accompanied by a substantial effort at debt repayment.

Public Enterprises

Public enterprises

The term "public enterprise" denotes an organization operating (or supposed to be operating) on commercial principles, wholly or partly owned and effectively controlled by a public authority. An enterprise of this kind may be a new creation or owe its existence to the nationalization of a privately owned concern. It may have as its main function the provision of some "infrastructural" service (*e.g.*, power or transport), the direct manufacture of a commodity, or the extension of certain forms of assistance (*e.g.*, credit, marketing) to enterprises in the private sector. As a commercial entity engaged in the sale of its goods and services to private or corporate consumers, it normally needs to be organized and controlled in ways that are different from those applicable to ordinary, noncommercial government agencies. In particular it requires a certain measure of operational freedom and an immunity from persistent governmental intervention in its current decision-taking processes.

CHARACTERISTICS OF PUBLIC ENTERPRISES

There are many possible reasons for the creation of a public enterprise. Perhaps the most ancient of motives is the fiscal, exemplified by the establishment of "state monopolies" in commodities such as tobacco, salt, gunpowder, and alcohol. In certain countries such enterprises are still important revenue earners, although an equivalent yield to the public purse might be obtained by the more simple expedient of imposing excise duties upon these commodities. Another reason for locating an enterprise in the public sector is the strategic. For instance, military considerations strongly influenced Bismarck's nationalization of the German railway system, and in many countries today the government has decided that prudence demands that it should assume direct responsibility for certain types of defense production (*e.g.*, arms and ammunition). The existence of a monopoly, or the desirability of creating one, offers another justification for the public enterprise. If, for social reasons, it is not considered appropriate to break up a monopoly so as to subject the producers to the automatic regulator of free competition. there are the alternatives of subjecting it to state regulation or bringing it under state ownership. The latter is frequently chosen because it seems to be simpler and less productive of tension. In some cases public enterprise has even been used to create a monopoly where none previously existed by bringing together independent units into one large undertaking in order to achieve economies of scale, as with the nationalized coal and electricity industries in Britain. Cultural and educational factors may also be responsible for the choice of public as distinct from private enterprises. Such examples are the creation of the British Broadcasting Corporation and the Swedish wine and spirits enterprise known as the AB Vin und Spritcentralen.

Public enterprises have traditionally been regarded as acceptable alternatives to private enterprises in the field of "utilities" such as transport and power. In some countries, however, of which the United States provides the best-known example, even utilities are uredominantlv run bv private companies operating under strict legal regulation. By contrast, in Communist countries public enterprises embrace not only utilities but almost the whole range of industrial production, commerce, and finance. Here there prevails an anticapitalist ideology that strongly favours the public enterprise as an essential constituent of a socialist pattern of society. Ideological predispositions toward public enterprise are also found in varying degrees of strength outside the Communist countries and particularly in certain developing countries such as Egypt, Syria, Iraq, Algeria, Guinea, Sudan, Tanzania, Burma, and—more doubtfully—India. Socialist parties in the non-Communist developed countries, although frequently committed by their- founding charters to a massive extension of vublic enterprise through nationalization., nowadays tend to adopt a much more pragmatic attitude toward the public-private balance, particularly when they occupy governmental office.

The mixed economy

Indeed, except where Communist governments are in power, the principle of the "mixed economy" universally prevails. Although the constituents of the mixture vary widely from country to country, it usually contains a much larger public enterprise element than would previously have been regarded as either necessary or tolerable. Developing countries, especially, have often found it necessary to use public enterprises on a large scale as a result partly of their urgent need for infrastructural investment—which in these days can rarely be undertaken by private agencies—and partly of the unwillingness or incapacity of their private entrepreneurs and investors to initiate and bring to fruition projects that are regarded as essential constituents of national development programs. For reasons of this kind Pakistan, although predisposed to favour private enterprise, has built up a relatively larger public enterprise sector than is to be found in India, a country which, at least in theory, has adopted the "socialist pattern."

The actual extent of the public enterprise sector, however, is not always easy to define, whether one measures it by its contribution to the gross national product (GNP), its absorption of investment resources, or its generation of productive employment; for the sector includes not only public utilities and other directly productive undertakings but also (1) state-controlled agencies that provide financial and other services for the benefit of private industrial and agricultural undertakings and (2) state-controlled agencies charged with the task of entering into active collaboration with the private entrepreneur and investor in the development of certain areas of the economy. In most countries with mixed economies there has been an increasing interpenetration between public and private enterprise. The most obvious form that this takes is the creation of "mixed" companies whose shares are partly state-owned and partly privately owned. The state shareholdings in such companies frequently are managed by large "holding" corporations, such as the Istituto per la Ricostruzione Industriale in Italy, the Industrial Development Corporations in Pakistan, or the Corporación de Fomento de la Producción in Chile, which are themselves public enterprises. Another form of interpenetration is illustrated by the Gezira Corporation in Sudan, through which individual peasant cultivation is supervised, serviced, and partly financed by a government agency. Indeed, there are some countries where the public-private links provided by financing institutions, development corporations, mixed companies, and organized cultivation schemes are so close that the question "What is a public enterprise?" becomes difficult to answer. A United Nations survey in 1969, using figures provided by a limited number of mixed-economy countries, estimated that the amount of employment generated by public enterprises varied from 1.3 percent in Ceylon (now Sri Lanka) to 7 percent in France, its share of gross fixed investment from 14.6 percent in Greece to 39 percent in Ghana, and its contribution to GNP from 2.5 percent in Ceylon to 12.3 percent in Italy. Although these percentages should not be treated too seriously, they may be taken as representing rough orders of magnitude.

The role played by public enterprise in the context of a national economy is as variable as its size, but there is no necessary correspondence between these two criteria. As has been indicated, it would be a mistake to regard the existence of a large public enterprise sector as indicative of socialistic proclivities. Conversely, a small one provides no evidence of devotion to "economic freedom" in its traditionai sense. Sweden, for instance, although widely regarded as a successful example of a social-democratic state, has comparatively few public enterprises, whereas Italy, which has never been ruled by a socialist government, has many. Nor does a large public enterprise sector invariably mean that the governments responsible for its creation have adopted or intend to adopt a system of centralized, "command-type" planning. Although the operation of such a system is obviously facilitated by having most productive undertakings in state ownership, planning via the price and credit mechanisms remains a viable alternative, as the Yugoslav example has shown.

It should also be noted that, particularly in developing countries, the balance between public and private enterprise has been a shifting one. Both policies and perspectives have undergone change as a result not only of movements in political opinion but of the accumulation of experience. Both Turkey and Pakistan, for instance, found themselves compelled by circumstances to give public enterprise a much larger role in their economies than was originally envisaged for it. Mexico, on the other hand, became less enthusiastic about public enterprise as its revolutionary period receded and political conditions were established that opened up opportunities to its relatively numerous would-be private entrepreneurs. What seems to be well established, however, is that in the modern world even the less socialistically inclined of the developing countries find that, at a certain stage in their progress toward economic maturity, they need to make fairly extensive use of public enterprise as a catalytic agent.

THE GROWTH OF PUBLIC ENTERPRISE SECTORS

Nationalization

Of the developed European countries operating mixed economies, Britain, France, and Italy provide the most interesting examples of the evolution of reasonably successful and well-integrated public enterprise sectors. In both Britain and France there were extensive nationalizations during the period immediately following World War II, but neither country lacked previous experience of running public enterprises. During the interwar period, Britain had nationalized broadcasting, the long-distance transmission of electricity, London passenger transport, and civil airways. These enterprises, together with the Post Office, the Royal Ordnance Factories and Admiralty Dockyards, the Port of London, and the numerous electricity, gas, and transport enterprises owned by local authorities, constituted a small but significant public enterprise sector of the economy. In France, successive governments had established the National Nitrates Office, acquired a majority of shares in the Compagnie Générale Transatlantique and the railways, nationalized the aircraft manufacturing companies, and become a majority or minority participant in the equity of a number of other undertakings. Neither country, therefore, was entirely unprepared administratively for the massive nationalizations that followed the end of World War II, which were placed on the statute books by governments of a "leftist" kind—the Labour Government of 1946–50 in Britain and the short-lived Socialist-Communist-MRP coalition in France. Both countries nationalized coal, gas, electricity, and civil airlines, to which Britain added railways (already nationalized in France), long-distance road haulage, and steel. France, however, undertook a much more extensive nationalization than Britain of financial enterprises. While Britain brought the Bank of England under public ownership, France nationalized not only the Bank of France but the four great deposit banks, 34 insurance companies, and a variety of other finance houses. In addition, the state took over some important manufacturing concerns forfeited by their private owners for wartime collaboration with the Germans. The most famous of these was the Renault Motor Works. Since then there have been no further major nationalizations in either country. Britain, in fact, witnessed the denationalization of both steel and road haulage by a subsequent Conservative government. The steel industry, however, was renationalized by the Labour government that came into office in 1964. It may be noted that, to promote the deveiopment of the most important of all the new industries, which called for heavy investment with a comparatively distant and—at the time—uncertain yield, both countries established atomic energy commissions, with commercial as well as research and development responsibilities.

Reconstruction and development

Italy has had a very different experience. Whereas the extension of public enterprise in Britain and France took place, for the most part, through a series of deliberate legislative acts—in Italy it occurred largely as a result of an expansion, sometimes gradual, sometimes rapid, but never very well coordinated—of state shareholdings. Until the 1930s the Italian state had undertaken very few commercial functions, although the railways had been nationalized in 1905 and corporations subsequently created to take over the administration of the postal, telephone, and telegraph services; the state monopolies; and the state forests. In 1923 the state monopoly of life insurance, created in 1912, was disbanded before it had even begun effective operations. In 1933, however, the Fascist government was compelled by the severity of the impact of the world economic crisis on Italy's financial and industrial structure to mount a massive rescue operation by which the three main commercial banks, with their considerable holdings in industry, agriculture, and real estate, were taken over and a holding company, the Istituto per la Ricostruzione Industriale (IRI), created to administer the newly-acquired state shareholdings. The original idea was that the state should disinvest as soon as the economic situation sufficiently improved; but the IRI was retained, and during the postwar period it expanded its shareholdings to become Italy's greatest commercial enterprise, employing through its totally owned and partly owned subsidiaries a work force of some 300,000. It became one of a small group of comparable holding corporations, all working to what has become known as the "IRI formula," which evoked considerable interest and some imitation abroad. The distinctive features of the Italian public enterprise sector are that it enjoys a high degree of entrepreneurial autonomy and that its interpenetration with the private sector of the economy is close.

Among the developed countries, the U.S., the most developed of all, makes least use of public enterprise. Although the emergency requirements of the two world wars and the Great Depression of the 1930s produced a considerable proliferation of public enterprises, mainly for purposes of finance and procurement, most of these were subsequently disbanded. In this respect the policies pursued by the U.S. differed considerably from those of its neighbour, Canada, which not only retained in the public sector one of the most important of the commercial agencies created during World War II, Polymer Corporation, but subsequently created a number of new ones such as the Canadian Commercial Corporation (1946), the Canadian Sugar Stabilisation Corporation (1947), the Northern Transportation Company (1944), the North-West Territories Power Commission (1948), the Canadian Overseas Telecommunications Corporation (1949), and Atomic Energy of Canada, Ltd. (1952). Nevertheless, the U.S. has one of the most famous public enterprises in the world, the Tennessee Valley Authority (TVA) which, founded in 1933, has been paid the compliment of widespread imitation by countries wishing to undertake the integrated development of their great river valleys for purposes of irrigation, flood control, navigation, soil conservation, and the generation of hydroelectric power.

In general, the less developed countries have tended to copy the patterns of public enterprise already established in the more developed, although some of them have undertaken a pioneering role. Japan was the first of them systematically to use public enterprise for promotional purposes, while the U.S.S.R. pioneered its use for the building up of a socialist type of economy. Contemporaneously with Italy, Turkey experimented vigorously with the "holding company" type of enterprise through the creation of the Sümerbank and Eti Bank (which still occupy a very prominent place in its industrial structure) in the 1930s, while in Africa Egypt created a unique system by which a multitude of public enterprises were brought under the supervisory authority of 39 "Public Organizations."

Except in those developing countries where nationalization policies have been adopted for ideological or political reasons, the main role of the state has been to create new public sector enterprises for the expansion and diversification of the economy, rather than to take over existing private sector enterprises. Some countries, such as India, have attempted to define in advance which branches of their economies shall be reserved, for purposes of expansion and development, respectively to the public and private sectors.

FORMS OF PUBLIC ENTERPRISE

The decision to establish a public enterprise invariably raises questions of legal status and organizational structure. Before World War I there was a widespread assumption, among socialists and nonsocialists alike, that a public enterprise could be fitted into the "normal" departmental structure of the executive government. Post offices, in fact, provided the prototype. The justification for this assumption was that in those days governments rarely entered into the more competitive or technologically experimental types of business where entrepreneurial abilities were required of management. The postal, communications, and transport enterprises that, in most countries, constituted the bulk of the government's business responsibilities were monopolies or quasi-monopolies engaged in supplying standardized services at fixed prices. Broadly speaking, the same was true of the local enterprises that were owned and controlled by municipalities. Hence there seemed little advantage in the adoption of more "autonomous" forms of organization, which tended to create constitutional complications by breaking the normal chain of command that culminated in the absolute responsibility of the departmental minister.

These conditions have disappeared; today the demand is for a specific form of organization that enables those who are actually managing the enterprise to enjoy, in a measure compatible with ultimate public control, the innovatory freedom and discretionary authority normally possessed by the private businessman. Even where the "departmental" form of organization is retained—as it may well be where the "social service" responsibilities of an enterprise rival its commercial responsibilities in importance—it is invariably modified in various ways; *e.g.*, to confer exemption from normal budgetary and appropriation procedures and to provide greater flexibility in matters of personnel management. Where it is discarded—*e.g.*, for much of a government's business responsibilities—recourse is had to specialized organizational types, all more or less inspired by the joint-stock company.

The public corporation

One of the major institutional innovations is the public corporation, which is the form given to most of the British nationalized industries. Owned by the state, it is normally created by a special law defining its powers, prescribing its form of management, and specifying its relationships with superior governmental authorities. As a body corporate, it can hold property and sue and be sued in its own name. Although financed by treasury appropriations, treasury loans, or treasury-approved fixed-interest stock, it meets its current costs from the sale of its goods and services, makes normal commercial provision for depreciation and reserves, and may be authorized to reinvest its profits. Its budget is separate from the state budget; it is exempt from the normal regulations applicable to the expenditure of public funds; and its accounts are subject to a commercial-type audit, whether by public authority or by especially appointed private accountants. Its employees are not normally civil servants and are recruited, remunerated, promoted, and disciplined by the corporation itself, subject to whatever general legal regulations may be applied. Governmental powers over the public corporation are usually limited to those assigned by its constituting statute. These, however, may be widely or narrowly defined, and in any case the relevant minister, being responsible for the nomination of the corporation's top-level management (which is usually a board), can sometimes exercise an informal influence over its decisions that considerably exceeds the scope of his formal powers.

The distinction between the public corporation and the government department, however, may be much less precise than the above account suggests, since there are various degrees to which an enterprise, whatever it may be called, can be integrated with the normal machinery of government. For instance, the French form of public corporation, the ***entreprise publique***, is subject to considerably more detailed supervision and control than its British counterpart. Moreover, there are examples of enterprises that cannot be clearly categorized as either "departmental" or "corporate." Of these the best known are the Swedish trading agencies which, although constitutionally responsible to the king-in-council and staffed by civil servants, enjoy a degree of financial autonomy denied to other governmental agencies and are authorized to recruit, on a "temporary" basis, personnel to whom the ordinary civil service regulations do not apply.

The company

An alternative to the public corporation is the state company. When this is used, the law relating to ordinary joint-stock companies (sometimes embodied in a commercial code) is applied to the enterprise, and public control is ensured by the government's exercise of shareholding rights. Originally the state company device was developed in the European countries, but it is now widely employed throughout the world. The public corporation form is frequently used for utilities, while the state company form is favoured when the government enters the field of manufacturing industry. This tends to be the case, for instance, in India. It is often claimed that the "company" confers on the public enterprise concerned a greater degree of commercial flexibility. This may be so, but examples are not infrequent of the imposition on state companies of rigid patterns of organization and control through special laws or articles of association. The creation of a company may be effected by executive decree; often, however, it owes its existence to a development corporation, which is authorized to found subsidiaries organized on the joint-stock principle. When the intention of the government is that the development corporation shall eventually dispose of its subsidiaries to the private investor, their establishment in the form of companies has obvious conveniences.

The company form is even more clearly indicated when a government wishes to establish a "mixed" enterprise, through which it aims to enter into partnership with private investors. Such enterprises are found in almost all countries that have not decided to adopt fully socialized patterns of economic development. Sometimes they are regarded as transitional, insofar as the government intends to retain its participation only until such time as private investors prove willing to take up the whole of the share capital; but in other cases the public-private partnership is considered as a means of giving the government permanent influence or control over the enterprise's management. It has become conventional to consider **a** mixed enterprise as part of the public sector when the government owns 51 percent or more of the share capital, and as part of the private sector when it owns less than this. This distinction, however, is often unreal since a government that owns only a small number of shares in a company can usually control it if the remainder are widely scattered among members of the investing public. Moreover, it is by no means unknown for the government-appointed directors of a mixed enterprise, whether they be in a majority or in a minority, to be given powers superior to those possessed by the privately appointed directors. A true partnership is normally achieved only when a government makes special contractual arrangements with a major private undertaking, either indigenous or foreign. Such an arrangement sometimes provides for the management of the enterprise, either permanently or temporarily, by personnel nominated by the private partner. Otherwise, the main advantage of the mixed enterprise is that it enables the mobilization of private capital, which might not be available to an enterprise that did not enjoy the advantage of government support. Another circumstance that may justify its use is the need to rescue from bankruptcy, by the injection of government resources, a private enterprise whose continued existence is regarded as essential to the national economic welfare.

PROBLEMS AND ISSUES

Although the form given to a public enterprise is of undoubted importance, it has tended to receive excessive discussion at the expense of more vital issues; for there is rarely any close correspondence between form and performance, which depends on the efficiency of internal organization and procedures, the quality of personnel at all levels, the adequacy of the incentives that they are given, and the capacity of the management and willingness of the political authorities to ensure that, de facto as well as de jure, the enterprise actually enjoys the degree of commercial flexibility it is supposed to have.

Efficiency versus politics

The promotion of efficiency in public enterprises raises certain special problems. There is a widespread tendency to subject the enterprise to meticulous political control, incompatible with the development of managerial initiative and self-confidence, and to impose on it inappropriately bureaucratic forms of organization, usually adopted from the noncommercial branches of the public service. It is clear that, whatever legal powers over the enterprise the minister may possess, those powers need to be exercised with restraint and to be concentrated on the broader issues of policy such as capital requirements and long-term development plans. Only thus can the agency be simultaneously "clothed with the power of government" and "possessed of the initiative and flexibility of private enterprise," to quote the famous words used by Pres. Franklin Delano Roosevelt when inaugurating the Tennessee Valley Authority. It is also clear that a public enterprise needs to be equipped with a management at least as well trained and experienced (and hence as well remunerated) as the management of a private enterprise of comparable size and complexity and should be given the opportunity to install the most up-to-date managerial techniques. In the more developed countries marked progress has been made toward the achievement of both these desiderata; but in the less developed ones there is usually much room for improvement.

Efficiency will also partly depend on the manner in which an enterprise is fitted into the country's general administrative structure. Experience suggests that the best pattern is one that brings each enterprise under the jurisdiction of the "relevant" minister (*i.e.*, the minister of industry for industrial enterprises, the minister of agriculture for agricultural enterprises, the minister of finance for financial enterprises, etc.). In some cases, however, there may be strong countervailing arguments for placing most of the public enterprise sector under a minister of state enterprises. A special problem may arise when a large variety of individual enterprises have been created as subsidiaries by a development corporation, functioning partly as a holding company and partly as a superior managerial agency. The normal experience is that when one of these enterprises has become fully established and has reached a certain size, it needs to be detached from its parent body and brought under the direct supervision of the minister whithin whose area of jurisdiction it naturally lies. Conversely, there may be the problem of bringing together in a single organization a number of separate but related enterprises in order to simplify the process of control and to achieve economies of scale. The circumstances in which this is appropriate always require detailed investigation by the political and administrative authorities in collaboration with the enterprise managements likely to be affected. Some patterns of organization may create resistances to unification proposals of undoubted economic and administrative rationality. Yugoslavia, which has confided the management of its enterprises to workers' councils operating in association with local or regional government authorities, has experienced difficulties of this kind. In general, the importance of patterning the public enterprise system in terms of what Paul Appleby called "coherent missions" can hardly be overemphasized.

The assessment of performance

A further problem relates to the criteria by which the performance of a public enterprise is to be assessed. When it is operating in a fully competitive market situation, profitability obviously provides a reasonably adequate measurement, but when there is an element of monopoly, more sophisticated criteria based on cost-benefit calculations have to be brought to bear. The task of assessment may be further complicated by the imposition of special burdens on a public enterprise or the extension to it of special privileges. On the one hand, it may be denied the freedom to charge a fully economic price for its goods and services or may be instructed by superior authority to engage in operations of an allegedly socially beneficial kind that involve it in commercial loss; on the other hand, it may receive various forms of protection denied to its competitors or potential competitors or enjoy the use of its capital resources on especially favourable terms. From the standpoint of facilitating public control over the patterns of production and distribution, all this has great advantages, but its disadvantages are no less obvious. It is wide open to abuse; it may lower the morale or undermine the incentives of both managers and workers; and it immensely complicates the task of producing a reliable and operationally useful assessment of public enterprise performance. For these reasons, and particularly the last of them, some countries have established expert, independent agencies to develop tools of performance measurement, to keep public enterprises under more or less continuous review, and to advise both enterprises and government of the likely consequences of the pursuit of alternative policies. Of such agencies the most famous and most successful is the Commission de Vérification des Comptes in France. It should be noted, however, that no agency of this kind can be of much use unless the "targets" that a public enterprise is expected to achieve have been specified as clearly as possible by the responsible authorities. Of recent years, in both Britain and France, such "targeting" has made notable advances. In Britain, for instance, each enterprise is now given an objective, stated in financial terms, which takes into account its social responsibilities as well as its expected commercial performance. This exercise not only makes the process of assessment more rational; it also provides a series of parameters within which management may be left relatively free to go about its business.

Another "control" device that has achieved some success is the appointment of a special parliamentary committee to provide the legislature with information and advice on matters relating to public enterprise. The expectation is that this will enable parliament to exercise its supervisory functions with greater intelligence and discretion and restrain it from inciting the relevant minister to use his powers in harmful ways. The best-known examples are the Select Committee on Nationalised Industries in England and the Committee on Public Undertakings in India. Despite these advances, however, it would be an exaggeration to suggest that any country has as yet succeeded in finding the ideal balance between autonomy and control, the search for which raises all the main problems in this field of governmental activity.

Public Health Services

Public health has been defined as the art and science of preventing disease, prolonging life, and promoting physical and mental efficiency through organized community effort. Man is a social being, and humans characteristically associate with each other for their mutual protection and advantage. From the interactions involved in dealing with the many problems of social life, there has emerged a recognition of the importance of community action in the promotion of health and the prevention and treatment of disease. This recognition is expressed in the concept of public health.

The approach to and understanding of public health has changed from century to century and, more recently, from year to year. Insights into the nature of public health can be gained by examining these changes.

In primitive communities, society's defense against sickness was to isolate or destroy the sufferer. As knowledge of sources and modes of infection increased, governments attempted to control implicated environmental factors, such as public water supplies, milk and other foods, human waste, insects, and various forms of pollution. In the 20th century there has been an increasing interest in social legislation for the welfare of mothers and children and of the aged or physically handicapped; attention has been given to housing and special diseases, such as cancer, venereal disease, heart disease, and mental illness. Public health emphasis accordingly has changed from a large impersonal approach through environmental controls to a more personal approach through preventive medicine. In a number of countries there has been recognition of the inadequacies of personal medical care and increased emphasis on more accessible, efficient, and effective forms of medical care. The full range of health services—promotive, preventive, curative, and rehabilitative—is now seen to be inseparable, and the emphasis is on developing methods of integrating these sectors into comprehensive health-service systems aimed at both individuals and communities.

The range of health services

One way of defining the scope of public health is by consideration of the threats to the health of members of a community and the steps needed to protect man from those threats and to increase the likelihood that he will live a full and healthy life.

Diseases and hazards to health vary from region to region, and different countries handle their health problems in different ways. The greatest differences are between the less developed and the more developed nations.

This article is concerned with the historical development of public health, beginning in ancient times and emphasizing how various public health concepts have evolved. It deals with organizational and administrative methods of handling these problems in both the more developed and the less developed parts of the world. Special attention is given to the developing countries and to how the health problems, limitations of resources, education of health personnel, and other factors must be taken into account in designing health-service systems. Finally, there are descriptions of the most recent developments in public health, together with some indications of the problems still to be solved.

General history of public health

BEFORE THE INDUSTRIAL REVOLUTION

Beginnings in antiquity. Most of the world's primitive people have practiced cleanliness and personal hygiene, often for religious reasons, and, apparently, a wish to be pure in the eyes of their gods. For thousands of years epidemics were looked upon as divine judgments on the wickedness of mankind; but the idea that pestilence is due to natural causes, such as climate and physical environment, developed later—and gradually. This great advance in thought took place in Greece during the 5th and 4th centuries BC and represented the first attempt at a rational, scientific theory of disease causation. The association between malaria and swamps, for example, was established very early (503–403 BC), even though the reasons for the association were obscure. In the book *Airs, Waters, and Places,* thought to have been written by Hippocrates in the 5th or 4th century BC, the first systematic attempt was made to set forth a causal relationship between man's diseases and his environment. For hundreds of years, until the new sciences of bacteriology and immunology emerged, well into the 19th century, this book provided a theoretical basis for the comprehension of endemic disease (that persisting in a particular locality) and epidemic disease (that affecting a number of people within a relatively short period).

Greek theories of disease causation

The Middle Ages. In terms of disease, the Middle Ages can be regarded as beginning with the plague of 542 and ending with the Black Death (bubonic plague) of 1348. Diseases in epidemic proportions included leprosy, bubonic plague, smallpox, tuberculosis, scabies, erysipelas, anthrax, trachoma, sweating sickness, and dancing mania (see INFECTIOUS DISEASES).

The isolation of persons with communicable diseases first arose in response to the spread of leprosy. This disease, uncommon in antiquity, became a more serious problem in the Middle Ages and particularly in the 13th and 14th centuries.

The Black Death reached the shores of southern Europe from the Middle East in 1348 and in three years swept throughout Europe. The chief method of combatting plague was to isolate known or suspected cases as well as persons who had been in contact with them. The period of isolation at first was about 14 days and gradually was increased to 40 days (see QUARANTINE AND ISOLATION). Stirred by the Black Death, public officials created a system of sanitary control to combat contagious diseases, using observation stations, isolation hospitals, and disinfection procedures.

Major efforts to improve sanitation through these years included the development of pure water supplies, garbage and sewage disposal, and food inspection. These efforts were especially important in the cities, where people, though they lived in crowded conditions, did so in a rural manner with many animals around their homes.

During the Middle Ages a number of beginnings in public health were made: these included attempts to cope with the unsanitary conditions of the cities and, by means of quarantine, to limit the spread of disease; the establishment of hospitals; and provision of medical care and social assistance. These efforts were especially impressive because they were made in a period in which people were powerfully swayed by superstition, and scientific knowledge was inadequate to deal effectively with the public health problems of the day.

The Renaissance. Centuries of technological advance culminated in the 16th and 17th centuries in a number of scientific accomplishments. These included the discovery, by William Harvey, of the circulation of the blood: the growing use of experimental methods; progress in the study of disease in the individual and in populations; and the first consistent explanation—by the Veronese physician Girolamo Fracastoro—of the spread of disease by contagion.

Educated leaders of the time recognized that the political and economic strength of the state required that the population maintain good health. No national health policies were developed in England or on the Continent, however, because the government lacked the knowledge and administrative machinery to carry out such policies. As a result, public health problems continued to be handled on a local community basis, as they had been in medieval times and would be until well into the 19th century.

The great scientific advances of the 16th and 17th centuries laid the foundations of anatomy and physiology as medical sciences. Observation and classification made possible the more precise recognition of diseases. The idea that microscopic organisms might cause communicable diseases had begun to evolve. Such developments were to provide the basis for later change.

DURING AND AFTER THE INDUSTRIAL REVOLUTION

National developments in the 18th and 19th centuries. Nineteenth-century movements to improve sanitation that occurred simultaneously in several European countries were built upon foundations laid in the period between 1750 and 1830. From about 1750 the population of Europe increased rapidly, and with this increase came a heightened awareness of the large numbers of infant deaths and of the unsavoury conditions in prisons and in mental institutions.

This period also witnessed the beginning and the rapid growth of hospitals. Hospitals founded in Britain, as the result of voluntary efforts by private citizens, helped to create a pattern that was to become familiar in public health services. First, a social evil is recognized; then studies or experiments are undertaken through individual initiative, and these efforts mold public opinion and attract governmental attention. Finally, such agitation leads to governmental action.

This era was also characterized by efforts to educate people in health matters. In many countries appeals to reason were based on a belief in progress and the perfectibility of society.

The health of industrial workers

As the Industrial Revolution developed, the health and welfare of the workers deteriorated. When the discrepancy between the harsh social reality and the optimism of the prevailing economic philosophy was brought into focus, the serious need for coping with the problems of public health was also recognized.

In England, where the Industrial Revolution and its bad effects on health were first experienced, there arose in the 19th century a movement toward sanitary reform that finally led to the establishment of public health institutions. Between 1801 and 1841 the population of London doubled; that of Leeds nearly tripled. With such growth there also came rising death rates. Between 1831 and 1844 the death rate per thousand increased in Birmingham from 14.6 to 27.2; in Bristol, from 16.9 to 31; and in Liverpool, from 21 to 34.8. These figures were the result of an increase in the urban population that far exceeded available housing and of the subsequent development of conditions that led to widespread disease and poor health.

The Poor Law Commission, created in 1834, explored problems of community health and suggested means for solving them. Its report, in 1838, argued that "the expenditures necessary to the adoption and maintenance of measures of prevention would ultimately amount to less than the cost of the disease now constantly engendered." Sanitary surveys proved that a relationship exists between communicable disease and filth in the environment, and it was said that safeguarding public health is the province of the engineer rather than of the physician. Filth was declared to be a public enemy that endangers the health of whole communities.

A General Board of Health was established to furnish guidance and aid in sanitary matters to local authorities, whose earlier efforts had been impeded by lack of a central authority to which they could appeal for help and leadership. The board had authority to establish local boards of health and to investigate sanitary conditions in particular districts.

Advances in public health in England had a strong influence in the United States, where one of the basic problems, as in England, was the need to create effective administrative mechanisms for the supervision and regulation of community health. Catastrophe often precedes social change. In America recurrent epidemics of yellow fever, cholera, smallpox, typhoid, and typhus made the need for effective public-health administration a matter of terrifying urgency. The so-called Shattuck report, published in 1850 by the Massachusetts Sanitary Commission, reviewed the serious health problems and grossly unsatisfactory living condition in Boston. Its recommendations included an outline for a sound public-health organization based on a state health department and local boards of health in each town. A change from a haphazard administration to an efficient one became essential to the development of a complicated urban industrial society. In New York City (in 1866) such an administration was created for the first time in the United States.

Developments in Germany and France in the 19th century

Nineteenth-century developments in Germany and France pointed the direction in which future public health action would yo. During the first half of that century France was pre-eminent in the areas of political and social theory, and as a result the public-health movement in France was deeply influenced by a spirit of public reform. The greatest French contribution to the advancement of public health at that time, however, was in the application of scientific methods to the identification, treatment, and control of communicable disease.

Although many public health trends in Germany resembled those of England and France, the absence of a centralized government until after the Franco-Prussian War did cause significant differences. After the end of that war and the formation of the Second Reich, a centralized public-health unit was formed. Another development was the emergence of hygiene as an experimental laboratory science. In 1865 the creation at Munich of the first chair in experimental hygiene signalled the entrance of science into the field of public health just at the time it was also becoming involved in clinical medicine.

During the 19th century, knowledge of the health problems of industry was slowly accumulating, but it was not until the 20th century that substantial advances in this area were achieved where the combined efforts of medical research, administrative action, and social reform were focussed on the problem.

There were other advances. The use of statistical analysis in handling health problems emerged. The forerunner of the United States Public Health Service came into being, in 1878, with the establishment in the United States of port quarantine on a national basis and with assignment of enforcement of the quarantine to the Surgeon General of the Marine Hospital Service. (Port quarantine was the isolation of a ship at port for a limited period to allow time for the manifestation of disease.)

A number of investigations that were pursued during the 19th century suggested that communicable disease is caused by living organisms.

Developments from 1875 to 1950. A growing understanding of infection has resulted in either the virtual eradication or the effective control of many communicable diseases.

The work of an Italian bacteriologist, Agostino Bassi, with silkworm infections early in the 19th century prepared the way for the later demonstration that specific organisms cause a number of diseases. Some questions, however, were still unanswered. These included problems related to variations in transmissibility of organisms and in susceptibility of individuals to disease. Light was thrown on these questions by discoveries of human and animal carriers of infectious diseases.

Nineteenth-century developments in bacteriology

In the last decades of the 19th century the French chemist Louis Pasteur, the Germans Ferdinand Julius Cohn and Robert Koch, and others developed methods for isolating and characterizing bacteria; the English surgeon Joseph Lister developed concepts of antiseptic surgery; the English physician Ronald Ross identified the mosquito as the carrier of malaria; a French epidemiologist, Paul Louis Simond, provided evidence that plague is primarily a disease of rats spread by rat fleas; and two Americans, Walter Reed and James Carroll, demonstrated that yellow fever is caused by a filterable virus carried by mosquitoes. Thus, modern public health and preventive medicine owe much to the early medical entomologists and bacteriologists. A further debt is owed bacteriology because of its offshoot, immunology.

In 1881 Pasteur established the principle of protective vaccines and thus stimulated an interest in the mechanisms of immunity that has persisted to the present. The development of microbiology and immunology had immense consequences for community health. In the 19th century the efforts of health departments to control contagious disease consisted in attempts to improve environmental conditions. As bacteriologists identified the micro-organisms that cause specific diseases and learned how they produce their effects, however, progress was made toward the rational control of specific infectious diseases.

In the United States the diagnostic bacteriological laboratory was developed—a practical application of the theory of bacteriology, which evolved largely in Europe. These laboratories, established in many cities to protect and improve the health of the community, were a practical outgrowth of the study of micro-organisms, just as the establishment of health departments was an outgrowth of an earlier movement toward sanitary reform. And just as the health department was the administrative mechanism for dealing with community health problems, the public health laboratory was the tool for the implementation of the public health program. Evidence of the effectiveness of this new phase of public health may be seen in statistics surrounding immunization against diphtheria—in New York City the mortality rate due to diphtheria fell from 785 per 100,000 in 1894 to 1.1 per 100,000 in 1940.

Poverty and disease

During the first decade of the 20th century, new developments vastly broadened the horizons of public health workers. While improvements in environmental sanitation were of great value in dealing with some problems, they were of only limited usefulness in dealing with many health problems found among the poor of the community. In the slums of England and the United States, for example, malnutrition, venereal disease, alcoholism, and other diseases were widespread. Nineteenth-century economic liberalism held that increased production of goods would eventually bring an end to scarcity, poverty, and suffering. By the turn of the century, it seemed clear to many that deliberate and positive intervention by reform-minded groups, including the state, would also be necessary. For this reason social action was entered into by physicians, clergymen, social workers, other public-spirited citizens, and government officials. Programs that were initiated included organized efforts to prevent tuberculosis, lessen occupational hazards, and improve children's health.

The first half of the 20th century saw further advances in community health care, particularly in the welfare of mothers and children and the health of schoolchildren. This period also saw the emergence of the public health nurse and the development of voluntary health agencies, health education programs, and occupational health programs. Problems of medical care also took on increasing importance around the world. The need to provide medical care for the poor was recognized in England in the 17th and 18th centuries and expressed as early as the Elizabethan Poor Law of 1601. In the second half of the 19th century there were two significant attempts to provide medical care for large populations. One was by Russia, and took the form of a system of medical services in rural districts. After the Communist Revolution, this was expanded to include complete government-supported medical and public-health services for all the people. Similar programs have since been adopted by a number of European and Asian countries.

The other course was prepayment for medical care, a form of social insurance first adopted toward the close of the 19th century in Germany, where prepayment for medical care had long been a familiar concept. A number of other European countries adopted similar insurance programs.

In the United Kingdom, a royal-commission examination of the Poor Law in 1909 led to a proposal for a unified state medical service. This service was the forerunner of the 1946 National Health Service Act, which represented an attempt by a modern industrialized country to provide services to all people, a milestone in the history of community health action.

In the United States, the widespread private-practice, fee-for-service approach to medicine has long provided very good care for some, adequate care for many, and entirely inadequate care for a large segment of the population. Two efforts toward reform have emerged: first, reorganization of medical care through governmental action; and, second, private, prepaid medical care programs.

Recent situation of public health

ORGANIZATIONAL AND ADMINISTRATIVE PATTERNS

International organization. Since ancient times, the spread of epidemic disease from country to country had demonstrated the need for international cooperation for health protection. Early efforts toward international control of disease appeared in the form of national quarantines in Europe and the Middle East. The first formal international health conference, held in Paris in 1851, was followed by a series of similar conferences aimed at drafting international quarantine regulations. A permanent international health organization was established in Paris in 1907 to receive notification of serious communicable diseases from participating nations, to transmit this information to the member nations, and to study and develop sanitary conventions and quarantine regulations on shipping and train travel. This organization was ultimately absorbed by the World Health Organization in 1947.

In the Americas, the organization of international health probably began with a regional health conference in Rio de Janeiro in 1887. From 1889 onward there were several conferences of American states, which led ultimately to the establishment of the Pan-American Sanitary Bureau; this was made a regional office of the World Health Organization in 1949, when it became known as the Pan-American Health Organization.

The rise and decline of health organizations has been influenced by wars and their aftermaths. After World War I, a Health Section of the League of Nations was established and functioned until it was destroyed by World War II. After World War II, the United Nations Relief and Rehabilitation Administration (UNRRA) was set up; one of its important activities was to handle displaced persons in such a way as to prevent the spread of disease. It was responsible for the planning steps that led to the establishment in 1948 of the World Health Organization as a special agency of the United Nations.

WHO definition of health

Health is defined in the constitution of the World Health Organization (WHO) as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity."

The work of the organization is carried out under the direction of the World Health Assembly, which is composed of representatives from the member states. The first assembly selected a number of projects for the program of the organization. The first consideration was to be given to diseases that exist in large areas of the world and that lend themselves to international action. On this basis the following fields were given priority: (1) malaria control; (2) tuberculosis control; (3) venereal disease control; (4) the promotion of health by positive means, such as a concentration on measures to improve the health of mothers and children; (5) amelioration of environmental conditions responsible for a significant proportion of deaths throughout the world; (6) the improvement of nutrition, an essential condition to the betterment of health for both children and adults. Since this first selection was made, other areas of need have been included in the work of the World Health Organization.

Among the most important functions of the organization are the advisory services offered to governments through its regional staff. For knowledge in specialized fields, a number of expert committees were created for the advisory services, to consider specific questions and develop reports, which are made available to all member nations.

The World Health Organization maintains close relationships with other United Nations specialized agencies, particularly the United Nations International Children's Emergency Fund (UNICEF) and the Food and Agricultural Organization, and with international labour organizations.

The World Health Organization undertakes both short- and long-term projects to control or eradicate diseases on a world scale. A spectacularly successful short-term project on a local scale was a 1953 campaign against typhus in Afghanistan, when the World Health Organization helped government workers to dust 345,000 persons and 19,000 houses and other facilities with insecticides. The biggest long-term undertaking among WHO field projects was the worldwide campaign against malaria, begun in 1955.

Advanced nations. Forms and functions of health administration vary from country to country. Major health functions are frequently grouped in a department that is held responsible for health and for closely related functions. In the United Kingdom such functions are carried out by the Department of Health and Social Security; in the United States the Department of Health, Education, and Welfare has jurisdiction over the programs covered by national legislation.

Departments of health

Few central departments of health are all-embracing; other departments also operate medical programs of some sort. No country, for example, places the health services of its military forces under the central health agency. Because unity of control at the centre is impracticable, coordination is most important. Central administration is further complicated in federal systems. In the United States, for example, there are 50 states, no two of which have the same patterns of health organization.

Patterns shared. The official responsible for the administration of national health affairs is usually a member of the Cabinet, and his political leadership is of great value in the development of a national health program. Advisory councils are frequently used to bring the thoughts of leading scientists, health experts, and community leaders to bear on national health problems.

An organization that provides basic community health services under the direction of a medical officer is called a local health unit. It is usually governed by a local authority. Its functions may include maternal and child health, communicable-disease control, environmental sanitation, maintenance of records for statistical purposes, health education of the public, public health nursing, medical care, and, often, school health services. The local health unit can provide the administrative framework for a wider range of community health services, including the care of the aged, of the physically handicapped, and of the chronically ill, and mental health services. Although social welfare services may be provided by a separate agency, there are advantages in amalgamating health and welfare services, because a family's health and social problems tend to be intimately interrelated. In England, welfare and public health are often integrated at the local level, whereas in the United States they are almost always separate.

The population served by a local health unit may number only a few thousand or as many as several hundred thousand. There are substantially different problems involved in administering health services for a large rural area that is sparsely populated and a municipality with a population of one or two million.

One problem of administering local health services centres on the question of whether they should be governed by independent local authorities or organized on a regional basis to ensure coordination, effective referral, and lack of duplication of services. This leads to the further question of regional planning, which will be considered later in this section.

Types of public medical service

Medical care is provided as a public service to some degree in most countries. Public medical service may be limited to hospitalization of persons with certain ailments, such as mental disease, tuberculosis, chronic ill. ness, and acute infections. Comprehensive health services may be provided for certain population groups, as in Canada and the United States, where the federal government provides such care for Indians and Eskimos. Many countries have compulsory sickness insurance, and some combine the socialization of hospitals with sickness insurance covering general medical care, as in Denmark. Full-scale socialization of health services exists in a few countries, including the United Kingdom, the Union of Soviet Socialist Republics (U.S.S.R.), and New Zealand.

In countries such as The Netherlands and the United States, in which voluntary and nonprofit organizations support a considerable share of the health services and operate most of the general hospitals, there is bound to be pluralism in health administration. This makes coordination difficult, but strong voluntary effort has the advantages of involving citizens directly in the development of their health services and of infusing the administration with a spirit of experimentation often lacking in governmental services.

Historically, hospitals have tended to develop haphazardly with little relation to one another. There is often a duplication of services to some population groups and an absence of services to others. The growth of modern general hospitals has tended to increase institutional care at the expense of care of patients in clinic facilities and homes. While the quality of inpatient care has increased markedly, there has often been a neglect of health problems that cannot be cared for in hospitals. Community-level services often are underfinanced and function without coordination with hospital programs.

Levels of health care

There is a trend toward regional planning of comprehensive health services for defined populations. In a somewhat idealized plan, the first level of contact between the population and the health system, which can be called primary care, is provided by health personnel who work in community health centres and who reach beyond the health centres into the communities and homes with preventive, promotive, and educational services. At the next level of care, general specialists in community hospitals provide secondary care for patients referred from the primary-care centres. Finally, tertiary, or superspecialty, care is provided by a major medical centre, often a university teaching centre. The various levels of this regional scheme would be linked by a two-way flow of medical records, patients, and health personnel.

Regionalization has been most fully achieved in Europe and least so in North America, where voluntary hospitals provide most of the short-term general services and retain autonomy in their administration. Rising costs of medical care, together with acknowledged inadequacies of the medical care system, have resulted in substantial pressures for reform in the United States and in experimentation on the development of improved systems.

Variations. Among the more developed nations, there is substantial variation in the organization and administration of health services. Three examples may be given here: the United Kingdom, which has a National Health Service with substantial autonomy given to local government for implementation; the Union of Soviet Socialist Republics, in which health services are accepted as the responsibility of the national government and administration is strongly centralized; and the United States, with a pluralistic approach to health services, in which local, state, and national governments have varying areas of responsibility, with the private sector playing a prominent role.

During the first half of the 20th century in Britain, the emphasis shifted gradually from environmental toward personal public health. A succession of statutes, of which the Maternity and Child Welfare Act (1918) was probably the most important, placed responsibility for most of the work on county governments. National health insurance (1911) gave benefits to 16,000,000 workers and marked the beginning of a process upon which the National Health Service Act (1946) was to build.

The National Health Service Act provided comprehensive coverage for most of the health services, including hospitals, general practice, and public health. The service remained at the periphery, however, in three types of care: (1) Primary medical care is given by family physicians or general practitioners. This service is organized on a local basis by an executive council. Each general practitioner has a list of people registered with him for whom he is responsible for providing primary care. (2) Specialist consultation and outpatient and inpatient treatment are provided in hospitals under the direction of regional hospital boards and boards of governors of teaching hospitals. A later concept makes each district general hospital responsible for providing hospital services for a defined population. (3) Services, such as health visiting, home nursing, home helps, domiciliary midwifery, the prevention of illness, and the provision of health centres are the responsibility of local authorities. This tripartite structure of the National Health Service was subjected to substantial criticism. Under an alternative proposal, area boards would be created, each having responsibility for the three combined branches of service.

Health services in the U.S.S.R.

In the Union of Soviet Socialist Republics, the protection and promotion of public health is the responsibility of the state. It is based on free public access to all forms of medical care. The principles upon which the health services are based are complete integration of curative and preventive services; medicine as a social service; the predominance of preventive programs; health centres or polyclinics (clinics in which a variety of diseases are handled) as the basis of operation; and community participation.

The public health services for the country as a whole are directed by the Ministry of Health under a minister who is a member of the Council of Ministers of the U.S.S.R. The ministry, through the 15 union republic ministries of health, directs all medical institutions within its competence as well as the public health authorities and services throughout the country.

The administration is centralized, with little local autonomy. Each of the 15 republics has its own ministry of health, which is responsible for carrying out the plans and decisions established by the U.S.S.R. Ministry of Health. Each republic is divided into *oblasti,* or provinces, which have departments of health directly responsible to the republic ministry of health. Each *oblast,* in turn, has *rayony* (municipalities), which have their own health departments accountable to the *oblast* health department. Finally, each *rayon* is subdivided into *uchastoki* (districts) with some three thousand to four thousand people in each.

In most rural *rayony* the responsibility for public health lies with the chief physician, who is at the same time medical director of the central *rayon* hospital. This system ensures unity of public health administration and implementation of the principle of planned development according to the social and economic plan for the country as a whole.

In the *uchastoki,* there are three types of salaried physicians: general practitioners or internists; pediatricians; and public health officers. There are also liberal numbers of other health personnel, including nurses, feldshers (*i.e.,* paramedical personnel trained in medical care), and midwives. In the more rural areas, there tend to be fewer physicians and more feldshers.

Feldshers generally undergo four years of training after eight years of general education, or three years if they have had the ten years of education. They function either as assistants to physicians when the number of physicians is adequate or relatively independently if the supply of physicians is inadequate. The use of the feldshers has helped the U.S.S.R. to make medical care available to large numbers of people who would not otherwise receive any care.

There are well-established referral procedures, from the polyclinics and smaller hospitals in the *uchastoki* to the larger *rayon* hospitals, and from feldshers and other paramedical personnel to internists and pediatricians and, when necessary, to more highly specialized personnel.

Medical education in the U.S.S.R. has four streams, currently chosen by students before their entry into medical school, leading to practice in internal medicine, pediatrics, public health, and stomatology (oral medicine).

The health services of the United States can be considered at three levels: local, state, and federal.

At the local level in cities or counties, there is substantial autonomy to function within broad guidelines developed by the state. The size and scope of local programs vary, but some of their typical functions are control of communicable diseases; clinics for mothers and children, particularly for certain preventive and diagnostic services; public health nursing services; environmental health services; health education; vital statistics; community health centres, hospitals, and other medical care facilities; community health planning and coordination.

At the state level, a department of health is charged with overall responsibility for health, though a number of agencies may actually be involved. The state department of health usually has five functions: public health and preventive programs; medical and custodial care such as the operation of hospitals for mental illness; expansion and improvement of hospitals, medical facilities, and health centres; licensure for health purposes of individuals, agencies, and enterprises serving the public; and financial and technical assistance to local governments for conducting health programs.

At the federal, or national, level, the Public Health Service of the Department of Health, Education, and Welfare is the principal health agency, but several other departments have specific health interests and responsibilities. Federal health agencies accept responsibility for helping to improve state and local services, for controlling interstate health hazards, and for working with other countries on international health matters. The federal government also has the following specific responsibilities: (1) protecting the United States from communicable diseases from abroad; (2) providing for the medical needs of military personnel, veterans, merchant seamen, and American Indians; (3) protecting consumers against impure or misbranded foods, drugs, and cosmetics; and (4) regulating production of biological products, such as vaccines. In addition, the federal government promotes and supports vast medical research, health services, and educational programs throughout the country.

Voluntary effort is a significant part of health work in the United States. There are more than 100,000 voluntary agencies in the health field functioning mostly at the local level but also at state and national levels. Supported largely through private sources, these agencies contribute to programs related to education, research, and health services.

Channels for medical care

Medical care is provided and paid for through multiple channels. It is provided through public institutions, such as municipal, county, state, and federal health centres, hospitals, and medical care programs, and through private channels, such as private hospitals and private practitioners working either alone or, increasingly, in groups. Generally speaking, medical care is financed by public funds, voluntary health insurance, or personal payment. There is a trend away from the traditional fee-for-service payment to individual practitioners toward prepaid-care systems including health teams working at community, health centre, and hospital levels.

Thus, in the United States there is great variety in the content, scope, and quality of health services. These services are provided by a multiplicity of independent agencies. In effect, however, they constitute a working partnership for the protection and promotion of human health.

In recent years, two factors have contributed to rapid change in the orientation of health services in the United States. One of these is an increasing awareness that, while the existing system for providing health services provides high quality services for many. there are many others for whom the care is either lacking or unsatisfactory. The second factor is that of steeply rising costs of medical care. These two issues have led to radical reconsideration of the entire system of personal medical care and proposals for entirely new systems of providing and financing health care.

Developing nations. ***Health problems and obstacles.*** The difficulties of providing health services for the people of the developing nations involve a cluster of interrelated problems. These problems may arise from the nature of the diseases and hazards to health, insufficient and maldistributed resources, the design of health services systems, and the education of health personnel who work in those systems.

With respect to, first, the diseases and hazards to health, an extreme situation is found in middle Africa, where infective and parasitic diseases, malnutrition, and environmental deficiencies are so prominent and destructive as to displace all other issues from major concern. By contrast, in the more advanced nations the only communicable diseases of major significance are tuberculosis and venereal disease, and the leading problems are those of age and industrial civilization. Woven through the health programs of the developing nations and complicating them at both family and national levels are the pressures associated with rapidly growing populations.

There are differences not only in the kinds of diseases prominent in different countries but also in the rates at which they occur and in the age groups involved. Life expectancy in some countries is less than half that in others, principally because of high death rates among small children in the developing countries. It is the children of the developing world who carry the great burden of ill health.

Infant mortality rates

In much of Southeast Asia, for example, 40 percent of children die by their fourth year, a death rate not reached until age 60 in North America. The infant (under one year of age) mortality rate in Middle and South America is two to four times that in North America, and the death rate in children one to four years of age is as much as 25 times greater. The differences for central Africa are even more striking: infant mortality in some areas has been 12 times that in the United States, and the mortality in preschool children has been more than 60 times the United States figure.

The principal causes of sickness and death among small children in the developing world are diarrhea, respiratory infections, and malnutrition, all of which are diseases intimately related to culture, custom, and economic status. Malnutrition is as often due to food customs as it is to the lack of food—taboos and simple oversight lead to deprivation of children too small to help themselves. Gastroenteritis (inflammation of the lining of the stomach and intestines. usually with accompanying diarrhea) and respiratory infections are often due to infectious organisms that are not susceptible to antibiotics. The interrelationships of these diseases increase the complexity of dealing with them. Malnutrition is often the underlying culprit; not only does it cause damage itself, such as retardation of physical and mental development, but it also seems to set the stage for other illnesses. A malnourished child develops gastroenteritis, inability to eat, further weakness, and then dehydration. Weakened in this way, the child is susceptible to a lethal infection, such as pneumonia. Or, to complete the vicious circle, infection can affect protein metabolism in ways that contribute to malnutrition.

Another factor that contributes to this grim picture is family size. Malnutrition, with associated death and disability, occurs most often in children born into large and poorly spaced families. The resulting high death rate among small children often reinforces the tendency of parents to have more children. People are not inclined to limit the size of their families until it is apparent that their children have a reasonable chance of survival. Thus, there is a fertility–mortality cycle in which high fertility, reflected in large numbers of small children crowded into a poor home, leads to high childhood mortality, which, in turn, encourages high fertility. This is the basis of the arguments that population-control programs should include effective means of reducing unnecessary deaths among children.

Ratios of medical personnel to population

Among limitations of resources, shortages of trained manpower are among the most important; ratios of population to physicians, nurses, and beds provide an indication of the seriousness of these deficiencies and also of the great differences from country to country (Table 1). Thus, the proportion of population to physicians in developing countries varies drastically. These figures change from year to year, but the changes are not dramatic. Nationwide figures are misleading because of the clustering of resources in the major cities. The number of persons per physician in Bangkok, Thailand, for example, is less than 1,000, while in the remainder of the nation it is 17,000. Even this latter figure is misleading, because there is another level of clustering in the provincial cities. Thus, the ratio for the truly rural population is about 200,000 per physician. In most countries of the developing world this rural figure is 50,000 or more.

Table 1: Ratio of Population to Physicians, Nurses, and Beds in Selected Countries

	ratio of population to physicians	ratio of population to nurses	beds per 1,000
Thailand	7,600	6,070	0.8
Jamaica	2,200	950	4.3
Colombia	2,000	17,100	3.1
Sudan	29,000	44,000	1.0
Senegal	20,000	5,500	1.3
Nigeria	50,000	7,100	0.4
Malawi	76,000	46,000	0.8
Guatemala	3,600	8,800	2.4
Iraq	4,900	6,700	2.1
Sweden	960	200	14.3

Money is a crucial factor in health care—it determines how many health personnel can be trained, how many can be maintained in the field, and the resources that they will have to work with when they are there. Governmental expenditures on health care vary from the equivalent of 20 cents (U.S. currency) per person per year in Indonesia to $56 in the United Kingdom. In contrast, the current expenditure by various governmental agencies in the United States is in excess of $300 per person per year. Rates of national development and the proportion of national income allocated to health indicate that health-expenditure figures will not change rapidly (Table 2).

Table 2: Governmental Expenditures on Health Services in Selected Countries

	year	government expenditure (in percent)	expenditure per inhabitant, U.S. (in dollars)
Nigeria	1964	12.0	0.50
Thailand	1963–64	3.4	0.60
Indonesia	1963	2.8	0.20
Malawi	1964	5.8	0.64
Sudan	1963–64	—	1.42
Iraq	1964–65	5.5	3.10
Colombia	1964	11.0	3.50
Jamaica	1963–64	11.0	9.60
U.K.	1963–64	12.9	56.00

Source: World Health Organization, ***Official Records, Third Report on the World Health Situation, 1961–64,*** no. 155 (1967).

For decades to come there will be less than one physician for every 50,000 people in the developing countries and only a few cents or a few dollars of governmental funds per person per year will be available for health expenditures. These realities of health care have important consequences on what can be done.

As it attempts to provide health care for its people, a nation, on the one hand, must meet the urgent and complex problems, such as obstetrical and surgical emergencies for which hospital care is essential. On the other hand, it must reach into the communities and homes to find those who need care but do not seek it and must discover the causes of such diseases as malnutrition and gastroenteritis.

Patterns shared. Developing countries have sometimes been influenced in the approaches they take to their health problems by the developed countries that have had a role in their historical development. The countries in Africa and Asia that were once colonies of Britain, for example, have educational programs and health-care systems that reflect British patterns, though there have been substantial adaptations to local needs. The health services are partly derived from British systems but are largely planned to meet the needs of those countries. Similar effects may be observed in countries influenced by France, The Netherlands, and Belgium.

The typical administrative pattern

Despite substantial variations from country to country, a reasonably common, if somewhat idealized, administrative pattern may be drawn for developing countries. All health services, except for a small amount of private practice, are under a ministry of health, in which there are about five bureaus, or departments — hospital services, health services, education and training, personnel, and research and planning. Hospital and health services are distributed through the country. At the periphery of the system are dispensaries, or health outposts, often manned by one or two persons with limited training. The dispensaries are often of limited effectiveness and are upgraded to full health centres when possible. Health centres and the activities that emanate from them are the foundation of the health-services system. Health centres are usually staffed by auxiliaries who have four to ten years of basic education plus one to four years of technical training. The staff of a health centre might include a midwife, an auxiliary nurse, a sanitarian, and a medical assistant. The assistant, trained in the diagnosis and treatment of sickness, refers to a physician the problems that are beyond his own competence. Together, these auxiliaries provide comprehensive care for a population of **10,000** to **25,000.** Several health centres together with a district hospital serve a district of about **100,000** to 200,**000** people. All health services are under the responsibility of the district medical officer, who has the exacting job of integrating the various health efforts into a comprehensive health program. He is assisted by other professional and auxiliary personnel.

Of central importance is the distribution of responsibilities between auxiliaries and professionals. The auxiliaries, by handling the large number of relatively simple problems, allow the professionals to look after only the more complex problems, to supervise and teach the auxiliaries, and to plan and manage the programs.

The district hospital is dependent on a regional hospital, to which patients with complex problems can be referred for more specialized services. Administrative direction of both regional health services and regional hospital services can be combined at this level under a regional medical officer. The central administration of the ministry of health provides policies and guidance for an entire health service and, in some instances, also provides a central planning unit.

Problems of transportation and communication over great distances, shortages of staff and other resources, and inadequacies in staff preparation and motivation often lead to malfunctions in the system. Nonetheless, the public health services developed in African and Asian countries have generally provided a sound basis for future development within the framework of national development.

Variations. The organization of public health services in Latin American countries differs substantially from those of Africa and Asia; these differences are largely an expression of their different historical backgrounds. The Latin American countries are generally more affluent than are the countries of Asia and Africa. Private practice is more widespread, and private or voluntary agencies are more prominent. Health services are provided largely by local and national governments. Many Latin American countries also have systems of clinics and hospitals for workers financed by employers and workers. The distribution of health services, with health centres, hospitals, and preventive services, is roughly as described in the previous section. The Latin American countries. however, have used auxiliaries less than African and Asian countries. Latin America has pioneered in the development of health-planning methods. Chile has one of the most advanced approaches to health planning in the world.

Differences between Latin America and Africa

Thailand is an example of a country that was never colonized and therefore has no historical influence favouring any particular pattern of health services. The Thai Ministry of Health has a well-developed system of hospitals and health centres distributed across the country to serve rural as well as urban people. It differs substantially from the pattern described in the previous section in that, despite the extreme shortages of physicians and nurses in rural areas, the nation has been reluctant to use auxiliaries for medical care. It does however, use auxiliary midwives and sanitarians. Hospital services and public health services have entirely separate administration. Within the public-health services, there are a number of separate divisions—*e.g.*, for tuberculosis, venereal disease, and nutrition — each with its own staff, budget, and facilities. The trend elsewhere has been away from relatively independent, disease-oriented approaches and toward integrated systems in which the same network of health services handles all or almost all problems.

***Education of** health personnel.* In the consideration of the education of health personnel, a particular set of problems emerges. Educational programs for auxiliaries are often well suited to the local situation, perhaps because they were not established in the more developed nations. Medical and nursing education, on the other hand, is similar to that of the more advanced countries, and it prepares students better for working in industrialized nations than in their own. This misfit between education and the jobs to be done has probably contributed substantially both to the lack of effectiveness of health services systems and to the migration of professional personnel to the more developed countries.

RECENT PROGRESS IN PUBLIC HEALTH

More developed nations. Among the more developed nations the following trends are apparent.

Increasing interest of national governments. An important trend in public health has been the increasing interest of national governments in the organization of medical care. Formerly, governments were chiefly concerned with basic health problems, such as environmental sanitation, medical care of the poor, quarantine, and the control of communicable diseases. Gradually, they have extended their activities into the field of medical care services in the home, clinic, and hospital, so as to provide comprehensive health care for entire communities. Three factors have influenced this trend: (1) the nongovernmental voluntary agencies have been unable to meet the rising cost of medical care; (2) there is an increasing appreciation of the economic loss to a country from sickness; and (3) there is an increasing public interest in social services.

Factors in the increase of government involvement

*The **broadening outlook on social welfare.*** Health and social welfare are now recognized as complementary, and social legislation tends to cover both areas. There is an administrative trend toward a close cooperation between health and social welfare services.

*Changing **concepts of preventable disease.*** Until recently, the term preventable disease referred to a circumscribed group of infectious diseases. The term is acquiring a broader meaning, however, as epidemiological methods are applied to other conditions. Preventive health services now deal with a wide range of health hazards, such as malignant tumours, rheumatism, cardiovascular diseases, other chronic and degenerative diseases, and even accidents.

Integration of preventive and medical care services. Medical care had its origin in the humanitarian motive of caring for the sick, while preventive services sprang from the need to protect a healthy environment from epidemic diseases. They grew apart from each other, but recently the trend has been to integrate them within a comprehensive health service. Such an integration is the fundamental principle of public health in the U.S.S.R. and in some other eastern European countries in which all local health services are centred in the district hospital under one administration. In other European countries, especially in rural areas, the two branches are brought together by the local medical practitioner. The focal point of many discussions is the role that the hospital should play in health services. Many authorities feel that its influence at present is too restricted and that it should spread beyond its walls to health centres and homes.

Provisions directed toward better mental health. A new orientation in mental health has allowed it to take a place in the preventive services. Improvements in arrangements for mental health include the provision of outpatient clinics and inpatient accommodations at general hospitals for early mental cases, an increase in child-guidance and marriage-guidance clinics, and schemes for the care of alcoholics and drug addicts. There have also been significant developments in the treatment of maladjusted members of society. Gains in understanding of psychoneuroses by general practitioners and the development of research facilities are also noteworthy.

Growing emphasis on health education. Many countries have expanded their work in health education, usually in cooperation with voluntary agencies. The most effective work is carried out at the local level, especially in schools. The trend is toward an expansion of health education as an essential preventive health service.

The biostatistical, epidemiological approach. A statistical service is essential in planning, administering, and evaluating health services. The interest of public authorities in medical-care schemes has vastly increased the importance of statistics on the incidence of diseases and other problems, as well as the epidemiology necessary to combat them. Both are vital in the planning, organization, and evaluation of medical care schemes. Traditionally, the epidemiological method was used for infectious diseases, but it is now being used increasingly for noninfectious diseases and the problems of medical care.

Changes resulting from an aging population. In more affluent nations, an increase in older age groups brings about the need for public health facilities to provide special services for them. Health care of the elderly includes measures to prevent premature aging and the chronic and degenerative diseases and to deal with the psychological problems resulting from loneliness and inactivity. Geriatric clinics have been set up to meet these needs and to conduct research into the process of senescence.

New hazards to health

Concern regarding the quality of the environment. There is widespread concern about environmental deterioration. The advent of controlled atomic radiation has created new hazards to health, such as the potential pollution of air or water by radioactive discharges, the possible effects from radioactive fallout on the public generally, and the dangers to workers in atomic installations in industry. An increasing population requires an increase in industrial and commercial activities, which add to the volume of pollutants that threaten the atmosphere, rivers, lakes, and oceans and have destructive effects on natural ecology. Individual countries have taken steps toward the control of environmental deterioration, and means of international regulation have also been proposed.

Developing nations. In view of the large numbers of serious health problems in the developing nations and their limited resources for dealing with them, it is understandable that along with substantial progress there would be some stagnation, or even regression.

Communicable-disease control. Smallpox and malaria are examples of diseases that have been brought under closer control throughout the world. For other diseases, such as hepatitis (liver inflammation), rabies, leprosy, and sleeping sickness, there have been important additions to understanding that can contribute to their eventual control.

Disease problems that await solution. El Tor cholera, which has appeared in epidemic form in previously uninvolved areas, represents one of the most serious challenges to public health. Venereal disease, an old problem, has increased at a disturbing rate. Certain parasitic diseases have spread as man has brought about changes in his environment—the increase in schistosomiasis (infestation with blood fluke by means of snails as the intermediate hosts) in irrigation and man-made lake areas is an example. Widespread malnutrition, particularly protein–calorie malnutrition in small children, remains a vitally important problem. Protein-rich food supplements and more effective educational programs are being developed to combat it.

Family health. The problems of rapidly growing populations have important consequences at both the family and the national level. Problems of maternal and child health, human reproduction, and human genetics, including family planning, are now seen as aspects of the greater problem of the health of the whole family as a single and fundamental social unit. Accordingly, family health is being viewed as a matter deserving high priority among the tasks of national public health services.

Health manpower. There is widespread recognition of inadequacies in both number and education of health personnel. The trend is in the direction of coordinating the education of all levels of health personnel with the particular health service in which the graduates will function. This trend, in turn, requires close relationships between educational institutions and the agencies responsible for health services.

Comprehensive community health services. The fragmentation of earlier health service organizations, such as single-disease-oriented programs and the separation of curative and preventive services, is giving way to more comprehensive organizational patterns. Health promotion, disease prevention, curing of the ill and their rehabilitation are brought together into one network of integrated services that reaches to the community level.

National health planning. Decisions of great complexity are involved in allocating limited resources to provide health services for large numbers of people. In order to achieve optimum results, there has been an increasing emphasis on the health-planning process and on the design of more effective health-services systems. A number of countries have established health-planning units in the ministry of health or the national planning organization. An important aspect of national health planning is the close coordination between planning, budgeting, implementing, and evaluating programs.

Public Opinion

There are many difficulties in the way of defining public opinion, the most important of which are discussed below. A simple definition is that public opinion is an aggregate of the individual views, attitudes, and beliefs about a particular topic, expressed by a significant proportion of a community.

HISTORICAL BACKGROUND

Although the term public opinion was not used until the 18th century, phenomena that closely resembled public opinion seem to have occurred in many historical epochs. One of the oldest written records from ancient Egypt, a poem entitled "The Dispute With His Soul of One Who is Tired of Life," refers to an upheaval that apparently involved a complete reorientation of mass opinion:

> To whom shall I speak today?
> People are greedy. . . .
> Gentleness of spirit has perished.
> All the people are impudent. . . .
> People laugh at crimes of him who before
> Would have enraged the righteous. . . .
> There are no just men.
> The earth has been given over to evil doers.

Similar references to popular attitudes can be found in the history of Babylonia and Assyria. The prophets of ancient Israel sometimes justified the policies of the government to the people and sometimes appealed to the people to oppose the government. In both cases they were concerned with swaying opinion. And in classical Greece it was observed by many that everything depended on the people, and the people were dependent on the word. Wealth, fame, and respect all could be given or taken away by persuading the populace.

Wide dissemination of news, which is usually necessary for the formation of public opinion, could be observed in classical Rome. Much of this took place through person-to-person channels. When the Roman statesman Cicero was in Cilicia in the year 51 BC, he asked his friend Caelius to keep him informed of what was happening in the capital. Caelius promised to do so: "If anything important of a political nature should occur . . . I will diligently describe to you its origin, the general opinion about it, and the prospects of future action that it opens up." Rome also had its wall newspapers, composed by Roman officials and posted in public places to inform the public about acts of the government and principal local events.

Public opinion in the Middle Ages

During the Middle Ages in western Europe, the masses were encased in a rural, traditional society in which most activities and attitudes were dictated by a person's station in life; but phenomena much like public opinion could be observed among the religious, intellectual, and political elite. Religious disputations, the struggle between popes and the Holy Roman Empire, and the dynastic ambitions of princes all involved efforts to persuade, to create a following, and to line up the opinions of those who counted. In 1191 the English bishop William of Ely was attacked by his political opponents for hiring troubadours to extol his merits in public places, so that "people spoke of him as though his equal did not exist on earth." The propaganda battle between emperors and popes was waged largely through sermons, but handwritten literature also played a part.

From the end of the 13th century, the ranks of those who could be drawn into controversy regarding current affairs grew steadily. 'There was an increasing spread of education among the lay population. The rise of humanism in Italy saw the emergence of a group of writers and publicists whose services were eagerly sought by the princes who were consolidating national states. Some of these writers were used as advisers and diplomats; others were employed as publicists because of their ability to sway opinion. Such a one was the Italian Pietro Aretino (1492–1556), of whom it was said that he knew how to defame, to threaten, and to flatter better than all others and whose services were sought by both Charles V of Spain and Francis I of France. The Italian political philosopher Niccolb Machiavelli, a contemporary of Aretino, wrote that princes should not ignore popular opinion, particularly in regard to such matters as the distribution of offices.

Influence of printing on the growth of public opinion

The invention of printing from movable type in the 15th century and the Protestant Reformation in the 16th increased still further the numbers of people able to form opinions on contemporary issues. Martin Luther broke with the humanists by abandoning the use of classical Latin, intelligible only to the educated, and turned directly to the masses. "I will gladly leave to others the honour of doing great things," he wrote, "and will not be ashamed of preaching and writing in German for the unschooled layman." Luther's 95 theses, which were printed against his will and widely spread throughout Europe, were of a theological nature, but he also wrote on such subjects as the war against the Turks, the Peasants' Revolt, and the evils of usury. His vigorous expressions and the counterblasts from his many opponents, both lay and clerical, led to the formation of larger and larger groups holding opinions on important matters of the day.

Extensive attempts to create and influence public opinion were made during the Thirty Years' War (1618–48). A flood of propaganda tracts, many of them illustrated with woodcuts, emanated from both sides. Opinions were also swayed by means of speeches, sermons, and face-to-face discussions. Not surprisingly, both civil and religious authorities attempted to control the dissemination of unwelcome ideas by increasingly strict censorship. The first pope to have an Index of Prohibited Books drawn up was Paul IV in 1559. Charles IX of France decreed in 1563 that nothing could be printed without the special permission of the king.

More quietly, but more significantly, newspapers and news services were developing. Rudimentary private news services had been maintained by political authorities and wealthy merchants ever since classical times, but they were not available to the public. By 1500, however, it was possible to buy specialized news sheets in many of the principal cities of Europe. One of these, printed in 1514 or 1515, contains an extract of a merchant's letter telling of the Portuguese discovery of Brazil. The first regularly printed newspapers appeared about 1600 and multiplied rapidly thereafter, although they were frequently bedevilled by censorship regulations. Regular postal services, started in France in 1464 and in the Austrian Empire in 1490, facilitated the spread of information enormously.

Bourses as sources of informed opinion

The great news centres of early modern times were the financial exchanges. With the introduction of a paid civil service and the employment of paid soldiers in the place of vassals, princes found it necessary to borrow money. The bankers, in turn, had to know a great deal about the credit of the princes, the state of their political fortunes, and their reputations with their subjects. All kinds of political and economic information flowed to the money-lending centres at Antwerp, Lyon, and Niirnberg, and this information gave rise to generally held opinions in the banking community. The ditta di borsa—the opinion on the bourse—is often referred to in documents of the period. Queen Elizabeth of England was regarded as especially well informed because Sir Thomas Gresham, the finance agent of the English crown, kept in constant touch with the Antwerp bourse.

Significantly, it was another financial official who first popularized the term public opinion in modern times. Jacques Necker, finance minister of Louis XVI on the eve of the French Revolution, noted repeatedly in his writings that public credit depended upon the opinions of holders and buyers of government securities about the viability of the royal administration. He, too, was vitally concerned with the ditta di *borsa*. But he also remarked on the power of public opinion in other areas. "This public opinion," Necker wrote, "strengthens or weakens all human institutions." As he saw it, public opinion should be taken into account in political undertakings. Necker was not, however, concerned with the opinions of all Frenchmen. For him, the people who collectively shaped public opinion were those who could read and write, who lived in cities, who kept up with the day's news, and who had money to buy government securities —in short, the bourgeoisie.

A public opinion that extended beyond the middle classes and embraced the urban masses took shape during the French Revolution. Observers of the Revolution were mystified, and often terrified, by this new phenomenon of public opinion, which seemed able to sweep aside the entrenched institutions of the time: the monarchy, the church, and the feudal system. Thinkers of the late 18th and early 19th centuries advanced a variety of definitions as to what public opinion actually was. One of the most detailed descriptions was given in 1799 by the German poet Christoph Wieland, who closely followed the stormy events in France and the rest of western Europe:

> I, for my part, understand by it an opinion that gradually takes root among a whole people, especially among those who have the most influence when they work together as a group. In this way it wins the upper hand to such an extent that one meets it everywhere. It is an opinion that without being noticed takes possession of most heads, and even in situations where it does not dare to express itself out loud can be recognized by a louder and louder muffled murmur. It then requires only some small opening that will allow it air, and it will break out with force. Then it can change all nations in a brief time and give whole parts of the world a new configuration.

A German philosopher of the time, Christian Garve, gave much more emphasis to the rational component:

> Public opinion as interpreted . . . by those French writers who are clearest on the subject is the agreement of many or of the majority of the citizens of a state with respect to judgments which every single individual has arrived at as a result of his own reflection or of his practical knowledge of a given matter.

The English philosopher Jeremy Bentham, who advanced the first detailed discussion of public opinion in English, was troubled by the difficulty of defining it and advised that the term be employed only in deference to common usage.

RECENT DEFINITIONS AND CONCEPTIONS OF PUBLIC OPINION

In spite of voluminous discussions of the subject, scholars still do not agree on a definition of public opinion. Members of a roundtable of the American Political Science Association that met in 1925 divided into three groups: those who did not believe that there was such a thing as public opinion; those who accepted its existence but doubted their ability to define it precisely; and those who could offer a definition. This last group could not, however, agree on the definition to be adopted. Although few scholars now question the existence of such a phenomenon as public opinion, differences in defining it have persisted to the present day.

These differences stem in part from the varying perspectives with which scholars have approached the study of public opinion and in part from the fact that the phenomenon is still not completely understood. Political scientists and some historians have tended to emphasize public opinion's role in the governmental process, paying particular attention to its influence on government policy. Some political scientists have regarded public opinion as equivalent to the national will. In this sense, there can be only one public opinion on an issue at any one time.

Sociological conceptions of public opinion

Sociologists usually give more emphasis to public opinion as a product of social interaction and communication. According to the sociological view, there can be no public opinion without communication among members of the public who are interested in a given issue. A large number of persons may hold quite similar views, but these will not coalesce into public opinion as long as each person remains ignorant of the opinions of the others. Communication may take place by means of the mass media of the press, radio, and television or through face-to-face discussions. Either way, people learn how others think about a given issue and may take the opinions of others into account in making up their own minds.

Sociologists suggest that there may be many different public opinions existing on a given issue at the same time. One body of opinion may be dominant or may be reflected in governmental policy, but this does not mean that other organized bodies of opinion do not exist. The sociological approach also sees the public-opinion phenomenon as extending to areas that are of little or no concern to government. Thus, fads and fashions are appropriate subject matter for students of public opinion, as are public attitudes toward movie stars or corporations.

It is often the case that opinions expressed in public may differ from those expressed in private and that only the former contribute to public opinion. Similarly, some attitudes--even though widely shared—may not be expressed at all. Thus, in a totalitarian state, a great many people may be opposed to the government but may fear to express their attitudes even to their families and friends. In such cases, an antigovernment public opinion fails to develop.

Private opinions, if expressed in public, may become a basis for public opinions. Until the 1930s, for example, there was an unwritten prohibition in the United States against discussions of venereal disease, although many indivduals had private opinions about it. Then, when the subject began to be treated in the mass media and public opinion researchers began to ask questions about it, opinions that had formerly been private were expressed in public, and sentiment in favour of government action to stamp out venereal disease developed.

Some public-opinion survey specialists have preferred a definition that links public opinion directly to their polling procedures. Public opinion is therefore defined as being identical to what people's responses to a survey questionnaire would be. Other similar definitions have been to the effect that public opinion is whatever is discovered by public-opinion polls. This definition, while widely used in practice, has the disadvantage of implying that public opinion does not exist in places and times in which there are no opinion polls. A more generally applicable approach that embodies much the same reasoning is that public opinion on any matter may be conceived as the hypothetical result of some imaginary survey or vote.

Those who are primarily engaged in the manipulation of public opinion, notably professional politicians and public relations men, rarely stop to define it. The American journalist and political scientist Walter Lippmann has observed that there has been a tendency in democracies to make a mystery out of public opinion but that "there have been skilled organizers of opinion who understood the mystery well enough to create majorities on election day." (**Public *Opinion,*** 1922.) Public relations practitioners have concerned themselves less with public opinion in general than with the opinions of specified "publics" that may affect the fortunes of a client: employees, stockholders, government officials, suppliers, and potential buyers, for example. Both politicians and public relations men are interested in influencing behaviour and thus in determining any attitudes and opinions that may affect that behaviour, whatever they may be called.

Nearly all scholars and manipulators of public opinion, regardless of the way they may define it, agree that at least four factors are involved in public opinion: there must be an issue; there must be a significant number of individuals who express opinions on the issue; there must be some kind of a consensus among at least some of these opinions; and this consensus must directly or indirectly exert influence.

THE FORMATION AND CHANGE OF PUBLIC OPINION

The democratic system itself defines a number of issues on which citizens are under pressure to form opinions. They are called upon to decide among various candidates in elections and, on occasion, to vote on constitutional amendments and various other propositions. Almost any matter on which the executive or legislature has to decide may become a public issue, if a significant number of persons wish to make it one. The attitudes of these persons are often stimulated or reinforced by outside agencies—a crusading newspaper, a pressure group, or a governmental agency or official. Even matters that are not within the purview of any governmental agency may become public issues. No agency, for example, has the authority to determine how many children a family may have or how long a man's hair should be, but discussion on these subjects has been sufficiently intense to generate widespread opinion about them.

Elements involved in the formation of attitudes

Once a public issue is identified, a certain number of people will begin to form attitudes about it. If the attitude is expressed to others by sufficient numbers of people, a public opinion on the topic begins to emerge. Not all people develop attitudes on public issues; some may not be interested, and others simply may not hear about them. The attitudes that are formed may be held for various reasons. Thus, four men may all be opposed to higher property taxes but for very different reasons. One man may not be against higher taxes in principle, but he opposes them because he is having trouble paying the mortgage on his house. This attitude serves an adjustment, or utilitarian, function in that it helps its holder to accommodate the immediate financial situation in which he finds himself. A second man may fight the tax because he does not want a certain social group, such as the poor or the unemployed, to derive any benefit from tax revenues. Such an attitude may be the result of a psychological insecurity, of a desire to keep the poor "in their place" in order to bolster his own sense of superiority toward underprivileged groups. For such a person, the atitude serves an ego-defensive function. A third man may esist the tax increase because he believes that governmental activities should be severely restricted. His attitude has a value-expressive function in that it reflects his overall philosophy. A fourth man opposes the increased tax because he is familiar with instances of governmental waste and is convinced that all necessary services could be rendered if officials spent the already available funds more rationally. His attitude is thus determined by knowledge or experience in that it is a reflection of what he has learned in the past. A fifth man, of course, might fight the tax for all four reasons. A seemingly homogeneous body of public opinion may thus be comprised of individual opinions that are rooted in very different interests and values. If an attitude does not serve a function such as one of the above, it is unlikely to be formed: an attitude must be useful in some way to the person who holds it.

How many people will actually form opinions on a given issue, as well as what sort of opinions they form, depends partly on their own pre-existing knowledge, attitudes, and values; partly on the personal situations in which they find themselves; and partly on a number of environmental factors. As far as pre-existing knowledge and attitudes are concerned, it is often surprising to discover how many people are not informed about major issues and therefore have no attitudes toward them. In 1964, for instance, one in four Americans did not know that the government in China was Communist, and about the same proportion at any given time is ignorant of any major issue of public policy. Substantially the same situation has been found to exist in western European countries, and ignorance is probably even more widespread in nations with lower levels of education. Values are of considerable importance in determining whether people will form opinions on a particular topic. If people feel that their moral principles or personal philosophies are involved in an issue, they are more likely to take a favourable or opposing stand.

Environmental factors play an extremely important part in the formation of attitudes and opinions. Most pervasive is the influence of the immediate social environment: family, friends, neighbourhood, place of work, church, or school. People usually adjust their attitudes to conform with those that are most prevalent in the social groups to which they belong. If a person who considers himself a liberal is surrounded in his home or at his place of work by people who profess conservatism, he is more likely to switch his vote than is a liberal whose family and friends share his political views. Similarly, it was found in World War II that men transferred from one unit to another often adjusted their opinions to conform more closely with those in the unit to which they were transferred.

The influence of mass media

Other important environmental factors involved in the formation of public opinion include the existence of pressure groups, advertising, and public relations and the attitudes of opinion leaders inside and outside government. The press, radio, and television are usually less important than the immediate social environment when it comes to the formation of attitudes, but they are still significant. They focus the attention on certain personalities and issues, and many people subsequently form opinions about these issues. Government officials have noted that their mail from the public tends to "follow the headlines"; whatever is featured in the press at a particular moment is likely to be the subject that most people write about. The mass media can also activate and reinforce latent attitudes. Political attitudes, for example, are likely to be activated and reinforced just before an election. Voters who may have only a mild preference for one party or candidate before the election campaign starts are often worked up by the mass media to a point where they not only take the trouble to vote but may contribute money or help a party organization in some other way.

The mass media play another extremely important role in letting individuals know what other people think and in giving leaders large audiences. In this way they make it possible for public opinion to include a large number of individuals and to spread over wider geographic areas. It appears in fact that in some European countries the growth of broadcasting, and especially television, has affected the operation of the parliamentary system. Before television, national elections were seen largely as contests between a number of candidates or parties for parliamentary seats. More recently, elections in such countries as West Germany and Great Britain have appeared more as a personal struggle between the leaders of the principal parties concerned, since these leaders were featured on television and came to personify their parties. Television in France and the United States has been regarded as a powerful force strengthening the presidential system, since the President can easily appeal to a national audience over the heads of elected legislative representatives.

Even when the mass media are thinly spread, as in developing countries or in nations where the media are strictly controlled, word-of-mouth can sometimes perform the same functions as the press and broadcasting, although on a more limited scale. In developing countries, it is common for those who are literate to read from newspapers to those who are not, or for large numbers of persons to gather around the one village radio. Word of mouth in the marketplace or neighbourhood then carries the information further. In countries where important news is suppressed by the government, a great deal of information is transmitted by rumour. The official newspaper of the Chinese Communist Party has denounced "little broadcasting stations," as rumour carriers are sometimes called in the People's Republic, criticizing them for distributing unauthorized news about the party and the state. Word of mouth thus helps public opinion to form in developing countries and encourages "underground" opinion in totalitarian countries, even though these processes are slower and usually involve fewer people than in countries where the media network is dense and uncontrolled.

The role of pressure groups

Pressure groups, or interest groups, also play an important part in the formation and spread of public opinion on issues of relevance to themselves. These groups may be concerned with political, economic, or ideological issues and often work through the mass media as well as by word of mouth in trying to influence attitudes. Some of the larger or more affluent interest groups in the U.S., western Europe, and elsewhere make use of advertising and public relations to influence opinion. During the late 1960s and early 1970s, for example, hundreds of thousands of dollars were spent in the U.S. on advertising by opponents and proponents of United States policy in Southeast Asia, and lesser amounts were devoted to interest group advertising on other public issues. In Britain, much advertising space was purchased by opponents of Britain's proposed entry into the Common Market.

Opinion leaders play a major role in defining important issues and in influencing individual opinions regarding them. Political leaders, in particular, can turn a hitherto relatively unknown problem into a national issue if they decide to call attention to it. One of the ways in which opinion leaders rally opinion and smooth out the differences among those who are in basic agreement on a subject is by coining or popularizing symbols or slogans: Sir Winston Churchill popularized the phrase cold war, and the Allies in World War I were fighting "a war to end all wars." Slogans are perhaps among the most useful tools that are available to the political leader. Once enunciated, symbols and slogans are frequently kept alive and communicated to large audiences by the mass media and may become the cornerstone of public opinion on any given issue.

Opinion leaders are not confined only to prominent figures in public life. There are likely to be persons in every social group to whom others in the immediate environment look for guidance on certain subjects. Thus, one person may be thought of by those in his own social group as especially qualified in the realm of local politics, another as a reliable guide in foreign affairs, and a third as an expert when it comes to buying a house. These local opinion leaders are generally unknown outside their own circle of friends and acquaintances, but their cumulative influence in the formation of public opinion is substantial.

Although a person's psychological makeup, his personal circumstances, and external factors such as pressure groups and opinion leaders all play a role in the formation of opinions, it is still not known exactly how public opinion on an issue takes shape. Many aspects of the public opinion process have yet to be explored. The same is true with regard to changes in public opinion. Some of these can be accounted for by changing events and circumstances, but others are more difficult to explain. It is known that public opinion on some subjects tends to follow events. Public attitudes toward other nations, for example, seem to depend largely on the relations between the governments of the two nations. Hostile attitudes do not cause poor relations; they are the result of them. People presumably change their attitudes when these attitudes do not correspond with their perception of prevailing circumstances and hence are not useful as guides to action. It is also frequently the case that an issue ceases to be important and simply fades from public attention, while new issues arise as the basis for new bodies of opinion. There are still, nevertheless, major changes in public opinion that are difficult to explain. During the second half of the 20th century in many parts of the world, attitudes toward religion, family, sex, international relations, social welfare, and the economy have undergone major shifts. There have been important issues claiming public attention in all these areas, but the changes in public opinion are difficult to relate to any major event or even to any complex of events.

PUBLIC OPINION AND GOVERNMENT

Many early thinkers saw public opinion as a powerful force that rulers must learn how to control. The 18th-century French philosopher Jean-Jacques Rousseau believed that all laws were based upon it but that this did not necessarily diminish the powers of government. It was Rousseau's opinion that "Whoever makes it his business to give laws to a people must know how to sway opinions and through them govern the passions of men." The 19th-century German philosopher G.W.F. Hegel described public opinion as containing both truth and falsehood together and added that it was the task of the great man to distinguish the one from the other. Jeremy Bentham saw the greatest difficulty of the legislator as being "in conciliating the public opinion, in correcting it when erroneous, and in giving it that bent which shall be most favourable to produce obedience to his mandates."

Public opinion as a safeguard against abuse of authority

At the same time, Bentham and some other thinkers believed that public opinion was a useful check on the authority of rulers. Bentham demanded that all official acts be given publicity, so that an enlightened public opinion could pass on them, as would a tribunal: "To the pernicious exercise of the power of government it is the only check." The British jurist and historian James Bryce, writing a century later, maintained that if government was based on popular consent, this would give a nation great stability and strength: "It has no need to fear discussion and agitation. It can bend all its resources to the accomplishment of its collective ends." Bryce did not, however, believe that mass opinion could or should dominate details of governmental policy, since most people did not have the leisure or inclination to arrive at a position on every question. Rather, the masses would set the general tone for policy, their sentiments leading them to take a stand on the side of justice, honour, and peace.

Those who worked to advance international understanding were particularly likely to invoke the power of public opinion. Both Bentham's "Plan for an Universal and Perpetual Peace" (1789) and Immanuel Kant's proposals in his essay "On Perpetual Peace" (1795) were based on the belief that public opinion is peace loving and that international peace can be sustained by it. Those who advocated establishment of the League of Nations after World War I also looked to world public opinion as the principal force that would sustain the League. Drafters of the charter of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) apparently had somewhat the same idea, noting that because the origins of war were to be found in the minds of the masses of men it was in the minds of men that the defenses of peace should be constructed.

Some scholars, while acknowledging the power of public opinion, warned that it could be a dangerous force. The 19th-century French writer Alexis de Tocqueville was concerned about the possible "tyranny of the majority" if government was in fact to be an expression of mass attitudes. Many other writers have expressed concern, often in a more extreme form, about the dangers of allowing government policy to be influenced too much by public opinion, which may well be uninformed, unthinking, and unstable. But whether public opinion is regarded as a constructive or a baneful force in a democracy, there are few politicians who are prepared to deny in public that government should follow public opinion.

An assessment of the significance of public opinion

In recent years, political scientists have been less concerned with what part public opinion should play in a democratic polity and have given more attention to establishing what part it does play in actuality. From the examination of numerous histories of policy formation, it is clear that no sweeping generalization can be made that will hold in all cases. The role of public opinion appears to vary from issue to issue, and the way it asserts itself differs from one democracy to another. The safest generalization that can be made is that public opinion does not influence the details of most policies but that it does set limits within which the policy maker must operate. That is, public officials will usually seek to satisfy a widespread demand, or will at least take it into account in their deliberations, and they will also try to avoid decisions that they believe will fly in the face of popular opinion. In addition, it has been observed that the relation between public opinion and public policy is two way; policy influences opinion, as well as the reverse, and there is usually at least an initial tendency for the public to accept a decision once it is made. Public opinion seems to be particularly effective in influencing policy making at the local level, as officials appear to feel themselves constrained to yield to popular pressures for better roads, better schools, or more hospitals.

Public opinion at the national level seems to play a more limited role—partly because of the inability of most people to understand the complexities of most issues faced by government and partly because of the growth of executive power and the development of large governmental bureaucracies that serve as screens between the policy maker and the public. Representative government itself also tends to limit the power of public opinion to influence specific decisions, since ordinarily the public is given the choice only of approving or disapproving the election of a given official.

PUBLIC-OPINION POLLING

Public-opinion polling can provide a fairly exact analysis of the distribution of opinions on almost any issue within a given population. Assuming that the proper questions are asked, polling can also reveal something about the intensity with which opinions are held, about the reasons for these opinions, and about whether or not the issues have been discussed with others. Polling does not usually reveal whether or not the people holding an opinion can be thought of as constituting a cohesive group, and it is unlikely to provide very much information about the elites who may have played an important part in developing the opinion. But in spite of these deficiencies, polling is a valuable tool for estimating the state of public opinion on almost any subject.

Origins of opinion research

Opinion research developed from market research. Early market researchers picked small samples of the population and used these to obtain information on such questions as how many people read a given magazine or listen to the radio and what the public likes and dislikes in regard to various consumer goods. About 1930, both commercial researchers and scholars began to experiment with the use of these market research techniques to obtain information on opinions about political issues. In 1935 the American psychologist George Gallup began conducting nationwide surveys of opinions on current political and social issues in the United States. One of the first questions asked by the Gallup Poll (its full name is the American Institute of Public Opinion) was "are Federal expenditures for relief and recovery too great, too little, or about right?" To this, 60 percent of the sample replied that they were too great, only 9 percent thought they were too little, and 31 percent regarded them as about right.

From the 1930s on, the spread of opinion polls conducted by both commercial and academic practitioners continued at an accelerated pace in the U.S. and, to a more limited extent, elsewhere. In 1937, the Public *Opinion Quarterly*, which later became the official organ of the American Association for Public Opinion Research, began publication. State and local polls, some sponsored by newspapers, were started in many parts of the country, and opinion research centres were organized at several universities. Before and during World War II, opinion polls were extensively used by U.S. government agencies, notably the Department of Agriculture, the Treasury Department, and the War Department, and some government-sponsored polls continued into the postwar period.

At the same time, opinion research was increasingly used in other parts of the world. Several affiliates of the American Institute of Public Opinion were organized in Europe and Australia in the late 1930s, and following World War II polling organizations appeared in numerous countries of Asia and Latin America. By 1970 the World Association for Public Opinion Research had over 300 members in 41 nations, including several eastern European countries. The association does not include any members from the Soviet Union, although numerous public-opinion surveys have been conducted there by Soviet scholars.

Polls have been successful in forecasting election results in nearly every case in which they have been used for this purpose. The two most notable failures were in the United States in 1948, when nearly all polls forecast a Republican victory and the Democrats won by a narrow margin, and in Great Britain in 1970, when all but one of the major polls predicted a Labour Party victory and the Conservative Party achieved a majority. In both cases the major polls did not show large deviations from the actual results but nevertheless picked the wrong winner. Professional opinion researchers point out that predicting elections will always be chancy because of the possibility of last-minute shifts and turnout problems; nevertheless, their record has been good over the years.

Although popular attention has been focussed on polls taken before major elections, most polling is devoted to other subjects, and university-based opinion researchers usually do not make election forecasts at all. Support for opinion studies comes largely from public agencies, foundations, and commercial firms, which are interested in such questions as how well people feel that their health, educational, and other needs are satisfied; how such problems as racial prejudice and drug addiction can be attacked; or how well a given industry is meeting public demands. Polls that are regularly published in newspapers or magazines usually have to do with some lively social issue—and elections are included only as one of many subjects of interest.

Methodology of opinion polling. The principal steps in opinion polling are the following: defining the "universe," choosing a sample, framing a questionnaire, interviewing persons in the sample, tabulating the results, and analyzing or interpreting the results.

Universe is the term used to denote whatever body of people is being studied. This is not always easy to define precisely. If, for example, one is making a study of college-student opinion, it is necessary to decide whether the universe should include full-time students only or whether it should include those who are not candidates for established degrees. The way in which these questions are answered will have an important bearing on the outcome of the survey and possibly on its usefulness.

Once the universe has been carefully defined a sample of the universe has to be picked. If possible, a "probability sample" should be chosen. Ideally, the best way to do this would be to assign a number to each person in the universe––or write his name on a slip of paper—place all the numbered or named slips in a container, mix thoroughly, and then pick a sample without looking at the names or numbers. In this way, each slip will have the same probability of being chosen. If each person is numbered, the same effect can be achieved by using tables of random numbers, which can often be purchased in book form. The random numbers are matched up with the numbered members of the universe, until a sample of the desired size is drawn. The numbering procedure is often not practicable, but a few universes are already assigned numbers —all the workers in a given factory, for instance, or all members of the armed forces. It is not surprising that some of the most reliable opinion surveys have been conducted by the military.

Another method, not quite so reliable statistically, is to include every "nth" member of the universe in the sample. Thus, if one wishes to study the attitudes of the subscribers to a certain magazine and the magazine has 10,000 subscribers, one could take every tenth name from the subscription list and end up with a sample of 1,000

Quota sampling

Neither of these methods is likely to be useful when the universe consists of a large population that has not been numbered and when the names of members of the universe are not listed in a card file somewhere. This is the situation that was faced by market and opinion researchers when they first started conducting large-scale surveys. They therefore adopted the simpler device of picking a "quota sample." In quota sampling, an effort is made to match up the characteristics of the sample with those of the universe, so that a small replica of the universe is achieved. If one knows, possibly on the basis of the most recent census, that there are 51 women to every 49 men in the universe, then the sample should reflect these proportions. The same principle should be applied with respect to age, income, education, occupation, religious preference, national origin, area of residence, and indeed every characteristic that might be relevant to the range of opinions being studied. Each interviewer is told the characteristics of the people that he must locate and interview.

Most survey organizations prior to 1948 used quota samples, and some still do. The British organization that correctly forecast the outcome of the 1970 parliamentary election used a quota sample, but it is, nevertheless, a risky technique. In many countries census data are poor or nonexistent. Even when there are reliable census data, some characteristics that may affect the opinions being studied cannot be taken into account. It is not known, for example, how many vegetarians there are in most populations or how many extroverts and introverts. Yet these characteristics may be related to opinions on certain subjects. Statisticians point out that in a quota sample it is impossible to give each member of the universe a known chance of being selected, and one cannot therefore calculate the range of error in the results that could be due to chance. In this type of sample, furthermore, interviewers have to use their judgment in selecting respondents, and their standards may vary. The great advantage of a quota sample is that it is rather inexpensive to design and interview. By contrast, selecting and interviewing a probability sample from a large population can be very expensive.

How large a sample should be depends on the precision that is desired. For many purposes, a sample of a few hundred is adequate—if it is properly *chosen.* A magazine, for instance, might poll a random sample of 200 of its subscribers and find that 18 percent wanted more fiction and 62 percent wanted more articles on current social issues. Even if each of these figures was wrong by as much as 10 percentage points, the poll would probably still be of value since it would give fairly accurate information about the way the subscribers ranked the types of content. An election poll, on the other hand, would have to be much more accurate than this, since leading candidates often split the vote rather evenly. For most purposes, a national sample of about 1,500 cases is adequate *unless* it is desired to make comparisons among rather small subgroups in the population or to compare one small group with a much larger one. In such cases a larger sample is required in order that a significant number of members of the minority group may be included.

Allowances for chance and errors

There are no hard and fast rules for interpreting poll results, since there are many possible sources for bias or error. Nevertheless, for a well-conducted poll the following "rule of thumb" allowances for error are helpful. When any group of people is compared with another and the sample size of the smaller group is about 100, the difference between the percentages based on the two groups should be greater than 14 if this difference is to be regarded as significant. If the smaller group is larger than 100, the allowance for error caused by chance decreases approximately as follows: for a group comprising 200 cases, allow 10 percentage points; for 400 cases, allow 7 percentage points; for 800, allow 5; for 1,000, allow 4; for 2,000, allow 3. Thus, if a national sample survey shows that 27 percent of college students favour a volunteer army, while 35 percent of adults who are not in college do, and there are only 200 students in the sample, the difference between the two groups may well be due to chance. If the difference were greater than 10 percentage points, then it is much more likely that the opinions of students actually differ from those who are not in college. Similar allowances have to be made when election polls are interpreted. The larger the sample and the larger the difference between the number of preferences expressed for each candidate, the greater the certainty with which the election result can be predicted.

Even larger variations than those due to chance may be caused by the way the questions are worded. If one poll asks "Are you in favour of increasing government aid to higher education?" while another poll asks: "Are you in favour of the president's (or premier's) recommendation that government aid to higher education be increased?" the second question is likely to receive many more affirmative answers than the first. Similarly, the distribution of replies will often vary if an alternative is stated. The question might be phrased: "Are you in favour of increasing government aid to higher education, or do you think enough tax money is being spent on higher education now?" In this form, it is probable that the question would receive fewer affirmative responses than if only the first half were used. As a rule, relatively slight changes in question wording do not cause great variations in response when people hold very strong opinions, but if their opinions are not firm then slight differences may sway them one way or another. Opinion researchers therefore frequently ask exactly the same question over a period of years. In this way, the results from an earlier survey can more safely be compared with the results from a later one.

Questionnaire construction, as with sampling, requires a high degree of skill. The question must be clear to people of varying educational levels and backgrounds. Questions must not embarrass respondents. They must be arranged in a logical order and so on. Even experienced researchers find it necessary to pretest their questionnaires. They send out interviewers to interview a small sample with the preliminary questions, and they may revise these questions to ensure that they are unambiguous and are actually obtaining the information sought.

Poll questions may be of the "forced-choice" or "free-answer" type. In the former, a respondent is asked to reply "yes" or "no" or else may be given a list of prepared alternatives. Even so, many respondents are likely to reply "don't know" or to prefer an alternative that the researcher had not listed in advance. A free-answer question allows the respondent to state his opinion in his own words. For instance, "What do you think are the most important problems facing the country today?"

Importance of careful interviewing

Interviewing is also a skilled operation. An inexperienced interviewer may bias a respondent's answer by the way he asks a question. He may antagonize some respondents so that they refuse to go on with the interview. He may nor record the replies to free-answer questions accurately, or he may not be sufficiently persistent in locating designated respondents. Most large polling organizations give interviewers special training before they are sent out on surveys or else contract with an interviewing service that has trained and experienced interviewers available. A good sample and a well-tested questionnaire are not sufficient to guarantee an accurate survey if interviewing is slipshod.

Tabulation is usually done by machine. To simplify this process, most questionnaires are "precoded," which is to say that numbers appear beside each question and each possible response. The answers given by respondents can thus be translated rapidly into a numerical form that can be used in a computer. In the case of free-answer questions, responses must usually be grouped into categories, each of which is also assigned a number. How the categories are defined may make a large difference in the way the results are presented. If a respondent mentions narcotics addiction as a major problem facing the country, for instance, this answer might be coded as a health problem or a crime problem or might be grouped with other replies dealing with drug abuse or alcoholism.

The final steps in a survey are the analysis and presentation of results. Some reports present only what are termed marginals—the proportion of respondents giving certain answers to each question. If 40 percent favour one candidate, 50 percent another, and 10 percent are undecided, these figures are marginals. Usually, however, a number of cross tabulations are also given. These may show, for instance, that Candidate A's support comes disproportionately from Jewish groups, and Candidate B's, from Irish groups. Sometimes a cross tabulation will substantially change the meaning of survey results. A poll may seem to show that one candidate is the favourite of black voters and another of white voters. But if the preferences of poor respondents and well-to-do respondents are analyzed separately, it may turn out that Candidate A is actually supported by most poor people, and Candidate B, by most well-to-do people. The most important factor in determining voting intention may thus not be whether a respondent is white or black but whether he is well-to-do or poor.

Assessing a survey's reliability

In judging the overall reliability of a survey, it is advisable to scrutinize at least eight factors: (1) the identity of the sponsor and the past record of reliability of the organization conducting the poll; (2) the exact wording of the questions used; (3) the care with which the population sampled has been defined; (4) the size of the sample and the method by which it was chosen; (5) the "completion rate," or proportion of the sample that actually responded (this is especially important in mail polls, in which frequently fewer than half of those in the sample respond); *(6)* the degree to which particular results are based on the whole sample or on small parts of it; (7) the way in which the interviewing was done (whether by telephone, mail, or face-to-face); and (8) the time that the survey was taken (intervening events frequently make people change their opinions).

Criticisms and justifications of opinion surveys. There have been many criticisms of public-opinion polling. Among these are that people are asked to give opinions on matters about which they are not competent to judge, that polling interferes with the democratic process, and that survey research causes annoyance and invasion of privacy.

It is often pointed out that most members of the public are not familiar with the details of complex policies such as those governing tariffs or missile defense systems. Therefore, it is argued, opinion researchers should not ask questions about such subjects. The results at best could be meaningless and at worst misleading, since respondents may be reluctant to admit that they are ignorant. Critics also refer to the fact that many people hold inconsistent opinions, as shown by the polls themselves. The same person may favour larger government expenditures and at the same time be opposed to higher taxes.

Poll takers usually acknowledge that these problems exist but maintain that they can be overcome by careful survey procedures and by proper interpretation of results. It is common for surveys to include "filter" questions, which help to separate those who are familiar with an issue from those who are not. Thus, the interviewer might first inquire: "Have you heard or read about the government's policy on the tariff?" Then the interviewer would ask only those who answered "yes" whether they were or were not in favour of the policy advocated by the government. Sometimes polls include factual questions that help to assess knowledge, such as "Can you tell me how the veto power in the United Nations Security Council works?" Furthermore, argue the researchers, if people are ignorant, or if they hold inconsistent opinions, this should be known. It is not possible to raise the level of information if areas of ignorance or inconsistency are not identified.

Critics allege also that election polls create a "bandwagon effect"—that people want to be on the winning side and therefore switch their votes to the candidates whom the polls show to be ahead. They complain that surveys undermine representative democracy, since issues should be decided by elected representatives on the basis of the best judgment and expert testimony—not on the basis of popularity contests. They point out that some well-qualified can dates may decide not to run for office because the polls indicate that they have little chance of winning and that a candidate who is far behind in the polls has difficulty in raising funds for campaign expenditures since few contributors want to waste money on a lost cause. Other candidates find out from polls what the public wants and merely pander to popular preferences rather than run on their convictions about what is best for the country.

Those engaged in election research usually concede that polls may dissuade some candidates and also may inhibit campaign contributions. But they also point out that candidates and contributors would have to make their decisions on some basis anyway. If there were no polls, other and less accurate methods would be used to test public sentiment; columnists and political pundits would still make forecasts. As far as the bandwagon effect is concerned, careful studies have failed to show that it exists.

An abuse that is recognized by both critics and poll takers is the practice of leaking to the press partial or distorted results from private polls. A politician may contract privately with a research organization and may then release only results for those areas in which he is ahead, or he may release old results without stating the time when the poll was taken, or he may conceal the fact that a very small sample was used and that the results may have a large margin of error.

Finally, critics aver that the proliferation of opinion polls and market research surveys places an unfair burden on the public. People may be asked to respond to questionnaires that take an hour or more of their time. Pollers may tie up their telephones or occupy their doorsteps for long periods, sometimes asking questions about private matters that are not suitable subjects for public inquiry. But insofar as public resistance to polling is concerned, researchers point out that the "refusal" rate in most surveys is rather low. Most people, in fact, seem to enjoy answering the questions. They also note that, with the use of small samples, it is unlikely that any one individual will be approached very often.

Legislation to deal with these and other problems of poll taking has been proposed in the United States, Britain, and a number of other countries; however, little legislation has been adopted. Survey researchers maintain that such abuses as exist should be dealt with by the profession and by educating the public to evaluate and criticize poll results, rather than by government regulation.

BIBLIOGRAPHY. There is no adequate history of public opinion in English. The best account is W. BAUER, *Die Öffentliche Meinung in der Weltgeschichte* (1929); see also H. SPEIER, "Historical Development of Public Opinion," *American Journal of Sociology*, 55:376–388 (1950); and P.A. PALMER, "The Concept of Public Opinion in Political Theory," in *Essays in History and Political Theory in Honor of Charles Howard McIlwain* (1936). General texts include: H.L. CHILDS, *Public Opinion* (1965); B.C. HENNESSEY, *Public Opinion*, 2nd ed. (1970); J.W. ALBIG, *Modern Public Opinion* (1956); N.J. POWELL, *Anatomy of Public Opinion* (1951); and L.W. DOOB, *Public Opinion and Propaganda* (1948). Classic treatments of public opinion include: J. BRYCE, *The American Commonwealth*, vol. 2 (1900); A.L. LOWELL, *Public Opinion and Popular Government*, rev. ed. (1926); A.V. DICEY, *Lectures on the Relation of Law and Public Opinion in England During the Nineteenth Century* (1914); and W. LIPPMANN, *Public Opiniorz* (1922). Historical approaches to the study of public opinion are explored in a special issue of the *Public Opinion Quarterly*, vol. 31, no. 4 (1967–68); a discussion of attitudes and attitude change, *ibid.*, vol. 24, no. 1 (1960). The nature and formation of public opinion in the U.S. are dealt with in G.A. ALMOND, *The American People and Foreign Policy* (1950); excellent use of poll data is made in V.O. KEY, JR., *Public Opinion and American Democracy* (1961). S. KELLEY, JR., *Professional Public Relations and Political Power* (1956), presents fascinating case histories of the manipulation of public opinion. Principal election studies, which reveal a great deal about public opinion, include: P.F. LAZARSFELD, B. BERELSON, and H. GAUDET, *The People's Choice* (1944); B. BERELSON, P.F. LAZARSFELD, and W.H. MCPHEE, *Voting* (1954); and A. CAMPBELL *et al.*, *The American Voter* (1960). Diffusion of information and opinion leadership is discussed in E. KATZ and P.F. LAZARSFELD, *Personal Influence* (1955). Two excellent expositions of sampling method are F.F. STEPHAN and P.J. McCARTHY, *Sampling Opinions* (1958); and M.H. HANSEN, W.N. HURWITZ, and W.G. MADOW, *Sample Survey Methods and Theory*, 2 vol. (1953). Detailed treatments of the conduct of surveys may be found in H.H. HYMAN, *Interviewing in Social Research* (1954), and *Survey Design and Analysis* (1955).

(W.P.D.)

Public Utilities, U.S.

The main services supplied by public utilities are (1) local and interregional transportation—airlines, buses, motor freight carriers, gas and oil pipelines, railroads, and water carriers; (2) telephone and telegraph; (3) power, heat, and light; and (4) community facilities for water, sanitation, and irrigation.

In nearly every country such enterprises are owned and operated by the state and as such are covered in the article PUBLIC ENTERPRISES. This article is confined to the coverage of the virtually unique situation of the U.S., where public utility services are supplied, by and large, by private firms subject to government regulation.

THE ECONOMIC BASIS OF REGULATION

Reasons for the special treatment of utilities

The tendency toward monopoly. The classic economic explanation of the need for extensive regulation of public utilities is that such businesses are "natural monopolies." The term is misleading. As James R. Nelson has argued:

> "natural monopolies" in fact originated in response to a belief that some goal, or goals, or public policy would be advanced by encouraging or permitting a monopoly to be formed. and discouraging or forbidding future competition with this monopoly. (From "The Role of Competition in the Regulated Industries," *The Antitrust Bulletin*, xi, Jan.–April 1966, p. 3.)

It is more accurate, therefore, to say merely that the technology of production, transmission, and distribution almost inevitably leads to a complete or partial monopoly of the market for the services rendered and that competition in the public utility sector is often less effective and desirable than competition in industry in general.

The tendency toward monopoly arises from the following factors. Some public utility enterprises are subject to "economies of scale"; that is, assuming a given state of technology, one firm of the most efficient size can produce all or more than the market demands at a lower average cost than can two or more competing firms. Or. stated another way, the larger the output of a utility plant, such as a generating station, the lower will be the cost of production per unit of output. Economies of scale, however, are not unique to public utility enterprises; they are found in virtually every business. What is of significance is the fact that a utility's market (in industries other than transportation) is restricted by the necessarily close connection between the utility plant and the consumers' premises. Further, because storage of a utility's service is limited at best and because a utility must have adequate capacity to meet its customers' peak demand requirements, it tends to have unused or surplus capacity most of the time. Competition serves to aggravate this situation; whereas if a utility is free to cultivate its market area intensively. it can attract commercial, industrial, and residential customers with diversified demands and thereby minimize its unused capacity.

Other reasons. These factors making for monopoly are reinforced by four others. First, utilities require a large investment in fixed, and highly specialized, plants. Electric utilities, for example, must invest about **$4.50** to get **$1** of annual gross sales, while manufacturing companies as a group must invest only about **47** cents to get **$1** of sales. This investment, largely bound to its original location, represents a significant percentage of a utility's total cost. Second, utility equipment must be located below, upon, and over public property. (Utilities, in fact, are provided with the governmental power of eminent domain, which makes possible the compulsory sale of private property.) Space limitations do not in themselves lead to monopoly; but as the number of conduits or mains increases, the streets are torn up more frequently, thus creating a public nuisance. Moreover, the number of desirable sites also may be limited, such as those for hydroelectric power plants. Third, for many uses, demand for the product tends to be "inelastic"; that is, as the price of a utility's service increases, consumers increase their expenditures rather than decrease their demand; utilities, therefore, to the extent that they are supplying basic necessities, have some (but far from absolute) control over the rates they charge consumers. Finally, price differentiation or discrimination among customers is both possible and generally attractive to utility enterprises. Fixed costs represent a large percentage of total costs; unused capacity exists much of the time; and there are important differences in the demands of various consumers. A utility company often finds that a single rate low enough to maintain full capacity output fails to yield revenues sufficient to cover costs, while one set high enough to cover costs will result in unused capacity. Under these circumstances, discrimination may increase revenues and minimize unused capacity.

While these are the major economic characteristics of public utilities, they are not confined to public utilities nor do they suffice to explain why such enterprises are subject to detailed regulation. For electric power generation transmission, and distribution, and for the transportation and distribution of natural gas, regulation is based on the existence of significant economies of scale in a given local or regional market. For telephone and telegraph services, regulation also is based on significant economies of scale as well as on the expense and inconvenience to consumers of having parallel competing systems. Few question the need of regulating these industries. Many, however, question the current need for detailed regulation of natural-gas producers and of the surface transportation industry. In these industries, economies of scale are not such an important consideration. Regulation of natural-gas producers is based on the proposition that the concentration of ownership is high enough to raise the possibility of monopolistic pricing practices. Regulation of the railroads was initially based on their oligopolistic market structure (*i.e.*, few competitors) over long-haul routes and their monopolistic market structure over local and short-haul routes. In both cases, discriminatory pricing was a profitable practice. The development of other, competing modes of transport reduced the economic justification for detailed regulation of the railroads, but instead of being abolished, regulation was extended to the competing modes. The regulation of bus, highway freight, and water transport was largely predicated on the need to prevent cutthroat or destructive competition within each of these modes and to prevent undue price discrimination throughout the transportation industry. Airline regulation was primarily based on safety considerations and on the promotion of the industry.

The real distinction between utilities and other businesses is thus one of degree; utilities possess certain economic characteristics to a greater degree than do non-utility industries. Economies of scale, for example, partly explain the need for large plants in many industries. High fixed costs are found in the concrete and steel industries, among others. Further, even though the services of public utilities are considered essential or necessary, society does not regard them as so necessary that they should be provided irrespective of the purchaser's ability to pay for them. And some important manufacturing industries have escaped regulation similar to that imposed upon public utilities not because they are more competitive than the utilities but because of the difficulties of regulating the manufacture of commodities. The desire to enforce competition in such industries led to the enactment of the Sherman Antitrust Act in **1890** and the establishment of the Federal Trade Commission in **1914.** The tendency for many businesses to practice price discrimination caused passage of a law limiting such discrimination as early as **1914** (Clayton Act) and the strengthening of this law in **1936** (Robinson-Patman Act).

THE LEGAL BASIS OF REGULATION

Major judicial decisions

Federal regulation of business proceeds under Article I, section 8, of the Constitution, which gives Congress power "to regulate Commerce ... among the several states." The interstate commerce clause has been broadly interpreted, particularly since the late 1930s, and it seems unlikely to impose significant limits on federal regulatory powers in the future. The Supreme Court held in a **1946** decision that federal power to regulate interstate commerce "is as broad as the economic needs of the nation." (From *American* Power & Light Co. v. Securities & Exchange Commission, **329** U.S. **90.)**

The public interest concept. The Constitution provides that those powers not delegated to the federal government and not specifically prohibited by it to the states may be exercised by the states. States thus have the broad authority to legislate for protection of the health, safety, morals, and general welfare of their citizens. These are known collectively as the "police powers" of the states and also have been interpreted broadly. In the words of the Supreme Court in Nebbia v. New ***York*, 291** U.S. **502 (1934)**:

> . . . a state is free to adopt whatever economic policy may reasonably be deemed to promote the public welfare, and to enforce that policy by legislation adapted to its purpose. . . . Price control, like any other form of regulation, is unconstitutional only if arbitrary, discriminatory, or demonstrably irrelevant to the policy the legislature is free to adopt.

The rights of corporations are protected against invasion by the acts of government in both federal and state constitutions. Corporations, in short, are guaranteed due process of law. Moreover, under the U.S. constitutional system, all acts of legislatures and administrators are subject to judicial review. The final authority is the Supreme Court of the United States.

The public-utility concept. In the well-known case of *Munn* v. *Illinois*, **94** U.S. **113** (1877), the Supreme Court attempted to establish a separate category of businesses, known as public utilities, that required detailed government regulation. In the *Munn* case, Chief Justice Morrison Waite, in upholding the validity of an **1871** Illinois statute fixing maximum rates for storing grain in elevators, noted both the importance of the grain trade and the strategic position of the grain elevators. ("They stand ... in the very 'gateway of commerce,' and take toll from all who pass.") Quoting from Lord Chief Justice Sir Matthew Hale's words of nearly two centuries earlier, he held that "when private property is 'affected with a public interest, it ceases to be *juris privati* only.' " Property becomes affected with a public interest

> when used in a manner to make it of public consequence, and affect the community at large. When, therefore, one devotes his property to a use in which the public has an interest, he, in effect, grants to the public an interest in that use, and must submit to be controlled by the public for the common good, to the extent of the interest he has thus created. He may withdraw his grant by discontinuing the use; but, so long as he maintains the use, he must submit to control.

In 1914 the Supreme Court upheld regulation of the fire insurance business (***German Alliance Insurance Co.*** v. ***Kansas,*** 233 U.S. 389). Said Justice Joseph McKenna: insurance

> is practically a necessity to business activity and enterprise. It is, therefore, essentially different from ordinary commercial transactions, and ... is of the greatest public concern.

In unanimously holding unconstitutional a state of Kansas statute providing for extensive control of commodity prices and wage rates in ***Wolff Packing Co.*** v. ***Court of Industrial Relations of Kansas,*** 262 U.S. 522 (1923), the court concluded:

> The circumstances which clothe a particular kind of business with a public interest, in the sense of Munn v. ***Illinois*** and the other cases, must be such as to create a peculiarly close relation between the public and those engaged in it, and raise implications of an affirmative obligation on their part to be reasonable in dealing with the public.

A majority of the Supreme Court, in 1928, opposed the extension of the public-utility concept to employment agencies, holding that the interest of the public in the matter of employment is not "that ***'public interest'*** which the law contemplates as the basis for legislative price control" (***Ribnik*** v. *McBride,* 277 U.S. 350). And a year later the Court held unconstitutional a Tennessee statute that sought to fix the prices at which gasoline could be sold within the state (***Williams*** v. ***Standard Oil Co.,*** 278 ***U.S.*** 235). The business of dealing in gasoline, said the Court, "does not come within the phrase 'affected with a public interest.' " The Supreme Court's last attempt to clarify the public-utility concept came in the 1934 ***Nebbia*** case cited above. The New York legislature, in 1933, enacted a statute that declared that the milk industry was affected with a public interest. The statute set up a Milk Control Board to control the prices and trade practices of milk producers and distributors. In upholding the statute, Justice Owen Roberts stated that (1) "the dairy industry is not, in the accepted sense of the phrase, a public utility"; (2) "there is in this case no suggestion of any monopoly or monopolistic practice"; and (3) "those engaged in the business are in no way dependent upon public grants or franchises for the privilege of conducting their activities." He added:

> It is clear that there is no closed class or category of businesses affected with a public interest. . . . The phrase "affected with a public interest" can, in the nature of things, mean no more than that an industry, for adequate reason, is subject to control for the public good. . . . If the law-making body within its sphere of government concludes that the conditions or practices in an industry make unrestricted competition an inadequate safeguard of the consumer's interests, produce waste harmful to the public, threaten ultimately to cut off the supply of a commodity needed by the public, or portend the destruction of the industry itself, appropriate statutes passed in an honest effort to correct the threatened consequences may not be set aside because the regulation adopted fixes prices reasonably deemed by the legislature to be fair to those engaged in the industry and to the consuming public.

It seems clear, then, that the public-interest concept is no longer synonymous with the public-utility concept and that the latter concept is included within the former. Nevertheless, the essential elements of the public-utility concept were succinctly outlined by Judge Frederick Vinson in a 1943 decision (***Davies Warehouse Co.*** v. ***Brown,*** 137 F. 2d 201):

> If a business is (1) affected with a public interest, ***and*** (2) bears an intimate connection with the processes of transportation and distribution, ***nnd*** (3) is under an obligation to afford its facilities to the public generally, upon demand, at fair and non-discriminatory rates, ***and*** (4) enjoys, in a large measure an independence and freedom from business competition brought about either (a) by its acquirement of a monopolistic status, or (b) by the grant of a franchise or certificate from the State placing it in this position, it is ... a public utility. ...

The obligations of public utilities

Public utilities have four major obligations imposed on them because of their special status. First, they are obligated to serve all who apply for service. Within a market (service) area, and within the limit of its capacity (ability to serve), a utility must be prepared to serve any customer who is willing and able to pay for the service. Second, they are obligated to render safe and adequate service and must be prepared for foreseeable increases in demand. Third, they have the obligation to serve all customers on equal terms. Unjust or undue discrimination among customers is forbidden. Finally, they are obligated to charge only a "just and reasonable" price for the services rendered.

THE DEVELOPMENT OF REGULATORY COMMISSIONS

Early regulation. Modem regulation is carried out largely by administrative commissions or agencies, but such has not always been the case. The earliest form of regulation was judicial: enforcement of the common law duties through lawsuits brought by individuals who thought themselves injured. Legislative regulation gradually supplanted judicial regulation during the second half of the 19th century, and by 1898 the function of the judiciary had been restricted to the review of legislative and administrative acts.

Legislative regulation by means of corporate charters or special franchise was the next to be tried. Above all else, such regulation proved to be inflexible. Each change in a charter required a special legislative amendment. But since legislatures were in session only a small percentage of the time, and since they found their attention being claimed by many other matters, the required adjustments often were delayed. Likewise, each change in a franchise provision had to be approved by both parties since the Supreme Court, in an 1819 decision (***Trustees of Dartmouth College*** v. ***Woodward, 4*** **Wheaton 518),** held that a franchise had the same status as a contract. Further, it was impossible for the legislature to pay much attention to financial and accounting control or to service and safety aspects of regulation.

Railroad commissions. As the early methods of regulation proved defective and, as the demand for more stringent and continuous control arose, "independent" regulatory commissions, operating under general legislative statutes, were created. The first commissions, generally those created before 1870, were largely advisory bodies, and their chief concern was with the railroads. They made recommendations to state legislatures and railroad managements; appraised property taken by the railroads under the right of eminent domain; enforced railroad safety standards; and, basically, served as fact-finding bodies. They had no control over rates.

Shortly after the beginning of the Granger movement in the Midwest—a populist movement that sought state legislation to control local railroad and grain elevator rates—the first commissions with mandatory powers were established. Between 1871 and 1874, Illinois, Iowa, Minnesota, and Wisconsin established commissions with power to set maximum rates, prevent discrimination, and forbid mergers of competing railroad lines. While the Granger laws, except in Illinois, were repealed by the end of the 1870s, they established a pattern followed by other states. By 1887, when Congress created the Interstate Commerce Commission (partly patterned after the British Railway Commission of 1873) to regulate the nation's railroads, 25 states had regulatory commissions.

State and federal regulation

Public utility commissions. The third, or modern, period began in 1907 with the creation of two powerful commissions: in New York under the leadership of Gov. Charles Evans Hughes, and in Wisconsin under the urging of Sen. Robert M. LaFollette. In both states the legislatures extended the regulatory powers of the commissions to utilities other than railroads: gas, light, power, telephone, and telegraph companies. Both commissions, moreover, were delegated broad powers, including security regulation, examination of accounts and property, the fixing of rates, the requirement of detailed reports in prescribed form, and the right to prescribe uniform systems of accounts. These two commissions became models, and by 1920 more than two-thirds of the states had regulatory commissions. The state commissions were strengthened, their jurisdictions extended, and their powers further increased after the stock market crash of 1929; and several federal commissions were established to regulate interstate commerce. Today, all 50 states, plus the District of Columbia, have commissions known as public-utility or public-service commissions, railroad commissions, corporation commissions, or commerce commissions.

There are five federal commissions with jurisdiction over the interstate activities of public utilities: (1) the Interstate Commerce Commission, with jurisdiction subsequently mtended to cover oil pipelines (1906), motor carriers (1935), interstate and coastal water carriers (1940), and freight forwarders (1942); (2) the Civil Aeronautics Board, created in 1940 (as a reorganization of the Civil Aeronautics Authority of 1938), with jurisdiction over commercial air transportation; (3) the Federal Power Commission, organized as an independent agency in 1930, with regulatory powers over hydroelectric projects and the transportation and sale at wholesale of electric power (since 1935) and natural gas (since 1938); (4) the Federal Communications Commission, established in 1934 (succeeding the Federal Radio Commission of 1927), with jurisdiction over broadcasting and—by a transfer of powers from the Interstate Commerce Commission—interstate telephone and telegraph services; and (5) the Securities and Exchange Commission, organized in 1934 and given power under the Public Utility Holding Company Act of 1935 to regulate the finances and corporate structures of electric and gas utility holding companies.

At the state level, a majority of the commissions are composed of three or five members appointed by the executive or elected either by popular vote or by the legislature with overlapping four-year to six-year terms. At the federal level, the commissions are composed of 5, 7, or 11 members appointed by the President, with Senate approval, for terms ranging from five to seven years. Federal commissions are bipartisan by law.

PRINCIPLES OF REGULATION

Setting a return on capital

It is the basic objective of regulation to prevent a public utility from earning excessive (monopoly) profits and from engaging in unreasonable (inequitable) price discrimination among customers, commodities, and places. Thus rate regulation—*i.e.*, control of the rate level (earnings) and control of the rate structure (rates or prices)—has been the major task of the commissions. But if rate regulation is to be effective, control also must be exercised over accounting procedures, financial matters, service, and safety.

The primary standard of rate regulation is the revenue-requirement or capital-attraction standard. Stated simply, a utility is permitted to set rates that (1) will cover operating costs and (2) will result in a reasonable rate of return (profit) on the property devoted to the business.

The rate level. The first aspect of rate regulation, the rate level, involves the determination of the utility's total revenue requirement and can be expressed as a formula:

$$R = O + (V - D)r$$

where R is the total revenue required, O is the operating costs, V is the gross value of the tangible and intangible property, D is the accrued depreciation of the tangible and reproducible property, and r is the rate of return.

Operating costs include all types of operating expenses (wages, salaries, fuel, maintenance, and research) plus annual charges for depreciation and operating taxes. For a typical electric or telephone company, operating expenses average about 44 percent of revenues, depreciation 12 percent, and taxes 22 percent—a total of 78 percent of revenues. Many of these costs are determined by normal competitive forces (wages, fuel. and maintenance) or bv various levels of government (taxes); others are determined by the individual firms (expenditures on advertising, research and development, and charitable contributions). While a utility legally may spend any amount it chooses for such purposes, all expenditures are subject to review by the relevant commissions as to their reasonableness.

The net or depreciated value of the tangible and intangible property is known as the rate base. The value of the utility's "used and useful" tangible property may be measured in either of two ways: original cost (cost of plant and equipment when built or purchased) or reproduction cost (value of plant and equipment expressed in current dollars). The proper measure has been a continuous source of controversy ever since the early days of regulation, with the utilities generally favouring reproduction cost (especially in times of rising prices) and a majority of the commissions favouring original cost. Regardless of the measure used, an appropriate amount of depreciation must be subtracted in order to reflect the depreciated value of the property. Land, usually separated from other tangible property, is commonly valued either at its original cost or at the value of adjacent property. No depreciation is subtracted since land tends to appreciate in value over time. The rate base also includes an allowance for working capital and, in some circumstances, amounts for interest during construction, water rights, and leaseholds. In former years the utilities argued that several intangibles—particularly franchise value, going concern value, and good will—should be considered, but current commission practices exclude these items.

The fair rate of return is usually expressed as a percentage of the rate base. For example, a rate base of $200,000,000 combined with an 8 percent return results in an annual allowance of $16,000,000 as the fair-return component. (To this figure must be added operating costs to determine the utility's total revenue requirement.) With respect to the fair rate of return, there is no formula that can be used; like other aspects of regulation, a fair rate of return is a matter of judgment. The return allowed, however, should perform two functions. It should be fair to investors so as to avoid the confiscation of their property. It should also preserve the credit standing of the utility to permit it to attract new capital so as to maintain, improve, and expand its services in response to consumer demand. Utilities must compete for investment funds in the capital market with non-utility businesses. Moreover, they are not guaranteed a fair rate of return; they are entitled to a fair return only if it can be earned.

The rate structure. The second aspect of rate regulation, the rate structure, involves the establishment of the rates (prices) the utility is to be permitted to charge its customers so as to earn the required revenue. Utility rate structures are highly differentiated. Customers are classified into various groups (*e.g.*, residential, commercial, industrial), and the rate charged each group is different. And within each group, rates are typically reduced as the quantity purchased increases, with the result that customers may not even pay the same average rate per unit. Such rates are based upon both supply (cost of service) and demand (value of service) considerations. When based upon the latter, discrimination results. As noted earlier, such discrimination is permitted as long as it is "just and reasonable," since often it is beneficial to the utility and to the customer. In recent years, with the growing strength of competitive forces, a new dimension has been added to the rate structure problem. This new dimension involves the complex issue of defining properly the costs relevant to competitive rates.

Accounting and financing. At the turn of the century and continuing into the 1930s, irregular accounting procedures such as the overstatement of property values and financial abuses such as overcapitalization occurred throughout American industry, including the utilities. As the accounting profession and business matured, abuses decreased markedly, and they now are primarily problems of the past. Today a majority of the commissions prescribe uniform systems of accounts and have power to regulate or control the issuance of securities. Most commissions also require competitive bidding on new security issues.

Service and safety. The control of service and safety has two aspects: quality and quantity. Quality refers to such matters as methods of billing, accuracy of meters, continuity of service, deposits and repayments, and treatment of complaints. Quantity refers to such matters as entry restrictions, service abandonment, consolidations, mergers, and acquisitions. Entry, for instance, including both the certification of a new company and the certification of an existing firm to serve a new area or a new route, is rigidly controlled by the commissions. Certificates of public convenience and necessity are required to provide most utility services. Each applicant must show that the proposed service is required by the public and that it is "fit, willing, and able" to perform properly the proposed service and to conform to all relevant regulations. Safety regulation is of particular importance with respect to the transportation industries and includes such matters as driver or pilot qualifications, air-traffic control, inspection and maintenance, and accident reporting and investigation. All jurisdiction over transport safety has been transferred, at the federal level, from the regulatory commissions to the Department of Transportation.

PROBLEMS OF SPECIFIC INDUSTRIES

Rate, service, and safety regulation are common to all public utilities. In other respects the problems of each industry differ.

utilities and the public interest

Transportation. Government policy toward the transportation industry has sought two basic, and often conflicting, objectives—promotion of its use (by extending public aid in many forms) and regulation (by controlling entry, mergers, rates, and service). But since present policy has evolved in a piecemeal fashion over three-quarters of a century, little attention has been given to the development of a coordinated policy. Several postwar studies have concluded that government policy has promoted waste and inefficiency throughout the transportation industry. Serious inconsistencies in policy have developed. Control of entry has worked to protect existing carriers; control of minimum rates has often allocated traffic among competing carriers without consideration of the carriers' relative cost advantages. The position of common carriers, plagued by overcapacity or financial problems, has grown increasingly difficult.

There is growing support for a radical change in government policy and for greater reliance upon the forces of competition. It is generally recognized that investment (both public and private) in transport facilities must be increased significantly for such purposes as improved airports and aviation safety and for long-run solutions to the pressing urban transport problem, including the acute commutation problem in the larger cities.

Electric power. The combined functions of generating, transmitting, and distributing electric energy comprise the nation's largest industry. Private (investor-owned) electric utilities dominate the industry, but public power (municipal and federal) and cooperatives (under the Rural Electrification Act of 1936) are of considerable significance. Indeed, the private versus public issue has been an important one for many years. Technological advances in generation (including nuclear power) and transmission have made feasible a rapid growth in interconnections and power pools but also have raised the issue of reliability (*i.e.*, how best to achieve coordination by all segments of the industry to prevent failures, such as the dramatic Northeast power failure of 1965, when a series of local failures led to a total blackout extending from New York City to Canada). A new wave of consolidations within the industry has resulted in fewer and larger systems, causing much concern as to the future of smaller (both private and public) electric systems. Competition between electric power and the fossil fuels has become stronger as electricity has invaded the winter heating market and natural gas the summer air-conditioning market. Greater emphasis has been placed upon promotional practices and competitive rate making. And in locating and building the new facilities required for the future, the electric utilities have come under increased pressure to consider the conservation of natural resources, the maintenance of scenic or natural beauty, and the preservation of historic sites.

Natural gas. Natural gas was an unimportant source of domestic energy prior to the 1920s. As large oil and gas fields were discovered and as improvements in pipeline construction were made, the industry's importance grew. Gas now supplies nearly one-third of the nation's total energy. It is generally accepted that pipeline and local distribution companies should be regulated; they have the traditional economic characteristics of regulated industries. The regulation of independent producers, however, has caused constant controversy ever since the Supreme Court, in 1954, held that the Federal Power Commission's jurisdiction extended to such producers (Phillips Petroleum Co. v. Wisconsin, 347 U.S. 672). A movement for exemption by Congress failed, and the FPC subsequently adopted an area-rate approach on the basis of Re Phillips Petroleum *Co.*, 35 P.U.R. 3d 199 (1960):

> the determination of fair prices for gas based on reasonable financial requirements of the industry and not on the particular rate base and expense of each natural gas company.

But many issues remain to be resolved before the new approach can be called a success. Among those issues are how high a reserves-production ratio is needed and what price is required to achieve it. Finally, since natural gas is limited in quantity, conservation inevitably enters into the commission's certification decisions.

Communications. The communications (telephone and telegraph) industry is dominated by the American Telephone and Telegraph Company and the Western Union Corporation. Competitive forces, however, have raised new problems and challenges in regulating this expanding industry. Technological advance has tended to blur the traditional distinction between voice and record communication and also has made feasible the entry of the common carriers into data processing and specialized information services. The convergence of communications and computer technologies also has induced the entry of equipment manufacturers and other firms into the supplying of communications systems and services. Recent decisions by the Federal Communications Commission appear to favour more competition for the domestic common carriers. As a result, competitive rate making has assumed greater importance. Other issues include the desirability of a domestic satellite system (and its ownership) and the proper allocation of the scarce radio spectrum. And on the international front, communications satellites and submarine cables offer alternative and competing means of providing telecommunications services.

CONTINUING QUESTIONS

Government regulation of private enterprise raises many complex problems. Some of these involve the regulatory process itself. In the early days of regulation the independent commission was thought to. have a number of advantages over legislative or judicial regulation, including continuity of policy, expertise, impartiality, and flexibility of procedure. In practice, commissions have not been able to escape their political environment. They are subject to pressures from the executive and legislative branches and also from the industries under their jurisdiction. They depend on the executive for their appointments and budget requests, on the legislature for their jurisdiction and appropriations, and on the judiciary for review of their actions. It has been argued that commissions tend to get transformed from vigorous protectors of the public interest into captives of the interests they are set up to regulate, with the regulatory process becoming simply a means of maintaining the status quo. Independence, in short, has not been achieved.

The future of the regulatory commission

Even if independence were possible, there is some question as to its desirability. Some have contended that cornmissions should not be isolated from the political support and leadership that is essential for the success of regulation and for the achievement of national economic goals.

Some of the problems are external to the commissions.

Appointments frequently have been made on the basis of political considerations rather than training or experience. The statutes that commissions seek to enforce often lack definitive standards and may even be out of date. Salaries, especially at the state level, are too low to attract and hold fully qualified personnel; budgets are insufficient to permit adequate staffs.

Some of the problems, finally, are perhaps inherent in regulation itself. As Clair Wilcox has argued in *Public Policies Toward Business:*

> Regulation is static, backward-looking, preoccupied with the problems of the past. It does nothing to stimulate change, seeking to maintain order on the basis of the old technology. It is slow to adapt to change; new problems appear, but regulatory thinking lags. Competition, by contrast, is dynamic. . . .
>
> Regulation is slower than competition. It must satisfy the requirements of due process: investigate, give notice, hold hearings, study the record, make findings, issue orders, permit appeals. All this takes time and delays action. . . .

While not everyone agrees with all of these criticisms, few would deny that there is room for improvement. Toward this goal, several steps already have been taken. The establishment of the Department of Transportation (1966) represents a partial attempt to coordinate domestic transportation policy; the Federal Power Commission's *National Power Survey* (1964) represents a similar attempt in the electric power field. Many commissions have tried to streamline their procedures and reduce regulatory delay: prehearing conferences are used to determine the areas of agreement and of dispute; previously prepared and distributed (so-called canned) testimony often is permitted, reducing the burden of trial examination; informal proceedings are increasingly being used in place of formal procedures. And, in an effort to provide for further improvements in administration, the Administrative Conference of the United States (a permanent, independent government agency) was established by Congress in 1964.

CONCLUSION

The problems of regulation are numerous, but this does not mean that regulation of public utilities has been a failure. The economic performance of many utilities has been impressive. With the exception of transportation, the growth of utilities in the postwar period has far exceeded that of the unregulated industries—nearly double the growth rate of the economy as a whole. Their output per man-hour in the last decade has increased faster than for any other industrial sector. Their rates have risen far less than prices generally (in many cases, their rates have actually declined), while their returns on capital have been considerably below those earned by other industries. They have accounted for a significant percentage of the nation's capital investment. And, finally, they have provided a wide variety and high quality of service. Only in the transportation industry does the economic performance reflect badly upon the regulatory process itself.

The great challenge to regulation is whether it can answer the requirements of the future. Many of the issues that commanded attention in the past have been largely settled. Others have taken their place—problems of pollution and aesthetics, competitive pricing, and promotional practices, to mention only a few. The goals and policies of regulation must be made more explicit; the flexibility of the regulatory process must be increased by eliminating complex, costly, and often confusing procedures; and criteria must be developed for evaluating the performance of the regulatory process itself. In short, public-utility regulation must find tools and concepts appropriate to industries that are technologically dynamic and increasingly subject to competitive forces, and that provide incentives for future technological progress.

Publishing, History of

Publishing is the activity that involves selection, preparation, and marketing of printed matter. It has grown from small and ancient beginnings into a vast and complex industry responsible for the dissemination of all manner of cultural material, from the most lofty to the most trivial; its impact upon civilization is impossible to calculate.

The history of publishing is characterized by a close interplay of technical innovation and social change, each promoting the other. Publishing as it is known today depends on a series of three major inventions—writing, paper, and printing—and one crucial social development—the spread of literacy. Before the invention of writing, perhaps by the Sumerians in the 4th millennium BC, information could be spread only by word of mouth, with all the accompanying limitations of place and time. Writing was originally regarded not as a means of disseminating information but as a way to fix religious formulations or to secure codes of law, genealogies, and other socially important matters, which had previously been stored in a succession of human memories. Publishing could begin only after the monopoly of letters, often held by a priestly caste, had been broken, probably in connection with the development of the value of writing in commerce. Scripts of various kinds came to be used over most of the ancient world for proclamations, correspondence, transactions, and records; but book production was confined largely to religious centres of learning, as it would be again later in medieval Europe. Only in Hellenistic Greece, in Rome, and in China, where there were essentially nontheocratic societies, does there seem to have been any publishing in the modern sense—*i.e.*, a copying industry supplying a lay readership.

The invention and original function of writing

The invention of printing transformed the possibilities of the written word but not without opposition from socially conservative forces. Printing seems to have been first invented in China in the 6th century AD in the form of block printing. The Chinese progressed to printing with movable type but abandoned it because it was unsuitable for their language and script. Other Chinese inventions, including paper (AD 105), were passed on to Europe by the Arabs but not, it seems, printing. The reason may well lie in Arab insistence on hand copying of the Qur'ān (Arabic printing of the Qur'ān does not appear to have been officially sanctioned until 1825). The invention of printing in Europe is usually attributed to Johannes Gutenberg in Germany about 1440–50, after a period of block printing from about 1400. Gutenberg's achievement was not a single invention but a whole new craft involving movable metal type, ink, paper, and press. In less than 50 years it had been carried over most of Europe, largely by German printers.

Gutenberg's achievement

Printing in Europe is inseparable from the Renaissance and Reformation. It grew from the climate and needs of the first, and it fought in the battles of the second. It has been at the heart of the whole expanding movement of the past 500 years. Although printing was thought of at first merely as a means of avoiding copying errors, its possibilities for mass-producing written matter soon became evident. In 1498, for instance, 18,000 letters of indulgence were printed at Barcelona. The market for books was still small, but literacy had spread beyond the clergy and had reached the emerging middle classes. The church, the state, the universities, the reformers and radicals were all quick to use the press. Not surprisingly, every kind of attempt was made to control and regulate such a "dangerous" new mode of communication. Freedom of the press was pursued and attacked for the next three centuries; but by the end of the 18th century a large measure of freedom had been won in most countries, and a wide range of printed matter was in circulation. The mechanization of printing in the 19th century and its further great development in the 20th, which went hand in hand with an ever-increasing spread of literacy and ever-rising standards of education, finally brought the printed word to its present powerful position as a means of influencing minds and, hence, societies. But even in the early 1970s, one-half of the world's people could not read or write.

The functions peculiar to the publisher—*i.e.*, the selecting, editing, and designing of the material, arranging its production and distribution, and bearing the financial risk or the responsibility for the whole operation—often merged in the past with those of the author, the printer, or the bookseller. With increasing specialization, however, publishing became, certainly by the 19th century, an increasingly distinct occupation on its own. Most modern publishers purchase printing services in the open market, solicit manuscripts from authors, and distribute their wares to shops for final sale. In some cases, the publisher may sell direct to the final user either by mail or with the help of a sales force. Encyclopaedias, for example, are often distributed in this way.

The great variety of published matter that has grown up over the centuries falls into two main categories, periodical and nonperiodical; *i.e.*, publications that appear at more or less regular intervals and are members of a series and those that [illegible] on single occasions (except for r[illegible]es of essentially the same material).

Of th[illegible] nonperiodical publications, [illegible]k[illegible]te by far the largest class; they are also, in one form or another, by far the oldest of all types of publication and go back to the earliest civilizations. In their main function, of giving permanence to man's thoughts and records of his achievements, they answer a deep human need. Not every published book is of lasting value; but a nation's books, taken as a whole and winnowed out by the passing years, can be said to be its main cultural storehouse. Conquerors or usurpers wishing to destroy a people's heritage have often burned its books, as did Ch'in Shih Huang Ti in China in 213 BC, the Spaniards in Mexico in 1520, and, a more futile gesture, the Nazis in modern times.

There is no wholly satisfactory definition of a book, as the word covers such a variety of publications (some books, such as *The* World Almanac, appear periodically). For statistical purposes, however, the United Nations Educational, Social and Cultural Organization defines it as "a non-periodical printed publication of at least 49 pages excluding covers."

Periodical publications divide further into two main classes, newspapers and magazines. Though the boundary between them is not sharp—there are magazines devoted to news, and many newspapers have magazine features—their differences of format, tempo, and function are sufficiently marked: the newspaper (daily or weekly) usually has large, loose pages, a high degree of immediacy, and highly miscellaneous contents; while the magazine (weekly, monthly, or quarterly) has smaller pages, is usually fastened together and sometimes bound, and is less urgent in tone and more specialized in content. Both sprang up only after the invention of printing, but both have shown a phenomenal rate of growth to meet the demand for quick information and regular entertainment. Newspapers have long been by far the most widely read published matter; the democratizing process of the past 200 years would be unthinkable without them. Magazines, close behind them, historically and in terms of readership, rapidly branched out from their learned origins into "periodicals of amusement." Today there is probably not a single interest, frivolous or serious, of man, woman, or child, that is not catered to by a magazine.

There are, of course, many other types of publications besides books, newspapers, and magazines that may be mentioned, though for various reasons they fall outside the scope of this article and reference to them must be sought under other headings. In many cases the same principles of publishing apply, and it is only the nature of the product and the technicalities of its manufacture that are different. There is, for instance, the important business of map publishing (see MAPS AND MAPPING; HYDROGRAPHIC CHARTING). Another important field is music publishing, of a great variety of material, from complete symphonic scores to sheet music of the latest popular hit. A further range of activities might be grouped under the term "utility publishing"; *i.e.*, the issuing of calendars, diaries, timetables, ready reckoners, guide books, and all manner of informational or directional material, not to mention postcards and greeting cards. A great deal of occasional publishing, of pamphlets and booklets, is done by organizations to further particular aims or to spread particular views; *e.g.*, by churches, religious groups, societies, and political parties. This kind of publishing is sometimes subsidized and not on a purely commercial basis.

This article is divided into the following sections:

I. Book publishing

THE ANCIENT WORLD

The first books. For 4,000 to 5,000 years books have been produced in many different forms. The oldest, the papyrus roll, goes back to about 3000 BC in Egypt, being made from the papyrus plant, which grew freely by the Nile. The roll itself derives from inscribed banners of papyrus that were hung in Egyptian temples; rolled up they became portable inscriptions. The Greeks and Romans also used it, and because the Greeks got their papyrus from the port of Byblos, they called it by that name, from which comes the word bible. To the Romans, a papyrus roll was a *charta* or *volumen.* In Babylonia and Assyria, which had no papyrus, writing was done on clay tablets (from about 3000 BC) in cuneiform script (wedge writing). A "book" then consisted of a number of cuneiform tablets in a labelled container. In China, tablets of bamboo were used up to about 200 BC and then scrolls made from silk waste and, finally, paper (after AD 105). In north India, birch bark was a popular material for manuscripts and in the south, palm leaves, held together by threads. Another material for scrolls in the Middle East was leather; from this, parchment or vellum is said to have been invented by Eumenes II of Pergamum (197–159 BC) when his rival book collector in Egypt cut off supplies of papyrus. In actuality, parchment is known from elsewhere at the same date.

Books began to approach their modern form with the

The codex

codex, for which sheets of papyrus were folded vertically to make leaves. The codex form was first used for Christian literature in the 1st or 2nd century AD, and it may have been devised in order to make up a book large enough to hold more than one gospel or epistle. By the 4th century its use had spread to pagan works, while at about the same time vellum took over from papyrus; for several centuries the vellum codex was then the standard form. The idea of the codex seems to have been suggested by the Roman notebook of waxed wooden tablets fastened with string (pugillares), and these may also have been the origin of the word book, which derives from the Germanic bdc, meaning "beech." Hinged, waxed tablets were also used by the Assyrians in the 8th century BC, however.

The contents of the earliest books, whatever their origin, are almost always religious or semireligious—hymns, prayers, and rites that put man in touch with the divine, and myths, legends, and epics that give an account of his origins. Books with such contents are usually followed by semi-sacred codes of law, collections of proverbs and precepts, and priestly profesaional texts on divination, medicine and magic, history, astronomy and astrology, and other instructional matter. Finally, a purely secular literature is set down, stories, poems, and love songs. All of these categories are well represented in the oldest civilizations, those of Egypt, Babylonia-Assyria, and India. Though there may have been some trade in texts—*e.g.*, of the Egyptian Book of the Dead, copies of which were required at every funeral—books were produced and preserved mainly in libraries attached to palaces and temples, each of the latter specializing in whatever was appropriate to its deity. Babylonia was particularly well endowed; education, including tablet writing, was compulsory for freemen, and some of the surviving tablets bear directions for getting a "book" from the library. Insofar as the contents of early books were made generally known, this was still done largely by word of mouth, by priests and sages, and by storytellers and singers. Many of the earliest works go back, of course, far beyond the invention of writing. Such sacred scriptures as the Indian Vedas, several times the length of the Bible, and such legendary works as the great Indian epic, *Mahābhārata*, were handed down orally for hundreds of years before being recorded in writing.

Libraries of Alexandria and Pergamum

Beginnings of publishing. *Ancient* Greece. The first signs of publishing in the modern sense appear in ancient Greece, but they are signs only; details are lacking. In the pre-classical period, books seem to have been used in the traditional way by reciters, actors, and singers as aids to the memory. By the 5th century BC, however, a small reading public was developing, mocked by Aristophanes as "highbrows." Books were copied by individuals (or their slaves) for private use and there are references in Plato and Eupolis to the possibility of buying them. In the Hellenistic period, after the founding of the great library at Alexandria (3rd century BC) and its rival at Pergamum (2nd century BC), a considerable traffic in books must have grown up. Other libraries, public and private, became common and the reading habit well established. By the 2nd century AD, Lucian was satirizing the ignorance of booksellers and their rich patrons. Throughout this period, except for the local experiment with parchment at Pergamum, the usual form of book was the papyrus roll, about eight or nine inches (20 to 23 centimetres) high (less for poetry or epigrams) and up to 35 feet (11 metres) long (more in Egypt), made by sticking sheets of papyrus together. The writing was arranged in columns according to fairly strict conventions but without much help in the way of punctuation or even word spacing. One 15-foot (five-metre) roll would have accommodated one of the books of Plato's Republic; the "books" into which longer works were divided were merely such rolls made in a convenient size for handling.

Ancient Rome. In ancient Rome, there is little trace of publishing before the 3rd century BC and none of libraries before the 1st century. Liber, the Latin word for "book," means "bark," which suggests that this was once used as writing material; but nothing has survived from the earliest period. After Greek models had been absorbed in its pre-classical period, Latin literature came into full flower, and with it a flourishing book trade grew up. At the time of Cicero (106–43 BC), it was well established and no longer dependent on Alexandria. Its best known figure was Titus Pomponius Atticus (109–32 BC), a rich patron of the arts who was a close friend of Cicero as well as his publisher. Atticus employed a large number of trained slaves to copy and produce books and eventually had retail branches of his business in the provinces as well as in Rome. The form was still the papyrus roll, though the better ones now had rollers, often with decorated knobs. Editions are estimated to have been of from 500 to 1,000 copies, and overproduction was not unknown; unwanted books ended up as wrapping paper. By the 1st century AD, according to Seneca, a library was considered as essential to a house as a bath; and in literature references to professional booksellers become more frequent. A bookshop is described by Martial as having its pillars covered with advertisements of books. Many of the familiar problems of the book trade already appear in Rome: censorship, plagiarism, piracy, and the author's lack of a just reward. There was no law of copyright, but early in the 2nd century AD publishers appear to have taken care of themselves by forming an association, "for the better protection of their interests in literary property."

Chinese inventions

Ancient China. At about the same time an equally vigorous publishing activity was going on in China. The classical period of Chinese literature is usually placed between 600 and 200 BC, the time of the Chinese philosophers Lao-tzu, Confucius, and Mencius, among many others. Although the first Chinese emperor, Ch'in Shih Huang Ti, tried to blot this out in 213 BC by burning books and executing hundreds of scholars, the tradition was rescued under the Han dynasty (206 BC to AD 220) and firmly consolidated by a system of state examinations in the classic texts, through which the civil service was recruited. It was this "literocracy," as it has been called, that provided fertile ground for the rich and humane literary culture of China. By 100 BC, the Imperial library is said to have contained 13,000 volumes. No less remarkable is a series of completely original Chinese inventions in writing technique: the bristle brush, a soft writing material made from silk waste, and, finally, paper, which greatly increased the availability of books (in the form of scrolls). In AD 175, Confucian texts began to be carved into stone tablets from which rubbings were taken. This process seems to have been the very beginning of printing. The invention of lampblack ink came in AD 400 and printing from wooden blocks in the 6th century—for religious pictures at first, then for complete texts. Much of this publishing was done under Imperial or local government direction, but private publishing also throve. A publisher's account from 1176 for a book of 1,300 pages indicates a 3 to 1 ratio of selling price to production costs, a useful profit margin in the absence of modern overhead costs. As one might expect, the oldest printed book in the world is Chinese: a paper scroll from AD 868, 16 feet long and one foot wide (five by three-tenths metres) bearing a Chinese translation of the Indian Diamond Sutra.

Scholarship in monasteries

Developments after the fall of the Roman Empire. With the decline of Rome after the 5th century, publishing in Europe fell into what may be called the primordial pattern: the production and distribution of books was confined largely to religious centres of learning; literacy was maintained henceforth, and spread to a limited degree, by the Christian Church. Elsewhere, this pattern continued to be general. At temples and retreats, Hindu and Buddhist, Zoroastrian, Jewish, and Manichaean texts, and those of other Christian sects and of the Muslims after the 7th century were copied, preserved, and carried abroad by priests, monks, and missionaries. Centres of study sprang up around distinguished scholars or under enlightened rulers; monasteries were founded through saintly inspiration. Though they were subject to decay from within and to destruction from without, these scattered foundations maintained a tenuous but effective web of learning through the centuries. The Venerable Bede (died 735) "published" his great history of the

English people from his cell at Jarrow, and it was copied as far away as Rome. Largely because of St. Benedict (died 543/547), who stressed work as one of the monastic virtues, scriptoria, or writing rooms, came to be regular features of Christian religious houses. In these, some of the most beautiful books in the world were produced, notably in Celtic monasteries, in the form of illuminated manuscripts, besides more everyday editions, not only of devotional and theological works but also of secular literature, especially chronicles. Books were inclined to be large and precious and were lent only under stringent conditions; they were often chained to the desks. An important practical development of the 9th century was the type of script known as Carolingian minuscule, which grew out of Charlemagne's drive to civilize the Franks. Besides other advantages, it regularized the use of small and capital letters and of spaces between words.

Spread of the use of paper. Though paper had been invented by the Chinese as early as AD 105, the Chinese kept the secret of its manufacture jealously. It reached Korea and Japan by about 600 but did not reach the West until much later. The Arabs in 751 captured some Chinese papermakers, extorted their secret, and set up a paper mill at Samarkand. From there, paper travelled via Baghdad, Damascus, and Egypt to Morocco and entered Europe through Spain and Sicily in the 11th to 12th centuries. For books, paper took the place of parchment increasingly between the 13th and 15th centuries. Its great advantage was, of course, its cheapness and abundance (vegetable fibre instead of skin), which reduced the cost of books and so made them more widely available.

The *stationarii*

Secularization of publishing. At the end of the 12th century, with the founding of the first universities, book publishing in Europe began to acquire a broader base. The schools of theology, law, and medicine at Paris, Bologna, and Salerno outgrew their origins and became independent of the church. Other universities soon followed and codices of all kinds were in greater demand. This led to the rise of a new class of book trader, the *stationarii*, or stationers, with fixed premises, as opposed to the itinerant peddlers of books. The latter continued to provide a private, sometimes clandestine, means of distribution, as appears, for instance, from the wide circulation in England, in spite of its proscription, of John Wycliffe's translation of the Bible (*c.* 1382 and 1388). The *stationarii,* however, were under the control of the universities, who authorized them to deal in approved texts only. The main function was to supply to students learned codices, both new (from their own copiers) and secondhand and to act as a kind of circulating library. They also sold writing materials; hence the modern word stationery. The script of the codices during the 12th to 13th centuries underwent a further change: the Carolingian minuscule broke into the Gothic style with its angles and flourishes—more decorative but less clear. As the Middle Ages advanced and monastic life decayed, book production became increasingly secular and, as the Renaissance got under way, more diverse. In the main centres, Paris above all, the scriveners and limners (illuminators) grew sufficiently numerous to form guilds. There was a growing demand for copies of the classics, not to mention all the fresh works—the fables, romances, and poetry—that were beginning to appear more abundantly. These were copied at will; and, because there was no title page as yet, the author often went unrecognized. By the middle of the 15th century, bookcopying in Europe had become quite an industry. A bookseller in Florence, Vespasiano da Bisticci, was employing as many as 50 scribes at a time; and in Haguenau in Alsace, Diebolt Lauber was running something like a book factory for the open market. Block printing had finally reached the west (*c.* 1400) and was being used for illustration and even for whole books. The stage was set for Gutenberg.

SPREAD OF THE ART OF PRINTING: 1450–1550

Before the invention of printing, the number of manuscript books in Europe could be counted in scores of thousands. By 1500, after only 50 years of printing, there were more than 9,000,000 books. These bare figures indicate the explosive impact of the press, the rapidity with which it spread, the great need that had arisen for an artificial script—and the tenuous nature of written culture up to that time.

The *incunabula*

The printed books of this initial period, up to 1500, are known as *incunabula; i.e.,* "swaddling clothes," "cradle," from a Latin phrase used in 1639 to describe the beginnings of typography. The dividing line, however, is artificial. The initial period of printing, a restless, highly competitive free-for-all, runs well into the 16th century. Printing only began to settle down, to become regulated from within and controlled from without, after about 1550. In this first 100 years, the printer naturally dominated the book trade with his new craft. He was often his own typefounder, printer, editor, publisher, and bookseller; only papermaking and, usually, bookbinding were outside his province. Yet even from the beginning, other arrangements cropped up that foreshadowed the future.

Gutenberg Bible

Printing has been called the great German contribution to civilization; in its early days it was known as the German art. After its invention (*c.* 1440–50) by a goldsmith of Mainz, Johannes Gutenberg, it was disseminated with missionary zeal—and a keen commercial sense—largely by Germans and largely along the trade routes of German merchants. Gutenberg himself is usually credited with what is known as the 42-line Bible (1456); the 36-line Bible; and a popular encyclopaedia called the *Catholicon* (1460). His employee and successor, Peter Schoffer, and his son Johann continued in business until 1459; but Mainz itself never became one of the main centres of the book trade. It was soon challenged by Strassburg where, in 1460–61, Johann Mentelin, with an eye for the lay market, brought out a Bible compressed into fewer pages and followed this with the first printed Bible in German or any other vernacular. A few years later, Cologne had its first press (1464) and became an important centre of printing in the northwest. There William Caxton, the first English printer, learned the art in 1471–72. Cologne's early production was almost entirely in Latin because of the heavy bias of its university toward orthodox Thomist theology. In the south, printing quickly spread to the other great trading centres, Basel (1466), Niirnberg (1470), and Augsburg (1472). Basel became famous for the scholarly editions of Johann Amerbach (died 1513) and Johann Froben, who had the benefit of distinguished advisers, including the Dutch Humanist scholar Erasmus. In Augsburg, the first press was set up alongside the renowned scriptorium of the Abbey of SS. Ulrich and Afra; and the tradition of the illuminated manuscript was carried over into equally sumptuous editions of illustrated printed books. At Niirnberg, which soon took the lead in the book trade, Anton Koberger (died 1513) operated on a large, international scale. At his peak, he ran 24 presses and had links with Basel, Strassburg, Lyons, Paris, and many other cities. He could be called the first great businessman publisher and the first publisher to rise socially—to membership of the town council. By 1500 there were presses in some 60 German towns, including Liibeck (1475), the head of the Hanseatic League. From there, printing spread to Denmark, Sweden, Rostock, Danzig, and Russia, though the first printer who went to Russia was apparently murdered before he could achieve anything. Russia began to print in 1552, with the help of a printer from Copenhagen. It could be said that book printing, after its birth in medieval Germany, was carried to maturity in Humanistic Italy.

Italy. The printing press reached Italy very early (1463), via the Benedictine monastery of Subiaco, near Rome, which had strong German connections and a famous scriptorium. Two German printers, Konrad Sweynheim and Arnold Pannartz, who had settled there, soon moved to Rome (1467), where the church encouraged the production of cheap books. In Italy as in Germany, however, it was the great commercial centres that became centres of printing and publishing. By 1500, Venice had no fewer than 150 presses; and two Venetian printers exercised a decisive influence on the form of the

First cheap pocket editions

book: an outstanding typographer, Nicolas Jenson, who perfected the roman type face in 1470, and Aldus Manutius, the greatest printer-publisher of his time. Aldus began printing in 1490 with a series of Greek authors. He then hit on the idea of bringing out cheap "pocket editions" for the new readers produced by the Humanist movement. Beginning in 1501 and continuing with six titles a year for the next five years, he issued a series of Latin texts in octavo format that were models of scholarship and elegance. To keep down the cost, Aldus printed editions of 1,000, instead of the more usual 250; and to fill the page economically, he used an "italic" type designed for him by Francesco Griffo, another innovation of far-reaching effect. The Aldine editions were widely copied, piratically and otherwise, and their dolphin and anchor was the first instance of a publisher's imprint that became a hallmark of excellence. Venice was also important as the source of printing for the south Slavs. About 75 percent of the incunabula in Yugoslavian libraries originated in Venice: printing began in Yugoslavia at Cetinje in 1493.

Patronage of Francis I

France. The way in which printing came to France is of special interest because it shows a publisher in command from the start. In 1470, the rector and librarian of the Sorbonne invited three German printers to set up a press on university premises. The scholars chose the books and supervised the printing, even to specifying the type. By deciding on roman, they greatly helped the eventual defeat of Gothic. Among the early French printers were Jean Dupré, a businessman publisher of ***editions de luxe*** ("luxury editions"), who set up in 1481; and Antoine Vérard, who began printing in 1485. Vérard was the first to print the Book of Hours, a book containing the prayers or offices appointed to be said at canonical hours, and set a standard for French elegance. After 1500, when the Renaissance had begun to be felt in France, a brilliant group of scholarly printers, including Josse Bade, Geoffrop Tory, and the Estienne (Stephanus) family, who published without a break for five generations (1502–1674), carried France into the lead in European book production and consolidated the Aldine type of book—compact, cheap, and printed in roman and italic types. The golden age of French typography is usually placed in the reign of Francis I (1515–47), one of the few monarchs ever to take a keen personal interest in printing. He was the patron and friend of Robert Estienne. In 1538 he ordered Estienne to give a copy of every Greek book he printed to the royal library, thus founding the first copyright library. In 1539 he laid down a code for printers, which included a prohibition on the use of any imprint that could be confused with another. Outside Paris, the only significant centre of printing in France was Lyons, which had close links with Basel. While Paris was under the watchful eye of the Sorbonne (University of Paris) theologians, Lyons was able to publish Humanist and Protestant works more freely. Among its foremost printers were Johann Trechsel and his sons, Melchior and Caspar; Sebastian Greyff of Gryphius; and a fine typographer, Robert Granjon. By about 1600, however, the pressure of the Inquisition and the competition of Paris had put an end to printing in Lyons. Thereafter, the French book trade was centred entirely in Paris.

Complutensian Polyglot Bible

Other European printers. The rest of Europe had presses almost as quickly; *e.g.*, Utrecht (1470), Budapest (1473), and Cracow (1474), in each case through Germans. Spain in particular shows the direct connection. There the first press was set up in 1473 at Valencia, where the German trading company of Ravensburg had an important base. Though Madrid eventually became dominant (after 1566), publishing flourished in the early period at Barcelona, Burgos, Zaragoza, Seville, and the university towns of Salamanca and Alcalá. In Lisbon, the first printed book was apparently produced in 1489 by a Jew; he was reinforced in 1495 by two printers sent for by the Queen of Portugal. Spain quickly evolved its own distinctive style of book, full of dignity and printed largely in Gothic types. The most remarkable production of the period was the magnificent Complutensian Polyglot Bible, sponsored by Cardinal Ximenes "to revive the hitherto dormant study of the scriptures," which it effectively did. It was printed at Alcalá, in Hebrew, Chaldee, Syriac, Greek, and Latin, by Arnaldo Guillermo de Brocar, the first great Spanish printer. Editorial work was begun in 1502, the six volumes were printed in 1514–17, and the book finally issued in 1522. From Spain, printing crossed the Atlantic during this early period. Juan Cromberger of Seville, whose father, Jacob, had set up a press there in 1502, secured the privilege for printing in Mexico and sent over one of his men, Juan Pablos. In 1539, Pablos published the first printed book in the New World, ***Doctrina christiana en la lengua mexicana e castellana*** ("Christian Doctrine in the Mexican and Castilian Language").

England. Comvared with the Continent. England in the early days of printing was in a state of backwardness, intellectually and economically, partly because of the Wars of the Roses in which the Lancaster and York families fought for the throne. Printing reached England fairly late (1476), and in 1500 there were still only five printers in England, all in London and all foreigners. Type seems to have been largely imported from the Continent until about 1567, and paper until about 1589 (except for a brief spell 1495–98). In an Act of 1484 to restrict aliens trading in England, Richard III deliberately exempted all aliens connected with the book trade, in order to encourage its domestic development. In the following year, Henry VII appointed a foreigner, Peter Actors of Savoy, as royal stationer, with complete freedom to import books. For about 40 years, England was a profitable field for Continental printers and their agents. This necessary free trade was brought to an end and native stationers protected under Henry VIII, whose acts of 1523, 1529 and 1534 regulated foreign craftsmen and finally prohibited the free importation of books. It has been estimated that up to 1535 two-thirds of those employed in the book trade in England were foreigners.

William Caxton and his press

It is all the more remarkable that England's first printer, William Caxton, was in fact an Englishman and the only native to introduce printing to his country. After learning to print at Cologne (1471–72), Caxton set up a press at Bruges (1474) and printed his first book, ***Recuyell of the Historyes of Troye,*** which was his own translation from the French and probably the main reason why this semi-retired merchant gentleman took to printing at the age of 50. He had returned to England through the encouragement of Edward IV and continued to receive royal patronage under Richard III and Henry VII. Caxton is important not so much as a printer (he was not a very good one) but because from the first he published in English instead of Latin and so helped to shape the language at a time when it was still in flux. Of the 90 odd books he printed, 74 were in English, of which 22 were his own translations. Some, such as the ***Ordre of Chyvalry*** and the ***Fayttes of Armes,*** were for the pleasure of his royal patrons; but his range was wide and included ***Dicts or Sayings of the Philosophres*** (1477; his first book in England); two editions of Chaucer's ***Canterbury Tales*** (the second because a better manuscript came to hand); ***The Fables of Aesop*** (in his own translation from the French); Sir Thomas Malory's ***Kyng Arthur;*** and his largest work, ***The Golden Legend,*** a compilation of such ecclesiastical lore as lives of the saints, homilies, and commentaries on church services, a considerable editorial labour apart from the printing.

Caxton's press was carried on after his death by his assistant, Wynkyn de Worde of Alsace. In the absence of court connections and also because he was a shrewd businessman, he relied more on bread-and-butter lines, liturgies and school books (educational reform was just beginning). He published some 800 titles, mostly small volumes for the ordinary citizen, and continued Caxton's standardizing of the language, a solid contribution to the native book trade. His contemporary, the best of the early printers, was Richard Pynson of Normandy, who began printing in 1492 and became printer to the king in 1508. Pynson, the first to use roman type in England (1509), published the first English book on arithmetic (1522). After his early liturgies and some fine illustrated books, he concentrated mainly on legal works. In 1521 he published Henry VIII's answer to Luther in defense of the papacy, for which the King received the title of *fidei defensor* ("defender of the faith) from the Pope.

The book trade. The book trade during this early period showed enormous vitality and variety. Competition was fierce and unscrupulous. A printer of Parma in 1473, apologizing for careless work, explained that others were bringing out the same text, and so he had to rush it through the press "more quickly than asparagus could be cooked." Though most of the early firms were small printer-publishers, many different arrangements were made and there was at least one individual, Johann Rynmann of Augsburg (died 1522), who published nearly 200 books but printed none of them. Publishing companies, which both financed and guided the printing enterprise, were also tried, as at Milan in 1472 and at Perugia in 1475. Publishers were not slow to develop their publicity. The medieval scribes had placed their names, the date when they finished their labours, and perhaps a prayer or a note on the book, at the end of their codices. From this grew the printer's colophon or tailpieces, which gave, besides the title of the book, the date and place of printing, the name of the printer, his device, and a bit of self-advertisement, often composed by a professional writer. By about 1480, the information of the colophon began to appear at the front of the book as a title page, along with the title itself and the name of the author. Advertisements for books, in the form of handbills or broadsheets, are known from about 1466 onward, including Caxton's of 1477, ending with a polite request not to tear it down, *Supplico stet cedula* ("Please let the poster stand"). Publisher's lists and catalogues occur almost as early. Distribution of books along the trade routes, with their courier services, appears to have been highly effective. In 1467, for instance, a bookseller in Riga had a stock of books issued by Schoffer in Mainz. There were also the regular trade fairs, especially those at Frankfurt, where a major annual book fair is still held today, and at Stourbridge in England, which was associated with the book trade up to about 1725. Besides the stationers, who may sometimes have functioned as wholesalers, there were also retailers known as "book-carriers."

Printing's effect on languages

Early printing had a profound effect on national languages and literatures. It began at once to create, standardize, and preserve them. Caxton, in the preface to his translation of the *Aeneid,* after telling a story of confused dialects, ended up "Lo! what should a man in these days now write, eggs or eyren?" By choosing words "understood of common people" and by printing all he could of English literature, he steered the English language along its main line of development. The early printing of great vernacular works, such as those of Dante, Petrarch, and Boccaccio in Italy, or the publishing of a vernacular Bible, such as that of Luther in Germany, gave many languages their standard form. The French language owes much to an early printer-publisher, the scholarly Robert Estienne, who is known as the father of French lexicography for his dictionaries as well as for his typographical innovations in the 1530s. Up to 1500, about three-quarters of all printing was in Latin, but thereafter it steadily declined as books appeared in the vernaculars and reached an ever-widening public.

Controls over printing. The church at first had every reason to welcome printing. Bibles (preferably in Latin), missals, breviaries, and ecclesiastical literature poured from the early presses of Europe; and the first printed best seller was a devotional work of universal acceptance, Thomas à Kempis's *De imitatione Christi,* which went through 99 editions between 1471 and 1500. Such sales were matched, however, between 1500 and 1520 by the works of a Humanist, Desiderius Erasmus, and, after 1517, by those of a heretic, Martin Luther. The church had always exercised a censorship over written matter, especially through the universities in the latter part of the Middle Ages. As the works of the reformers swelled in volume and tone, this censorship became increasingly harsh. The Inquisition was restored, and it was decreed in 1543 that no book might be printed or sold without permission from the church. Lists of banned books were drawn up, and the first general *Index Librorum Prohibitorum* was issued in 1559. Dutch printers in particular suffered under the Inquisition and a number went to the stake for publishing Protestant books. To avoid such a fate and to beat the censor, some resorted to the fake imprint, putting a fictitious printer or place of publication (or both, or neither) on the title page.

The Index of Forbidden Books

Censorship also began to be exercised in varying degrees by individual rulers, especially in England, where church and state had been united under Henry VIII after his defection from Rome. The Tudors, with little right under common law, arrogated to themselves authority to control the press. After about 1525, endless proclamations were issued against heretical or seditious books. The most important was that of 1538 against "naughty printed books," which made it necessary to secure a license from the Privy Council or other royal nominees for the printing or distribution of any book in English.

The Stationers' Company

In this attempt at control, an increasingly prominent part came to be played by the Stationers' Company. Since its formation in 1403 from the old fraternities of scriveners, limners, bookbinders, and stationers, it had sought to protect its members and regulate competition. Its first application for a royal charter in 1542 seems to have gone unheeded; but in 1557, an important date in the English book trade, the interests of the crown (then the Catholic Mary Tudor), which wanted a ready instrument of control, coincided with those of the company (under a Catholic first Master), and it was granted a charter that gave it a virtual monopoly. Thereafter, only those who were members of the company or who otherwise had special privileges or patents might print matter for sale in the kingdom. Under the system of royal privileges begun by Henry VIII, a printer was sometimes given the sole right to print and sell a particular book or class of books for a specified number of years, to enable him to recoup his outlay. This type of regulation now came into the hands of the Stationers' Company. After licensing by the authorities, all books had to be entered in the company's register, on payment of a small fee. The first stationer to enter a book acquired a right to the title or "copy" of it, which could then be transferred as might any other property. As the beginning of a system of copyright, this procedure was an admirable development; but the grip that the company obtained and its self-interested subservience to authority were to stunt the free growth of the English book trade for the next 100 years.

THE FLOURISHING BOOK TRADE: 1550-1800

During this period, there were virtually no technical changes in methods of book production, but the organization of the trade moved gradually toward its modern form. The key functions of publishing, selecting the material and bearing the risk, shifted from the printer to the bookseller and from him to the publisher in his own right; the author, too, at last came into his own. The battle with the censor became increasingly fierce before enlightenment triumphed, at least after a fashion. Literacy grew steadily and the book trade expanded, both within and beyond national boundaries. All this took place in outline by about 1800, when the mechanical inventions of the 19th century, among other factors, began to lift the trade to fresh levels.

The Netherlands. In Europe between 1550 and 1700, the lead in book publishing passed for a time to the Netherlands. The business founded at Antwerp in 1549 by Christophe Plantin, a Frenchman by birth, came to dominate the Catholic south of the country, both in quantity and in quality. Its finest production was probably the eight-volume Polyglot Bible (1568–73), the *Biblia regia.* The firm was carried on for generations by the descendants of Plantin's son-in-law, Balthasar Moretus, and today its premises are a museum of printing. In the Protestant north, the house of Elzevir occupied a similar position. After its founding by Louis Elzevir, who issued his first book in 1593, it was extended by succeeding generations to The Hague, Utrecht, and Amsterdam, with varying fortunes. A duodecimo (small-format) series of classi-

The Polyglot Bible

cal texts that the Elzevirs began issuing in 1629 more than matched the earlier Aldine editions in excellence at a reasonable standard price. The Dutch, as great seafarers, were pre-eminent publishers of atlases, a word that was first used when the maps of Gerardus Mercator were published by his son, Rumold, in 1595. The high skill of Dutch engravers also went into their emblem books (books of symbolic pictures with accompanying verse), for which there was a considerable demand between 1580 and 1650.

France. In France, as the monarchy reasserted itself after the wars of religion, publishing became increasingly centralized. In 1620, Louis XIII set up a private press in the Louvre, the Imprimerie Royale, which the Cardinal de Richelieu turned into a state establishment in 1640. Since then, this national press, through all its changes of name through changes of regime, has provided a continuous standard of excellence to which book production in France could refer. Louis XIII also tried to regulate the trade. By an ordinance of 1618, a body was established similar to the English Stationers' Company, the Chambre des Syndicats; because it contained two royal nominees, however, its control was even more absolute than that in England. Censorship, though it remained for a time with the Sorbonne, also passed eventually to officials of the crown. Under these cramping conditions, publishers were inclined to play safe; as elsewhere, more controversial works first appeared outside the country (often in Holland or Geneva) or under a false imprint. But French books fully upheld the influence of French taste in Europe. A remarkable publishing feat of the 18th century was the first collected edition of Voltaire's works (1785–89). It was produced at Kehl in Sud-Baden by Pierre-Augustin-Caron de Beaumarchais, the author of ***The Barber of*** *Seville* and ***The Marriage of*** *Figaro*, who bought the copyrights from Panckoucke in Paris and the printing equipment (especially for the purpose) from the widow of the great English typographer John Baskerville.

Publishing the works of Voltaire

Germany. After the Reformation, the intellectual life of Germany was predominantly Protestant and the book trade almost entirely so. Through its book fairs, Frankfurt had become the centre of German publishing and even a kind of European clearinghouse. In 1579, however, the fair came under the supervision of the imperial censorship commission (Frankfurt being a free imperial city), and this action gradually killed it. After about 1650, though Frankfurt continued to be important for the production of type and illustrated books, the centre of the trade shifted decisively to Leipzig. There, an enlightened government and a celebrated university favoured cultural life and books not least. Two Leipzig firms dating from the 17th century have come down to the present day: that founded by Johann Friedrich Gleditsch in 1694, which was taken over by F.A. Brockhaus in 1830, and that founded by Moritz Georg Weidmann in 1682. A Weidmann partner, Philipp Erasmus Reich, was known in the 18th century as "the prince of the German book trade." He could be said to have invented the net price principle (see below) and the idea of a booksellers' association (1765), which in 1825 became the Borsenverein der Deutschen Buchhandler, a unique organization of publishers, wholesalers, and retailers. At the culmination of the classical period of German literature toward the end of the 18th century, three publishers were outstanding—Georg Joachim Göschen in Leipzig; Johann Friedrich Cotta in Tiibingen and Stuttgart; and Johann Friedrich Unger in Berlin, all of whom had a share in publishing Schiller and Goethe. Unger also published the magnificent translation of Shakespeare by A.W. Schlegel (8 vols., 1797–1810).

England. In the golden age of Elizabeth I, publishing in England was probably at its most turbulent. Through her Injunctions of 1559, Elizabeth confirmed the charter of the Stationers' Company and the system of licensing by the crown or its nominees, which now included church dignitaries. Controls were tightened in 1586 by a decree of Star Chamber, which confined printing to London, except for one press each in the universities of Oxford and Cambridge. The Stationers' Company was given powers to inspect printing offices and to seize and destroy offending material or presses, which it zealously did, as much in defense of its monopoly as in support of the crown. But despite stern measures, including execution, the great religious question, in which Elizabeth steered a precarious course between Papists and Puritans, continued to be fought out with secret presses on both sides.

Within the legitimate trade, the booksellers had begun to get the upper hand. The incorporation of the Stationers' Company, like that of other London companies, was in itself an indication of the ascendancy of the trader over the craft's man. Under Elizabeth, as part of a developing system of monopolies, the former short-term privileges for particular works or classes of works were granted, for a consideration, as life patents with rights of reversion, such as those enjoyed by Richard Tottel for law books or John Day for ABCs and catechisms. The printers had already been driven by their costs to make arrangements with the booksellers, to their own disadvantage. Gradually, the best "copies" came into the hands of a rich few, who ruled the company and who, in the words of a report of 1582, "keepe no printing howse, neither beare any charge of letter, or other furniture but onlie paye for the workmanship." In 1577, an abortive revolt was led by John Wolfe, a former apprentice of John Day, who maintained his right to print what he pleased. He was twice imprisoned but was finally bought off by admission to the company. In 1584, to still the discontent, some of the rich patentees surrendered a number of "copies" to the company for the benefit of its poorer members. These were added to in 1603, when James I withdrew some patents from individuals and sold them to the company, again for "the poore of the same." In this way the company itself became a publishing organization; and having tasted the advantages, it bought up more and more "copies" on its own account. These came to be divided into "stocks," the English Stock, Bible Stock, Irish Stock, Latin Stock, and Ballad Stock, with shares allocated among its members. By 1640, through leasing the patents at its discretion, the company controlled most of the printing offices in London. The benefit to the poor stationers was somewhat marginal and the monopoly and lack of foreign stimulus caused England to lag behind the Continent in standards of production.

For all that, the privileged men did some good publishing; a few even supported their authors during their labours. Some landmarks of the period were John Lyly's ***Euphues,*** published by Gabriel Cawood (1578); Sir Thomas North's translation of Plutarch's ***Lives,*** so important for Shakespeare, by Thomas Vautroullier (1579); and Spenser's ***Faerie Queene,*** by William Ponsonbie (1589–96), not to mention the Authorised Version of the Bible (1611), which was completed in a room at Stationers' Hall and printed at the expense of Robert Barker, the king's printer. The city, however, had no love for the theatre, so the wealthy publishers missed the real glory of the age, its drama. Publication of drama was left, along with much of the poetry and the popular literature, to the unprivileged and to the outright pirates, who scrambled for what they could get and but for whom much of it would never have been printed. To join this fringe, the would-be publisher had only to get hold of a manuscript, by fair means or foul, enter it as his "copy" (or dispense with the formality), and have it printed. Just such a man was Thomas Thorpe, the publisher of Shakespeare's sonnets (1609); the mysterious "Mr. W.H." in the dedication is thought by many to be the person who procured him his "copy." The first Shakespeare play to be published (*Titus Andronicus*, 1594) was printed by a notorious pirate, John Danter, who also brought out, anonymously, a defective ***Romeo and Juliet*** (1597), largely from shorthand notes made during performance. Eighteen of the plays appeared in "good" and "bad" quartos before the great First Folio in 1623. A typical imprint of the time. of the "good" second quarto of ***Hamlet*** (1604), reads: "Printed by I.R. for N.L. and are to be sold at his shoppe under Saint Dunston's Church in Fleetstreet"; *i.e.*, printed by James Roberts for Nicholas Ling. For the First Folio, a large undertaking of over 900 pages, a syndicate of five was formed,

Printing of Shakespeare's sonnets

headed by Edward Blount and William Jaggard; the Folio was printed, none too well, by William's son, Isaac.

The struggle to govern and limit the press continued through most of the 17th century. In 1637, at the height of episcopal tyranny and Puritan pamphleteering in Britain, Star Chamber issued its most drastic decree, which confirmed previous enactments, laid down detailed licensing procedures, reduced the total number of printers to 23, and prescribed severe penalties for offenses. Four years later, however, Star Chamber itself was swept away by Parliament, and in the ensuing uncertainty the trade had a taste of freedom. This new situation quickly alarmed not only the Stationers' Company, who saw their privileges vanishing, but also Parliament, which proved to be as reactionary as the royalists. In 1643, it passed an ordinance restoring both licensing and the powers of the company. It was this Act that prompted Milton to write his *Areopagitica,* a noble and powerful plea for freedom of the press, which demolishes every argument for censorship. After the Restoration, the Licensing Act of 1662 was ruthlessly enforced until after the Plague (1665), when its rigours were mitigated; it lapsed in 1679. James II revived licensing in 1685, but Parliament refused to renew it in 1694. Thereafter, restraint, harassment, and persecution continued, but by other means, under a broad interpretation of the meaning of libel. With the end of licensing and the gradual breakdown of the whole guild system, the Stationers' Company declined in importance; but it remained useful in connection with copyright.

In the latter part of the 17th century, the trade gathered momentum rapidly, partly through the rise of the periodical press (see below), with its growing body of writers and readers. For successful books the rewards became considerable and the author's right to a proper share more widely recognized. Dryden, according to Pope, received a total of £1,200 for his *Virgil* (1697), at a time when a shopkeeper might receive £50 a year and a labourer £15. Patronage continued, with all its political implications; but dedications became increasingly cut-and-dried, costing five guineas for a poem, perhaps, or 20 for a play; royalty was naturally expected to pay more. By the 1750s it was virtually at an end; "We have done with patronage," said Dr. Johnson. In its place came the public at large, to whom Henry Fielding dedicated his *Historical Register* in 1737. In the expanding literary market, the enterprising publisher no longer built up monopolies in bread-and-butter lines (though he has never despised them) but tried instead to collect all the most promising authors. Through his personal inclinations, his sense of public taste, and his readiness to risk novelty, he began to play a part of his own in the course of literary development. As this side of the business absorbed more and more of his energies, the final separation of publisher and bookseller came about, though never so decisively as that between bookseller and printer. The bookseller, for his part, also had his hands full as the retail trade became better organized. The first advertisement claiming that his books were "available in every bookshop" seems to have been made by a Leipzig publisher in 1717.

Payment to authors

Copyright Act of 1709

In England this whole transition was marked—and fostered—by the passing of the Copyright Act of 1709, the first of its kind in any country. It was "An Act for the encouragement of Learning, by vesting of the copies of printed books in the authors or purchasers of such copies during the times therein mentioned." For books already printed, the time was 21 years, "and no longer" (from April 10, 1710, when the Act came into force). For unpublished works, it was 14 years, "and no longer," though if the author was still living at the end of that time, the copyright returned to him for a further period of 14 years. Penalties were laid down, and registration at Stationers' Hall was made a condition for their enforcement.

The Copyright Act of 1709, like all subsequent measures, tried to strike a balance between the needs of those who make a living from books—writers, printers, and publishers—and the interests of the reading public, which are far from identical; it tried, in other words, to limit privilege as well as piracy. The terms it set have since come to be regarded as too short; but in setting any term at all, and in focussing attention on the author as prime producer, it was revolutionary.

The fathers of modern publishing in England, which may be said to date from this time, were Jacob Tonson (died 1736), who acquired the copyright of *Paradise Losi* and published for Dryden, Addison, Steele, and Pope, among others; and Barnaby Bernard Lintot, who also published Pope, paying him some £5,300 in all for his *Iliad.* Two modern British firms go back to this period, Rivingtons and Longmans, Green & Co., Charles Rivington starting in 1711 and Thomas Longman in 1724, by buying the business of William Taylor, the publisher of *Robinson Crusoe.* At mid-century, the best known figure in the trade, and one of the best liked, was Robert Dodsley (1703–64), the footman-poet who was befriended by Pope. Among "his" authors were Pope himself, Goldsmith, Sterne, and Johnson. He is credited with suggesting the idea of the *Dictionary* to Dr. Johnson, and his name heads the list of "gentlemen partners" who financed it. Such co-operative associations were popular for longer works. They were known as congers and developed into a system of shares in individual books which could be bought and sold at will.

United States. During the 18th century, the book trade in the United States began to flourish. Printing had begun there in 1638, when the first printers, Stephen Daye and his two sons (Joseph Glover, who arranged the venture, died on the voyage), went out from Cambridge, England, to Cambridge, Massachusetts. After printing *The Oath of a Free-Mart* (1638) and *An Almanack for the Year of Our Lord 1639,* they produced their first book, *The Whole Booke of Psalmes,* in 1640. Cambridge, Massachusetts, had the sole privilege of printing, but the monopoly was broken in 1674, when Marmaduke Johnson, who had come over to print an Indian Bible (1663), moved his press to Boston. Gradually others followed; Philadelphia had a press in 1685; New York, in 1693. It was difficult for the colonial printer, as for any small printer, to produce large works because of shortage of type; but his patronage by the government helped to give his products a dignified style. Almanacs, primers, and law books were the staples; theology, as ever, was the leading category. Up to 1769, America bought its presses from England but thereafter became independent, as also for ink and paper. Books were sold in various ways—by subscription, by the printer himself, by hawkers, and through shopkeepers. Though Massachusetts passed a law against hawkers in 1713, it carefully excluded book peddlers, who had a valuable function in rural areas. The first bookseller seems to have been Hezekiah Usher of Boston, *c.* 1647, who added books to his general merchandise.

Spread of education and literacy. The great increase in available reading matter after about 1650 resulted from the spread of education to the middle classes, especially to women, with a fringe of literacy extending a lot further. The grammar school foundations in the wake of the Renaissance had been followed by a more practical approach to the needs of a child, stemming from Comenius (1592–1671), who produced the first instructional picture book, *Orbis Sensualium Pictus* (1658). Compulsory education seems to have begun in the little dukedom of Weimar in 1619, followed by Prussia in 1717, and France after the Revolution. England was comparatively late, 1870; but charity schools organized by various societies and religious bodies, such as the Society for Promoting Christian Knowledge (1698), and the Sunday School movement, started by Robert Raikes (1780), helped to compensate. The wider readership is reflected among the middle classes by the rich development of the prose novel in the 18th century and, among the less well-to-do, by the great sale for almanacs and chapbooks. The almanacs, such as Benjamin Franklin's *Poor Richard's Almanack* (Philadelphia, 1732–64), usually consisted of miscellaneous information and homilitic matter (religious and moral sayings), while the chapbooks, a few pages cheaply produced, contained a popular story or ballad illustrated by a crude woodcut; a well-known one is *The famous and remarkable History of Sir Richard Whittington, three times Lord Mayor of London,* 1656.

National copyright libraries

Growth of libraries. Growth in the book trade led naturally to growth in the scale, number, and types of libraries. Some of the oldest collections of books developed into national "copyright libraries," of immense value for bibliographical purposes. Sir Thomas Bodley opened his famous library at Oxford in 1602, and in 1610 the Stationers' Company undertook to give it a copy of every book printed in England. Later, Acts of Parliament required the delivery of copies of every book to a varying number of libraries; at present it stands at six, the most important being the library of the British Museum, founded in 1759. This idea of a definitive collection has been adopted elsewhere; *e.g.*, in the United States, where the Librarian of the Library of Congress (founded in 1800) was appointed copyright officer in 1870.

In the 18th century, a characteristic development was the commercial lending library, and in the 19th the free public libiary. Despite the fears of publishers and booksellers, circulating libraries have promoted rather than diminished the sale of books, besides being a steady market in themselves.

Decline of censorship. The general spread of more rational notions in the 18th century led to the waning of censorship in most western countries. It was abolished in Sweden in 1766, in Denmark in 1770, and in Germany in 1848. The clearest statement, to which lip service, at least, is now almost universally paid, came from the French National Assembly in 1789: "The free communication of thought and opinion is one of the most precious rights of man; every citizen may therefore speak, write and print freely." In the United States, no formal censorship was ever established; control over printed matter has always been exercised through the courts under the law of libel. This was also the case in England after the lapsing of the Licensing Act in 1694; but two important steps had yet to be taken: in 1766, Parliament put an end to general warrants; *i.e.*, for the arrest of unnamed persons and for the seizure of unspecified papers; and in 1792, Charles Fox's Libel Act finally gave the jury the right to decide the whole issue, which had previously depended mainly on the judge. In both of these fundamental reforms, a fighting part was played by John Wilkes (1725–97), Member of Parliament and writer. The removal of censorship has never, of course, prevented persecution; but the issues at any rate become more open.

MODERN PUBLISHING: FROM THE 19TH CENTURY TO THE PRESENT

Revolutionary inventions

The 19th century. In the 19th century, a whole new era began. A series of technical developments, in the book trade as in other industries, dramatically raised output and lowered costs. Stereotyping, the iron press, the application of steam power, mechanical rypecasting and typesetting, new methods of reproducing illustrations—these inventions, spaced out through the century and often resisted by the printer, amounted to a revolution in book production. Paper, handmade up to 1800, formed over 20 percent of the cost of a book in 1740; by 1910, it had fallen to a little over 7 percent. Bindings, too, became less expensive. After 1820, cloth cases began to be used in place of leather, and increasingly the publisher issued his books ready bound. Previously, he had done so only with cheaper books; the bindings of others had been left to the bookseller or private buyer. Improved means of communication led to wider distribution, and railway travel itself became a spur to reading. For Europe and America, expansion and competition were the essence of the century, and the book trade had a full share of both. While the population of Europe doubled, that of the United States increased fifteenfold. A thirst for improvement and entertainment greatly expanded readership, leading to a rapid growth in every category of book from the scholarly to the juvenile. The interplay of technical innovation and social change was never more close. The only victim in the book trade was design, part of the price that was paid almost universally in the first phase of machine production.

Publishing was now well established, with its characteristic blend of commerce and idealism. Though some older methods lingered, European publishing houses were, in function, what they are today. The stability of the pattern is reflected in the large number of firms that are still in business after more than 150 years. Some early English foundations have already been mentioned. Among others are: Thomas Nelson & Sons, Ltd. (1798), William Blackwood & Sons, Ltd. (1804), A. & C. Black Ltd. (1807), Blackie & Sons, Ltd. (1809), William Collins, Sons & Co., Ltd. (1819), and W. & R. Chambers, Ltd. (1820). For Germany, one might name Vandenhoeck & Ruprecht (1735), C.H. Beck (1763), and F.A. Brockhaus (1805); and for France, slightly later, Garnier (1833) and Plon (1854). Their tendency to specialize made French and German publishers more vulnerable to change than their English colleagues, who aimed as a rule at greater flexibility. Literary and intellectual currents were flowing strongly and the number of new books rose by leaps and bounds. Rough figures for England indicate 100 new titles per year up to about 1750, rising to 600 by 1825, and to 6,000 before the end of the century. Equally characteristic was the appearance of popular series at low prices, "literature for the millions," as Archibald Constable (1774–1827) was the first to call it. The forerunner was the publisher John Bell's ***The Poets of Great Britain*** (rivalling Dr. Johnson's), which appeared in 1777–83, in 109 volumes at six shillings each, when even a slim volume usually cost a guinea or more. By the 1850s, the application of the new techniques of mass production had brought down the price of a cheap reprint to one shilling, as in the Railway Library of novels (George Routledge, 1,300 volumes, 1848–98), for instance, or in the three series of classics issued by H.G. Bohn in 1846, 1850, and 1853. Later reprints were cheaper still. Cheapest of all was Cassell's National Library (209 vols., 1886–90), bound in paper for three pence and in cloth for six pence, that is, a twelfth the price of the Bell set. On the Continent, two German series were outstanding. The Tauchnitz Collection of British and American Authors (1841–1939) became known to thousands of travellers. Tauchnitz voluntarily paid royalties and forbade the sale of his editions in Britain. Even more successful was Reclam's Universal-Bibliothek, begun in 1867 and still going strong, with total sales running into hundreds of millions. An important factor in this series, as in others later, was the release of works through the expiration of copyright.

The low-priced popular series in England

Book piracy. In the United States, publishing gradually became centralized in a few cities—Philadelphia, Boston, and New York. As in Europe, several modern firms go back to the early 19th century and even further: J. B. Lippincott Co. (1792), John Wiley & Sons, Inc. (1807), Harper & Row (1817), G.P. Putnam's Sons (the first Putnam, 1840), and Charles Scribner's Sons (1846). Although American literature put down strong roots during this century, piracy from England rose to great heights. There was sharp competition to be the first to secure proofs of any important new book. Publishers would send to the dockside and produce an American edition almost within hours, as they did in 1823 with Sir Walter Scott's ***Peveril of the Peak.*** In the absence of international copyright agreements, the English author usually received nothing, but there were honorable exceptions; Harper Brothers, for instance, paid considerable royalties to Charles Dickens and Thomas Macaulay, among others. There was also at least one famous case of piracy in reverse. When Harriet Beecher Stowe's slavery novel ***Uncle Tom's Cabin*** came out in the United States in 1852, 1,500,000 copies rapidly appeared in England, some editions selling for sixpence. Though it can be argued with some justice that piracy is not only inevitable but possibly even desirable for the sake of cultural diffusion in some circumstances, the availability of cheap foreign books, if overprolonged as it almost certainly was in the United States, can damage the prospects for home-produced literature. Though there were some household names, such as Washington Irving, James Fenimore Cooper, Ralph Waldo Emerson, and Henry Wadsworth Longfellow, U.S. writers in general had a lean time; and the strong development of the magazine short story and the lecture tour in the United States has been attributed in part to their difficulties. Toward the end of the century U.S. publishing was further enriched by translations of many foreign works, as a result of the flood of immigrants into New York.

Price regulation. While 19th-century publishing was competitive and individualistic, its growing volume pointed increasingly to the need for greater organization. A major problem, once booksellers had become distinct from publishers, was suicidal price-cutting in the retail trade. Though price regulation ran counter to accepted notions of free competition and met with fierce opposition, in the general interest of the industry it was inevitable. Like copyright, it helped to provide a firm structure within which fair prices could be calculated. The "net price" principle, first raised in the previous century by the German publisher Reich (see above), was adopted in Germany in 1887 through the work of the Börsenverein, the trade organization founded in 1825. Under this principle, the publisher allows trade discount to the bookseller only on condition that the book is sold to the public at not less than its "net published price" as fixed by the publisher. In England a first attempt to introduce it by the booksellers in the 1850s was condemned to failure by the Free Traders; but toward the end of the century some publishers, led by Macmillan, began to replace the variable discounts by fixed prices. To press for the new system, the Associated Booksellers of Great Britain and Ireland was formed in 1895, and the Publishers Association was created in 1896. These two organizations then worked out the Net Book Agreement (1901), primarily through the efforts of Frederick (later Sir Frederick) Macmillan. The principle has since been generally adopted, although only to a limited extent in the United States. At roughly the same time, the founding of the Society of Authors (1884) in England and the Authors' League (1912) in the United States helped to standardize fair dealing over contracts and the payment of royalties to authors.

Trade catalogues. The trade also became better organized in the provision of comprehensive catalogues of current books. These began as early as the twice-yearly book fairs at Frankfurt (first catalogue 1564) and Leipzig (first catalogue 1594). So great was the value of the Frankfurt catalogue that an English edition was published in 1617–28. Eventually, all such semiprivate ventures, as ***A Catalogue of all the Books Printed in the United States*** (1804) or English catalogues deriving from ***The Publishers' Circular*** (1837) or ***Whitaker's*** **(1874),** became national lists, such as the ***Biblionravhie de la France*** (1811 ff.), the U.S. ***Cumulative Book List*** (1898 ff.), the ***Deutsche Nationalbibliographie*** (1931 ff.) and the ***British National Bibliography*** **(1950 ff.).**

Development of copyright law. Copyright, too, underwent considerable development. By the end of the century, most countries had some provision, and various terms of protection were tried, running from publication or from the date of the author's death. The United States first legislated in 1790, France in 1793, and Germany in 1839. Moves toward an international code began in 1828 with Denmark. They took the form of reciprocal treaty arrangements between individual countries by which foreign authors received the same protection as did native authors. Britain joined the movement in several arrangements between 1844 and 1886. In 1885 a uniform international system of copyright was initiated by the Berne Convention, which is still in force. The customary term of protection is the author's lifetime plus 50 years. Most countries subscribed to the Convention, but not the United States or Russia. The United States continued to protect its domestic printing industry up to 1955, when it joined the Universal Copyright Convention (UNESCO 1952). While the Berne Convention prescribed a minimum level of protection, the Universal Convention was based on the concept of "national treatment"—each member country treating works by citizens of other member countries as it would those of its own citizens. Thus the United States was able to enter into an international agreement without the necessity of immediately revising its own copyright law. Since the Universal Convention contained a provision that the Convention would not be applicable between any two countries that belonged to the Berne Union, it served primarily as a treaty between the United States and the countries that recognized international copyright. The Soviet Union became a party to the Berne Convention in 1973.

International copyright code

The 20th century. In the 20th century the effects of state education in the more advanced countries became increasingly apparent. Standards of living rose, and as in earlier times, these two conditions brought increased use and publication of books. During the late 1890s and the early years of the new century many new publishing houses were founded. In the industrialized countries, though wages were rising, a small business could be staffed economically, and printing costs were such that it was economically feasible to print as few as 1,000 copies of a new book. It was thus comparatively easy to make a start, especially because the long-term credit that printers were prepared to grant made a minimum of capital necessary.

Book publishing grew to a substantial industry, consisting mostly of small units in the Western world but also embracing a number of large concerns, many of which were public companies employing staffs of 1,000 or more. Specialization became frequent, particularly in educational books, as the potentialities of the new school populations were realized. Some, such as Macmillan, in both their British and U.S. houses, had begun to issue schoolbooks almost by chance; then, as their sales grew most profitably, they developed separate departments for lower school and college textbooks. Others, such as The American Book Company, and Methuen in London, had begun specifically with educational books in mind. For more than one leading London firm, India, despite its high illiteracy rate, began to grow strongly as a market and to repay the care and expense involved in setting up separate Indian branches.

Textbook publishing

The first literary agents. A new factor at this time, which was to change the financial climate for fiction publishers in particular, was the advent of the literary agent. The first agent began business in 1875, and between 1900 and 1914 many more appeared. Reasonable though it was that authors who were unable themselves to handle their business with publishers satisfactorily should employ a professional to bargain for them, the higher rates of royalty and larger advance payments thus secured cut seriously into a publisher's profit, making it considerably more difficult to finance the most speculative part of the business, the encouragement of new talent. The system of literary agents began in England but spread rapidly to the United States and also to Continental countries, though in the latter it did not assume so great an importance. Keenly resented at first, the literary agent, by pressing for higher payment to authors he represented, may have been indirectly responsible for the greater selling efforts that some publishers began to make early in the century.

Sales methods. The discreet sales methods of the 19th century, whereby the traveller merely showed his samples and the publisher took small spaces in newspapers for the bare announcement of title and author of his new books, were replaced by more forceful techniques. In this United States publishers took a prominent part. Less hampered by inhibitions over the more blatant forms of salesmanship than their European colleagues, New York City houses began to take large advertisements, make extravagant claims for the qualities of their books, and thus build up bigger sales for new books than was customary in other countries. As in Britain, the existence of a prosperous middle class with fast-growing incomes was one factor; the vast spread of the population across the continent was another. These factors, combined with the development of the railroad, led to the successful development of mail-order advertising and selling. The sale of books such as works of reference by subscription was another technique that rapidly developed and grew into business worth millions of dollars in the United States and elsewhere. It involved securing an undertaking to buy

Installment selling of books

on installments over many months an already published set of books; it could also be used to secure advance orders for an expensive work, probably in several volumes, that the publisher was planning to issue, as was sometimes done in the 18th century. Continental countries, too, exploited the method; and considerable use was made of the door-to-door canvasser.

Effects of World War I. The coming of war in 1914 naturally had a disrupting, though not wholly destructive, effect upon book publishing in European countries. Shortage of paper necessitated rationing to two-thirds of prewar consumption in the case of Britain, while from hundreds of thousands of those in the armed forces came a tremendous demand for light reading. Although at one time the cost of paper rose to eight times its prewar level, sales of books increased sharply. The extra quantities could be supplied only at the expense of quality, and the standards of paper and binding were appalling. It would have been disastrous for a publisher to be left with large stocks of these books since paper supplies quickly returned to normal after the war, and the poorly produced books became unsalable. Of Continental countries, Germany suffered the worst shortages, though the principal publishers were able to stay in business; a worse ordeal in many respects awaited them with their postwar inflation. In England, by contrast with the situation in World War II, there was reluctance to recognize books as of any special importance to the national effort; virtually no direct use of them was made by the government, and it was not until the last four months of the war that a small proportion of publishers' staffs were granted any relief from compulsory national service.

Loss of purchasing power by the middle class

An immediate aftereffect of the war in Europe was a sharp reduction in the purchasing power of the middle class. Whereas before, in most European countries, a proportion of the educated and professional classes could be relied upon to spend regularly upon new books, high taxation, inflation, and trade depression in the postwar years cut down on spare money. Those publishers who continued to cater only to that public found it increasingly difficult to trade profitably, and many went out of business or were absorbed into larger firms. In the United States, on the other hand, boom conditions in the postwar years produced a still more prosperous and enlarged middle class ready to absorb an increasing supply of books. The number of publishing houses grew; and more and more U.S. authors, such as Sinclair Lewis and Ernest Herningway, found a world market. British and Continental publishers turned more readily than before to New York City in search of fresh talent. Universities also increased in number more rapidly in the United States than elsewhere, producing a larger demand for college textbooks. Publishing them became an immensely important part of the business for many U.S. firms, which in some cases depended upon their college departments to carry other parts of their operation, such as the fiction side.

The book club. A new development of vast potential at this time was the book club, an association of members who undertook to purchase, usually each month, a book selected for them by a committee, the advantage being that the book in question was supplied at a lower price than that at which it could be bought in a bookshop. The scheme, of which an early forerunner was the Swiss Cooperative Movement in about 1900, had obvious attractions for that part of the reading public that had no direct access to a bookseller. The pioneer Book-of-the-Month Club in America (1926) developed a membership that ran into hundreds of thousands, followed by The Literary Guild, its great rival, and specialized book clubs that covered a variety of special reader interests. These clubs were strongly opposed at first by both publishers and booksellers, who disliked the additional emphasis placed upon the potential best seller, but they came to supply a genuine need. They also helped to offset the enormous amount of book borrowing from libraries. From the 1950s onward, however, their popularity was somewhat affected by the availability of inexpensive paperbound books sold in thousands of outlets outside the regular book channels.

Design standards. As noted above, machine production had lowered standards of design. William Morris and his Kelmscott Press, however, had begun to work for better typography and book design in the 1890s; and his example had led to the establishment of other private presses, such as The Doves Press and the Ashendene Press, which produced editions (usually limited) of exceptional beauty, printed on handmade paper. Though aimed essentially at the collector and issued at high prices, such books began to influence the more discerning publisher; and by the 1920s a few firms, such as Alfred Knopf in New York City, Chatto and Windus and Jonathan Cape in London, and the Insel Verlag in Leipzig, were seen to be far ahead of their competitors in their standards of design. With careful planning, skillful selection of type face, and provision of layouts to guide the printer, more and more publishers managed to achieve typographically handsome books at a commercial price. It was all part of the Design in Industry movement, which sought to demonstrate that mass production need not preclude beauty. It should be noted, however, that responsibility for design was passing from the printer to the publisher; as the former, with the growth of his business, became more the industrialist and less the craftsman, the latter realized that he must himself take charge of this aspect of the book.

The Great Depression. The great trade slump that began in October 1929 brought a swift decline in the prosperity of U.S. publishing. By 1931 British publishers could no longer depend upon selling a high proportion of their books to the United States, either in the form of physical copies or by way of a contract conceding the U.S. rights. Though the book trade of Europe proved a little more resilient than some other industries, it passed through a difficult period. Sales declined, profits were negligible, and there were many bankruptcies. Attempts were made to find new outlets for books and fresh ways to attract the public to them. In London an annual Book Exhibition was run by ***The Sunday Times*** from 1933 to 1938; and ***The New York Times*** tried a similar venture in its city. The Germans continued to hold their annual Book Fair in Leipzig, but this was primarily a trade function. Some British newspapers, striving for higher circulations, approached publishers to supply them with huge numbers of their popular books, specially printed, to be given away or sold very cheaply, in exchange for coupons from the papers. Booksellers resented the practice, but for hard-pressed publishers it was financially attractive. In the rather desperate climate of the times, some publishers also spent inordinate amounts on newspaper advertising. Reprint book clubs proliferated too, again to the benefit of the few publishers and authors fortunate enough to secure a choice. In 1932 a valuable innovation that stimulated sales was the Book Token, a form of gift certificate. The invention of an English publisher, Harold Raymond, it was at first opposed by many booksellers; but it went on to become a major factor in Christmas sales, and the system was adopted in other countries and by other trades. It was the complete solution to the problem of a donor who wished to make a gift without knowing the recipient's taste.

Appearance of paperbacks

Even in the depressed conditions, publishers still dreamed of tapping a wider readership. This began to become a reality in 1935, when Allen Lane launched his pioneer Penguin series of paperbacks. It was a risky operation, involving speculatively high initial printings to keep down the unit cost. But despite the strongly held belief that paperbacks would not appeal outside the Continent, where they had sold freely, and the resistance of booksellers, who feared a sharp reduction in their receipts, the new series quickly caught on. They represented unprecedented value at the original price of sixpence, equivalent to the cost of a small item in a variety store. Though printed on cheap paper the books employed good typography—far superior to that of any earlier attempts at paperbacks—and the original cover design was attractive in the bold simplicity of its orange and white stripes. A United States agency was arranged shortly before the war and was later taken over by Victor Weybright, who subsequently established the highly successful New American Library for the mass promotion of paperbacks in the world market.

Nazi persecution of the Jews in the immediate prewar years and the impact of the war itself caused a wave of emigration, from Germany and Austria in particular, which brought fresh publishing talent to both Britain and the United States, as well as to other countries, including Australia. Some of the striking developments in the production of art books, with beautiful coloured illustrations, were a direct result of this movement, which bore its fullest fruit after the war. A curious by-product of the Nazi era was the final disappearance of the Gothic typeface in Germany. In order to take the sensible step of abolishing it, the Nazis decreed in 1941 that ***Fraktur*** was a Jewish invention.

Effects of World War II. The war in 1939 that European publishers had feared would utterly destroy their business proved in many respects less terrible in its effects on books than had been imagined. While the destruction of buildings, plant, and vast stocks of books, most notably in London and later in Leipzig, brought publishing to a standstill for individual firms, the activity as a whole continued. As in 1914, but to an even greater extent, the demand for reading matter, both for instruction and entertainment, grew enormously. The nature of the war, with its long periods of waiting alternating with intense bouts of frenzied activity, both induced the need and provided the opportunity for reading. As a result, book sales in the "free" countries rose to fresh heights. The occupied countries of Europe had to endure censorship and a tight control of materials; but most publishers survived and were swift to renew contacts with London and New York City colleagues immediately after the war.

Wartime paper shortages

In the United States, though they were subject to some shortages and inconvenience, publishers were comparatively untouched by the war, and their business expanded rapidly. In Britain, however, because of the acute pressure on shipping, the import of esparto grass, that essential ingredient for good book papers, was strictly limited; and a publisher's paper ration was reduced to 37½ percent of his prewar annual consumption. By closer setting of type and the use of much thinner paper, the ration was stretched to produce the maximum number of copies; but the final appearance of British books inevitably suffered, and they began to compare very unfavourably with those of the United States.

In countries that suffered severe paper shortage there was, of course, a sharp reduction in the number of new books and in size of editions; consequently, with the increase in demand, the available books were rapidly sold out. The result was an enormous, if illusory, increase of profitability for publishers; and despite heavy wartime taxation they found themselves in far better shape financially than ever before. Instead of holding large, and often very slow-selling, stocks with insufficient cash resources, publishers had little stock but ample cash. Thus "birth control" for new books, so often preached but never practiced, had come about and had undoubted commercial benefits in the short term. There was, too, the marginal advantage that those new authors who were able to secure publication in the war years could be virtually certain that their books would be quickly sold out. In these artificial conditions, many publishers were more prepared to risk the work of an untried author. Against this, however, was the very serious shortage of standard works of every kind, classics and educational and reference books; at one time the cry went up that "Shakespeare is out of print!" While a small extra tonnage of paper was released in England in 1942 for the reprinting of books that were considered "nationally important" in wartime, no one could possibly pretend that there was not a real book famine in most European countries. After the war it took about five years for paper to become reasonably plentiful again. Despite the disruption of the war, however, interest in books had increased enormously; and sales were furthered by the total disappearance or severe rationing in most of the warring countries of so many consumer articles that normally compete with books. Contrary to the fears of many publishers, a new reading public was emerging, and it was not lost in the postwar world.

The postwar period. After the end of the war, there was an awkward year or so of reorganization and anticlimax, when many wartime publications suddenly became unsalable; but then publishing, in almost every country, once more expanded rapidly. People who had been cut off entirely from the rest of the world displayed an immense hunger for the books in English that had appeared during the previous six years. Much new business developed in the sale of the actual books and in translation rights. Such conditions continued at a higher level than they had attained in the 1930s, and they were to be further stimulated with the rise of the Frankfurt Book Fair. Social change came to many countries, bringing a broader spread of purchasing power and above all wider educational opportunity for much of the population. The change was to set book publishing upon a bolder and more adventurous course, turning it from a minor industry into one of sufficient growth and profitability to attract even the professional investors. The steady expansion of publishing in Great Britain after the war is illustrated by the following figures for new books and reprints, which may be compared with the 14,904 produced in 1939: 1947, 13,046; 1957, 20,719; 1967, 29,619; 1971, 32,538; and 1980, 48,158. The trend in the United States has been similar.

Revival of German publishing

A feature of the early postwar years was the remarkable phoenixlike rise of the German book trade, literally from the ashes of the Allied air raids, which had destroyed the principal cities with their publishing offices and printing works. Because Leipzig was in the Russian-controlled zone of Germany, however, the centre of the trade moved to Frankfurt for the first time since about 1650. As part of its drive to become the commercial capital of West Germany, Frankfurt developed its exhibition facilities rapidly. Thus, the book trade fair had ideal conditions in which to thrive. Before 1939 it had been largely a domestic affair at which German publishers displayed their new works to booksellers, with only a small number of foreign publishers participating and those almost entirely Continental; but it has steadily grown to be the greatest meeting place for publishers from all over the world. Each year more firms take stands at the fair, and an enormous amount of reciprocal business is done. It provides unique opportunities for the planning of the lavishly illustrated trade, or general, book aimed at an international market. Such books, known as coproductions, depend upon the printing of a large edition, often 100,000 or more, of the coloured illustrations, which are allocated to the participating firms; each firm then arranges for the translation of the text into its particular language.

Iron Curtain publishing. Behind the Iron Curtain, which was not wholly impenetrable to the book trade, publishing was subjected to a state control similar to that initiated in Soviet Russia in 1917. Very few of the famous publishing houses of Poland and Czechoslovakia remain, and in every case they have become state owned and controlled. The normal pattern is for all books upon a particular group of subjects to be issued from one publishing house. Thus in Hungary of the 18 publishers listed in 1981, the principal ones dealt respectively with science, political history, agriculture, music, belles-lettres, military, and technical subjects. The organization in Romania is similar; but in East Germany it is significant that many of the prewar firms remain, 10 dating back more than 100 years, though all are subject to government control. From such statistics as are available, it would appear that there are many fewer individual publishing houses in the Iron Curtain countries; but their output is large, and the number of copies of each title is probably greater than in Western countries. It may be also that more books are bought annually in Eastern Europe, for there are fewer rival consumer goods there. In 1980 in the Soviet Union 80,700 new books and reprints were issued in 145 languages, almost 90 of them being languages of the Soviet Union. The number of copies of books and pamphlets printed in the Soviet Union in 1980 amounted to 1,760,000,000.

Rise of photocomposition

The Paperback Revolution. Besides the economic and social changes that favoured publishing after 1945, an outburst of knowledge, particularly in science and technology, produced many new subjects, many of them subdivided into the highest degree of specialization, all of which called for new books. The many new universities and colleges of technology that sprang up all over the world formed a strong market for the thousands of college books, which came to make up such a large part of many a publisher's list. At the same time there was a major advance in printing, a break away from the traditional letterpress system dependent upon lead type. Photocomposition (composing of printed matter by photographic means rather than by hand), coupled with offset printing technique, obviated much of the hand work of the earlier methods, improved working speeds, and prevented costs from rising as steeply as they would otherwise have done. The trend was toward giant machines for mass production, giving a favourable price for cases in which 100,000 or more copies were needed. Such giant machines became essential for the printing of paperbacks, but the problem remained of printing economically those "short runs" of 3,000 or so in which new authors, from whom many of the important books of the future must come, are normally tried out. Many find grounds for believing that computer typesetting will help cut costs.

By the early 1950s the Paperback Revolution was well under way. Growing from the prewar Penguins and spreading to many other firms, paperbacks began to proliferate into well-printed, inexpensive books on every conceivable subject. Generally known as Pocket Books on the Continent, they swept the world, converting book borrowers into buyers and creating new book readers on a scale never known before. Their use has been particularly widespread in the developing countries, notably those of Africa. Besides their cheapness, putting books for the first time into the area of impulse buying, and the wide range of first class literature available, the new paperbacks had remarkable ubiquity, being found not only in bookshops but in drugstores, street kiosks, and newsstands in railway stations, airports, and hotel lobbies.

By far the greater number of paperbacks have been reprints of books that have had some success in their original clothbound form. Normally the paperback publisher makes an offer for the rights of the hardcover edition and the royalties are shared between the author and the publisher. The cheapness of the paperback is due essentially to the large number printed, seldom fewer than 30,000 and frequently far more, and not, as is often supposed, to the use of paper instead of a hard cover for the binding. While many of the big paperback houses have produced a certain number of new, hitherto unpublished books, the paperback operation is dependent in the main upon books originating with the conventional publishers. It is a fallacy therefore to suppose that, for all their seeming dominance, the paperback is likely to oust the hardcover book.

Scholarly paperbacks

A smaller selling type of paperback has sprung from the enormous growth in the number of university students all over the world. This is the reissue of works of scholarship, science, religion, literature, and art. Many had been out of print for years, and they had often been issued originally in small editions of no more than 2,000 copies by university presses or other specialized publishers. This great extension of the market began in the United States in the 1950s, with prices ranging from 65 cents to $1.95, at that time unheard-of levels for paperbacks; the idea soon spread to Britain and the Continent. This type of operation has usually remained in the hands of the original publishers of the books, who have developed their own series of "University Paperback Books." It became customary for many new academic books to be issued simultaneously in both cloth (hardcover) editions and as paperbacks, the usual price of the latter being a little more than half that of the cloth edition.

University and government presses. The increase in the number of universities was accompanied, as might be expected, by an increase in the number of university presses. The purpose of the presses, like that of the older ones, is to serve the needs of scholarship, to publish specialized material that a purely commercial firm would find impracticable to handle. Their freedom from the more acute profit-making pressures, often a result of direct subsidies, coupled with their assured, if limited, market, enables many to reach high standards of production and commercial viability. Some of the older establishments, such as the Oxford University Press, are, of course, enormous and profitable organizations with worldwide connections and a large list of more general publications.

Another type of publishing house not usually in direct competition with ordinary firms is the state printing office, which is responsible in many countries for issuing all manner of public and official material. In England, Her Majesty's Stationery Office, originally created in 1786 to coordinate office supplies for government departments, has come to issue a wide range of excellent books and pamphlets in connection with museums, galleries, and the advisory function of ministries, besides official papers. In the United States, the Government Printing Office in Washington, D.C., was set up by Congress in 1860 for similar purposes; it too has steadily widened its field of operations. The Soviet Union and China have similar organizations to issue their publications.

The censorship problem. Since 1900 the more overt forms of censorship have continued to wane in the West, though they have never wholly disappeared. The last vestiges of formal religious censorship came to an end in 1966, when the Second Vatican Council decreed that the Roman Catholic Index was not to be renewed. There has been, however, a fierce recrudescence of political or ideological censorship, especially in Germany under the Nazis and in Communist-dominated areas. An intractable problem in the mid-20th century is censorship on moral grounds, with reference in particular to "obscene publications." The pressures tend to be covert and dependent on the prevailing moral climate. This situation leaves a publisher in the invidious position of being forced, on occasion, to risk the outcome of a prosecution. Short of complete freedom, for which the case remains as strong as ever, there seems to be no satisfactory solution.

Despite some pessimistic prophets, books seem unlikely to be supplanted in the foreseeable future. They have already survived several threats—*e.g.*, from radio and television—and have in fact gone from strength to strength. A new threat comes from alternative, electronic methods of storing and presenting information. Some publishers view this rival seriously enough to acquire active interests in the cassette business, for instance. Yet this action is usually taken more as a diversifying operation, to broaden the publisher's base, than from the conviction that books are dying. For convenient, portable availability, nothing compares with a book. Nor is there any pleasure, for a large proportion of mankind, that is capable of replacing the reflective, interior communion that only a book can offer.

Role of the editor

Current publishing practice. Every publishing house has its manufacturing, marketing, and accounts departments, but the heart of the business lies in the editorial function. This has changed in its mode of operation over the years and still varies from one country to another and between firms, but not in essentials. The editor, or sponsor as he is sometimes called, who is often a director, selects the books to be published, deals with the author, and is responsible for the critical reading of the typescript (and its revision if necessary) and for seeing the book through the press, in consultation with the manufacturing and marketing departments. So vital can the editor's part be that his presence in a firm, or his transference to another, can be a major factor in attracting authors to it. In a firm of some size, the editor travels extensively, with regular visits to London, New York City, and other principal cities of the world being as much a part of the work as the quieter but equally demanding desk work upon which the quality of the published book may ultimately depend. A particular branch of editorial work that has grown to be of cardinal importance since World War II concerns the conception, planning, and publication of the hundreds of books needed for the educational schemes, at every level, that have been initiated in the developing countries. From Britain in particular, but also from other former colonial powers and the United States, editors specializing in school and college books have made long journeys to visit teachers and lecturers to promote the writing of the required textbooks. The educational editor has to concentrate almost wholly upon the commissioning of books to fit a particular syllabus in a school or university. Rarely, if ever, does the editor receive an unsolicited typescript that can be accepted at once. The editor must seek material by regular visits, either personally or by one of his assistants, to schools or colleges to find the teachers who have the makings of authorship. Capable teachers often fail to produce a usable book at the first attempt, and much time must then be spent on its revision. The school book that is widely adopted may sell for a generation and reward author and publisher on a scale beyond the dreams of those concerned only with general books. Equally, nothing can fail so completely as the school book that gets no adoptions. Besides the editor as described, there is also the editorial department, which is responsible for the detailed preparation of the typescript before it is printed. This receives more attention today than it used to. Facts, figures, and references are checked, and inelegancies of style are polished where necessary. Many authors owe much more to the work of a good editor at this level than is generally acknowledged.

Subsidiary rights

Broadcast and television rights

Remote copying

Forms of copyright. Book publishing depends fundamentally on copyright (see above), which is the sole right to copy or to produce a work, conceded to the publisher by the author in their mutual agreement. Without this element of monopoly it would be impossible for a publisher to trade. It is also the guarantee for an author that he has legal rights to prevent the use of his material without fair compensation. On the expiration of copyright, anyone is free to publish the work in question without payment to the author or his heirs. Copyright used to be simple and indivisible; nowadays, however, there are many alternative forms in which the text may be reproduced. Their exploitation is governed by individual clauses in the agreement. These subsidiary rights may be briefly summarized. American rights for a British publisher and British rights for a book of American origin can prove to be exceptionally profitable. Though a book normally has its greatest sale in its country of origin, there are cases in which it does even better abroad. The richness of the U.S. market gives it a particular attraction for publishers and authors of almost every other country. Translation rights have become a valuable source of additional revenue, particularly since the establishment of the Berne Convention. All the signatory countries agreed to copyright protection for the unpublished works of nationals of other member countries and for all the work first published in the Convention countries. While many books may earn no more than a few hundred dollars from the rights of translation in a single country, some world best-sellers, by authors of international stature, have a demand in almost every country, new or old, for a translation, and the aggregate earnings are then immense. Paperback rights for the more salable books, whether fiction or fact, are customarily offered to one of the major paperback houses, which flourish in most larger countries. For a best-seller there can be keen competition between the paperback houses, and advances well into seven figures may be offered to the original publisher, who normally controls the reprint rights. The original publisher also stipulates the earliest date at which the paperback may appear; as a rule, this is not less than 12 months after first publication. Serial rights may be sold in several divisions: first serial rights, for which the best price can be obtained probably from a large circulation newspaper or magazine in the capital city, can be in a number of installments appearing several weeks ahead of the issue of the book, or such publication may "straddle" the appearance of the book, some installments before, the rest after. Second serial rights, for which much less is paid, can still yield useful sums: after first serialization has taken place, lesser papers in other parts of the country, or in other countries where the same language is spoken, can use the book. While no publisher would lightly set aside a rich offer for first serial rights, it is often a question whether such publication may not damage the sales of the book. On the other hand, the sum paid can be the equivalent of royalty earnings on many, many thousands of copies, which might in fact never have sold. Digest rights, and their allied condensed book rights, represent another lucrative subsidiary use for books of wide general appeal. ***The Reader's Digest*** in the United States, with its great circulation and numerous foreign language editions, is the most important market for such rights; large sums are paid for the books thus used. Again, a publisher must face the likelihood that this use will seriously affect sales, but the handsome payments made are full compensation for both the publisher and the author, who divide the receipts more or less equally between them. Book club rights are also among those the publisher can exploit; here again, fees received from the clubs are shared with the author. Broadcast and television rights in books interest a publisher primarily for the possibility of bringing a book and its author to the attention of a large segment of the public, rather than for the amounts paid. As a rule, there must be direct quotation from the text if a broadcasting company is to pay anything to the publisher. A television interview with the author, including sight of a copy of the book, is of great publicity value, and the author may even receive a fee for the appearance, but this is not part of the book's earnings. If the author can show a film relating to the book, it would be paid for at the appropriate rates for television use. In sound broadcasting, the reading of a book as a serial is one most remunerative possibility; the other is its full dramatization as a serial. The latter is, of course, still more valuable on television, but such use of new books is rare; more commonly this treatment is accorded to works of classic status. Dramatic and film rights can have importance for fiction, biography, and other general books, but only a small fraction of one percent of those published can be exploited by these means. From the publisher's standpoint, it is reasonable to share in the proceeds from the sale of these rights, for they result from the publisher's efforts. The last group of subsidiary rights, rights for mechanical reproduction by film micrography, xerography, tape or disc recording, or any other technique of sight or sound, are of increasing concern to publishers. Dry-copying machines, easily operated, are to be found all over the world in public, university, and school libraries, and while ordinarily only single copies can legally be made solely for the purposes of private study, it is a simple matter, though illegal, to run off a number of copies of long extracts, which then make it unnecessary to buy more than one copy of the book. Similarly, microfilm enables a single copy to satisfy many users and reduces the number of copies of the book that must be kept available in a library. Remote copying appears likely to make certain types of scholarly and reference publications unnecessary. A perfect copy of the material in question has merely to be held at a central station, from which it can be reproduced on a copying machine at other and distant points; ***e.g.,*** in public libraries. The situation could even arise in which a primary copyright resided in an electronic store of a computer, and the publisher would receive "subsidiary" volume rights. Wherever material originates in the form of a book, however, the publisher must retain an interest in all forms of reproduction as part of his resources for promoting experimental and imaginative work.

Publisher's agreement. A publisher's agreement with an author normally specifies that in consideration of certain payments the former shall, during the legal term of copyright, have the exclusive right to produce or reproduce the said work in any material legible form throughout the world. In many cases, however, this agreement is modified to exclude some of the subsidiary rights named above, depending on the bargaining power of the author or his agent. After clauses specifying the extent of the rights conferred, the basic clause of a royalty agreement is that which states the rate of royalty to be paid. A typical wording is as follows: "On all copies of the said work sold on the normal terms a royalty of 10 percent shall be paid on the published price rising to 12 percent after the sale of 5,000 copies and to 15 percent after 10,000 copies." Other clauses provide for somewhat lower royalty rates on export sales and on cheap editions, on which the publisher's margin of profit is considerably less. Provision is also made for division between author and publisher of any payments received for such subsidiary rights as are included in the agreement. A publisher can fairly claim a share in them if they arise from the fact of book publication. Proofreading is another important matter covered by the agreement, the author being responsible for this. If the cost of making his corrections exceeds a stated figure, he has to pay for the excess. Lastly, in the majority of publishing agreements there is an option clause under which the author undertakes to give the publisher the first offer of his "next literary work suitable for publication in book form," usually with the addition that if, after a stipulated time, no terms shall have been agreed on for its publication the author is free to submit it elsewhere. The exact form of the legal instrument varies in detail; it is possibly drawn up in the greatest detail by U.S. firms because of the complexities of their system of selling: *e.g.*, by mail order, subscription, and similar means, in which the publisher must incur abnormal costs in order to secure the business. The vital condition for this publisher–author relationship, in the past often conducted with complete informality, is that there must be a legal document, a contract, setting out the rights and obligations of the two parties.

Literary agents and scouts. Several references have already been made to literary agents. They have become increasingly important and prominent as publishing has grown more complex. A high proportion of the more successful authors of novels and general books employ literary agents to place their books with publishers and to handle negotiations with them, the author being charged a commission of 10 percent. Besides negotiating and drawing up the contract with the firm, the good agency is equipped to handle the many subsidiary rights. Because an important element in the value of agents to authors is their capacity to extract better terms than the authors would themselves, it is not surprising that publishers have resented their intrusion into the personal, and often very friendly, relationships between themselves and their authors. There can be no doubt, however, that agents do perform a valuable service in relieving authors of the considerable amount of routine work that their literary affairs may involve. Advice on possible new books to be written and occasionally, for the author of exceptional promise, an advance on anticipated earnings are also part of the assistance that the agent may offer. It must be emphasized, however, that agents are interested mainly in general books; they are seldom equipped to handle specialized and technical works.

Literary scouts

Another publishing auxiliary who became significant in the 1950s and 1960s is the literary scout. Though a few had been employed earlier, mainly by U.S. publishers, who had their "lookouts" in one or two European cities, the practice has become more widespread. Many Continental publishers, including Scandinavian firms, employ men or women resident in London, Paris, and New York City to alert them at once to any promising new book, either written or just published. The scouts, who may be connected with a newspaper or literary agency, are usually paid some modest amount as a retainer, probably with a commission of 1 or 2 percent on the published price of the books they recommend, in effect a small royalty on sales. On occasion a valuable find can be quite lucrative to the lucky scout; frequently everything depends upon the speed with which a copy of the work can be got into the hands of the publisher.

Selling and promotion. The publisher's techniques for the promotion of his wares have become increasingly sophisticated in all advanced countries. Typical travellers or booksellers are likely to have college educations, certainly in the United States; they set out only after careful briefing at their home office, with elaborate samples and sales aids, often in a car provided, or partly provided, by the firm. The itinerary for their calls on bookshops (or in the case of educational books to schools and colleges) is prescribed by a supervisor, who usually checks the resulting orders against a quota. A well-run publishing house issues two or three seasonal announcement lists with details of its forthcoming books, as well as an annual catalogue of its present and past books still in print, which are sent to the principal booksellers and librarians. For many books a prospectus may be issued, both for the use of booksellers and for direct mailing by the publisher. The distribution of review copies to the press is the last item in the normal program. These three steps, travelling, catalogues, and reviews, are the vital elements in the machinery of book distribution, which it is virtually impossible to accomplish without the professional work of a publisher. The capacity of some authors to produce a quite presentable book with the help of a printer still leaves them far from their objective unless they can find a publisher to undertake its distribution.

Book advertising

Newspaper and periodical advertising is the publisher's principal means of reaching the public, and standards here have also risen considerably since World War II. Originally handled entirely by the publisher's own staff, it is now not uncommon for the larger houses, especially in the United States and in some Continental countries, to employ advertising agencies to prepare the copy and the general details of the campaign for any important book. While few authors consider that their books are advertised adequately and most publishers are highly doubtful whether press advertising does in fact sell books, the amounts spent in relation to sales revenue are much higher than for most other commodities, seldom less than 5 percent for new books. Without their receipts from publishers' advertising, some periodicals would find it impossible to devote so much space to book reviews, which are in themselves a most valuable aid to sales. The news value of many new books also enables them to secure free publicity through references in the general, as distinct from the literary, pages of a newspaper. A publisher with imagination, or the press officer if there is one, can often suggest aspects of a book susceptible to such treatment. Broadcasting and television services, too, can sometimes be interested in books and their authors, and the resultant publicity may then be extremely effective.

Over the whole field of sales promotion, as publishing houses have grown in size and profitability, there has been a marked tendency for the more commercial methods of general business to be applied to books, which are aggressively promoted to retailers and the public in the same manner as are many other commodities. Though this may increase sales, at least in the short term, it may be doubted whether it is in the interests of the public and to the long-term advantage of good publishing.

II. Newspaper publishing

ORIGINS AND EARLY EVIDENCES

If the essence of a newspaper is the regular publishing of information about recent events, then something of the kind must be as old as civilization. "A community needs news," said the distinguished English author Dame Rebecca West, "for the same reason that a man needs eyes. It has to see where it is going." But there is a gulf between all the early methods of spreading news, such as public announcements by a town crier, the posting of proclamations, or the private circulation of newsletters, and a modern daily paper. The variety and amount of the information, the regularity and speed with which it is published, and the number of people it reaches have grown in ways undreamed of a century ago. This has come about largely through technical developments in printing and communications, but it has involved also a radical change of outlook. Those to whom news is especially important (that is, governments and commercial interests) have always had their own ways of gathering intelligence; but they use it for their own ends and only make public what they choose and in the manner they choose. Until the invention of printing, the public at large had to take what little it was given or make what it could of rumour and hearsay. Printing, however, by offering a powerful new

The public right to know

means of spreading news, eventually gave rise to a powerful new idea: that the public was in a fundamental sense entitled to know—to know, not merely from official or interest& sources but from a free and voluntary source with an ethic of its own, responsible to the public itself, both for standards of truth and for completeness of information, and to know, not merely to satisfy curiosity but also as a means of participating in public affairs. The growth of this idea, the attempts to realize it through newspapers, and the limitations imposed by the forces of authority, ideology, and economics (not to mention human frailty) make up the history of the press. It has been closely bound up with the growth or suppression of democratic ideas. Though the small Athenian democracy could rely on word of mouth to create public awareness, a large modem state depends on its press; and so the freedom and quality of its press have become sure indications of the freedom and quality of a state. Nor has this situation been greatly changed since the advent of radio and television.

The *Acta Diurna* of ancient Rome

Rome. Whatever methods of spreading news there may have been in the oldest civilizations, the earliest of which there are definite facts date from ancient Rome, where a form of gazette was published daily from 59 BC called the ***Acta Diurna.*** Copies of it, written in manuscript, appear to have been hung in prominent places in Rome as well as in the provinces; its origin is attributed to Julius Caesar. The "gazette" recorded important social and political events: plebiscites, public appointments, edicts, treaties, trials and executions, naval and military news, births, marriages, and deaths; anything of special interest, such as the fall of a meteorite or similar portents; and even sports news—*i.e.*, the outcome of gladiatorial contests. The ***Acta Diurna*** were, of course, official notifications from the various authorities and not news gathered freely and independently. They were complementary, for the public at large, to the ***Acta Senatus,*** which recorded the proceedings of the Roman Senate and could be consulted by senators. In addition, the Romans were the first to cultivate the art of general correspondence; and the newsletter, as opposed to the family letter or letter of condolence, was a recognized type.

China. The only other really early approach to a newspaper seems to have existed in China. This too was an authorized gazette, a kind of court circular, ***pao,*** or "report," which began to be issued among officials in the T'ang dynasty (AD 618–907). It appeared in various forms and under various names more or less continually to the end of the Ch'ing dynasty in 1911. Under the Sung dynasty (960–1279), it was known as ***Ti-pao,*** "Palace Report," or ***Ti-chan,*** "Court-Reading-Matter." During the Ming dynasty (1368–1644), there was a government bureau called ***T'ung-cheng-ssu,*** responsible for circulating official news, and this was also the name of its bulletin. Finally, under the Ch'ing (Manchu; 1644–1911), the circular was known as ***King-pao,*** and as the ***Peking Gazette.*** It was handwritten or printed from blocks up to the 17th century, when it began to be printed from wooden type. Though essentially a means of communication among officials, it reflected the accomplishments of the mandarin class.

BEGINNINGS IN EUROPE, AMERICA, AND ASIA: 1400–1800

The development of the newspaper tends to fall into three phases: first, sporadic forerunners, gradually moving toward regularity of appearance; second, more or less regular journals, liable to suppression and subject to censorship and licensing; and, third, a phase in which direct censorship is abandoned but attempts at control continue through taxation, bribery, and prosecution. Thereafter, some degree of independence has followed in favourable circumstances.

Manuscript newsletters

Forerunners of the newspaper. The earliest forerunner was the manuscript newsletter, containing political and commercial information, which was circulated in the late Middle Ages between the various branches of the large trading companies. The newsletters of the financial house of the Fuggers of Augsburg were particularly well known and available even to selected outsiders. Venice, as an important centre of commerce, was also a great centre for newsletters. During the war with Turkey in 1563, the Venetian government issued regular ***fogli d'avvisi,*** or written newssheets which were read aloud in public. Since the cost of admission to a reading was a ***gazeta*** (approximately three-fourths of a penny), this became a common term for such official sheets, even after copies were printed and sold.

Another forerunner was the printed news book or news pamphlet, which usually related some single topical event, political, scandalous, or marvellous. The earliest example known in England is a pamphlet of four leaves printed by Richard Fawkes, known as ***The trew encountre,*** an eyewitness account of the Battle of Flodden Field, with a list of Englishmen who distinguished themselves. It appeared in September 1513, soon after the battle. There were many such pamphlets on the Continent. As early as 1566 in Strassburg and Basel, some were numbered and thus members of a series. In England these pamphlets became more frequent toward the end of the century; about 450 were published between 1590 and 1610. In addition, monthly, half-yearly, and yearly summaries of news began to appear. One of the earliest was the ***Mercurius Gallobelgicus,*** which was issued yearly in Latin from 1594 to 1635. This was the first publication to adopt the name Mercury (the messenger of the gods), which later became popular almost everywhere.

The first true newspapers. Publications usually regarded as the first true newspapers because they combined miscellaneous topical information with some pretensions to regular, periodic appearance began in 1605–10. Possibly the earliest was the ***Nieuwe Tijdinghen,*** published from 1605 onward in Antwerp by Abraham Verhoeven, though the oldest known copy dates only from 1621. It seems to have grown from a commercial bulletin, the ***Courante Bladen,*** which circulated among the merchants of Antwerp and Venice. Three other very early papers, like many of the forerunners, were German: the ***Avisa*** (later ***Aviso***) ***Relation oder Zeitung*** (1609), founded by Duke Heinrich Julius of Brunswick-Wolfenbuttel and printed at Wolfenbüttel; ***The Relation,*** also in 1609, printed by Johann Carolus in Strassburg; and the ***Gedenckwürdige Zeitung*** (1610) of Cologne. The Dutch, as great traders with plenty of foreign correspondents to supply them with intelligence, were not far behind in publishing these "corantos," as they were called ("currents of news"; ***krant*** is still a common name for a Dutch newspaper). The ***Courante uyt Italien*** and ***Courante uyt Duytslandt*** began publication in 1618 and the ***Tijdinghen uyt verscheyde Quartiere*** in 1619, once or twice a week. The first coranto in English was a translation from the Dutch published in Amsterdam in 1620 by Pieter van den Keere. Corantos in French also appeared in Amsterdam in 1620, though not in France until 1631, when the ***Nouvelles ordinaires de divers endroits*** was produced by the Parisian booksellers Louys Vendosme and Jean Martin. In the same year, however, it was superseded by the official ***La Gazette*** (later ***Gazette de France),*** published by Théophraste Renaudot under the patronage of the cardinal de Richelieu. Many other European countries had their first rudimentary newspaper in the 17th century: Switzerland (1610), Austria (1620), Denmark (1634), Italy (1636), Sweden (1645), and Poland (1661).

Dutch "corantos"

England. In England corantos first appeared in 1621. From references in letters of the time, the earliest seem to have been issued by a London stationer, Thomas Archer; but they were unauthorized, and Archer was imprisoned for his pains. Another stationer, Nathaniel Butter, "got licence to print them honestly translated out of the Dutch"; thus he and not Archer is usually regarded as the father of English journalism. The first to appear was a small sheet published in London on September 24, called a ***Corante, or newes from Italy, Germany, Hungarie, Spaine and France, 1621.*** Between 1621 and 1641 Nathaniel Butter, often in conjunction with Archer, Nicholas Boume, and others, was the main publisher of a stream of corantos, relations, and avisos. These included a numbered and dated series of ***Weekley Newes,*** beginning in 1622. This was far from regular, however, since it

depended on the arrival of boats. Domestic news was confined by censorship to trivialities, and even the foreign news got the publishers into trouble. In reporting the progress of the Thirty Years' War, their partiality for the anti-imperial forces brought complaints from Spain and Austria and upset Charles I. As a result, all news books were suppressed by a decree of Star Chamber, from October 17, 1632, until the lifting of the ban on December 20, 1638. During this period, the demand for foreign news, especially of the campaigns of Gustavus Adolphus, was met partly by corantos printed in Amsterdam and partly by a half-yearly compilation brought out by Butter and Bourne, called *The Swedish Intelligencer.*

The English *Mercurius*

After the abolition of Star Chamber in 1641, the English press had a short spell of freedom, and domestic news at last began to appear. At the same time, the news book finally became a newspaper in form. Under pressure on space and the urgency of events, the old title page and its blank verso (underside) were dropped. The news began directly beneath the title, which was now constant; and aeries became increasingly regular, numbered, and dated. It has been estimated that between 1640 and 1660, nearly 300 distinct news publications were brought out. Many of these were occasional papers reporting the English Civil War, such as *News from Hull* or *Truths from York;* but there were also the propaganda papers on each side, mostly weekly but becoming more frequent. Mercuries abounded; the *Mercurius Aulicus,* followed by the *Mercurius Academicus* on the Royalist side and the *Mercurius Civicus* and *Mercurius Britannicus* (the second of this title; the first in 1625–27) on the side of Parliament. The *Mercurius Civicus* was the first paper to use illustration at all regularly. After the Mercuries came the *Intelligencers, Scouts, Spies,* and *Posts.* Then, under Cromwell (1649–58), strict control was reimposed, and only two official publications were permitted—the *Mercurius Politicus* (which Milton edited for a time) and the *Publick Intelligencer—both* run by Marchmont Needham. When the move to restore the monarchy began, these were superseded by two more official papers, *The Parliamentary Intelligencer* (later *The Kingdom's Intelligencer*) and the *Mercurius Publicus,* both started in 1659 by Henry Muddiman, who was to become the best known journalist of the century. With the Licensing Act of 1662, control became tighter still; and in 1663 Roger L'Estrange was appointed surveyor of the press, with the sole privilege of publishing newspapers; his two were the *Intelligencer* and the *Newes.* L'Estrange soon fell out of favour, however, and in 1665 Muddiman was licensed to start the official *Oxford Gazette,* so called because the court had removed to Oxford to escape the plague. When it returned to London, the paper became the *London Gazette* (1666), under which name it has continued to appear ever since, on Tuesdays and Fridays, though it now contains only public appointments and announcements.

As censorship slackened after the revolution of 1688 and the Licensing Act was allowed to lapse (1694), the English press began to expand and move into its second phase. In 1690, the first provincial paper was started, the *Worcester Post Man* (later *Berrow's Worcester Journal)* and, in 1699, the first in Scotland, the *Edinburgh Gazette;* others followed, mostly biweekly. In 1696, Edward Lloyd, whose coffeehouse had become a centre of marine insurance, began to issue *Lloyd's News,* a single sheet with both general and shipping news. After offending the House of Lords in 1697, he stopped publication rather than apologize but restarted in 1726 what became in 1734 *Lloyd's List and Shipping Gazette,* London's oldest newspaper still in existence. The improvement in packet and post systems after 1691 led to the start of daily papers, which eventually replaced the biweeklies and triweeklies. The first was *The Daily Courant,* a single sheet 13¼ by seven inches (34 by 18 centimetres), begun on March 11, 1702, and lasting until 1735. Like the old corantos, it consisted largely of extracts from foreign journals. The regular voicing of opinion on current political topics and thus the start of the leading article, or editorial, began with Daniel Defoe, in his triweekly *Review* (1704–13), which he wrote almost entirely himself. Finally, the social, artistic, and entertaining aspects of the newspaper got off to a magnificent start with the famous *Tatler* (triweekly, 1709–11) and *Spectator* (daily, 1711–12), both at one penny, the first begun by Sir Richard Steele, the second by Steele and Joseph Addison. These had a tremendous influence, especially on the development of the magazine (see the section of this article entitled *Magazine publishing)*; *The Spectator's* subscribers often numbered as many as 3,000.

The Tatler and *The Spectator*

The nascent power of the press was bound to disturb the government. In 1712 an attempt was made to curb it with the notorious Stamp Act. This imposed a duty of one-half penny on every periodical of half a sheet and one penny on every whole sheet (*i.e.,* four pages). In addition, a duty was levied on advertisements, which had already become a valuable source of revenue to newspapers; and there was an excise on paper. These "taxes on knowledge," as they came to be called, had the desired effect of at once killing off many newspapers, including *The Spectator;* but their effect was only temporary. Despite various increases in the rates the number of newspapers grew throughout the century. To defend itself against attacks—Whig and Tory could be equally scurrilous and venomous—the government relied partly on organs of its own, or on those it subsidized, and partly on bribery. Secret handouts to journalists or regular annual stipends were taken for granted right down to the Reform Act of 1832. For anything really "obnoxious," the government's powers of arrest and seizure of papers and type under the law of libel were still all too ample. Among countless examples, Daniel Defoe was imprisoned and pilloried in 1702 for his pamphlet "The Shortest-Way With The Dissenters"; and as late as 1810 William Cobbett was imprisoned and fined for denouncing flogging in the army. A great fighter for the freedom of the press was John Wilkes, who founded the *North Briton* in 1762 to attack the government of Lord Bute. Wilkes was also involved in the struggle for the full right of juries to decide libel cases (instead of the judge) and for the right to report the proceedings of the houses of Parliament. The latter were regarded as privileged, and only the bare votes were allowed to appear. Before long, however, discreet accounts of debates began to be published in *The Political State of Great Britain* (1711–40), which appeared monthly, and these were developed by several journals, often under a transparent disguise. Fulminations and prosecutions failed to stop them, and in 1771 Parliament was forced to concede this important right.

Improvements in typography

Of the many newspapers that came and went in 18th-century London, the steadiest was probably *The Daily Advertiser* (1730–1807), which offered a good news service, political, social, and commercial news, and plenty of advertising space. One of the longest lived foundations was the *Morning Post* (1772–1937), which finally merged with the *Daily Telegraph.* It was started by a remarkable publisher, John Bell, who in one of his other papers, *The World* (1787), revolutionized newspaper typography and layout. *The World* was printed in Bell's own type and was the first paper to allow sufficient space between lines of type for ease of reading; it also abolished the long "s," the symbol used up until then for the letter "s." Its style was copied at once and in full by the *Daily Universal Register,* the paper founded in 1785 by John Walter, which in 1788 assumed its rather more familiar name, *The Times.* Perhaps typically, however, *The Times* retained the long "s" until 1803. One other distinguished paper of the period was *The Observer* (1791), a "quality" Sunday paper that is still flourishing. In 1795, a circulation of 2,000 was regarded as good; the *Morning Post* was down to 350, but *The Times* had risen to 4,800.

The European continent. On the Continent, the authoritarian phase lasted longer and was more stringent than in England. In France, apart from the official *Gazette de France* (1631–1914), the only pre-Revolution papers of any consequence were the weekly *Mercure de France* (1672–1853, originally founded as the *Mercure galant*), which was more of a magazine (see below); and the first daily, the *Journal de Paris,* which was not started

Paris' Revolutionary papers

until 1777. Those responsible for clandestine papers were persecuted without mercy. During the Revolution, the number of papers in Paris rose to 350; but under the consulate they dropped back to 13 and under the empire to only four. The *Journal des Débats* (1789–1944), a daily founded by François Jean Badouin to report the sessions of the National Assembly, managed to maintain a moderate, liberal line under all regimes. Under Napoleon, *Le Moniteur Universel* (1789–1869), founded by the bookseller Panckoucke, became the official organ. In Germany most cities had incipient newspapers in the early 17th century, but the Thirty Years' War set them back to little more than fly sheets. When they developed again and increased in number, few were of great quality. Among the exceptions were the *Augsburger Zeitung* (1689), the *Hamburgische Correspondent* (1714), and, in Berlin, the *Vossische Zeitung* (1705) and the *Spener'sche Zeitung* (1749), the latter surviving to 1827 as the *Berlinische Nachrichten von Staats und Gelehrten Sachen.* Censorship, though it varied and fluctuated, was, of course, general all over Europe. The first country to have a law guaranteeing freedom of the press was Sweden, as early as 1766. The official Swedish gazette, the *Post och inrikes tidningar,* is also the oldest continuously published paper; it was started as a weekly, the *Ordinarii post tijdender,* in 1645. The world's oldest daily still in existence is usually considered to be the Austrian *Wiener Zeitung,* which goes back, under different names, to 1703.

United States. In North America, where the newspaper was to acquire so much of its modern character, its beginning was entirely typical. In Boston in 1690, Benjamin Harris, a radical from London, issued No. 1 of *Publick Occurrences Both Forreign and Domestick,* intending to continue monthly. It was at once suppressed by the Governor of Massachusetts. Under the colonial governments, there was no question of free printing or even free speech. News was spread via proclamations and pamphlets and by newsletters and papers from London. Though printing had begun in America as early as 1638, the first regular paper did not appear until 1704 and then by the authority of the government. This was the weekly *Boston News-letter,* published by John Campbell, the postmaster, and distributed without mailing charge as a public service. A change of postmaster led to a fresh paper, the *Boston Gazette* (1719), printed by James Franklin, elder brother of Benjamin. A further change led James Franklin to start his own paper, the *New-England Courant* (1721), and this marked the beginning of independent journalism in the colonies. Philadelphia had its first paper in 1719, the *American Weekly Mercury,* founded by Andrew Bradford; and New York City's first paper, in 1725, the *New-York Gazette,* was founded by Andrew's father, William Bradford. The other colonies gradually followed; by the start of the War of Independence there were 37 newspapers in America. The colonial printing office, with its multiple functions, became an important centre of community life, a clearinghouse of information, often set up and maintained under great difficulties. Editors cooperated in passing news to each other and were conscious of their role in creating a historical record.

Establishing the right to criticize government

The right to criticize the government was established in 1735, when John Peter Zenger, publisher of the *New-York Weekly Journal* (1733), was acquitted of criminal libel. From then on, the press became increasingly polemical. After the Stamp Act of 1765, newspapers were sharply divided into patriot and royalist, with passions rising high. The Boston Tea Party (1773) is supposed to have been planned in a backroom of the *Boston Gazette,* nicknamed "Monday's Dung Barge" by the royalists. With independence came the first dailies. The *Pennsylvania Evening Post,* founded by Benjamin Towne in 1775 as a triweekly, became a daily in 1783; and the *Pennsylvania Packet,* founded in 1771 by John Dunlap, became the *Pennsylvania Packet, and Daily Advertiser* in 1784, under Dunlap and David C. Claypoole. The first paper to be founded as a daily was the New York City *Daily Advertiser,* in 1785, by Francis Childs. By the end of the century, dailies were general in the larger cities, smaller towns having weeklies. Burning issues in the new republic soon gave rise to a highly partisan national press. On the side of Hamilton and the Federalists was the *Gazette of the United States* (1789–1818), published by John Fenno in New York City and then in Philadelphia; and on the side of Jefferson and the Republicans (later Democrats), the *National Gazette* (1791–93) of Philip Freneau, followed by the *Philadelphia Aurora,* started in 1790 by the grandson of Benjamin Franklin, Benjamin Franklin Bache. William Cobbett was in exile in the United States at this time and publishing *Porcupine's Gazette* (1797–99), in which he maintained the British standpoint. In the First Amendment to the U.S. Constitution, Congress was restrained from in any way "abridging the freedom of speech or of the press." In 1798, under the threat of war with France and the vitriolic tone of the newspapers, the Alien and Sedition Acts were introduced, which involved an element of censorship. But when these expired in 1801, the right to criticize the government was reaffirmed. Since then the press has been subject only to the law of libel.

Japan. Broadsheets called *yomiuri kawara-ban,* published in the Edo period (1603–1867), are regarded as the traditional forerunners of the Japanese newspaper. *Yomiuri* means "selling by reading out loud," which is what the vendors did, and *kawara-ban* describes printing with engraved tile (engraved woodblocks were also used). The artist-writers who produced these broadsheets usually chose anonymity rather than risk open confrontation with shogunate officials enforcing decrees against public discussion of political and social problems. Many *kawara-ban* featured only popular festivals; personal scandals, notably the double suicides fashionable during the Genroku era (1680–1709); and natural disasters. Some, however, dealt with dramatic events, the oldest known example (1615) describing the Battle of Abeno Osaka between the forces of Tokugawa Ieyasu and Toyotomi Hideyori. *Kawara-ban* conveyed the news of Commodore Perry's arrival (1853) to the Japanese public and were still appearing in the first years of the Meiji era.

19TH-CENTURY DEVELOPMENTS

During the 19th century, the newspaper grew to full independence in most literate countries, beginning with Britain and the U.S. At the same time, by broadening its appeal and reducing its price, it began to reach the mass of the population in a way that no other reading matter had ever done before. As a result, it became big business, largely through the value of its advertising revenue.

Technological advances. The impact of technical developments was enormous and many-sided. At the start of the century, when circulations were measured in thousands, newspapers were printed, like books, on the hand-operated, flatbed wooden press. By the end, rising circulations and the drive for ever greater speed had led to the development of highly specialized, reel-fed (web) rotary machines, driven by steam (after 1814) and later electricity (after 1884), which produced hundreds of thousands of cut and folded copies in a matter of hours. Behind this evolution lay numerous other, equally necessary inventions: methods of stereotyping, special inks and inking devices, cheap cellulose paper, and mechanical typecasting and typesetting.

No less startling was the transformation in news-gathering techniques, which occurred because of the invention of the telegraph and the telephone. In 1815, when the mounted courier was the chief means of getting quick news, it was four days before the Battle of Waterloo was reported in London, only 240 miles (390 kilometres) away; and that was a record, set up by the *Morning Chronicle.* After the laying of cables (*e.g.,* Dover–Calais, 1851; transatlantic, 1866), the time lag all but disappeared. Finally, the distribution of the daily newspaper on any great scale would have been impossible without a general speeding up of transport, especially through the railway.

Growth of an independent press. In Europe, the first signs of a move toward popularization appeared in France, with the founding of *La Presse* (1836) by Émile de Girardin, who might be called one of the earliest press magnates. He introduced new methods, serials, and "features" to raise circulation (to as much as 20,000) and to bring down the price of his papers. Also influential in the first half of the century was Louis Désiré Véron, who founded ***Revue de Paris*** (1829), a magazine to encourage new writers, and revived the liberal daily ***Le Constitutionnel*** (1835). French journalism, however, was already characterized by its literary slant; it was to develop little social responsibility until much later. Characteristic, too, was the signed article, made compulsory by the Tanguy Law of 1850, which gave the individual journalist greater prominence than he received elsewhere. In Germany, the press was still severely restricted; but a distinguished daily of some independence was the *Allgemeine Zeitung*, founded in Tiibingen in 1798 by Johann Friedrich Cotta, the publisher of Schiller and Goethe. It soon got into trouble with the authorities and had to move; but it eventually came to rest in Augsburg, where it achieved wide influence. Scandinavia continued to lead the Continent in press freedom. Sweden had long had favourable laws (1766); but its modern press is usually dated from 1830, when Lars Johan Hierta founded *Aftonbladet*, a liberal organ combining good news coverage with lively comment and human-interest material. Denmark enjoyed a similar freedom after 1849, when the nation received a new constitution, which included among its articles the abolition of censorship. Switzerland, too, abolished censorshio with its federal constitution of 1848. Elsewhere in Europe, revolution or threat of revolution caused the authorities to keep the press on a tight rein.

Success of *The Times*

Even in Britain, where the press had largely won its freedom, fear of the spread of revolutionary ideas prompted an increase in the Stamp Tax, in 1815, and the passing of the Six Acts of 1819, considered a high point in legislation restricting the press in England. But despite prosecutions for sedition and blasphemy, publications obnoxious to authority continued to appear; and William Cobbett's radical weekly, ***The Political Register*** (1802–35), had a wide circulation; Cobbett even managed to issue it from prison. The "respectable" press was naturally less affected; and one paper, ***The Times,*** rose to great heights, dwarfing all others. In the 19th century, under the management of its proprietors, John Walter II and John Walter III, and the editorship of two outstanding journalists, Thomas Barnes and John Thaddeus Delane, it kept free of all subsidy and political pressure and became a model of what a responsible, independent newspaper should be: quick and reliable with the news (during the Napoleonic Wars it was often ahead of the government), influential in opinion (it opposed slavery and backed reform), and technically well produced (it led the way in the use of new machinery). Its circulation rose from 5,000 in 1815, when it cost seven pence, to 50,000 in 1850 (price five pence), at a time when its nearest rivals, the ***Morning Advertiser*** and the ***Daily News,*** were selling only 5,000 copies and other dailies a mere 2,000 to 3,000. Its appeal was still limited, being confined to the mercantile middle class, which was just coming into its own; but it demonstrated for the first time the absolute value of journalistic independence.

On the other side of the Atlantic, an independent press developed even more strongly, and there it appealed from the beginning to the mass of the people. In the first part of the century, American newspapers were fiercely partisan and political, and presidents made early and ample use of them; Pres. Andrew Jackson had 60 full-time journalists on the government payroll. It was largely disgust with this party involvement that led James Gordon Bennett, in 1835, to found the *New York* ***Herald,*** with which modern American journalism may be said to begin. It was not the first of the cheap, popular papers, the so-called Penny Press, for Benjamin H. Day had successfully exploited the human-interest formula with his New York *Sun* (1833); but the ***Herald*** was the first to proclaim and maintain complete independence. As Bennett wrote in his prospectus, his paper would support no party; it would endeavour to record facts, "with comments suitable, just, independent, fearless and good-tempered." His public was the teeming immigrant population of New York City, whose significance he grasped and whom he presented with an exciting amalgam of news and views in an unvarnished language they could understand and at a price they could afford. In little over a year, the circulation of the ***New York Herald*** was running at 30,000 to 40,000; and as it prospered, Bennett led the way in rapid news-gathering and efficient production methods. His nearest rival was Horace Greeley, who founded the ***New York Tribune*** (1841). Both men came up the hard way, but where Bennett was primarily an entertainer, Greeley was an idealist and crusader, a fierce opponent of slavery and coiner of the phrase "Go West, young man!" The weekly edition of the ***Tribune*** had a great influence beyond New York City. Bennett and Greeley, with their personal brand of popular journalism, dominated the New York City press for 30 years; but a third paper, of equal independence though less startling character, was the *New* ***York Times*** (1851), co-founded and first edited by Henry Jarvis Raymond. There were, of course, many papers outside New York City, notably the ***National*** *Intelligencer* (1800) in Washington, D.C., the ***Philadelphia*** *Public* ***Ledger*** (1836), and the ***Baltimore Sun*** (1837); by 1850, with the westward expansion of the country, the number of dailies had risen to nearly 400, and the weeklies were correspondingly more numerous. Though the majority of papers continued to be party political organs, Bennett and Greeley and those who followed them had established a firm tradition of journalistic independence.

The newspaper reporter

News gathering. In the early days of journalism, news was gathered by a more or less anonymous system of newsletter writers, agents, and couriers; the key men were inclined to be those at home, who offered their comments on events. As newspapers grew, however, staffs were built up of full-time reporters who were sent out to get the news. This development was greatly stimulated by the several wars of the 19th century, which necessitated special correspondents and drew attention to them. One of the earliest and greatest was William Howard Russell, correspondent of the London ***Tintes*** in the Crimea during the war of 1853–56. His dispatches exposed the scandalous conduct of the war and moved Florence Nightingale to take up her mission. Similarly, the U.S. Civil War (1861–65), in which more than 150 correspondents followed events in the field, gave the reporter a new status. His emergence as something of a folk hero, the man on the spot fearlessly finding out facts in the name of democracy, may be said to date from this period. As newspapers became increasingly competitive, especially in their efforts to "scoop" each other—*i.e.*, be the first to publish an item of news—the reporter more and more replaced the editor in the popular imagination.

Development of Reuters and other agencies

At the same time, the cost of large-scale news gathering, prohibitive for the smaller paper, led to the rise of news agencies, especially after the invention of the telegraph. The earliest of note was founded in Paris, in 1835, by Charles Havas, who bought the Correspondance Garnier, mainly a translating office, and turned it into an agency culling extracts from the chief European papers for the French press. Before long, he extended his business to other subscribers, ran a regular carrier-pigeon service between London, Brussels, and Paris and had correspondents in most European capitals. In 1856, an advertising agency was added, news being paid for with space, which put the Havas Agency in a very strong position. In 1849, the opening to the public of the Prussian State telegraph line from Berlin to Aachen prompted a former Havas employee, Bernhard Wolff, to start the first telegraphic bureau in Berlin. Commercial news, stock-exchange prices, and market rates were the main elements in this service to begin with, as they had been in the early newsletters—*e.g.*, of the Fuggers. Another former Havas man, Paul Julius Reuter, saw his opportunity at the other end of the line, in Aachen, and ran a small office there before moving to England in 1851. In London, Reuter's first venture was, again, to supply the city with overseas commercial information; but in 1858 he was ready to inaugurate his famous service of foreign telegrams to the press. This was steadily expanded, along with British influence and the cable system, until it covered a large part of the world. Initially, these three agencies, Havas, Wolff, and Reuters, struggled fiercely for territorial news monopolies; but in 1870, in a remarkable series of Agency Treaties, they agreed to divide the world among them into exclusive preserves, with Reuters getting the lion's share. The smaller European agencies, such as Stefani (Italy, 1854), Korrespondenz-Bureau (Austrir, 1857), and Ritzaus (Denmark, 1866), all fell into line. In the U.S., meanwhile, a very different type of agency had arisen. The cost of covering the war with Mexico (1846--48) inspired six New York City newspapers to form a cooperative news-gathering organization, the New York Associated Press, which eventually, after major changes in 1892 and 1900, became the modern Associated Press. In 1893, this agency, too, lined up with the European triumvirate in a mutual agreement with Reuters for the exclusive supply of European news to America and American news to Europe. The Associated Press was an important development because it was the first agency run by newspapers themselves, which proved in the long run to be the most desirable arrangement. Naturally, newspapers continued to maintain correspondents and roving reporter's according to their resources; but the news agencies greatly helped the worldwide flow of "spot news"—*i.e.*, the bare facts about events as they occur.

Journalistic changes in the United States. In the second half of the 19th century, the press of the United States, in keeping with American society, expanded with enormous vigour. Between 1850 and 1880, the number of papers more than doubled (to about 850), and by 1900 they had done so again (to over 1,950); a high proportion, up to two-ihirds, were now afternoon papers. The press became the great means by which the American way of life was brought to the heterogeneous, often illiterate masses of immigrants. Its keynotes were sensationalism, to ensure that it was read, and idealism, to right wrongs and build civic and national consciousness. Typical of the sensationalism in the Middle West was the *Chicago Times* (1854) under Wilbur F. Storey (after 1861); and of civic consciousness, the *Chicago Tribune* (4847) under Joseph Medill (after 1855) or the *Kansas City* (Missouri) *Star* (1880) under Rockhill Nelson: who used the weapons of investigation and exposure to check corruption and promote good government. In the South, a new outlook was needed after the desolation of the Civil War; and here again newspapers helped to create it, notably the *Atlanta* (Georgia) *Constitution* (1868) under Henry W. Grady (after 1880) and the *Louisville* (Kentucky) *Courier-Journal* under Henry Watterson (after 1868). Among the many flourishing New York City papers, the Sun rose in style and prominence under Charles A. Dana (after 1868); the *Times* struck its own crusading note by exposing "Boss" Tweed of Tammany Hall, in spite of his attempt to bribe the editor with $5,000,000; and the *Evenirig Post* acquired great infiuence tinder a scholarly editor, Parke Godwin.

Joseph Pulitzer and the "new journalism"

Then, in 1883, the press was carried to fresh heights by Joseph Pulitzer, a Hungarian immigrant whose name in particular is linked with what is known as the new journalism. He began in St. Louis in 1878 by merging two papers into the *St. Louis Post-Dispatch* and turning it into a vigorous crusading journal. In 1883, he bought the failing *New York World* and in threo years raised its circulation from 15,000 to 250,000, to make it the most successful paper ever. He did so by taking the old blend of sensationalism and idealism and presenting it with new vitality in an endless series of stunts and campaigns. The press, he believed, should always be devoted to the public welfare, drastically independent and never afraid to attack wrong.

Exciting journalism, it would seem, could go no further; yet it was given a final, often excessive twist by William Randolph Hearst, who came from the far West, where journalism was at its brashest and toughest. Hearst ran the *San Francisco Examiner* (after 1880) and in his early days did his share of cleaning up corruption through exposure. By the rime he came to New Y'ork City, however, he was more interested in sensation at any price. He bought the *Morning Journal* in 1895 and within a year was challenging. though not exceeding, the *World* in circulation. Hearst's style of journalism, based on scare headlines, plenty of pictures, pseudoscientific articles, Sunday supplements with comic strips, and ostentatious campaigns, came to be known as yellow journalism, from a comic picture series called "The Yellow Kid," which played a part in the rivalry between the *World* and the *Journal.*

In the competition for circulation some of the other papers naturally suffered, and among them was the *Times.* In 1896, however, it was taken over by Adolph S. Ochs and re-established as the predominant serious journal with the slogans, "All the news that's fit to print" and "It will not soil the breakfast cloth." Many of the techniques of yellow journalism became permanent and spread far and wide, but the comeback of the *Times* could be said to mark the end of the era of highly personal journalism begun by James Gordon Bennett.

Expansion in Britain. In Britain, the press was somewhat slower to expand; but a major turning point came in 1855, when the stamp tax was abolished. It had been reduced to one penny in 1836; and this had released a flood of cheap crime sheets and a number of sensational Sunday papers, such as the *News of the World* (1843), whose great popularity dates from this period. The final abolition of the stamp tax and that of the other "taxes on knowledge" (the advertisement duty in 1853 and the paper excise in 1861) led to an immediate upsurge in the number of dailies. The tax was ended partly as a result of a campaign for cheaper papers but equally because the authorities could no longer endure what Lord John Russell called "the vile tyranny" of *The Times.* Among the new journals was London's first penny paper, the *Daily Telegraph* (originally the *Daily Telegraph aad Courier,* 1855). By 1861, it had a circulation of 130,000 (double that of the *Times*), and by 1870 this had risen to 240,000, then the largest in the world. Yet the *Daily Telegraph,* despite a rather more colourful style, was still not a popular paper in the American sense; its appeal was to the growing middle class, for whom it assembled a wealth of writing talent. The new editors followed Barnes in upholding journalistic independence; but in the age of Gladstone and Disraeli, when party lines grew sharper, they tended to support one side or the other.
