Rubens, Peter Paul

If the Baroque style is thought of as powerful, exuberant, sensuous, and even explosive, Peter Paul Rubens is its perfect example in painting. He was able to infuse his own astounding vitality into his religious or mythological paintings, portraits, and landscapes. Rubens was a painter of illimitable resource in invention, and he organized his complex compositions in vivid, dynamic designs. Limitations of form and contour are discounted in favour of a constant flow of movement. His voluptuous women may not be to the taste of a less vigorous age, but are related to the full and opulent forms that were the ideal of womanhood and life in general for both Rubens and the Baroque period.

Rubens, self-portrait, oil painting, c. 1640. In the Kunsthistorisches Museum, Vienna.

One of the most prolific geniuses of painting, Rubens was a great Humanist scholar and an important diplomat, as well as an artist. Although he came to live the life of a wealthy bourgeois, his art shows strong roots in the robust life of the Flemish people. Rubens' laborious life was well ordered; the creator of so many delightful pagan mythological feasts went to mass each morning before proceeding to his studio, where he worked all day. He is one of the best examples of the well-balanced genius, who combined passion and science, ardour and reflection.

Rubens studied to emulate the works of Michelangelo, Raphael, Titian, Tintoretto, Veronese, and Correggio, as well as those of his contemporaries the Carracci and Caravaggio. All these influences were fused in his own highly personal and dramatic style. By no means all of the canvases attributed to Rubens were painted by him. He established a huge workshop employing on occasion a great number of assistants and apprentices. But the original inventive designs underlying his paintings are his own.

Although Rubens' father, Jan, was born a Roman Cath-

olic, his name had appeared on a list of Calvinists as early as 1566. This accounted for the Rubens' family exile to Germany, where Peter Paul was born on June 28, 1577. Victims of the hysterical religious persecution following the decapitation in 1568 in Brussels of the freedom-seeking Counts of Egmond and Horn, the Rubens family fled the wrath of the Spanish rulers of their native Flanders. Jan Rubens became a diplomatic agent and adviser to the Protestant Princess Anna of Saxony (d. 1577), second wife of the latitudinarian Catholic William the Silent, who led the resistance to Spanish rule of the Netherlands. An unfortunate pregnancy revealed the intimate extent of the relationship between this princess of the house of Orange-Nassau and Rubens' father. She obtained clemency from her husband for Jan, but he and his family were placed under house arrest at Siegen, a Nassau stronghold in Westphalia. Here Peter Paul was born, as well as his brother Philip. The Rubens children were grounded in the classics by their exiled father, who was a doctor of both civil and canon law. Jan died in 1587, after he had been allowed to leave Siegen and go to the German city of Cologne. Rubens' mother then thought it prudent to take her four surviving children to Antwerp, where their father had been an alderman.

Antwerp training. At the age of ten, Peter Paul was sent with Philip to a Latin school in Antwerp. There the future painter befriended a contemporary, Balthasar Moretus, who was to be a future patron and head of the leading Flemish publishing house, the Plantin Press. In 1590, shortage of money and the need to provide a dowry for his sister Blandina forced Rubens' mother to break off his formal education and make him a page to the Countess of Lalaing. Soon tired of courtly life, he was allowed to become a painter. He was sent first to his kinsman Tobias Verhaecht, a minor painter of Mannerist landscapes in the tradition of the more important Antwerp painter Joos de Momper. Having quickly learned the rudiments of his profession, he was apprenticed for four years to an abler master, Adam van Noort, and subsequently to Otto van Veen, one of the most distinguished of the Antwerp Romanists, a group of Flemish artists who had gone to Rome to study the art of antiquity and the Italian Renaissance. Vaenius, or Venius, as van Veen called himself, had been in Italy an active admirer of the proto-Baroque painter from Urbino, Federico Barocci, as well as of the great masters of the Florentine-Roman tradition of Renaissance art such as Michelangelo and Raphael. His culture and vision impressed Rubens, whose earliest independent works are reputed to have resembled his style.

Italian Period. In May 1600, with two years' seniority as a master in the Antwerp Guild of St. Luke, Rubens set out with Deodatus del Monte, his constant travelling companion and first pupil, for the visual and spiritual adventure of Italy. Reaching Venice in about a month, he had the good fortune to meet a gentleman in the service of Vincenzo I Gonzaga, duke of Mantua. He was offered employment in Mantua, which duchy held one of the largest and finest collections outside the Vatican of works by Italian artists. Moreover, Mantua was ideally located for sightseeing in the northern Italian provinces of Lombardy, Emilia, and the Veneto. During the eight years that Rubens was to call Vincenzo his lord, he had unmatched opportunities of fulfilling his expressed intention "to study at close quarters the works of the ancient and modern masters, and to improve himself by their example in painting." The Early Renaissance painter Andrea

Early
life in
exile

Mantegna and the Mannerist architect and painter Giulio Romano were his admired predecessors in the service of the Gonzaga family. The abundant achievement in mural decoration of Giulio Romano, especially, had a lasting and highly productive effect on him.

Rubens was sent to Rome (1601–02) by the Duke to paint copies of pictures, and to live under the protection of Cardinal Montalto. There, through Flemish connections, he obtained his first public commission to paint three altarpieces for the crypt chapel of St. Helena in Sta. Croce in Gerusalemme. In Rome, the Bolognese painter Annibale Carracci and his assistants were at work in the gallery of the Palazzo Farnese. Their bold scale in drawing and working methods decidedly influenced the young Rubens. Through Annibale's example, he could apprehend the nobility and energy of design of Leonardo da Vinci, Raphael, and Michelangelo, the masters of High Renaissance painting. He assimilated Venetian colour, light and loose application of paint first through the works of Tintoretto, then through those of Veronese, long before he could penetrate the inward meaning of Titian's art. His copies, and his reworking of drawings, offer the most complete conspectus of the achievement of 16th-century Italian art in a pungently personal revision.

In 1603 he was entrusted with his first diplomatic mission, to bring Philip III and the Spanish court costly presents from Mantua. This mission gave him a first view of the royal collections in Madrid. Two paintings in the groups of copies offered to Philip's favourite, the duke of Lerma, being rainsodden beyond repair, were promptly replaced by him with a "Democritus and Heraclitus" (1603: private collection, England) of his own invention. His resource and his tact in dealing with the temperamental regular Mantuan representative to the Spanish court raised him in the Duke's estimation and helped prepare him for future diplomatic missions. His fruitful association with the banking patriciate of Genoa, of whom he was to paint many elegant portraits, began with his return voyage and his meeting with Nicolò Pallavicino, the Duke of Mantua's banker, in order to recoup the extraordinary expenses of the mission.

The only major works he executed for Mantua were the three pictures finished by Trinity Sunday 1605 for the Jesuit church of SS. Trinità ("The Baptism of Christ," Musée Royal des Beaux-Arts, Antwerp; "The Transfiguration," Musée des Beaux-Arts, Nancy, France; and "The Gonzaga Family in Adoration of the Trinity," Palazzo Ducale, Mantua). In the same year he completed the "Circumcision" for the high altar of the Jesuit church in Genoa. Only portraits of court beauties by Rubens himself were commissioned by the Duke for the Gonzaga Gallery itself, of which Rubens was curator. One of his major achievements while in this position was inducing the Duke to buy for his gallery the "Death of the Virgin" (c. 1605; Louvre, Paris), a masterpiece by Caravaggio that had been rejected for its excessive realism by the monks of Sta. Maria della Scala in Rome.

Toward the end of 1605, Rubens obtained leave from the Duke of Mantua to continue his studies in Rome. There he shared a house with his brother Philip, then librarian to Cardinal Ascanio Colonna, a member of one of Rome's most wealthy and powerful families. Daily contact with Philip, a brilliant student of the famed Flemish Humanist and Classical scholar Justus Lipsius (1547–1606), added zest to his personal discovery of the antique world. They combined their interest in the antique by collaborating to produce the book *Electorum Libri II*, published in Antwerp in 1608 by the Plantin Press. Dealing with Roman social life and customs, Philip wrote the text, and Peter Paul prepared drawings for the execution of the engraved illustrations.

During the two years he spent in Rome, Rubens was left largely undisturbed by the Duke of Mantua. In the summer of 1607, however, he was asked to accompany the Gonzaga court to the Italian seaside resort of San Pier d'Arena, where he continued to paint with splendour portraits of the Genoese aristocracy. Chronic arrears in payment of his salary, and an ambition to establish him-

self as an international, rather than just a Mantuan artist, motivated him to accept other patronage. He received the backing of the wealthy Genoese banker to the papacy, Monsignor Jacopo Serra, who was instrumental in obtaining for him the coveted commission for the painting over the high altar of the Roman church of S. Maria in Vallicella (popularly known as the Chiesa Nuova, the New Church). He concurrently painted the altarpiece of the "Adoration of the Shepherds" for another church of the Oratorian Order in Fermo. In October of 1608, his brother summoned him to their mother's deathbed in Antwerp. She died before he could reach her.

Return to Antwerp. Soon after his mother's death Rubens was "bound with golden fetters" to the service of the Spanish Habsburg regents of Flanders. Although he was never to return to Italy, he kept up his Italian contacts. He supplied, for example, cartoons or model drawings for tapestry to Genoese patrons as late as the 1620s. He always remained an *Italophile*. Fluent in six languages, Italian was his favourite for correspondence. The house that he built for himself, the pride of Antwerp, was filled with paintings, statuary, cameos, coins, and jewels from Renaissance and ancient Roman Italy. He built a private pantheon to house his antiquities. His enthusiasm for Italian architecture is best expressed in his publication the *Palazzi di Genova*. Printed in Antwerp in 1622, this book of engravings illustrates the great Renaissance palaces of Genoa. He practiced the spirit of the book's preface, which extols Italian design, in the magnificent new church of the Antwerp Jesuits, St. Charles Borromeo, where he was the chief designer, along with the Flemish architect Pieter Huyssens (1577–1637), of the facade, tower, and all architectural detail. Rubens was also the master decorator, and provided oil sketches as designs for the ceiling paintings on which he was to be assisted by Anthony Van Dyck (1599–1641) and others.

Settling permanently in Flanders, he married in October 1609, Isabella, daughter of Jan Brandt, a leading Antwerp Humanist and lawyer. He became not only the court portraitist but a major religious painter. His Baroque altarpieces of the "Erection of the Cross" for St. Walburga's in Antwerp; "Descent from the Cross" for Antwerp Cathedral; and "The Miracle of St. Bavon" for the Cathedral of St. Bavon in the neighbouring city of Ghent, established Rubens as the leading painter of Flanders and one of the most important in Europe. Because of his prestige, he was allowed to live in Antwerp, rather than in Brussels, where the Flemish court was based. He was also exempt from the regulations of the Antwerp painters' guild and thus was free to engage pupils or collaborators without having them enrolled in this organization. By 1611 he wrote that he had to refuse more than 100 applicants who wished to become his pupils.

Rubens' international reputation spread not only because of the large number of works produced in his studio but because he reproduced so many of his paintings in prints, which served further to advertise his art. Many of the large-scale pictures that prolifically issued from his studio were largely painted by his students and assistants, although generally certain areas were by the hand of the master, even if it was only a retouching of the work. During the period of 1606–07 he used small wood panels prepared with gesso, a priming substance made of plaster of paris and glue, to present models to clients or to instruct engravers, sculptors, tapestry weavers, and painting assistants. These marvellous exercises in the painter's craft are often only inches high and executed in colour or in tones of grey, brown, and white. Rubens also evolved his compositions according to the Renaissance practice of doing preparatory drawings in chalk, charcoal, or pen and ink.

Diplomatic career. In the period between 1621 and 1630, Rubens was increasingly used as a diplomat by the Spanish Habsburg rulers. His contact with the leading political and intellectual personalities of Europe, as well as his gracious manner, made him the ideal political agent. Furthermore, as a painter, he could often act as a covert diplomat or observer.

His first important diplomatic functions were in connec-

tion with the attempt of Spain and the Spanish Netherlands to renegotiate the Twelve Years' Truce (1609–21) between the Habsburg-controlled area of Flanders and the independent Dutch Republic to the north. The regent of Flanders, the Archduke Albert, a Habsburg of the Austrian line, died in 1621, leaving the renewal of the truce to his widow, the infanta Isabella, the daughter of the Habsburg ruler of Spain, Philip II. Rubens became her adviser and tried unsuccessfully to intercede with the Dutch. The French ambassador wrote in 1624 from the Flemish capital of Brussels:

Rubens is here to paint the likeness of the prince of Poland, by order of the infanta (Archduchess Isabella). I am persuaded he will succeed better in this than in his negotiations for the truce.

War again broke out in the Netherlands between the predominantly Protestant Dutch and the Catholic Flemish, and continued for the rest of Rubens' life.

Early in 1622 Rubens was summoned to Paris by Marie de Médicis, the widow of Henry IV and mother of the reigning king of France, Louis XIII. This Florentine princess, whose wedding by proxy Rubens had attended in Florence in 1600, commissioned him to paint two series of paintings for two long galleries in her newly constructed Luxembourg Palace. One cycle of 21 pictures representing episodes from Marie's life now hang in the Louvre, while the other proposed series of pictures, dealing with the life of Henry IV, was never completed. After six weeks of discussion and arrangements, Rubens returned to Antwerp, where he worked for two years on his most artistically important secular commission.

When Rubens returned to Paris in 1625 to install the Medici pictures, the political atmosphere at court had changed. Formerly friendly to Spain and the Spanish Netherlands, France had signed before 1624 treaties with the Dutch, the Danes, and the English, all hostile to the Habsburgs. This new French alliance was due to the influence of Cardinal Richelieu, the powerful adviser to young Louis XIII. Not without reason, the Cardinal suspected that Rubens was more spy and agent than artist during his second Paris visit. Further suspicions were aroused when Rubens was seen frequenting the company of the Duke of Buckingham, the favourite of Charles I of England, who was in Paris for the marriage by proxy of his master and the youngest daughter of Marie de Médicis and Henry IV, the princess Henrietta-Maria. The Duke was an avid art collector. His head was drawn by Rubens in Paris. He ordered from him an equestrian portrait (1625; formerly Osterley Park, near London); and he bought the painter's famous collection of antiquities, with some paintings. This is often considered more a diplomatic gesture on Rubens' part to stay in Buckingham's graces than an economic necessity. During their acquaintance in France, Rubens tried to persuade the Duke that England should enter into an alliance with the Spanish Netherlands and cease supporting the Dutch. Since Buckingham was currently engaged in promoting a war between England and Spain, he was uncommittal; but through his Flemish-born servant, agent, and painter, Sir Balthasar Gerbier, a hopeful secret correspondence was maintained by Rubens until the Duke's assassination in 1628. The English-Spanish war proved economically disastrous for Flanders, since its sea and land trade was cut off by its neighbours—France, the Dutch Republic, and the Palatinate of the Rhineland, who were allied with England. Rubens described Antwerp as "languishing like a consumptive body, declining little by little."

The death of Buckingham reopened the way for Rubens to attempt the negotiation of a peace treaty on behalf of the sorely tried Spanish Netherlands. Unfortunately, the minister of Spain, the count of Olivares, persuaded his master, Philip IV, to make a close pact with France to reconquer England for Catholicism. In 1628 Rubens travelled in secret haste to Madrid to plead for peace, rather than another war between Spain and England. The Papal Nuncio reported of his arrival:

It is considered certain that Rubens, the Flemish painter, is the bearer of a negotiation, for we hear that he often confers in secret with the *conde-duque* (Count of Olivares), and in a

manner very different from that which his profession permits. Since he is said to be a great friend of Buckingham, it is believed that he comes with some peace treaty between the two crowns. Others think his main object is the truce of Flanders, and that he had received this commission as one who enjoys the confidence of all that country.

During nine months in Madrid, besides pleading for a peace treaty rather than war with England, Rubens painted royal portraits. He again studied Titian's masterpieces and revisited the extensive art collection in the royal monastery of the Escorial with the gifted young Spanish painter Diego Velázquez. He eventually was deemed a suitable envoy by Philip IV and was named Secretary of the Privy Council of the Spanish Netherlands to give him sufficient status for a special peace mission to England. Rubens hastened across France, again avoiding the hostile Cardinal Richelieu, to report to the archduchess Isabella. News awaiting his arrival in Brussels made his mission even more urgent and difficult: on April 24, 1629, England had signed a treaty with France.

Charles I waived the formalities of exchanging ambassadors and sent for Rubens directly, indicating that he was most eager to meet a man with such an international reputation for intellect and artistic genius. He was not disappointed, and it is to Rubens personally that the peace treaty of 1630 between England and Spain largely can be attributed. He was knighted and given an honorary degree by Cambridge University. "Peace and War" (c. 1630; National Gallery, London) is Rubens' painted proclamation of success. He discussed painting with Charles I, a great connoisseur of the arts and the only prince to whom Rubens ever vouchsafed a self-portrait (c. 1625; Windsor Castle). The king commissioned him to decorate the ceiling of the royal Banqueting House (1619–22) designed by the court architect Inigo Jones as a part of the Whitehall Palace complex of buildings in London. Finished in 1634, the nine huge panels allegorize the reign of James I, the father of Charles I. Rubens was struck by the beauty and peacefulness of the English countryside. The "Landscape with St. George" (1630; Buckingham Palace) incorporated his view of the River Thames from his lodgings as a background to King Charles and Queen Henrietta envisaged in *masquerade* as the patron saint of England and the princess he reputedly rescued from a dragon.

Late years in Flanders. On his return to Flanders in 1630, Rubens was rewarded by the Archduchess with exemption from further missions. "This favour I obtained with more difficulty than any other she ever granted me," he was to write. "Now, for three years I have found peace of mind, having given up every sort of employment outside my beloved profession." The peace Rubens had worked for nearly ten years to achieve, however, did not last, and for most of the next 20 years Europe continued to be embroiled in the Thirty Years' War. In a letter written two years before his death, Rubens explains the figures in his allegorical painting "The Horrors of War" (1637–38; Pitti Palace, Florence), which he sold to the Medici in Florence:

that grief-stricken woman clothed in black, with torn veil, robbed of all her jewels and other ornaments, is the unfortunate Europe, who, for so many years now, has suffered plunder, outrage, and misery.

Having been a widower for four years, he married in December of 1630 the 16-year-old Hélène Fourment, whose charms recur frequently among his later figure subjects. He bought the château (Het Steen) of Elewijt, in 1635. In his last years, he spent much time there depicting the rural life and scenery outside of Antwerp such as in "The Kermesse" (c. 1636–38; Louvre, Paris). His long-established interest in landscape painting, early expressed in drawings of his Roman period, reached its grandest and most emotionally romantic expression in such late works as "Landscape with a Rainbow" (c. 1636; Wallace Collection, London) or "Château de Steen" (c. 1635–37; National Gallery, London). Another long-established interest that he revived at this time was the planning of civic stagings and decorations designed

to welcome a dignitary, in this case the Infante Ferdinand, who in 1635 succeeded his aunt, the Archduchess Isabella, as regent of Flanders. Thirty-seven years before, Rubens had assisted Vaenius in converting the city of Antwerp into a theatre of celebration to welcome the Archduchess Isabella as ruler of the Spanish Netherlands. Rubens' major commission during these last years, however, was to provide for the Infante's brother, King Philip IV of Spain, models for about 120 scenes from the writings of the Roman poet Ovid and other classical authors to decorate the Torre de la Parada, the royal hunting lodge near Madrid.

Rubens died at Antwerp on May 30, 1640, when gout, which had for months troubled his painting arm, reached his heart.

Achievement. Rubens is one of the most methodically assimilative, most prodigiously and variously productive of Western artists. Schooled in the confusing stylistic traditions of Mannerism in Antwerp, he educated himself to be heir of the full range of Renaissance art both north and south of the Alps. His abundant energy fired him to study and emulate the masters both of antiquity and of the 16th century in Rome, Venice, and Parma. His warmth of nature made him responsive to the artistic revolutions being worked by living artists: to the plein air study of nature and times of day in the Roman campagna by the German landscape painter Adam Elsheimer; to the colour combinations and delicate appreciation of warm and cool tones vibrant on flesh of the proto-Baroque Italian artist Federico Barocci; to the emotive exploitation of strong Tenebrism by Caravaggio; and, most profoundly and lastingly, to Annibale Carracci's impassioned yet strenuously disciplined approach to the practice of figure composition.

Robust powers of comprehension nourished his limitless resource in invention. The larger the scale of the undertaking the more congenial it was to his spirit. The success of his public performance as master of the greatest studio organization in Europe since Raphael's in Rome has obscured for many the personal intensity of his vision as evinced in such works as his oil sketch for "All Saints" (Museum Boymans-van Beuningen, Rotterdam) and in his deeply felt study for the head of St. John in the Antwerp Cathedral "Descent from the Cross," as well as in portraits of his family and friends and in his treatment of the mood and grandeur of landscape. Not only Sir Anthony Van Dyck, Jacob Jordaens, and his immediate following in Flanders but artists at almost every period have responded to the force of his genius. The architect and sculptor Gian Lorenzo Bernini, the other seminal mind of the early Baroque, developed in his Roman altarpieces figurative ideas and the dramatic handling of light parallel to Rubens' work. And in the fulfillment of the Italian Baroque, the painters Domenico Fetti (c. 1588/9–1623), Giovanni Castiglione (c. 1600?–65?), and Bernardo Strozzi (1581–1644) are in individual ways Rubensians. Antoine Watteau (1684–1721), Jean-Honoré Fragonard (1732–1806), Eugène Delacroix (1798–1863), and Pierre-Auguste Renoir (1841–1919) are only the four most distinguished in the long succession of French painters who were attracted after the late 17th century to some aspects of his art. Sir Joshua Reynolds (1723–92), Thomas Gainsborough (1727–88), and John Constable (1776–1837) are outstanding among his English admirers. He is a central figure to Western art history.

His own deepest love as a painter, consummated by his second visit to Spain, was for the poetry, the control of glowing colour, and the sheer mastery in handling of oil paint that excelled in the art of Titian. In these qualities Rubens himself became supreme, whether with the brilliant play of fine brushes over the white reflecting surface of a small panel, or with masterful gestures often more than six feet long, sweeping a richly loaded brush across some huge canvas.

MAJOR WORKS

Portraits: "Rubens and His Friends at Mantua" (c. 1602; Wallraf-Richartz Museum, Cologne); "Duke of Lerma" (1603; Museo del Prado, Madrid); "Rubens with His

First Wife, Isabella Brant, Amidst Honeysuckle" (c. 1609; Alte Pinakothek, Munich); "Le Chapeau de Paille" (c. 1620; National Gallery, London); "Thomas Howard, Earl of Arundel, with His Wife Alatheia Talbot" (c. 1620; Alte Pinakothek, Munich); "Marie de Médicis" (c. 1622–25; Museo del Prado, Madrid); "Vladislav Sigismund IV, King of Poland" (1624; Metropolitan Museum of Art, New York); "Philip II of Spain" (c. 1628–29; Museo del Prado, Madrid); "Hélène Fourment with Fur Cloak" (c. 1638–40; Kunsthistorisches Museum, Vienna); "Self-Portrait" (c. 1639; Kunsthistorisches Museum, Vienna).

Genre and Landscape Paintings: "The Garden of Love" (1632–34; Museo del Prado, and Waddesdon, Buckinghamshire, England); "The Kermesse" (c. 1636–38; Louvre, Paris).

Mythological and Historical Paintings: "The Toilet of Venus" (c. 1613–15; Collection of the Prince of Liechtenstein); "The Rape of the Sabines" (1635; National Gallery, London); "Venus and Adonis" (c. 1635; Metropolitan Museum of Art, New York); "The Three Graces" (c. 1638–40; Museo del Prado, Madrid); "The Judgment of Paris" (1638–39; Museo del Prado, Madrid).

Picture Cycles and Decorations: "Médicis Cycle" (c. 1622; Louvre, Paris); Whitehall ceiling (c. 1634; London).

Religious Subjects: "Circumcision" (1605; S. Ambrogio, Genoa); "Adoration of the Magi" (1609; Museo del Prado, Madrid); "Deposition Triptych" (1612–14; Cathedral, Antwerp); "The Rockox Altarpiece" (1613–15; Musée Royal des Beaux-Arts, Antwerp); "The Holy Family" (c. 1615; Wallace collection, London); "The Last Judgment" (c. 1616; Alte Pinakothek, Munich); "Judith with the Head of Holofernes" (1616–18; Herzog-Anton-Ulrich-Museum, Braunschweig, Germany); "Lot Fleeing from Sodom" (1625; Louvre, Paris); "The Ildefonso Altarpiece" (1630–32; Kunsthistorisches Museum, Vienna); "Bathsheba Receiving David's Letter" (c. 1635; Gemäldegalerie, Dresden); "The Brazen Serpent" (c. 1638; National Gallery, London); "The Massacre of the Innocents" (c. 1635–39; Alte Pinakothek, Munich); "Christ on the Cross" (1635–40; Musée des Augustins, Toulouse, France).

Bibliography. C.V. WEDGWOOD, *The World of Rubens, 1577–1640* (1967); and MICHAEL JAFFE, "Rubens," *World Encyclopedia of Art*, vol. 12, col. 590–606 (1966), are the best modern biographies. The latter contains the most useful modern bibliography, including the early Italian, Latin, German, and French sources. For illustrations and discussion of the works, the following remain the most worthwhile: R. OLDENBOURG, *Peter Paul Rubens* (1922), in German; J.S. HED, *Rubens: Selected Drawings*, 2 vol. (1959); F. VAN DEN WJNGAERT, *Inventaris der Rubeniaansche Prentkunst* (1940); and the exhibition catalog, E. HAVERKAMP-BEGEMANN (ed.), *Olieverfschetsen van Rubens* (1953). They supplement M. ROOSES, *L'oeuvre de P.P. Rubens*, 5 vol. (1886–92). Rubens' letters were edited by R.S. MAGURN, *Letters of Peter Paul Rubens* (1955); and his diplomacy was the subject of an exhibition catalog by F. BAUDOUIN, *Rubens diplomate* (1962).

(M.I.J.)

Rugby

Rugby is a football game played with an oval ball by two teams of 15 or 13 players each, its distinctive features being: (1) players may use their hands and catch, throw, or run with the ball (a practice introduced at Rugby School in the 1820s) in addition to manoeuvring it with their feet as in association football (soccer); and (2) the **scrum**, or scrummage (from "scrimmage," tussle, confused struggle), a method of putting the ball in play from a set formation in which eight men on each team—six in a 13-per-side game—form a closely packed group behind two front rows of three men each, the ball being thrown onto the ground between them and each team trying to get possession. Although the ball may be kicked or carried or passed from player to player by hand or foot, it may not be passed forward. Permitting players to run with the ball inevitably made tackling a part of the game. A tackle occurs when a player carrying the ball is sent to the ground or is held by one or more opponents so that he is unable to free himself without delay and cannot play the ball.

There are two principal types of rugby football: Rugby Union, which is the amateur game; and Rugby League, a mainly professional game; the chief differences between the two are described under *Rugby League*, below. For the background, origins, and history of these games see the article FOOTBALL, AMERICAN AND CANADIAN: *Early History*. See also ASSOCIATION FOOTBALL (SOCCER).

RUGBY UNION

History. The formation of the Rugby Football Union, the governing body of the sport in England, on Jan. 26, 1871, was closely followed by the first match between England and Scotland, at Edinburgh on March 27 of the same year, Scotland winning in front of a crowd of 4,000 spectators. At that stage there was no official central authority for the game in Scotland, but the Scottish Football Union—which changed its name to Scottish Rugby Union in 1924—was formed in 1873. The game had grown in Scotland, as in England, through the schools and especially through the numerous public schools grouped in and around Edinburgh. In Ireland too it was in academic circles that the first organized Rugby took place. A club was formed at Trinity College, Dublin, in 1865; and others soon followed as students continued to play in their home towns, both during vacations and after they had finished their university careers. The visit in 1873 of the Dingle Football Club of Liverpool to play Trinity in College Park, Dublin, prompted the formation in 1874 of the Irish Football Union. This body, however, did not embrace the whole of Ireland; and after a match in Belfast between North of Ireland Football Club and Wanderers (from Dublin), a North of Ireland Football Union was set up, also in 1874, as a rival authority. The two unions amalgamated in 1879 to form the Irish Rugby Football Union. With the formation of the Welsh Rugby Union in 1881, Rugby was established in all four divisions of the British Isles.

By this time the game had already been started in distant countries of the British Empire, sometimes through the influence of the army, sometimes by men who had travelled from Britain to the colonies, sometimes by students from different corners of the Empire who attended English educational establishments. Thus the Southern Rugby Football Union, ancestor of the Australian Rugby Football Union, was founded as early as 1875. That same year is generally accepted by the game's historians as the year in which Rugby was first played in southern Africa, at Cape Town. In 1882 a club was formed at the University of Stellenbosch, and the return of students to their homes soon led to the establishment of Rugby clubs in other areas.

The presence of British regiments led to formation of a club in King William's Town in 1878; the discovery of diamonds helped to establish the game in the Kimberley area between 1883 and 1886; and the gold rush encouraged its spread in the region of Johannesburg and Pretoria by 1888. The first provincial union was that of Western Province formed in 1883, and the South African Rugby Football Board was founded at Kimberley in 1889. Meanwhile C.J. Monro, son of the Speaker of the New Zealand House of Representatives, had returned home from England to Nelson, in the South Island of New Zealand, fired with enthusiasm for the game of Rugby, which he had got to know while at Christ's College in London, and in 1870 had organized the first Rugby match ever played in New Zealand—Nelson Football Club versus Nelson College. Monro then went to Wellington, in the North Island, and organized a game between his Nelson players and a collection of players from Wellington. A Wellington club was officially formed in 1871, and by 1890 there were approximately 700 clubs playing Rugby throughout New Zealand. These were soon organized in various unions, the first being the Canterbury Rugby Union in 1879, and the New Zealand Rugby Football Union was founded as the country's central authority in 1892. Thus was the game established in those countries that were destined to become its most formidable exponents.

Rugby soon also found its way from the British Isles into France. British businessmen, especially those engaged in the wine trade, took the game to such Channel ports as Le Havre, Nantes, and Bordeaux; and students, embassy and consular officials, and others introduced it to Paris. It has been written that British residents were playing Rugby in Paris by 1877, and certainly Rosslyn Park, the London club, played (and beat) Stade Français in Paris in 1893. In the early days the Union des Sociétés Françaises de Sports Athlétiques (USFSA), a multisports organization founded

in 1887, looked after the interests of French Rugby players and set up competitions for them. In 1919 the Rugby club broke away from the USFSA and formed the Fédération Française de Rugby (FFR), to which 173 clubs affiliated. It was largely through the influence of France that the game took root in Romania. The contact was made by Romanian students who discovered the game at the university in Paris and then went home and formed clubs of their own. Romanian clubs became affiliated to a multisports organization in 1912, and the *Federatia Romana de Rugby* was founded in 1931. Other continental European countries took up the game, but none to the extent of France and Romania.

Before the end of the 19th century, Rugby was played in many lands outside the European area, besides New Zealand, South Africa, and Australia. Immigrants from the British Isles had established the game in Ontario by 1882; it reached Argentina in the 1880s, thanks largely to British residents in Buenos Aires and to engineers involved in constructing railways, and the Argentine Rugby Union was founded in 1899; the local police are believed to have played Rugby as early as 1880 in Fiji, and the Fiji Rugby Union dates from 1913; the game was introduced into Japan in 1899 by Ginnosuke Tanaka, who had discovered it at Cambridge University.

Although Rugby was being played in all these countries and many others by the early years of the 20th century, it remained predominantly a game of the British Empire and Commonwealth. This was reflected in the membership of the International Board (International Rugby Football Board, established 1886), which for many years was confined to the four home countries, 6 of its 12 members being English, 2 Scottish, 2 Irish, and 2 Welsh. This proportion was maintained until 1911, when England's representation was reduced from six to four. In 1948 New Zealand, South Africa, and Australia were admitted, with one member each, and England's representation was reduced from four to two to conform with the other home countries. In 1958 all seven member countries were allowed two representatives each.

At the instigation of Germany, some of the other Rugby countries held a meeting in 1933, and in January 1934 the *Fédération Internationale de Rugby Amateur* (FIRA) came into being. Represented at the inaugural meeting were Germany, France, The Netherlands, Italy, Portugal, Romania, Sweden, Czechoslovakia, and Catalonia. Membership has expanded since then but has not extended beyond Europe and the Mediterranean coast. The FIRA constitution requires that every match within its organization be played in accordance with International Board laws. In the 1970-71 European season, the centenary of the Rugby Football Union, the representatives of 50 countries throughout the world attended the Centenary Congress at Cambridge. At that time, England was able to report a membership of 1,600 clubs with more than 100,000 regular players. And, to give some examples from less prominent Rugby countries, Japan reported 60,000 players, Fiji 12,000, and Romania 6,500.

The progress of Rugby inside the various countries has been steady rather than spectacular. An exception to this norm occurred in France between 1960 and 1970, when the number of French clubs almost doubled—from 646 to 1,160—and the number of French players increased from 39,000 to 75,000. These increases were attributed largely to television. France was also involved in one of the two famous "splits" in the history of the game. Allegations of professionalism in the French club championship led to the breaking off of relations between the U.K. and France, from 1931 to 1939, but the Second World War prevented the resumption of fixtures until 1947. The other split directly concerned England alone, although its effects were felt throughout the Rugby world. This occurred in 1895, when 22 clubs in the North of England resigned from the RFU because they wanted payment to their players for "broken time"—i.e., for loss of wages due to playing the game. The RFU would not agree to such payment, and the 22 clubs promptly set up the Northern Union, which evolved into the Rugby League game (see below Rugby *League*).

sionalism

On the other hand, the partition of Ireland in 1922 did not lead to the cancellation of any international Rugby matches; and Dublin, Belfast, Limerick, and Cork all regularly contribute players to Ireland's team for the home unions' championship.

Development of the game. From the general free-for-all, with hacking (kicking in the shins) and tripping that existed in the early days, the game was gradually refined until it reached its present shape. When the first match between England and Scotland was played in 1871, there were 20 men on each team, and it was not agreed to reduce the number to 15 until 1877. Scotland won the 1871 game, scoring the only goal of the match. Scotland and England each achieved a try, but it was not possible to win a match in any other way than by scoring goals. A try, touching the ball down in the goal area behind the opponents' goal line, scored no points but allowed the player's team an unimpeded place kick at goal from a point on the field not further from the touchline than the try had been scored. In 1875–76 it was agreed that if the number of goals (field goals) kicked by each side was the same or if no goal was kicked, the result would be decided by the number of tries achieved. Thus was the try (in U.S. and Canadian football, a touchdown), the scoring of which was to become the chief aim of the game, for the first time brought into the reckoning. A further refinement was introduced during the 1886–87 season with the adoption of the Cheltenham College rating, which had been in force at that college for some 20 years, making three tries equal to one goal. Then in 1905 the modern scoring values were introduced, a try being worth three points, its subsequent conversion into a goal providing an additional two points. Dropped goals, at that stage worth four points, in the 1947–48 season were devalued to three. A dropped goal is scored by a dropkick from the field—i.e., when a player, in play, lets the ball fall from his hands and kicks it at the first rebound as it rises so that it goes between the goal posts and above the crossbar. Three points may also be scored by a successful free kick or by penalty kick at goal awarded for an infringement of the laws by the opposition. A free kick (a place kick or dropkick at goal or a punt not at goal but to gain a territorial advantage) may be taken by a player catching while stationary a ball kicked or otherwise propelled by an opponent if he simultaneously calls "mark"; the kick is taken from behind the mark. A penalty kick is taken from a mark at the spot of the infringement.

The try in Rugby is the same as the touchdown in U.S. and Canadian football; while in Rugby a "touchdown" is

the grounding of the ball behind his own goal line by a defending player, in the U.S.-Canadian game this is called a "touchback."

The two basic set pieces or formations of the game are the scrum and the line-out. A scrum is formed by the eight forwards of each side bending forward, binding one another with their arms, and pushing against the opposing eight forwards similarly bound in three ranks or rows. The ball is put into the tunnel between the two front rows, whose members use their feet to try to procure the ball for their team.

A line-out is the method of bringing the ball back into play after it has gone out over the touchline (out-of-bounds). To form a line-out, at least two forwards of each team line up in single files in a line perpendicular to the spot where the ball crossed the touchline. A gap or space is left between the two lines of players, and the ball is thrown in above this gap so that the forwards of both teams may try to grab it or otherwise obtain possession of it for their team.

While the forwards are forming a scrum or a line-out, the other players, normally divided into two halves, four three-quarters (the left- and right-centre backs and left- and right-wing backs), and a fullback, take up position several yards apart in various formations between their forwards and their own goal line. For a line-out the three-quarters stay at least ten yards back, the idea being that by passing or running or kicking the ball in the open field they may find a way either of scoring a try or of dropping a goal.

Besides the scrum and the line-out there is also the loose maul or ruck. This occurs when, in the open field, the progress of the ball is temporarily checked—by a player dropping it, falling over while carrying it, or being held by an opponent while in possession of it, for instance—and two or more players gather round and struggle to procure the ball for their team. The maul or ruck is an especially profitable source of possession because the opposing defense is unlikely to be as strictly aligned as it is for a scrum or a line-out.

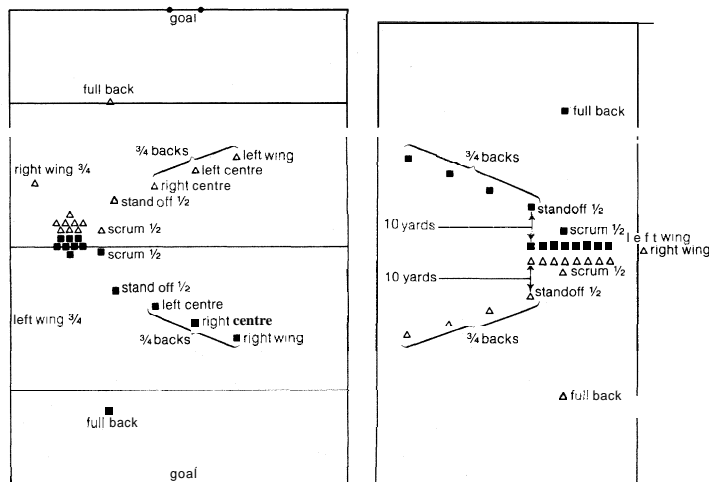

The game settled into the pattern of big forwards struggling for the ball so that their faster and more agile backs could pass it and run with it in the hope of scoring goals. But as players increased in pace through improved fitness, without a corresponding increase in the size of the field, the open spaces became fewer, defenses became more effective, and attacking moves were all too easily stifled.

(Left) Players in position for a scrum. (Right) Positions of players for a line-out.

Play began to stagnate and to become dull, both for the player and for the spectator. In order to reverse this trend and to encourage the return of flowing movement to the game, the International Board made several important changes in the laws in 1964. It was ruled that while a line-out (putting the ball back in play after it had gone out-of-bounds) was taking place, each set of three-quarters must remain at least ten yards nearer their own goal

line than the point of the line-out, thus leaving a clear no-man's-land in which attacks could be developed; that backs must not advance beyond the hindmost foot of scrums until the ball was out; that forwards must not advance from a scrum until the ball was out; and that the team throwing in the ball at a line-out had the right to determine the shortness of the line-out, thus preventing opponents from straggling across the field in a defensive screen. Another change, in 1970, made it illegal for a player to kick the ball directly over the touchline or sideline except from within 25 yards of his own goal line. Thus the player retained the right to kick his way out of a desperate defensive situation but was dissuaded from seeking the safety of kicking out-of-bounds from positions in which he could attack through running and passing.

Styles of play. When it was customary to have 20 players a side, they were arranged in the formation of 13 forwards, 3 halfbacks, 1 three-quarter, and 3 fullbacks. With the reduction of a team to 15 men in 1877, the normal formation became eight forwards, two halfbacks, two three-quarters, and three fullbacks. Scotland used the innovation of three three-quarters in 1881 and was followed in this by England and Wales in 1882 and by Ireland in 1883. Wales used four three-quarters in the 1885–86 season; England, Ireland, and Scotland adopted this formation in 1893–94. At that time, the two halfbacks both played close to the scrum, and when the ball came out it was taken by whichever of them seemed the better placed to use it. The fixed positions of scrum half and stand-off half were introduced in the early years of the 20th century.

Overseas the game developed slightly differently, especially in New Zealand, where they had a scrum with only two men in the front row instead of the normal three, but the International Board outlawed this formation in 1932. New Zealand also considered the first three men to handle the ball behind the scrum as a halfback and two five-eighths, whereas in the British Isles the first two were known as halfbacks. Australia kept the British conception of two halfbacks but emphasized that one of the centres would always be considered the inside centre and would always position himself next to the stand-off half. Thus the Australians looked upon their centres as one inside centre and one outside centre, whereas in the British Isles the centres played left and right rather than inside and outside.

Quite apart from their formations, different countries developed different styles of play, partly because of the differences in climate. In Scotland, where the grounds tended to be wet and muddy, the ball was more often kicked or dribbled along the ground than in other countries. While their opponents on wet days dropped the ball or slipped in trying to pass or to change direction while running with the ball, Scotland's men would put the ball on the ground and drive it up the field with their boots. Scotland's teams, of course, have tried more sophisticated methods as the game has developed over the years, but they are still best known for their hard forward play. Irish teams, too, have made a reputation for uncompromising forward play. The Welsh, on the other hand, have complemented their tough forward game with clever, elusive play at halfback. It has been their misfortune that their grounds and their weather have often been too wet for full profit to be drawn by their talented halfbacks. England, from the early days, established itself as the country of the orthodox in Rugby and has generally relied on teamwork and cooperation within well-balanced teams. New Zealand, as was to be expected from a community largely devoted to farming, developed big, strong, capable forwards. Its teams have sometimes used these tough forwards as the mainspring of their attack, and at other periods they have trusted in the hard running of their backs to make full use of the clean and regular possession provided by the forwards. When the New Zealanders visited the British Isles in 1905–06, the brilliance of their open play was much appreciated; and they won much acclaim with the same kind of attractive football when, as the New Zealand Army team, they toured Britain imme-

diately after World War II. But for a period after that they neglected back play and sought to win matches through tight forward play and kicking. In the 1950s and 1960s they had a good deal of success with these methods and with what became known as "second-phase Rugby," in which, instead of attacking directly as soon as the ball had been obtained, they deliberately sought, by running into a tackle or by accurate kicking, to create loose play. The theory behind this style was that an attack direct from a set piece (a scrum or a line-out) was unlikely to succeed because the defense would be lined up in a set position; but if the defense could be drawn out of position by an initial thrust, which might well cause at least one defender to be pinned on the ground, then the attack had a greater chance of bearing fruit. This style of play was widely copied, but the New Zealanders then surprised everyone by reverting to all-out, flowing, open football on a tour of the British Isles in 1967, during which they remained unbeaten in 15 games. While New Zealand has led the world in these ways, South Africa has pioneered the techniques of scrummaging. While other countries settled for a scrumage formation of three men in the front row, two in the second, and three in the back row, the South Africans discovered that more efficient scrummaging could be obtained with three in the front row, four in the second, and one in the back. Their mastery of this formation was largely responsible for making them the outstanding Rugby country of the 1930s. At times, the South Africans, like the New Zealanders, have concentrated on forward play to the detriment of back play, but the solid work of their scrum pack over the years has been an eminently reliable basis from which to proceed. The game in Australia has remained almost invariably spectacular and entertaining to watch. The ball has been thrown about, and running and passing have been carried out at high speed. The hard grounds and dry climate of the country have undoubtedly contributed to Australia's emphasis on open Rugby rather than on hard forward play. Another important reason why Australian teams have played in this style over the years has been the strength of the professional Rugby League game in and around Sydney and Brisbane. In Australia, Rugby Union, an amateur game, is the poor relation of Rugby League, and it is felt that Rugby Union players must play attractive football to win and hold public support. Like the Australians, the French have become famous for their open attacking Rugby. Here again the influence of the climate has been considerable, for the game is largely confined to the southern half of the country where sunshine and dry grounds are the rule. But it was not until shortly before World War I that the French adopted the fluid style for which they were to become so admired in later years. A vital influence in the adoption of this method was exerted on the French by a Welshman, Owen Roe, who settled in the town of Bayonne and taught the local club team the intricacies of back play as he had learned them at Penarth in south Wales. In 1913 Roe's Bayonne team not only inflicted a first ever championship home defeat on the great Bordeaux club but also took their brilliant three-quarter play up to Paris and there won the final of the French club championship by 33 points to 8. Such a score immediately attracted attention, and Bayonne's style was soon copied by teams in other parts of the country. In the 1950s, France gave the Rugby world a lesson in the art of getting a scrum half and loose forwards to attack in intimate combinations close to their pack: and in 1958, in particular, they had great success with peeling, or churning, moves from the back of the line-out. The ball would be tapped down from the line-out, and other forwards, often spearheaded by Lucien Mias, would go hurtling towards their opponents' goal line. This method sometimes led directly to tries, and sometimes tries were scored from a subsequent quick ruck or scramble for the ball, rather in the manner of the New Zealanders' second-phase attack. The most uninhibited and improvised of all Rugby played at an international level has been that of the Fiji, who drew a crowd of 42,000 to one of their matches when they visited Australia in 1952. Their play has been the very antithesis of the

Second-phase Rugby

The open styles of Australia and France

Formations

National styles

orthodoxy of England. They have simply run and passed the ball at every possible opportunity, making the job of planning a defense against them an extremely difficult task.

Competition. In most Rugby countries a need for competitions was felt at club level early in the game's development, but the club game in England, Scotland, and Wales remained largely based on friendly matches. England has had county cup competitions, confined to the clubs within individual county areas, for many years; but these were knock-out competitions rather than leagues, and it was not until the 1970s that a national club competition was set up. A national competition for county, as opposed to club, teams was started as early as 1889, however, and there was also a national competition for university teams. The club game in Scotland had its first official national competition in the 1970s, and the Scots also have a competitive interdistrict championship. Wales similarly developed a national club competition in the 1970s and also has a county championship. Ireland early developed a comprehensive pattern of league and cup competitions for clubs, although the competitions are based on the provinces rather than on the country as a whole, and many friendly matches are also played. Ireland also has a thriving interprovincial championship.

Outside the British Isles, club Rugby was almost universally based on the league system, often with cup competition as well. In New Zealand, for instance, competitive leagues were set up almost as soon as there were sufficient clubs to make this feasible, and New Zealand club Rugby has remained highly competitive with interclub leagues for 15 separate grades of players, from the 15th grade with its little boys to the top teams of senior clubs. By the 1970s New Zealand had 28 unions with competitions for 500 senior clubs and many more junior clubs. Some clubs were reporting more than 700 playing members each. New Zealand also developed a keenly contested interprovincial competition, stimulated by the presentation in 1902 of the Ranfurly Shield by the Earl of Ranfurly, Governor General of New Zealand. The competition for the Shield is run on a challenge basis, the holders retaining the Shield until beaten by a challenging provincial union. A similar pattern developed in South Africa, with local leagues for clubs and a national competition for teams representing provinces. The trophy awarded to the top province is the Currie Cup, dating from 1892 and originally presented by Sir Donald Currie, of the Castle Shipping Line, to the captain of the 1891 British team about to tour South Africa, for presentation to the South African side that put up the best performance. It was duly awarded to Griqualand West, which in turn presented it to the South African Rugby Board as a trophy for the interprovincial competition. In Australia local club leagues were established early in the game's development, but the institution of a full interprovincial competition remained impractical because Rugby of quality was largely confined to the two states of New South Wales and Queensland. The club game has been differently arranged in France, where a championship for clubs, with a trophy called the Bouclier de Brennus, has been organized on a national basis for many years. The details of this championship have been varied from time to time, but by 1970 the regular formula was a First Division divided into eight groups of clubs with eight clubs in each group. The clubs in each group played one another at home and away on a league basis; then the four leading clubs in each group went forward to form the 32 clubs needed for five knockout stages. Including this First Division, the French regularly have had 13 annual national championships at various levels as well as local and regional club competitions. Like New Zealand, the French have arranged competitions for the schoolboy teams of clubs, but they have not followed the New Zealand pattern of establishing a championship for representative provincial teams. As a result, although teams have often been chosen to represent regions, notably against touring teams from overseas, there has been no regular representative Rugby that the ambitious French player might use as a stepping stone between his club team and France's national team.

In Rugby, as in cricket, the highest form of competition is the Test series consisting of two or more games between representative national teams—*i.e.*, teams made up of the best players in each country. Also in Rugby, the four "Home Unions," England, Scotland, Ireland, and Wales, are considered as "countries" and their teams as national teams (teams representing the whole of the British Isles are known as the Lions). Thus the first "international" match was that between Scotland and England in 1871. A complete program of matches was established for England, Scotland, Ireland, and Wales in the season of 1883–84. This championship has continued more or less every year since, except during World Wars I and II. The regular formula has been for each "country" to play the other once a season, at home one year and away from home the next. France entered this championship in the 1909–10 season but had to wait until 1954 before managing to come out on top of the championship table. Even then, France had to share top place with England and Wales, and it was not until 1959 that a French team won it unshared for the first time. In 1970, however, France beat England 35–13, the biggest number of points ever scored against England in one match.

On the other side of the world, the first international activity occurred in 1882, when a team from New South Wales visited New Zealand. This was, in fact, the first international Rugby tour made anywhere in the world. The New South Wales side did not meet a full New Zealand team, but in 1894 such a match did take place, New South Wales winning this first Test. The Queensland state team also visited New Zealand in this period, and from 1903 onwards the Australian states combined, whenever possible, to form representative teams for international matches. Thus, in the strictest sense, the first Test match between the two countries took place in 1903. The two countries have continued playing each other more or less regularly since then. The New Zealanders have generally been the more successful, but in 1929 the Australian Wallabies beat New Zealand in three Tests played in Australia and in 1949 two Tests in New Zealand. Since 1931 the Tests have been played for the Bledisloe Cup, presented by Lord Bledisloe, Governor General of New Zealand.

South Africa's first international competition occurred when the British team toured South Africa in 1891, playing 16 matches including three Tests, all of which the visitors won. Such tours were to become a distinctive feature of Rugby Union, and other tours of South Africa by teams from the British Isles followed in 1896, 1903, and 1910. Meanwhile, a British team, in which England, Scotland, and Wales were represented, had toured New Zealand and Australia in 1888. This was the first overseas tour ever made by a team from the British Isles, and it established a precedent of tours to Australasia that has been followed at fairly regular intervals ever since.

Nor was the traffic one-way. The season of 1888–89 was enlivened by a visit by 26 New Zealanders, the first team from overseas ever to visit the British Isles, who played 74 matches in the British Isles, 16 in Australia, and 17 in New Zealand. This team, officially called the New Zealand Native Team, became known as the Maori although four of the players were in fact of European stock. They beat Ireland but lost to England and Wales. This tour was followed in the 1905–06 British season by a visit by New Zealand's fully representative team, known as the All Blacks, who won 32 of the 33 matches they played on tour and established New Zealand as one of the two most powerful Rugby countries in the world. During the following season, a fully representative team from South Africa, the Springboks, toured Britain for the first time; and they, together with their successors in 1912–13, who beat all four home countries and France, made it clear that they were to be reckoned in the same bracket as New Zealand. Since then, teams from New Zealand and South Africa have continued to make tours of the British Isles, usually including a brief visit to France, at more or less regular intervals. Australian teams, too, have made similar tours to Britain, normally, like New Zealand and South Africa, playing roughly 30 matches on each visit.

boks

In the 1920s, New Zealand, South Africa, and Australia settled into the routine of making tours of one another's country, the first such tour taking place in 1921, when South Africa toured New Zealand and Australia. In the middle years of the 20th century, international matches between New Zealand and South Africa became recognized as being for the unofficial world championship, and each found great difficulty in winning on the other's territory. An exception to this rule was the 1937 South African tour of New Zealand, when the South Africans won the international series 2-1 and also won all their 14 provincial matches there. The South African government's policy of apartheid (racial segregation) led to the postponement of New Zealand's scheduled 1967 tour of South Africa, the South African prime minister refusing to allow the New Zealanders to include Maori in their touring team. When the tour did finally take place in 1970, however, the New Zealanders became the first multiracial sports team ever to tour South Africa. Anti-apartheid demonstrations during South Africa's tour of the British Isles in the 1969-70 British season caused unpleasant moments for the tourists; but in general the national Rugby unions, unlike the national bodies of many other sports, held firmly to the belief that the political activities of a country's government should not be a reason for refusing to take part in a sport against players of that country.

France and international Federation competition

The first international team to play in France was the 1905-06 New Zealanders, and England first met France later the same season in Paris. The French themselves did not make an overseas tour until 1958, when they went to South Africa and surprised the Rugby world by becoming the first international side to win a Test series in South Africa since the British team of 1896. In 1961 the French tried their luck in New Zealand for the first time but were defeated in all three Tests. France has also played international Rugby against Romania for many years, their first meeting having been in 1924, when France won 59-3. But by 1938 the score was no more than 11-8 to France, and in 1960 Romania beat France for the first time, the score being 11-5. France's first match against Italy was in 1937. Italy and Romania have played international matches against each other, and they have also played frequently against other Rugby countries under the jurisdiction of the *Fédération Internationale de Rugby Amateur*, such as Spain, Czechoslovakia, Poland, and Germany.

Other countries that have made their presence felt in international Rugby include Fiji, which regularly plays against Tonga and which has beaten Australia; Canada, which has played against major touring teams that have been on their way to or from Britain or Australasia; Argentina, which has beaten Wales, Scotland, and Ireland at Buenos Aires; and the United States, which won the Rugby competition at the Olympic Games of 1920 and 1924.

For all-time records of Rugby Union international (or Test) matches see **RELATED ENTRIES** under **SPORTING RECORD** in the Ready Reference and Index.

The game. Rugby is played on a rectangular field not more than 75 yards (68.6 metres) wide; the maximum distance between the goal lines is 110 yards (100 metres) and beyond each goal line the end zone, called "in goal," extends not more than 25 yards (23 metres). At the centre of the goal lines are two goal posts 18 feet 6 inches (5.6 metres) apart with a crossbar 10 feet above the ground.

The ball is oval, less pointed than the U.S. and Canadian football, and is inflated. It is 11 to 11¼ inches (28 to 29 centimetres) long, 24 to 25½ inches (61 to 65 centimetres) in circumference, and weighs 13½ to 15 ounces. The outside casing of the ball is usually of leather.

The players wear jerseys, shorts, stockings, and studded (cleated) boots. They are not allowed to wear protective harness or shoulder pads. The game is controlled by a referee assisted by two touch judges, and in international matches there are two periods of 40 minutes each.

One of the charms of the Rugby Union game is the infinite variety of its tactics. In a basic orthodox situation, like a scrum on the right-hand side of the field, the ball may simply be passed rapidly by hand through the half-

Forwards engaged in a scrummage (Wales-France Rugby International. Paris, 1970).

Sports Illustrated photograph by Gerry Cranham, © Time Inc.

backs and the centre three-quarters to the left-wing three-quarter, each man running a few yards before parting with the ball; the wing may then be able to run past his immediate opponent by swerving or sidestepping or simply by using strength and speed; a try will probably be scored. But the attacking team may already have tried an orthodox move of this kind and may have discovered that the opposition is especially strong defensively and also possesses exceptional speed. In this case, the attacking team must depart from the orthodox and try to discover a chink in their opponents' armour elsewhere. One of the halfbacks, for instance, might discover that the defence in his particular sphere is vulnerable to a sudden change of direction. He may therefore run himself rather than pass the ball out, and he may decide, after making his initial breach, that a try is most likely to be scored if he subsequently passes the ball not outside to his three-quarters but inside to his big and heavy forwards, who may be able to barge their way over the opponents' goal line.

An attack may also be launched not into the open field but, for the sake of surprise, on the other side of the set piece. Instead of passing at all, the halfback may prefer to test the nerve of the opposing fullback by kicking the ball high into the air and instructing his teammates to bear down menacingly upon the opposing fullback as he is about to try to make the catch. A harassed fullback may drop the ball, leaving it conveniently placed for an attacker to pick up and run off with.

The weather has a big influence on the tactics adopted. If the day is very wet and the field very muddy and slippery, a team's captain may prefer to keep play confined largely to his forwards rather than to risk seeing one of his halfbacks or three-quarters let the wet ball slip from his hands in the open field. He may therefore instruct his forwards not to deliver the ball from a line-out to the scrum half but to hold on to it and try to make headway in a closely knit group. Similarly, at a scrum he may order his forwards to try to retain the ball and take it up the field at their feet.

RUGBY LEAGUE

Origin. The Rugby League game was originated by 22 Rugby Football Union clubs in the North of England who broke away from the parent body because they wanted their players to be paid for "broken time"—i.e., loss of wages due to playing the game. The matter first came to a head in 1893 when the Yorkshire Rugby Union proposed "that players be allowed compensation for bonafide loss of time." The proposal was defeated, but the RFU was frequently called upon to hold inquiries into alleged acts of professionalism in the North. When the RFU therefore proposed some even stricter "laws against professionalism," in 1895, these were rejected by many of the leading clubs in the counties of Yorkshire and Lancashire, which then formed "the Northern Union Football Union," later, in the 1920s, to become the Rugby Football League.

The main difference between the Rugby League game

Playing the game: tactics

Differences between League and Union games

and the Rugby Union game is that Rugby League is partly professional whereas Rugby Union has remained entirely amateur. The two games are played on similar fields, and the aim in League, as in Union football, is to score tries and goals. A try in Rugby League is worth three points, as opposed to four points in Rugby Union, but in both the League and Union game every successful kick at goal is worth two points.

There are only 13 men on a Rugby League team instead of 15. The two who have been dispensed with are the two wing forwards, so that a League scrum has three men in the front row, two in the second, and one in the back. There are no line-outs in Rugby League; if the ball goes out of play over the touchline, a scrum is ordered. Nor is the Union game's ruck or maul to be found in Rugby League. When a player is brought down in possession of the ball, he has to be allowed to stand up face-to-face with an opponent and attempt to tap the ball back to his own teammates with his foot.

Development of game. Although it has been played in other parts of the British Isles, such as south Wales and the London area, the Rugby League game has established a firm foothold in Britain only in the three northern counties of Yorkshire, Lancashire, and Cumberland. In those areas it is organized into numerous competitions of which the best known are the Northern Rugby League and the Rugby League Challenge Cup competition. Both these are for club teams, the former on a league basis, the latter a knockout event.

The game has also taken firm root in France, Australia, and New Zealand. Like Rugby Union, the League game in France is largely confined to the southern part of the country, and it has flourished on a strictly competitive basis. In Australia the main centres of the game are Sydney and Brisbane, though it is widely played in cities and towns throughout the country and has a larger following than has Rugby Union. In New Zealand the game is less firmly established than Rugby Union, but it is played in most cities and big towns and is notably strong in Auckland and Wellington.

As a largely professional game, requiring a steady intake of money from gate receipts, Rugby League has been ahead of Rugby Union in developing along crowd-pleasing lines. The reduction of a team from 15 to 13, with the removal of wing forwards, for instance, left the field less cluttered and so more suitable for attractive open play. Rugby League was also ahead of Rugby Union in introducing laws to curb the stagnation of repeated kicks over the touchline.

Competition. Although Rugby League has been played at strength in no more than four countries, the national teams of these four, Great Britain, France, Australia, and New Zealand, have managed to come together from time to time to play a World Cup tournament. This has provided the summit of international competition, but there have also been regular tours somewhat after the manner of Rugby Union tours, by Australia, for example, in Great Britain and France and by Great Britain in Australia and New Zealand. The French have toured Australia and New Zealand, and the New Zealanders have toured in Great Britain and France. Great Britain had an exceptionally successful tour in Australia and New Zealand in 1970, when they played 24 matches, winning 22, drawing one, and losing one, with a points record of 753 for and 288 against. They scored 165 tries.

In less far-ranging international encounters, Great Britain has settled into a pattern of playing France at home and away each season, and Australia has had more or less regular matches against New Zealand. Matches between Australia and New Zealand are for the Trans-Tasman Cup, which is retained by the one country until beaten in a Test series by the other.

A national team has also been raised, though less regularly, to represent Wales. The Welsh team is chosen chiefly from former Welsh Rugby Union players who have joined Rugby League clubs in the North of England. Such players, of course, are eligible for the Great Britain team; but during periods when there have been sufficient numbers of them, they have also formed a Welsh team to

play against England or against France. In October 1969 a special triangular tournament was held in England involving the national teams of England, France, and Wales. The countries finished in that order in the final table, but later that season Wales had the satisfaction of beating France 15-11 at Perpignan, becoming the first Welsh Rugby League team to win in France since 1936.

Rugs and Carpets

The term carpet was used until the 19th century for any cover made of a thick material, such as a table cover or wall hanging; since the introduction of machine-made products, it has been used almost exclusively for a floor covering. Both in Great Britain and in the U.S. the term rug is often used for a partial floor covering as distinguished from carpet, which is tacked down to the floor and covers it wall-to-wall. In reference to handmade carpets, however, the terms rug and carpet are used interchangeably and are so used in this article, which deals almost exclusively with handmade products. Since such carpets are not always intended for use on the floor, the article extends the term rugs and carpets to cover products intended for other uses as well.

Handmade carpets are works of art as well as functional objects. Indeed, many Oriental carpets have reached such supreme heights of artistic expression that they have always been regarded in the East as objects of exceptional beauty and luxury in the same way as masterpieces of painting have been in the West. Handmade carpets are discussed in this article in terms of their elements of design, material, technique, ornament and imagery, use, and stylistic characteristics in different periods and cultures.

This article is divided into the following sections:

- Elements of design
 - Field and border designs
 - Design execution
 - Colour
- Materials and Technique

ELEMENTS OF DESIGN

Field and border designs. Designs usually consist of an inner field—the pattern in the centre of the carpet—and a border. The latter serves, like the cornice on a building or the frame on a picture, to emphasize the limits, isolate the field, and sometimes control the implied movements of the interior pattern. The design of inner field and border must harmonize pleasingly, yet remain distinct.

The border consists of a minimum of three elements: a main band, which varies greatly in width according to the size of the rug and the elaborateness of the field design, and inner and outer guard stripes, decidedly subordinate bands on either side of the main band. The guard stripes may be the same on both sides of the main band or be different. The most common decoration for the field is an all-over pattern, a panel composition, or a medallion system. The all-over pattern may be of identical repeats (Figure 1), either juxtaposed or evenly spaced, though the latter, while common on textiles, is rare on carpets; or it may be of varied motifs in a unified system (e.g., different plant forms of about the same size), but even this freest type of design almost invariably includes bilaterally balanced repetitions. The varied motif type of design is found most typically in formalized representations of the parks or woods that were a feature of Persian palace grounds (see Figure 7).

Another type of all-over design appears to be entirely free but is actually organized on systems of scrolling stems, notably on the east Persian carpets of the 16th and 17th centuries.

The value of panel subdivisions for controlling patterns had been discovered in a simple rectangular version by the Upper Paleolithic period (c. 25,000 BC), and panel systems have been a basic form of design since 4000 BC, when pottery painters were already devising varied systems. On carpets, the lattice provides the simplest division of the field, often a diagonal lattice as on an embroidered carpet found in an excavated tomb (1st century BC to 1st century AD) at Noin Ula in northern Mongolia; the diagonal scheme also appears on Sāsānian capitals and in Coptic tapestries. But a characteristic field design of the Persian court carpets of the Shāh 'Abbās period, the so-called Vase pattern, is constructed from the ogee, a motif that became prominent in Near Eastern textile design in the 14th century. Simple rectangular panelling—really a large-scale check—is typical of one style of Spanish rugs of the 15th and 16th centuries.

The most frequent medallion composition consists of a more or less elaborate medallion superimposed on the centre of a patterned field and often complemented with cornerpieces, which are typical quadrants of the central medallion (Figure 2). But multiple-medallion systems also are developed: either a succession or a chain of medallions on the vertical axis; two or more forms of medallions alternating in bands, a scheme typical of the Turkish (Ushak) carpets of the 16th and 17th centuries; or systematically spotted medallions that may or may not be interconnected or that may interlock so that the scheme logically becomes an elaborate lattice.

Persian carpets of the 15th–17th century commonly have multiple-design schemes; that is, composition systems on two or more "levels." The simplest is the medallion superimposed on an all-over design, but more typical are subtler inventions such as two- or three-spiral stem systems, sometimes overlarded with large-scale cloud bands, all intertwining but each carried independently to completion. The finer Vase carpets have double or triple ogival lattices set at different intervals (staggered), each with its own centre, and tangent motifs that also serve other functions in the other systems. What at first sight appears to be a great multiplicity of independent motifs thus proves on careful examination to be ingeniously contrived and firmly controlled.

Occasionally, stripe systems are used, either vertical or diagonal; but this conception is more natural to shuttle-woven fabrics, and, when employed in the freer techniques of rug weaving, it is probably an imitation of textiles.

Design execution. Transferring the design is done in various ways. It can be transferred to the carpet directly

Medallion
carpets

Types of
field
decoration

from the mind and hand of the craftsman or indirectly from a pattern drawn on paper. Using the latter technique, a rug can be executed directly from the pattern, or the design can be transferred first to a cartoon. The cartoon, or *talim*, is a full-size paper drawing that is squared, each square representing one knot of a particular colour. The weaver places the *talim* behind his loom and translates the design directly onto the carpet. The cartoon is used for reproduction of very intricate designs and as a master pattern for the production of more than one carpet. Many of the finest Oriental rugs, which achieve a magnificent effect through wealth of detail, are thought to have been woven from cartoons drawn by manuscript illuminators. Such methods of transfer result in unavoidable irregularities of pattern that, because they are signs of the artistic individuality of the craftsman, lend a particular charm to the handwoven carpet. The major difference between handmade and machine-made carpets is that the mechanical transfer of design in the latter creates a uniformity of pattern, obliterating signs of individual workmanship.

Colour. From earliest times until the late 19th century, only natural dyes were used. Some have come from vegetables such as madder, indigo, sumac, genista, and woad; some from minerals such as ochre; and some from animals, mollusks, and insects. Most have been improved by the addition of various chemicals, such as alum, which fix colours in the fibre. Except for dark brown to black dyes, which have high iron-oxide content that often decomposes fibres, natural dyes have proved to be excellent; they have remarkable beauty and subtlety of colour, and they are durable. Much of the charm of antique carpets lies in the slightly varying hues and shades obtained with these natural dyes. In the 19th century, synthetic, aniline dyes were developed, becoming popular first in Europe and, after 1860, in the East; but their garish colours and

poor durability were later thought to outweigh the advantages of brilliance and quick application, and natural dyes regained favour with many craftsmen. More recently, synthetic dyes have been improved.

MATERIALS AND TECHNIQUE

Most carpets are made of sheep's wool, which is durable, dyes readily, and handles easily. Camel or goat wool is rarely used. Too dull to make an attractive pile, cotton's strength and smooth yarn make it an ideal warp (see below); it is used in the East for the entire foundation or for the warp only.

Silk is so expensive that its use is restricted; but no other material produces such luxurious, delicate rugs, displaying subtle colour nuances of particular charm in different lights. Some of the finest 16th- and 17th-century Persian carpets are entirely of silk. It has never been used for knotting in Europe; but often since the 15th century it has augmented wool in the weft of European tapestries.

Linen was used in Egyptian carpets, hemp for the foundations of Indian carpets; and both materials are used in European carpets. Since around 1820, jute has been used in the foundation of machine-made carpets.

Knotted pile carpets, combining beauty, durability, and possibilities for infinite variety, have found greatest favour as floor coverings. Long ago, weavers first began to produce pile fabrics or fabrics with a surface made up of loops of yarn, attempting to combine the advantages of a woven textile with those of animal fleece. Knotted pile is constructed on the loom on a foundation of woven yarns, of which the horizontal yarns are called weft yarns and the vertical are called warp yarns. Coloured pile yarns, from which the pattern is obtained, are firmly knotted around two warp yarns in such a way that their free ends rise above the woven foundation to form a tufted pile or thick cushion of yarn ends covering one side of the founda-

(Bottom right) Enlarged section of above showing the herringbone effect created by the Soumak method of brocade.

dation weave. The knots are worked in rows between several interlocking, tautly drawn weft yarns that keep every row of knotted tufts securely in place in the foundation. When a row of knots is tied, it is beaten down against the preceding rows with a heavy mallet-like comb so that on the front the pile completely conceals both warp and weft. When a certain area has been woven, the pile ends are sheared to an even height. This varies according to the character of the rug, being short on the more aristocratic type and as much as an inch (2½ centimetres) on some shaggy nomadic rugs.

There are various ways of knotting the pile yarn around the warp yarn. The Turkish, or Ghiordes, knot is thought to be the oldest. It is used mainly in Asia Minor, the Caucasus, Iran (formerly Persia), and Europe. The Persian, or Sehna, knot is used principally in Iran, India, China, and Egypt. The Spanish knot, used mainly in Spain, differs from the other two types in looping around only one warp yarn. After the 18th century it became extremely rare. The kind of knot used affects the delicacy and tightness of the pile. Knotting each pile yarn by hand is comparable to setting small pebbles in a mosaic, and expert execution is vital in achieving a beautiful finished product. Angular-patterned carpets requiring only a coarsely knotted pile are easier to produce than curvilinear and finely patterned ones, which require finer material and a much more densely knotted pile for clear reproduction of their intricate designs. Some Chinese carpets have fewer than 20 knots per square inch (three per square centimetre); certain Indian ones, more than 2,400. The highest density can be achieved with the Persian, or Sehna, knot.

Brocading can be added to the pile, heightening its colourfulness. The gold and silver thread in this procedure lies flat against the woven foundation, giving the appearance of low relief (Figure 3, left). Metal threads, however, quick-wearing and with diminishing lustre, are less suitable as floor coverings than as hangings.

Many carpets do not have knotted pile. Called *kilims*, they are woven similarly to tapestries. The weft yarns of a given colour area never cross into another area, and if the weft yarns of different colour areas are hooked around adjacent warps rather than around one another or around warp yarn, small slits are created where different colours meet (Figure 3, centre). A variation is used in fully brocaded Soumak carpets in which one or two rows of coloured pattern weft alternate with an invisible functional weft. Brocading with passes of alternate rows given a differing direction, or slant, produces a herringbone effect (Figure 3, right).

Embroidery has rarely been used on floor coverings. Embroidered rugs are almost exclusively European and American, except for certain Turkmen *kilims* and Turkish *cicims* (ruglike spreads or hangings). Only relatively strong backings can be used, such as in *appliqué* work or embroideries done in designs of counted stitching (the cross-stitch, and the gros point and petit point of needlework) that cover the entire surface.

ORNAMENT AND IMAGERY

Individual motifs. Three main classes of motifs are used: geometrical; conventional, or stylized; and illustrative, or naturalistic. The geometrical repertoire is built up from variations and combinations of meanders, polygons, crosses, and stars. Meanders, chiefly for borders, range from the simple serration employed from earliest times to fairly complex hooked forms, characteristically the angular "running wave," or "Greek key," which is also very ancient. Little trefoil (tri-lobed) motifs are used for guard stripes in the Caucasus, central Iran, and India. Chief among the polygons employed are the lozenge and the octagon. The Maltese cross is frequently used, as is the gamma cross, or swastika. Purely geometrical stars are usually based on the cross or the octagon. Many of these motifs, which are rudimentary and very ancient, may have originated in basket weaving and the related reed-mat plaiting, for they are natural to both techniques; but in rug weaving they have survived chiefly in the work of Central Asia, Asia Minor, and the Caucasus, in both pile-knotted and flat-woven fabrics.

One of the principal stylized motifs in 16th- and 17th-century Persian carpets is the so-called arabesque, an ambiguous term that generally implies an intricate scrolling-vine system. In a common Persian ornamental scheme, two asymmetrical members cross at an acute angle, forming a lilylike blossom, and then describe curves in opposite directions, readily continuing into further scroll systems (Figure 4). This highly individual form was begun in China in the late Chou period (c. 600 BC), notably on a few bronze mirrors and was beautifully developed during the Han dynasty (206 BC–AD 220). It appeared in Persia in the 12th century (on pottery and architectural stucco ornament), possibly influenced by the Chinese form.

Directly traceable to China are the cloud knot and cloud band, or ribbon—both in use by the Han period at least and with a continuous history thereafter. The cloud knot, a feature of the Persian court carpets of the time of Shāh 'Abbās, was continued to the end of the 18th century. The cloud band became important on 16th-century carpets; it was employed with especial elegance and skill by Persian designers and perhaps most beautifully in Turkish court carpets, which owed much to Persian inspiration. The cloud band and knot motifs moved from Syrian textile design into Asia Minor with the Ottoman Turkish conquest in the 15th century and became typical of one group of 16th–17th century Turkish carpets.

Palmettes, a second major class of stylized motifs dominant in a considerable range of carpet designs from Asia Minor to India, originated in Assyrian design as styliza-

tions of the palm, a symbol of vitalistic power that was often, if not always, associated with the Moon (Figure 5). Many of the almost uncountable variations that developed through the centuries continued to refer directly to the palm. As early as the 1st millennium BC, however, others derived from the lotus blossom, a complementary motif connected primarily with the fertility symbolism of the Sun. Still others involved the pomegranate, another fertility symbol, utilizing primarily the fruit, while yet another group presented the vitalistic emblem of the vine, this last design being built on the single leaf. The forms of these four main types of palmettes found in Oriental rug designs are directly descended from styles current in textile designs from the 4th century onward and are often modified by Chinese influences. The patterns in the 16th and early 17th centuries were beautifully and realistically elaborated, and blossoms such as the Chinese peony sometimes compete with the more stylized lotus. The lanceolate leaf, often associated with palmettes (especially in east Persian designs), is generally stylized. The chalice, fan, and half-palmette, all evolved from the palmette and used in Oriental rugs, were also used in 17th- and 18th-century European designs.

Naturalistic motifs

Outstanding among the more naturalistic plants are cypresses and blossoming fruit trees, symbolizing life eternal and resurrection, respectively. Willows and jasmine flowers are prominent in the *Shāh 'Abbās* Vase carpet and tulips in Turkish court carpets. Many minor foliate and floral forms had no specific botanical identification, though they give a realistic effect (Figure 6). Naturalistic red or pink roses, rare in Oriental rugs before the 19th century, were already widespread in European designs by the mid-16th century. Under European influence, they appeared in Oriental designs, particularly Persian, in the later 19th century.

The most important illustrative motifs, other than naturalistic plants, are those connected with the garden and the hunt: many small songbirds (in Persia, especially the nightingale); the pheasant (*feng-huang*), taken over from China and much favoured in the 16th century; occasionally the peacock; lions and a semi-conventional lion

mask, sometimes used as the centre of a palmette; tigers; cheetahs; bears; foxes; deer of numerous species; goats, sometimes picturesquely prancing; the wild ass, a fleet prey; ferocious-looking Chinese dragons, and the gentle *ch'i-lin*, a fantastic equine also imported from China. Fish sometimes swim in pools or streams or are conventionally paired to suggest a shield, or escutcheon, in the borders of the carpet. Huntsmen, usually mounted, are the major human figures, though musicians are also depicted. Angels are occasionally present (see Figure 8).

The underlying theme of both the stylized and naturalistic vocabularies is nearly always fertility or abundance. The great Persian carpet of Ardabil (1539–40; Victoria and Albert Museum, London), for example, embodies a huge golden stellate medallion, developed from the multi-pointed rosette that from time immemorial symbolized the Sun. At its centre are four lotus blossoms floating on a little gray-blue pool, which represents the source of rain in the heavens. The medallion thus symbolizes the two basic vitalizing elements—Sun and water. As proof of its magical potency, a complex system of tendrils and blossoms issues from it (see Figure 12).

In Oriental carpet design, a flat surface pattern is always emphasized, even where small details are plentiful. European designs, however, tend more toward the illusionistic effects of painting, often using shading and picture-like

Oriental versus European design

compositions and incorporating architectural motifs (a cornice, for example) and even portraiture. This tendency is particularly evident in French carpets of the 17th and 18th centuries.

Symbolism of overall design. In addition to the symbolism inherent in individual motifs incorporated into the design of the carpet, the total design—indeed, the carpet itself—can be symbolic, as are some of the earliest Persian designs. The ultimate example is the Spring (or Winter) of Khosrow Carpet made for the audience hall of the Sāsānid palace at Ctesiphon (southeast of Baghdad) in the 6th century. The carpet has not survived, but, according to written records, it represented a formal garden with watercourses, paths, rectangular beds filled with flowers, and blossoming shrubs and fruit trees. Yellow gravel was represented by gold; and the blossoms, fruit, and birds were worked with pearls and different jewels. The outer border, representing a meadow, was solid with emeralds. Made of silk and measuring about 84 feet square (about 26 metres square), the carpet must have seemed overwhelmingly splendid when the great portal curtains of the hall were drawn back and the sun flooded the interior.

This dazzling carpet symbolized the divine role of the king, who regulated the seasons and guaranteed spring's return, renewing the earth's fertility and assuring prosperity. On another plane, it represented the Garden of Eden, a symbol of eternal paradise (the English word paradise is ultimately derived from the Persian word, which means "walled park"). With its flowers, birds, and water, it symbolized deliverance from the harsh desert and the promise of eternal happiness.

This most sumptuous of fabrics made a profound im-

pression on everyone, especially the Persians. For centuries it bewitched Persian imagination, becoming a legend in history, poetry, and art. Vain attempts at emulation were made by Oriental craftsmen for more than a millennium; and though its realistic depiction has disappeared, the Garden of Eden concept lingers on in Oriental designs (Figure 7). The garlands, vines, flowers, trees, animals, and beasts all strive to create a landscape, picturing hunting scenes or game, lakes with water birds, and often images of supernatural or celestial beings, such as jinn, houris (maidens who are among the pleasures of the Muslim paradise), or a gathering of the blissful righteous at a banquet or dance (Figure 8). Accompanying verses support the image, lyrically extolling the carpet as a garden, for example, or a blooming meadow and comparing its beauty to that of the Garden of Eden.

USES OF RUGS AND CARPETS

Carpets originated in Central and Western Asia as coverings for beaten-earth floors. From time immemorial, carpets covered the floors of house and tent as well as mosque and palace. In the homes of wealthy Eastern families, floor coverings serve an aesthetic as well as a practical function. Rugs are often grouped in a traditional arrangement, partly to allow for simultaneous display; and the carpet's size and shape is determined by the intended place within that arrangement. There are usually four carpets. The largest, called *mīān farsh*, usually measuring some 18 feet by 8 feet (5.5 by 2.5 metres), is placed in the centre. Flanking the *mīān farsh* are two runners, or

kanārehs, which are mainly used for walking and which measure some 18 feet by 3 feet (5.5 by 1 metre). The principal rug, or *kellegi*, averaging 12 feet by 6 feet (3.7 by 1.8 metres), is placed at one end of the arrangement of three carpets, so that its length stretches almost completely across their collective widths.

The prayer rug

The intended use sometimes determines both design and size, as in the prayer rug, or *namāzlik*. Because a Muslim must carry it everywhere, the prayer rug is relatively small (Figure 9, right). Design, naturally linked to religious imagery, is characterized by the *mihrāb*, or prayer niche (an imitation of the prayer niche in the wall of a mosque), the apex of which could be pointed toward Mecca. But other religious properties also appear, such as hanging lamps, water jugs, or "hand prints" to mark the place of the worshipper on the rug.

Until mid-17th century, Asian carpets imported into Europe were considered too precious to serve as permanent floor coverings. Placed on the floor only on church holidays or in an aristocrat's presence, they were otherwise used on the wall or to cover tables, benches, and chests; and, particularly in Italy, they were hung over balconies as decoration during festivals. Taking this European attitude into account, the Egyptian manufacturers created several unusual shapes and sizes for the European market: square, round, and cruciform carpets, obviously designed for tables rather than floors (Figure 9, left). During the 17th century, covering the entire floor with costly knotted carpets became fashionable. The mid-20th century witnessed a boom in antique-carpet prices that resulted in choicer pieces ending up back on the wall.

Table carpets

Oriental carpets frequently served many uses besides covering floors. They made handsome curtains, served as tribute money, and were frequently gifts of one state to another. They were used as blankets, canopies, coverings for tent openings, and tomb covers. They have also made excellent saddle covers and storage bags for use in tents. Such modest rugs were always close to the life of the people, who lavished care on them and into them wove

life-protecting symbols. Other, more bizarre, uses have included assisting in the demise of Baghdad's last caliph—who in 1258 was wrapped in a carpet and beaten to death—and dramatically enhancing Cleopatra's introduction to Julius Caesar, when she stepped out of an unrolled rug. In less well-documented instances, they have assumed magical properties and taken flight, transporting their owners through the air.

PERIODS AND CENTRES OF ACTIVITY

Floor coverings of plaited rushes have been used at least since the 4th or 5th millennium BC, and rush weaving in the Middle East had reached a high standard by medieval times.

Oriental carpets. Oriental carpets are those made in Western and Central Asia, North Africa, and the Caucasus region of Europe. Rug design, in Western Asia at least, had gone beyond felt and plaited mats before the 1st millennium BC. A threshold rug represented in a stone carving (now in the Louvre) from the 8th-century-BC Assyrian palace of Khorsabad (in modern Iraq) has an all-over field pattern of quatrefoils (four-leafed motifs), framed by a lotus border. Other Assyrian carvings of the period also show patterns that survive in modern designers' repertoires.

Excavation of royal graves, dating from the 5th to the 3rd century BC, at Pazyryk, in the Altai Mountains of Southern Siberia, has uncovered the oldest known examples of knotting. The finds include various articles of felt with appliqué patterns and a superb carpet (Figure 10) with a woollen pile, knotted with the Ghiordes, or Turkish, knot (Hermitage). The carpet, probably of Persian origin, measures 6 X 6½ feet (1.8 X 2.0 metres). The central field has a checkerboard design with a floral star pattern in each square. Of the two wide borders, the inner one shows a frieze of elk, the outer one a frieze of horsemen.

Knotting was not necessarily the only or even the most important method of carpet making. Felt carpets were

Figure 10: Detail of the wool carpet from the royal graves at Pazyryk in the Altai Mountains of Southern Siberia, 5th to 3rd century BC. Probably of Persian origin, the rug is knotted with the Ghiordes, or Turkish, knot. The central field is an all-over checkerboard pattern. The two wide bands of the fivefold border contain friezes; the outer one has men mounted on stallions, the inner one grazing elk. In the Hermitage, Leningrad. 2.0 X 1.8 m.

used for a long time in Central and East Asia, as indicated by magnificent 1st-century-AD specimens from Noin Ula in Northern Mongolia (1st century BC to the 1st century AD; in the Hermitage) or those in the Shōsō-in (Japanese Imperial storehouse) in Nara near Osaka (before the 8th century). The costly rugs with figure motifs and gold mentioned by Greek and Arab writers may have been woven or embroidered and were probably exhibited on the wall as well as on the floor. The large carpet made in the 6th century for the Sāsānid palace in Ctesiphon (see above Ornament and imagery: Symbolism of overall design) is the most famous; but other Oriental courts, such as the caliphate at Baghdad (8th–13th century), also used valuable carpets.

In the 13th, 14th, and 15th centuries, Asia Minor and the Caucasus produced coarse, vividly coloured rugs with stars, polygons, and often patterns of stylized Kūfic writing. A special group with simple, highly conventionalized animal forms was also woven; the most important of these carpets are represented by seven fragments of strong, repeating, geometric patterns in bold colours—red, yellow, and blue—found in the mosque of 'Alā' ad-Dīn at Konya in Anatolia and now in the Museum of Turkish and Islamic Art, Istanbul. They probably date from the 13th century. In the Staatliche Museen zu Berlin and in the Nationalmuseum at Stockholm are two primitive rugs, one, a highly conventionalized dragon-and-phoenix combat (Figure 11), the other, stylized birds in a tree. Both of these rugs are probably early-15th-century Anatolian.

Later, many rugs of finer weave, more delicate patterns, and richer colour—mostly geometric and possibly from Seljuq looms in Asia Minor—appeared in Europe. They were depicted by Flemish painters, such as Hans Memling, Jan van Eyck, and Petrus Christus, with such skill that the separate knots are sometimes visible. Many of these designs are repeated in the Bergama district of Asia Minor and the Southern Caucasus today, a complication when dating work.

Persia. Little is known about Persian carpet making before the 15th century, when the art was already approaching a peak. The Mongol invasion of the 13th century had depressed Persia's artistic life, only partly restored by the renaissance under the Mongol Il-Khan dynasty (1256–1353). Although the conquests of Timur Lenk (died 1405) were in most respects disastrous to Persia, he favoured artisans and spared them to work on his great palaces in Turkistan.

Under Timur's successor, Shāh Rokh (died 1447), art flourished, particularly carpets. Their production exclusively by palace workshops and court-subsidized looms gave them unity of style; and a sensitive clientele and lavish royal support guaranteed perfect materials and the highest skill: sheep were especially bred, dye plantations were cultivated like flower gardens, and designers and weavers could win court appointments. These conditions continued under the Safavids (1501/02–1732).

In the 15th century the art of the book, which had long been considered the supreme artistic accomplishment and already had behind it centuries of superb achievement, reached a degree of elegance and sophistication unknown either before or since. The bindings, frontispieces, chapter headings, and, in the miniatures themselves, the canopies, panels, brocades, and carpets that furnished the spaces all received the richest and most elegant patterning. These beautiful designs were appropriated in various degrees by the other arts and account in no small measure for the special character of the court carpets of the period, the variety of colour, the ingenuity and imaginative range of pattern schemes, and the superlative draftsmanship that is both lucid and expressive.

Among the products inspired by book illumination were the Medallion carpets of northwest Persia, which consist of a large centre medallion connected with pendants or cartouches on the long axis and with quarter-section designs of the medallion in the corner areas. First used on ornamental pages and bindings of Persian books, on carpets this arrangement provided an effective centre and allowed several layers of designs to overlap because the

rugs

medallions could cover multiple vine and flower patterns. The depiction of the latter motifs is more relaxed than their medieval rendering, and new motifs (inspired by painting) such as animals, humans, and landscapes began to be worked in.

A special court atelier, possibly located in *Soltānīyeh*, translated the most gorgeous illuminations into carpets. Among the 12 or so surviving examples are the world's most famous carpets, each a masterpiece of superb design, majestic size, purity and depth of colour, and perfection of detail. The best known are two carpets from the mosque at Ardabil in eastern Azerbaijan, Iran, dated 1539–40. The better, skillfully restored, is now in the Victoria and Albert Museum (Figure 12); the other, reduced in size, is in the Los Angeles County Museum of Art. An extremely rich, intricate system of stems and blossoms covers a velvety, glowing indigo field, the whole dominated by a complex gold-star medallion. A near rival to the Ardabil weaving is the *Anhalt Carpet* (possibly 19th century), named after a previous owner, the Duke of *Anhalt*, and now in the Metropolitan Museum of Art, New York City. An intricate star medallion dominates a brilliant yellow field covered with scrolling arabesques and fluttering cloud bands, framed by a scarlet border. One of the most beautiful of northwest Persian rugs is the "animal" carpet, half of which is in Krakow Cathedral, Poland, and half in the *Musée des Arts Décoratifs*. It has the same glowing scarlet and gold as the *Anhalt Carpet* but with more subtle halftones (buff on yellow, gray on taupe, brown on gray) and represents paradise more pictorially. Historically more important, and in beauty a rival of any, is the great "hunting" carpet in the Museo Poldi Pezzoli in Milan (Figure 13), inscribed: "It is by the efforts of *Giyath-ud-Din Jami* that this renowned carpet was brought to such perfection in the year 1521." A scarlet and gold medallion dominates a deep blue field, covered with an angular network of blossoming stems, across which hunters dash after their prey.

These carpets, in the opinion of many, represent the supreme achievement in the whole field of carpet designing. Nonetheless, other royal workshops were also producing many beautiful rugs. Particularly costly silk carpets with figure motifs (such as the silk hunting carpet in Vienna's *Osterreichisches Museum für Angewandte Kunst*; see Figure 8) were woven in Kashan, Persia's silk centre. Smaller silk medallion carpets were also made there during the later 16th century, their designs mostly variations of the original medallion system. The court manufacture of Kashan also produced silk carpets with a decidedly royal style.

The distinctive rugs called Vase carpets (because of the flower vases in their designs) are generally thought to be *Kerman*. The pattern usually consists of several lattice systems with profuse blossoms and foliage. Many of these carpets survive as fragments; but only a scant 20 are intact, the finest of which is in the Victoria and Albert Museum. The rugs were apparently not for export but for court and mosque. Woven on a solid doublewarp, their boardlike stiffness holds them flat to the floor. In Iran they are still called "*Shāh 'Abbās*" carpets after the monarch of that name. The typically Persian style widely influenced carpets in Kurdistan and the Caucasus and also Indian court carpets, as well as embroideries from Bukhara.

Later in the 17th century, increasing luxury and wealth demanded the production of so many gold- and silver-threaded carpets that soon they were available in bazaars and exported to Europe, where more than 200 have been found. Some were made in Kashan, but many of the finest came from Isfahan. With their high-keyed fresh colours and opulence, they have affinities with European Renaissance and Baroque idioms. The Polish nobility ordered many gold-threaded rugs from Kashan, for Poland and Persia had close relations in the 17th century. Because there had been a rug- and silk-weaving industry using gold thread in 18th-century Poland, these imported Persian rugs, when first exhibited at the Paris exposition in 1878, were considered Polish, especially as nothing quite like them had at the time been found in Persia itself. They

were accordingly dubbed "*tapis Polonais*," or Polish carpets, and the name has stuck. The type degenerated in the later 17th century, materials deteriorating, weaving coarsening, and designs muddling.

East Persian *Herāt* carpets, which were named after their centre of production and were characterized by their combination of a wine-red field and a border of clear emerald green with touches of golden yellow, became known in Europe as the typical Persian carpet. Many of the European artists of the period owned them, and Anthony Van Dyck and "Velvet" Brueghel (Jan the Elder), in particular, rendered them with complete fidelity in datable paintings. Indian princes also were enamoured of them and acquired them by plunder and pur-

chase alike. Their popularity resulted in mass production with all its attendant deleterious effects, and the style finally expired in mediocrity.

Throughout 17th-century Persia, increasing refinement accompanied slackening inspiration. Silk carpets woven to surround the sarcophagus of Shāh 'Abbās II (died 1666) in the shrine at Qom (in Central Iran) were the last really fine achievements in Persian weaving. Even Orientalists have mistaken their finish for velvet; the drawing is beautiful, the colour varied, clear, and harmonious. The set is dated and signed by a master artist, Ni'mat Allāh of Jūsheqān.

At the end of the 17th century, nomads and town dwellers were still making carpets using dyes developed over centuries, each group maintaining an unadulterated tradition. Not made for an impatient Western market, these humbler rugs of the "low school" are frequently beautifully designed and are of good material and technique. A great rug industry was developed in western Persia in the Solṭānābād district; and from individual towns come beautifully woven rugs such as Sarūks, with their ancient medallion pattern; Serabands, with their repeating patterns on a ground of silvery rose; and Ferahans, with their so-called Herāti pattern—an all-over, rather dense design with a light-green border on a mordant dye that leaves the pattern in relief. The earlier Ferahans (two are known, dated to the end of the 18th century) are on fields of dark lustrous blue with a delicately drawn open pattern. Later, Ferahans degenerated in colour and material, and the pattern became clumsy and crowded. "Low school" rugs maintained their standards down to the later 19th century, when insatiable Western demand ruined their artistry; but in the 20th century fine weaving in Persia has been somewhat revived.

Turkey. After the 16th century, Turkish rugs either

followed Persian designs, indeed, were possibly worked by immigrant Persians and Egyptians, or followed native traditions. The former, made on court looms, displayed exquisite cloud bands and feathery, tapering white leaves on grounds of pale rose relieved by blue and emerald green. Turkish patterns embellished stately carpets, designed for mosques or noble residences, with rich, harmonious colours and broad, static patterns. They contrast with the lively, intricate Persian designs, in which primary, secondary, and tertiary patterns often interact with one another in subtle dissonances and resolutions.

Turkish styles are best illustrated by the carpets from Uşak in Western Anatolia, in which central star medallions in gold, yellow, and dark blue lie on a field of rich red. So-called Holbein rugs, similar to Caucasian carpets (see below), have polygons on a ground of deep red, dark green, or red and green; they often have green borders and conventionalized interlacing Kiiic script. Such a carpet is depicted in a portrait of Georg Gisze by the 16th-century German painter Hans Holbein the Younger—hence the name. Similarly, a handsome carpet pattern of interlacing yellow arabesques on a ground of deep red appears so often in the paintings of the 16th-century Venetian artist Lorenzo Lotto that they are called Lotto rugs. Carpets with a muted deep-red ground of wonderful intensity, patterned with small medallions, hail, perhaps, from Bergama. In the 17th century they developed into a type known as Transylvanian, so called because so many of them, particularly prayer rugs, were found in Transylvanian churches. They are nonetheless purely Turkish, with rich, quiet colour and sturdy designs. The majority are dominated by a fine red, though a few have faded to the colour of old parchment.

In the 17th century, the "bird carpet," or White Ushak, with conventionalized floral motifs suggesting birds, developed (Figure 14). The few surviving examples are

Uşak
carpets

Turkish
"bird
carpets"

serenely beautiful, with fields of soft ivory and various discreet colours.

Eighteenth- and 19th-century "low school" rugs from Asia Minor continued the tradition of blending sober patterns and luxurious colour. Yürük "low school" rugs, made by nomadic Anatolian peoples like the Kurds, have attracted collectors because of their wide range of rich colours and the use of simple patterns, often geometric, that are organized in bold designs, frequently having a diagonal rather than a vertical emphasis (Figure 15). But the chief creations were prayer rugs, more plentiful among the Turks than among the other faithful. Hand-some pieces were woven in Anatolia at Melas, Konya, Lâdik, and Kirşehir, Lâdik's being the most brilliant, both in colour and pattern. The most famous Anatolian prayer rugs came from Ghiordes and Kula, mostly in the 18th and 19th centuries; and in the United States they became the first passion of the collector. Regions such as Smyrna (İzmir) produced a great number of utility carpets for the West.

The Caucasus. Fine rugs were woven in the Caucasus from the earliest times. During Persia's long political and cultural dominance, the magnificent carpets produced at the Persian court furnished models for the more ambitious Caucasian rugs, such as those woven for the local nobles, or khans. But the Caucasus has its own individual character; while it borrowed motifs from other areas, it completely transformed them by a furious vigour of design unequalled in the textile world. For example, al-

Figure 14: Wool "bird carpet," possibly from Uşak, Turkey, 17th century. The ivory white ground is patterned with an all-over, stylized floral motif reminiscent of a bird. In the Metropolitan Museum of Art, New York. 4.44 X 2.31 m.

Figure 15: Wool nomad carpet, either Yürük or Kurdish, from near the border between Anatolian Turkey and Iran, 19th century. The geometric pattern of hexagons and lozenges is diagonal rather than vertical. In the Textile Museum, Washington, D.C. 1.73 X 1.48 m.

The Textile Museum Collection, Washington, D.C.; photograph, Otto E. Nelson—EB Inc.

though the Dragon carpets of Kuba continue medieval Persian motifs, the beasts, recognizable in the earliest Caucasian examples, are later stylized and enclosed in repeated rhomboid designs (Figure 16). This stylization process resulted perhaps from the combination of a taste for abstract design and the poverty of the region. The dense knotting required for curvilinear, natural designs is possible only with fine material, which the Caucasians could not afford. Their rugs, therefore, were of coarse weave, the Dragon carpets often having fewer than 80 knots per square inch (12 per square centimetre).

The "low-school" rugs are among the most individual and satisfactory. Their patterns are practically all geometric, densely juxtaposed, generally without organic connection and without implied movement; but they are clear, ingenious, and entirely suitable for floor decoration. More recent examples seem a little dry in colour; but many of them, such as the rugs woven by the Kazakhs, Sarıqs, and other nomads, are sometimes of flaming brilliance; and the older rugs from Dagestan, Kuba (both west of the Caspian Sea), and Shirvan (on the borders of Iraq and Iran) are done in beautifully clear, discreet, and well-balanced tones.

Shirvan *kilims*, or tapestry rugs, with their broad horizontal stripes, have bold motifs assembled in harmonious colours.

Another type of flat-stitch carpet, brocaded with a mass of loose threads at the back, comes from the Shemakha region (in Azerbaijan). It has mistakenly been called cashmere because of its superficial resemblance to cashmere shawls. The design usually embodies large, beautifully articulated mosaic-tile patterns in rich and sober colours.

Turkistan. The carpets of western Turkistan (wrongly called Bokhara carpets) are made by nomadic Turkmen tribes. Few extant examples are more than 100 years old, though similar rugs have almost certainly been made for centuries. Many older pieces are not intended as floor coverings. Some, called *jovāls*, are bags (about 5 by 3 feet; 1.5 by 1 metre) for storage in tents. Some are sad-

Caucasian
"low-
school"
rugs

Characteristics of Turkmen rugs

dlebags consisting of two squares of about 2 feet (0.6 metre), joined together. There are also long tent bands (called *kibitkas*) about 1 foot (0.3 metre) wide and perhaps 60 yards (55 metres) long, used for decorating large tents, and rugs (called Tekkes) used as hangings for tent doorways. Small, squarish rugs and larger ones of about 10 by 7 feet (3 by 2 metres) seem later and were made perhaps mainly for sale. Turkmen carpets have woollen warp, weft, and pile, two lines of weft, and either Sehna or Ghiordes knots. Except for the Baluchi, Turkmen rugs are characterized by a dark-red colouring and geometric designs. After the predominant red, the chief colours are blue, white, and a natural black wool toning pleasantly to brown. The characteristic design is the octagon, or elephant's foot, arranged in rows and columns, often with diamond-shaped figures in between. Door hangings have cross-shaped panelling, smaller pieces a rectangular diaper (allover pattern). Woven end webs and tassels are used freely as embellishments. Carpets made by Turkmen tribes are the Tekke, Yomud, Afghan, Sarük, Ersar, Beshir, and Baluchi.

Chinese Turkistan. The oldest surviving Chinese Turkistan rugs date perhaps from the 17th century. Most have a silk pile and some metal and gilded thread, with floral, Persian-influenced patterns showing distinct Chinese treatment. Later carpets are loosely woven with the Sehna knot and have a wool or, more rarely, silk pile and a cotton warp. Eighteenth-century examples have rich, dark colouring, which became brighter in the 19th century and, at last, excessively crude. There are two main types of design. The Medallion carpet usually has three squarish medallions placed down the centre and, almost invariably, one border with a conventional Chinese pattern of foam-crested waves (Figure 17). This design is generally called Samarkand in the trade, though the rugs themselves come from Kashgar, Khotan, Yarkand (modern Su-fu, Hot'ien, So-ch'e in China's Sinkiang region). The Five-blossom carpet has a floral diaper with groups of five blossoms. The colouring is often red and orange with a little clear blue.

Egypt. Egyptian carpets used to be called Damascus carpets but are now termed Mamlūk, after the Muslim

dynasty (1250–1517) that subsidized their manufacture, or Cairene rugs after Cairo, the city in which they were made.

Knotting was thought to have reached Egypt from Asia Minor, but early Cairene carpets differ from Anatolian ones: they are knotted with the Persian knot, and their colours are red, yellow green, and light blue, applied evenly in inner field and border. Moreover, Egyptian designs concentrate on the centre, subordinating surrounding motifs. Border designs match rectangular with square panels. Although filled with plants, the carpet designs seem geometric (Figure 18). The heyday of these rugs occurred during later Mamlūk rule, when there was extensive export.

India. Carpets are less important in India than elsewhere in Asia because the climate makes knotted floor coverings unsuitable. As an art, carpet weaving was brought from Persia by the 16th- and 17th-century Mughal emperors, who subsidized the manufacture of beautiful rugs with an almost silken sheen. Although Indian artistry was influenced by Southern and Eastern Persian carpets, it maintained a native taste for pictorial representation (Figure 19).

The carpets made for the courts of the grand Mughals were of extravagant and luxurious beauty. Expense was ignored, and a series of carpets was made with 600 to 1,200 knots per square inch (95 to 190 per square centimetre). Special carpets were of even finer weave, 2,100 knots per square inch (325 per square centimetre; Metropolitan Museum of Art). For the palace of Shāh Jahān

Mughal carpets

Figure 18: Cairene wool carpet from Egypt, 18th century, Mamlūk period. The field features a star medallion centred in a geometrically designed ground, covered with stylized forms of the papyrus and other plants. In the Metropolitan Museum of Art, New York. 2.41 X 2.17 m.

(died 1666) a set of rugs was made from the most precious wool, imported from Kashmir and remote Himalayan valleys. But because the sources of the art were in imitation, not in the life roots of the people, these wonderful fabrics never reached the artistic height that characterized many periods of Persian weaving. Once established, the rug industry continued, becoming a jail industry, particularly in the Punjab. Designs degenerated, and good wool was difficult to obtain. Later Indian carpets are thus mostly inferior to Persian work.

China. The rugs of China are recognizable by their characteristic Chinese ornament. Of coarse texture, they are Sehna-knotted on a cotton warp. The pile is thick, smooth-surfaced, and "sculptured" so as to form a furrow at the pattern's contours. Yellow predominates, sometimes intentionally, sometimes as the result of the fading of red and orange. Blue and white are commonly used; but true red, brown, and green are rarely seen.

Some carpets have repeating plant scrolls; others scattered flowers and various Chinese symbols. Frets, or key designs, often decorate the border.

Peculiar to China are Pillar carpets, designed so that when wrapped around a pillar the edges will fit together to form a continuous pattern, usually a coiling dragon (Figure 20). Small mats and seat covers are also common. Chinese rugs are virtually impossible to date, since they vary little with time. Many large carpets have been made for export in the 20th century.

Western carpets. **Spain.** Spain's close ties with Islām after the 8th century made it quick to accept and produce knotted carpets. Early examples of the unusual Spanish knot suggest manufacture as early as the 12th century, but not until the 15th century do enough examples remain to allow grouping of work. Many designs imitate Anatolian forms (Figure 21); others, with coats of arms or Christian emblems, indicate purely European origin. During the 16th century, Renaissance influence was prevalent. The manufacturing centres were **Cuenca**, **Alcaraz**, and possibly **Almeria**. The knotted carpet lost ground during the 18th century; and native work, known as **Al-**

pjarra (after the district), is embroidered or done in uncut weft-loop technique.

France. In France, too, the stimulus for the production of knotted carpets came from the East; but the designs of the rugs were inspired by contemporary French decoration rather than Oriental carpet design. Jean Fortier and Pierre Dupont won fame knotting pieces in the Hospice de la Savonnerie at Chaillot, which was converted from a soap factory to a carpet factory in the early 17th century. "Savonnerie" became a mark of distinction in French carpets, reaching a zenith during the later 17th century with Louis XIV's immense order for Versailles. Combined since 1826 with the Gobelins factory, the firm still operates. Thick and strong, these carpets consist of a woollen pile on a mostly linen warp. During the 18th century and afterward, many tapestry-woven carpets were made at Aubusson as well as at other tapestry factories. Even though their production has not been confined to that city, they are known as Aubusson carpets.

The European concept of carpet design, as distinguished from the Oriental concept, is most explicit in the Savonnerie carpets, in which three-dimensional compositions complement architecture, and even portraits are reproduced (Figure 22). The style of such carpets is best seen in sketches of rug design made by Charles Le Brun for Louis XIV (mostly in the Mobilier National in Paris).

United Kingdom and Ireland. The growth of a native craft in the United Kingdom soon followed on the introduction of carpets from Turkey, though 16th- and 17th-century intact specimens number only about a dozen. They are characterized by a hemp warp and weft, medium-fine woollen pile, and the Ghiordes knot. The background usually is green, and there are so many shades of the other colours that the entire number of tints is greater than in Oriental carpets. The designs can be divided into two groups. In the first are typically English patterns resembling contemporary embroidery, often with heral-

dic devices and dates. The oldest specimen, dated 1570, belongs to the Earl of Verulam. In the second group are many pieces of carpet knotting—called at the time "Turkey work"—imitating Oriental designs and made to cover chairs and stools. As the demand for carpets increased in the 18th century, factories were established at Paddington, Fulham, and Moorfields, near London, and at Exeter and Axminster in Devon. Axminster worked on well into the 19th century, when it merged with the Wilton Royal Carpet Factory Ltd, at Wilton, Wiltshire, which still operates. The industry dwindled and almost disappeared with the advent of mechanization until about 1880. The craft was revived by the English artist and poet William Morris. Later in the 19th century, a factory opened in Donegal, Ireland; and during the 20th century, many small rugs have been knotted by handicraft societies.

Scandinavia. Scandinavian work is similar in concept despite national differences of colour and motif. Abundant handmade products include floor coverings, coverlets, upholstery for benches, chairs, stools, and pillows. Techniques dating from the Vikings (and probably imported by them from Turkey) are continued in Swedish and Finnish rugs, called Rya rugs. Knotted work includes pieces with pile on either side, many Ghiordes on three warps, and braided and woven patchwork carpets with interwoven strips. Geometric designs, rooted in the native arts, are common, appearing, for example, in opulent "wedding carpets." Design was also influenced by Dutch tapestry flower motifs.

Eastern Europe. Knotted Mazovian rugs of East Prussia show the strongest Oriental influence, though at the

same time they are deeply rooted in peasant traditions. Many other textiles untouched by west European influence, however, came from southeast Poland, the Ukraine, and southern Russia; some are characterized by ancient textile motifs (such as simple stripes) and forceful colour harmonies, others by geometric designs resembling those of the Orient. Kilims, or tapestry-woven carpets, are common in those areas, as they are in the Balkans. In Romania, government promotion and the interest taken by contemporary artists in folk idiom have stimulated modern production during the 20th century.

European folk carpets. Carpet making is so widespread in European folk art that it probably would have developed even without stimulus from the Orient. The most varied techniques are represented in these tradition-bound products the designs of which remained unchanged for generations. The work includes floor coverings, chest covers and bedcovers, and draperies, most of modest size (or pieced together) and many made in sets. The colour scheme is very limited, for even the raw materials were homemade. Machine-made carpets in the latter 19th century quickly engulfed home products, but a conscious revival and renewal followed in the 20th century.

North America. The technique of knotting has not been used by the Indians, but many tribes have been making flat-woven floor rugs and blankets since the earliest days of their known history. Before sheep were introduced in the 16th century and wool became dominant, the principal material was cotton, together with various fibres and dog's hair. Indian designs are traditionally abstract, making much use of stripes and a zigzag, or "lightning," motif. The colours are black, white, yellow, blue, tan, and red, the latter often dominant. Among the most skillful carpet makers are the Pueblo and Navaho tribes.

Rugs were made by the colonists in a variety of techniques: knitting; crocheting; braiding thin strips of material into small squares and then sewing them together; and embroidering on a coarse-woven foundation. Hooking (drawing material through a canvas foundation) be-

gan around the turn of the 18th century and became very popular; early examples have crude floral, geometric, or animal designs and are very colourful. No knotted carpets were manufactured by the early settlers. In 1884, however, a factory established in Milwaukee (and later moved to New York City) began to weave carpets in traditional European designs. During the 1890s a branch of the English Wilton Royal Carpet Factory made Axminsters at Elizabethport, New Jersey; and a few beautiful, flat-woven carpets in French Baroque and Neoclassical designs were produced around the turn of the century by a tapestry factory located in Williams Bridge, New York. After this time, machine weaving, which had begun in the United States in the late 1700s, gradually began to displace hand weaving.

BIBLIOGRAPHY. For further study in this area the following summaries are recommended: FRIEDRICH SARRE and HERMANN TRENKWALD, *Altorientalische Teppiche*, 2 vol. (1926–28; Eng. trans., *Old Oriental Carpets*, 2 vol., 1926–29), excellent large plates with exact description and technical analysis of masterpieces of Oriental rugs and carpets, including a comprehensive bibliography; KURT ERDMANN, *Der orientalische Knüpfteppich*, 3rd ed. (1965; Eng. trans., *Oriental Carpets*, 2nd ed.; 1962), an important discussion of Oriental rugs and carpets with regard to artistic development—contains a comprehensive bibliography for all areas of the Oriental carpet, including newspaper and journal essays, and museum and auction catalogs, arranged according to subject areas; and *Siebenhundert Jahre Orientteppich* (1966; Eng. trans., *Seven Hundred Years of Oriental Carpets*, 1970), a posthumous collection of the author's articles, presenting material not found in his earlier works; WILHELM VON BODE and ERNST KUHNEL, *Vorderasiatische Knüpfteppiche aus alter Zeit*, 4th ed. (1955; Eng. trans., *Antique Rugs from the Near East*, 4th rev. ed., 1970), a handbook on the scientific study of rugs and carpets; ALBERT F. KENDRICK and C.E.C. TATTERSALL, *Hand-woven Carpets, Oriental and European*, 2 vol. (1922, reprinted 1973), a monographic treatment of the individual types, including products after 1800; ARTHUR U. POPE and PHYLLIS ACKERMAN, *The Art of Carpet Making in a Survey of Persian Art from Prehistoric Times to the Present*, 7 vol. (1938–39), a comprehensive study of the art of carpet making in Persia, richly illustrated; CORNELIA B. FARADAY, *European and American Carpets and Rugs* (1929), a comprehensive study of European and American carpet production, including material on native arts and machine-made carpets; that is very richly illustrated but without a bibliography; C.E.C. TATTERSALL, *A History of British Carpets*, rev. ed. (1966), an extensive study of carpet production in England, including machine-made carpets; M.J. MAJORCAS, *English Needlework Carpets, 16th–19th Centuries* (1963), a richly illustrated treatise on the subject; MADELEINE JARRY, *Manufacture nationale de la Savonnerie* (Eng. trans., *The Carpets of the Manufacture de la Savonnerie*, 1966) and *The Carpets of Aubusson* (1969), two studies of French floor coverings, with ample illustrations; and VALERIE JUSHIN, *Flat-Woven Rugs of the World: Kilim, Somak, and Brocading* (1980).

Rummy Games

Rummy refers to a family of card games whose many variants make it the best known and most widely played family of games in the United States, if not in the world. The basic principle of all Rummy (rum, rhum, romme) games is to form sets of three or four cards of the same rank (e.g., four eights, three sixes), or sequences of three or more cards of the same suit (e.g., $\diamond 6-5-4-3$). Some variants allow only one or the other of these combinations. In Canasta, for example, sequences are not permitted.

History. Many games of the 17th century, during which card playing became popular in Europe, included the principle of building such structures, or melds, before or during a period of play. The ancient Chinese game of Mah-Jongg (see BOARD AND TILE GAMES), played with tiles long before the invention of playing cards and based on forming matching groups of three and four, is a venerable ancestor of Rummy. The earliest modern form of Rummy, however, became popular in Mexico in the latter half of the 19th century as Conquian, from *con quien* (Spanish: "with whom"), a mysterious misnomer since it was a two-hand rather than a partnership game.

Conquian, better known as Cooncan (or Coon-Can) as it spread to Texas and the southern United States early in the 20th century, used the "Spanish pack" of 40 cards—the regular 52-card pack with tens, nines, and eights removed. The modern game of Panguingue (or Pan as it is often called in the many gaming clubs on the Pacific Coast and in the southwestern United States, where it is very popular) uses eight such packs shuffled together to make it possible for the game to be played by as many as 15 players, although the usual game is for six or seven. Pan is one of the few games that still follows the principle of dealing and playing to the right instead of to the left. Pan also requires that the winner have a hand of 11 matched cards; no discard can be made on the last turn.

In the United States, Cooncan soon developed into Rum. It is not clear whether this name followed the theme of "Whiskey" in the game of Whiskey Poker or whether it was adopted when the game was characterized by an Englishman as "Rum" ("Queer") Poker. A later variant, however, introduced as a two-hand game in 1909 in New York by Elwood Baker, was named Gin with the deliberate intention of keeping it in the alcoholic beverage family. Because it seemed desirable to remove card playing from the same sinful category as drinking, both names were soon bowdlerized, becoming Rummy and Gin Rummy. Another variant, Canasta, originated in Uruguay in the 1940s and quickly became the most popular game in the clubs of Argentina. In the 1950s it temporarily eclipsed Contract Bridge in popularity in the United States, but was only moderately popular in Europe.

Earliest modern form

The game of Rum

Principles and procedures. There are no official rules for the basic game of Rummy, but the following procedures are generally observed.

From two to six may play, using a standard deck of 52 cards, with or without jokers. Cards rank: K (high), Q, J, 10, 9 etc., to A, low. In some variants, but not generally in the basic game, A-K-Q is allowed as a sequence. In two-hand play, ten cards are dealt to each, face down, one at a time beginning with the player on dealer's left and continuing clockwise. For three or four players, a hand is seven cards; for five or six players, six cards are dealt. The remainder of the pack, the stock, is placed face down; the top card of the stock is faced to begin the talon, or discard pile. Each player in his turn may take the top card of the discard pile or draw the top card of the stock; he may then place face up on the table any legal meld of three cards or more or add (lay off) one or more cards from his hand that match his own or any other player's exposed melds. He ends his turn by discarding one card face up on the discard pile, except that on the turn when a player goes out no discard need be made. A player goes out when he has melded all the cards in his hand. Joker may be used as any needed card.

Melding and scoring The melds, as previously noted, may be sets of three or four cards of the same rank or sequences of three or more cards in the same suit or additions of such cards to melds previously tabled. Melding an entire hand at one turn is called going rummy and counts double.

The winner of each deal collects from each of the other players the index value of the cards each still holds in his hand, even if such cards are matched up. Face cards count 10 each; aces 1 or 11 as previously agreed; jokers, if used, count 15.

When stock is exhausted, play ends and the hand with the lowest unmatched count wins. In some games, each player is permitted an additional turn to take or refuse the top card of the talon.

A running score is kept and the game ends when any player reaches the predetermined goal (as 100 points) or after an agreed number of deals.

500 Rum **Variants.** Among the most widely played Rummy games is 500 Rum, also called Pinochle Rummy, and its variants including Michigan Rum, Oklahoma, Persian Rummy, and Canasta and its many derivatives, Samba, Bolivia, and others. From two to eight may play. With five players or more, two full packs shuffled together are used. When two play, each is dealt 13 cards; with three or more, 7 cards are dealt to each.

At his turn, each player draws the top card of the stock or any card in the discard pile provided that: (1) he melds such card at once, and (2) he takes into his hand (to meld immediately or not, as he pleases) all cards lying above the one he has drawn. Melds and layoffs are the same as in the basic game of Rummy, but each player keeps his melds in front of him, and when the deal ends he receives credit for their index value minus the value of all cards remaining in his hand. Aces count 15 if left in hand or if melded as a set of aces; they count one if melded A-2-3. Game ends when any player has scored 500 or more. No bonus is given for winning the game.

Canasta In the variant Canasta, two full packs plus four jokers are used and all jokers and deuces are wild. Each player is dealt 11 cards. If a player takes the top card of the discard pile, which he must be able to meld immediately, he must also take the entire pile. A meld of seven or more cards of the same rank (sequences cannot be melded) is a natural Canasta worth 500 points if it contains no wild card, and a mixed Canasta worth 300 points if it contains at least four natural cards and one or more wild cards. Each card is assigned a point value and there is a 100-point bonus for going out. The game ends when either side's score is 5,000 or more, the higher score winning.

Knock Rummy In Knock Rummy any player, at his turn and after drawing and discarding, may knock (lay down his entire hand) and declare the total value of his unmatched cards. If his assumption that he has the lowest total of unmatched cards proves correct, he collects the difference in counts from each opponent. If another hand is lower, the low hand wins from all and collects an extra ten points from

the knocker. (Some play that knocker must pay double.) If a player ties for low, he collects from all but the knocker, who neither pays nor collects. If two or more other players tie for low, they divide the winnings.

At first played sporadically as a game between two players waiting for a fourth at bridge clubs, Gin Rummy became an American fad in the 1940s. Essentially a competition between two players, it is widely played with two, three, or four players on two teams. Each plays head-to-head against one adversary, but the scores made by each of the players in his individual match are combined, and the net result is entered as the score of each deal.

Each player is dealt ten cards, and the top card of the stock is turned face up. Nondealer may take it; if he refuses, dealer has the opportunity to do so. If both refuse, nondealer draws the top card of the stock. Thereafter, each player may take the other's discard or draw from stock.

Melds are as in basic Rummy. Either player in turn may knock if the total of his unmatched cards will be ten or less after he has discarded. (Some play that the rank of the first up-card determines the number for which a player may knock on that deal, a turned ace requiring completing "gin" to go out; some play that if a spade is turned the score of that deal is doubled.)

Opponent of the knocker may lay off any of his unmatched cards upon the knocker's melds, thereby reducing his count. If the knocker wins, he collects the difference between the total of his and his opponent's unmatched cards. If the opponent remains with an equal or lesser count, he has undercut the knocker and wins the difference (if any) plus a bonus of 25 points.

If all of the knocker's cards are matched (after he discards), he announces "gin" and receives a bonus of 25 points in addition to the total of his opponent's unmatched cards. Some play that an opponent cannot lay off on a gin hand; others permit layoffs to reduce the loser's total, but the player who goes gin cannot be undercut and is assured at least of his 25 point bonus. Some pay an additional 25 point bonus for 11-card gin (no discard).

A deal ends with no score when only two cards remain in the stock and neither player has knocked. First to reach 100 points wins the game and receives, in addition to the difference in scores, a 25-point bonus. Each player then adds to his score 25 points for each deal he has won, called a box. If the loser failed to score, the game is a shutout, or schneider, and the winner's total score is doubled.

Some score (Hollywood system) as if three games were being played simultaneously—each player's first score is entered under game one, his second score under game one and game two, his third and subsequent scores under all three; if he does not score in game one, his first score is entered under game two, his second and subsequent scores under games two and three. Bonuses are scored for each game independently of the others.

In a four-hand or six-hand game, the winning side must reach 150 or (by agreement) 200.

Rural Society, Contemporary

Rural societies differ from urban in many obvious ways, but it is not easy to define the differences so that they fit every case. This article will classify as rural societies those in which the predominant human activities are those which are involved in the production of foods, fibres, and raw materials. These field activities require a relatively high ratio of land per person. To the extent that a population is engaged in such field activities, it can be considered rural. A population can be considered urban, on the other hand, if it is engaged in activities by which the foods, fibres, minerals, and raw materials from the field are processed and distributed to their users. These activities are usually performed in densely settled areas. Most actual communities display a mixture of the two kinds of activities, combining rural and urban features

in varying proportions. This article is divided into the following sections:

- Rural society delineated
 - Rural relationships
 - Problems of transition
- Rural peoples
 - Settlement patterns
 - Rural demography
 - Age composition
 - Sex composition
 - Birth rates and death rates
 - Kinship structures
 - Technological and economic influences
 - Social rank
 - Organizations
- Problems of change
 - Large farms versus small
 - The role of planning

RURAL SOCIETY DELINEATED

In industrialized countries, large metropolitan areas usually consist of one or two very large centres within which are overlapping groupings of localities of various sizes. The progression from the centre of the urban area to the open country usually is uneven: minor concentrations of centre activities occur here and there between the urban heart and the rural periphery.

In nonindustrialized countries, the change from city to countryside is often more abrupt. Within the city itself, there is likely to be a considerable mixture of urban and

rural elements. While the city dwellers in the nonindustrialized country will be chiefly engaged in centre pursuits, they may also carry on field activities, such as poultry and dairy production and gardening. The city itself in such societies is usually less urban than the city in an industrialized society. The nature of transportation and communication facilities in nonindustrialized societies has a profound influence on both the urban centre and the rural hinterland. When there are few such links, the transition from city to countryside becomes a cultural and social transition as well. Passage from the city to its hinterland in societies of low technological development has been described as passing from the modern world to one in which people's actions are governed largely by tradition.

A difficulty in classifying places as urban or rural is that governments do not use the same definition, a difficulty nowhere better demonstrated than by the data on rurality and urbanity supplied to the United Nations. As shown in the accompanying Table, which is based on the *Demographic Yearbook* 1970 of the United Nations, definitions of urban area vary from places of 500 inhabitants to places of 30,000. The United States and Canada profess to have almost identical urban population ratios, but this similarity exists because, as shown in the footnotes of the Table, their definitions of urban area differ. Albania reports all centres with 400 or more inhabitants as urban, while Czechoslovakia requires that a town have a popula-

tion of at least 5,000, that there be a density of more than 100 persons per hectare (40 persons per acre), and that there be other specific urban characteristics. In Japan, which is a densely settled country, an area is classed as urban when it is a municipality having 30,000 or more inhabitants.

Rural relationships. One way of comparing the distinctive characteristics of rural and urban personalities and organizations is by means of ideal, or constructed, types. Such a type is called ideal because it is a construct embodying all of the characteristics of the thing it seeks to describe in their most concentrated state; it is not a sample drawn from reality. Probably the most generally used of these types are those untranslatable concepts of the German sociologist Ferdinand Tönnies, *gemeinschaft* and *gesellschaft*, sometimes rendered in English as community and society. The *gesellschaft*-like organization is one that has an all-important, functionally specific goal, such as profit making for a factory or battle winning for an army. Toward the attainment of its goal it employs all of its mean and resources, including the relationships among the human beings who compose it. Organizations possessing such qualities are sometimes called rational organizations, and those who efficiently and economically operate them are said to be rational actors. The polar opposite of the *gesellschaft*-like organization is a *gemeinschaft*-like entity. Among actual organizations the family-sized farm and small peasant community are much closer to the *gemeinschaft* pole than to the *gesellschaft* pole: they carry on farming as a way of life, viewing its relationship as ends in themselves rather than as means to an end. Such an organization is said to be natural willed; its members are rational minded only to the extent that they do not embody the *gemeinschaft*-like characteristics but instead take on some of the impersonal characteristics of the *gesellschaft*. Just as actual states and territories are neither completely rural nor completely urban but a mixture of both, so organizations and their personnel in real life are neither completely *gesellschaft*-like nor completely *gemeinschaft*-like.

Until the time of the Industrial Revolution in the 18th and 19th centuries, agricultural organizations were almost universally *gemeinschaft*-like; the relationships within them were either those of kinship or resembled those of kinship. Extensions of parent-child relationships were common; thus the feudal lord was a surrogate father to his vassal, who was a surrogate child to his lord. A person's rank was commonly determined by his parentage, his sex, and other inborn characteristics, whereas in *gesellschaft*-like organizations and societies rank is more likely to be determined by achievement. In traditional agricultural societies the resistance to change and to the adoption of improved practices is generally very great. There are many explanations for this resistance to change. A commonly accepted sociological explanation is that there is a widespread fear that change may result in starvation. In few societies in which starvation and famine are common is land treated as a commodity in a completely rational manner.

Because land is so important for the food supply, its ownership and transfer becomes hedged about by many restrictions. In some present-day peasant societies (such as those in the Yucatan Peninsula of Mexico), food crops are considered sacred and their use and movement must be accompanied by proper ritual. These crops lose their sacred nature once they are sold. Various other human and nonhuman resources come to be infused with sentiments that prevent completely rational use. The resistance to change among peasant peoples and their dislike of the ambitious individual may stem from the belief that if any individual accumulates more wealth than his associates, he must have done so at their expense. The prevalence of suspicion, distrust, and lack of faith in people in peasant societies may arise from the common belief that there is a given sum of wealth and that one person can become rich only if his associates are deprived or exploited.

Problems of transition. Some of the problems of rural societies and rural people are the result of changes that

are being forced upon them. Everywhere, even in some rural areas, the old *gemeinschaft* relationships are giving way to *gesellschaft* ones. Whereas the work teams of simple rural communities have known each other well and have relationships that are fused with sentiment resulting from prolonged and intimate associations, the bureaucratic work teams of rationalized rural and urban societies know each other in very limited, segmented ways. Workers reveal to each other on the job only a small part of their total beings. Rural migrants thrust into such organizations find the rational bureaucracy emotionally sterile. Devices such as management cafeterias and executive elevators are foreign to the worker who has previously rubbed elbows with his father and others as authority figures. In Communist countries in which bureaucratic administration is applied to farming as well as to urban life, it is not uncommon for authorities in collective farms to tell their counterparts in the cities that they should come to the country to experience how difficult administration can be.

The problems of transition from the old traditional society to the new bureaucratic one are not confined to the developing countries. Only one farm boy out of every ten growing up in industrial countries, such as the United States, will have the opportunity to acquire an adequate-sized commercial farm. If he is one of the nine forced to leave the land, he must learn to conduct himself in a way totally different from the way he behaved in his old setting where he was known to everyone. He will have contacts with groups the meaning of which for him will be so segmented that he will conceal from each individual he meets far more than he will reveal. He will have to learn that the anonymity that he despises as cold and sterile is in reality the only means by which he can have freedom and privacy in the midst of a dense population. The tenth boy, who realizes his dream of operating a farm, will also have to make an adjustment. He will have to understand and use a bewildering array of new machines, chemical fertilizers, improved seeds, and new strains of livestock. If he does not master the constantly changing technology, he will not be able to stay in business. To the extent that he values the traditional aspects of farming, he will accept innovations with some reluctance.

These problems relate to what sociologists call institutionalization. Stable rural societies are usually strongly institutionalized—that is, they have certain accepted organizational structures and predictable patterns of action and interaction. In some cases they may even be described as overinstitutionalized if their norms and goals are so intensely felt by their members that deviation from the norms or failure to achieve the goals is regarded as intolerable. Such overinstitutionalization is found in rigid, traditional societies that resist social change. Thus, among the Amish in the United States, a farmer who adapts a new forbidden practice, such as use of a truck for hauling or a tractor for draft power, is subjected to the *Meidung*, a sanction requiring that none among the Amish, not even the members of the person's family, speak to him. Suicide or complete loss of memory has resulted from the application of this powerful sanction. A society may be underinstitutionalized if norms and goals are absent or so loosely structured that they fail to give direction to the activities of individuals. Underinstitutionalization is usually found in rapidly changing societies in which the old norms and goals are no longer applicable and in which new forms of organizational structure have not yet coalesced. Transient labourers, especially those without family or other similar bonds, who must work here and there for short periods in different cultures or societies or conditions, may suffer from underinstitutionalization. High rates of mental disturbance and suicide are common in such groups. In societies experiencing rapid migration from rural villages to the cities, members may suffer from both overinstitutionalization and underinstitutionalization. In many parts of India and in numerous African countries, the rural-bred migrant to the city finds little to guide him in his new surroundings. When he returns to his village, he is equally at a loss, for different reasons. Although the problem is particularly acute in developing countries, it also exists

tivity

for the Southern sharecropper in the United States who moves to a Northern industrial city and for the large number of Puerto Ricans who have migrated to New York.

As a society becomes urbanized and industrialized, the countryside must increasingly produce food and raw materials for the urban population. It must do this with reduced manpower, because the urban areas are populated with recruits from the countryside who man the city's factories. In scarcely any developing country has agricultural production kept pace with urban growth. In the industrialized West, on the other hand, farm output has not only been sufficient to feed the farmers but has been great enough to take care of the burgeoning cities and even to supply surpluses, while at the same time the number of farm workers has decreased. In 1970 only 6.7 percent of the gainfully employed persons in the United States were engaged in agriculture, forestry, and fisheries. The typical farmer in the U.S. can produce enough to supply the needs of his household and 50 or more others. This situation contrasts strongly with that in the United States a century earlier or with the present situation in such countries as India. In India the typical farm worker produces enough for himself and for three others, two of whom are in his own household. Most countries fall between these extremes.

The countryside not only produces food and fibre for society; it also produces people. The birth rates among those engaged in rural occupations have historically been higher than among others. This demographic difference increases the difficulty of adjusting to modern society because so few children born to farm life can reasonably expect to choose farming as a career and because those who migrate to the cities not only encounter personal hardship but contribute to the overpopulation there.

RURAL PEOPLES

Settlement patterns. Most of the farm and peasant peoples of the world have lived in villages until recent times. Another common settlement pattern is the isolated holding, found in most parts of Canada and the United States. After the passage of the Northwest Ordinance of 1785, westward expansion in the U.S. followed the so-called checkerboard system in which one-mile-square sections of 640 acres (260 hectares) were homesteaded as four equal quarter sections of 160 acres (65 hectares) each. When settlers were free to build their dwellings wherever they wished, they built along roads and within reasonable distance of neighbours. When the settler followed principles dictated by economic use of energy, he might build in the middle of his square holding, but in time the pattern created by such choices gave way, in more thickly populated areas with improved highways, to string-along-the-road or line-type settlements resembling those common in France.

The typical French holding consists of narrow strips; the house is located at one end of the holding, most frequently on a road, river, or stream. In Germany, the traditional settlement, or *Gewannndorf*, was centred on a core of houses, barns, churches, and other buildings. Extending out from this core were small garden plots, then cultivated lands, then pasturelands, and finally the wastelands and wooded areas. This pattern fostered cooperation in the management of common lands and in such activities as harvesting, seeding, and pasturing. The German example influenced villages in England and New England. Spanish-Portuguese settlements, especially those developed in colonies, often centred on a plaza where the church and other community buildings were located. The extension of the square plaza resulted in straight streets and quadrangle blocks, unlike the crooked streets of the Germanic form.

The automobile and the highway have changed settlement patterns in at least four ways: (1) on the outskirts of cities, fringe areas have developed that combine rural and urban characteristics; (2) string-along-the-road developments have sprung up, inhabited by people who rely on their automobiles to carry them to the relatively distant city, resulting sometimes in tentacle-like extensions

of the city into the surrounding country; (3) the expansion of the suburbs has reduced the importance of the central-city shopping areas as additional shopping areas have grown up in the outskirts; (4) a hierarchy of centres and subcentres has emerged as a working interchange between rural and urban life; these include populated places of various sizes, from regional centres to towns, villages, and hamlets, all of which exchange goods and services with the rural population.

Rural demography. Much information about rural society is to be found in demographic statistics, such as sex ratios, age structures, birth rates and death rates. The United Nations publishes demographic data of international scope in its *Demographic Yearbook*, which, together with reports of the U.S. Bureau of the Census, constitutes the basis for the following analysis.

Age composition. The age composition of rural populations tends to differ from that of urban. Rural-farm populations have higher concentrations of the young and lower proportions of those in the most productive ages. If one draws a chart showing the numbers of individuals of various ages in a particular population, with the young ages at the bottom and the old ages at the top, the chart will be roughly pyramidal in shape. Countries in which both the birth rate and the death rate are high will tend to have age pyramids that are very broad at the base because of the large numbers of children, and taper fairly rapidly and evenly to a peak because of the comparatively small number who live to old age. A quite different profile is presented by such countries as New Zealand or the United States, where relatively fewer children are born, relatively few die in infancy, and relatively many live to old age: the pyramid is not so evenly tapered, being "pushed outward" by those of working and older ages. The opposite pattern is common in Latin America and much of Africa and the Middle East, where the age pyramid has a relatively high proportion of children. In a number of industrialized countries, the pyramid bulges in the middle because of the high proportion of persons in the productive ages of life and older.

Sex composition. The sex composition of a population is usually given in terms of the number of males per hundred females. Among newborn infants the ratio is about 105. It varies in succeeding years because of differences in the death rate (usually higher among male children) and in rates of long-distance out-migration (usually higher among young males) and of short-distance out-migration (usually higher among young females). More males than females die at all ages, except in such countries as India, where the girl child receives less care. Most of the differences in sex ratios among countries can usually be attributed to different migration patterns. Males in the productive periods of their lives often leave areas of limited economic opportunity to take work elsewhere. Malaysia, an area of colonial and plantation industry, reports a higher sex ratio for the age bracket 15-64 than it does for the age bracket under 15. Frontier districts, such as Alaska, report even higher sex ratios. Sex ratios are generally low in urban areas and high among farming populations, especially where rural women can find urban employment. Marriage rates and birth rates are lower in these areas than they would be if rural women were available in sufficient numbers to rural men and urban men in sufficient numbers to urban women.

Birth rates and death rates. Traditional rural societies have very high birth rates; modern public health techniques have reduced death rates to a degree that has resulted in rapid population growth in these societies. The developing countries are now faced with the task of lowering their birth rates to a level more compatible with their economic possibilities. One difficulty in doing so is that the factors governing rural birth rates are often religious and cultural. The rural Hindu father, for example, not only wants to have enough children to carry on the farm work but also needs a male child to take him in his aging years to the sacred places.

Population is affected by numerous variables. Sex differentials, for example, have much to do with the rate of reproduction, and these, in turn, are related to the rural-

of the
auto-
mobile

urban character of a particular area: the more urban an area, the lower the fertility of the population and, the more rural an area, the higher the fertility.

Kinship structures. Rural societies also differ from urban societies in their family structures. Rural families throughout history have generally been larger and more extended than urban families. In some cultures they include several generations of the male line (grandfather, father, son, and grandson) as well as uncles, aunts, and cousins. The family in old China and Japan sometimes extended to 200,000 or 300,000 members. Such families, known as clans, and other clanlike organizations have been important in the history of human society and still constitute the major organizational device for millions. Family and kinship relationships are closely involved with the institution of property, the institution of marriage, and basic norms of behaviour such as those governing the definition of incest. The extended family makes easier the transfer of property and with it the transfer of role responsibility from an aging farmer to a younger family member, particularly when the norms of succession have been institutionalized as is common in many peasant societies. Certain privileges and rights are accorded the retiring peasant owner-operator, and certain duties and responsibilities accompany the assumption of the role by his successor.

In cultures in which the family is the most important organizational structure for every facet of life, including the economic, the norms supporting it are all-prevailing and are deeply felt. Marriage is typically very strictly controlled. Relatives within a clan often marry but only according to the prescriptions of accepted custom. In most Arab countries, children of two sisters or children of two brothers may marry. In old Chinese families, children of siblings of opposite sexes (brother and sister) could marry. In both cases the rationale behind the mating norms is the protection of the larger family; the definition of incest varies according to the requirements of social stability.

The kinship structure of rural societies affects the age at which men marry and determines what proportion of them must remain unmarried. If the marriage bond gives primacy to the male line and is subordinate to the filial bond, as in the family structure of old China, it is not necessary to attain economic independence before marriage within the extended family. The father or grandfather need not worry about any threat to his authority at the marriage of his son or grandson. In the families of northwestern Europe, the situation is very different. Reluctance to permit a son to marry before the father is ready to relinquish control of the farm enterprise appears to delay or prevent marriage there and to be associated with lower birth rates.

The small nuclear family of northwestern Europe is an advantageous arrangement in an industrial society, in which mobility of the labour force is more important than the rights of property in land. There are wide variations in the closeness of the relations maintained between the nuclear family and other relatives such as grandparents, sisters, brothers, uncles, and aunts. Even when these relations are intimate, the immediate family is usually considered to be the married pair and their children.

Technological and economic influences. In the developing countries, farmers tend to be self-sufficient. Only a small amount of the produce goes to market, most of it being retained to support the farmer and his household. Agriculture in highly mechanized societies produces much more than can be used by the household.

Increased production in agriculture requires that there be some surplus income that can be put back into the productive process in the form of tools or fertilizer or other improvements. Farmers may, instead, choose to have larger families that guarantee a larger work force. This is particularly true in traditional agricultural societies and is in part due to the fact that the life cycle of families there differs from that of families in modern agricultural and industrial societies. In the life cycle of a given family in traditional agriculture, a time will come when the ratio of the young, nonproductive family members to the

adult producers is very high. Survival then will require the adults to work harder. This situation will be followed by a period during which income will be higher and directly proportional to the number of workers available. When the people in the productive enterprise consume an amount just equal to what they produce, economic development is almost impossible because gains are literally eaten up. In societies in which, one way or another, capital has come to be invested in agriculture, production may increase without a corresponding need for manpower, and surplus labour will migrate to the city. To avoid the creation of new urban slums, many experts on agricultural development recommend practices that will increase production without displacing masses of workers; these include soil technology, improved seeds, irrigation, and drainage but not large-scale mechanization. The effects of mechanization on the use of labour can be seen in the United States, where less than 6 percent of the labour force is employed in farming. The tendency of Western industrialized countries to export their own patterns and institutions is giving way to the realization that agricultural techniques must be adapted to the particular needs of each society if they are to be accepted and put to profitable use.

Some basic agricultural patterns are set by nature. Land-use specialists can tell by looking at maps showing farm population density, along with such other variables as temperature and precipitation, what is being produced in a particular area and how. But nature cannot be taken for granted. In some parts of the world, timber and livestock are being produced with little thought for anything except short-run profit. Sustained yields of forests and grazing lands require that society take a long view, or the consequence will be erosion and despoilment.

Social rank. Karl Marx thought of farmers as capitalists exercising private and exploitative control over one of the major means of production—the land. Thomas Jefferson saw in the farmer a free yeoman who, because he was free and independent, was the mainstay of the republic. Consistent with Marx's views, the leaders of the Soviet Union have abolished most private holdings except for small household plots and have sought to model agricultural management upon that of the factory. Practice in the West and in areas under Western influence has been in the direction of breaking up large estates and creating family-sized enterprises. Under proper conditions, the family-sized farm has been efficient and progressive, yielding some of the social and civic benefits anticipated by Jefferson. To say this is not to deny that farms may be too small, as often occurs after centuries of equal land division among sons. An efficient family-sized farm may be formed by the bringing together of small pieces of land as well as by the division of large tracts.

The owner-operator of a family-sized farm is both labourer and entrepreneur. Political movements among farmers sometimes have ties with labour, sometimes with business, and sometimes they have had Socialistic tendencies.

In areas in which large holdings prevail, the social class assigned to rural workers is lower than that in which family-sized holdings are common. Thus, throughout Latin America the day labourers and sharecroppers on haciendas form a rural proletariat. The owners of the land, the managers of agricultural processing plants, and the store owners form an upper class. In between are the supervisors, teachers, and other specialists or professionals. In India and Pakistan, caste distinctions prevail even on the family-sized farm. Elsewhere, however, even where there are distinctions of rank, the categories are not rigid enough to constitute classes. The Costa Rican peasant who lives in a floorless *ranchito*, covered only by a thatched roof, is ranked by his associates lower than the inhabitant of the casa with a metal roof and a floor; but, because they may be rather closely related and have a considerable amount of interaction, they cannot be considered members of different classes.

In rural society generally, social rank—whether reflected in caste, class, or estate—is determined more by birth than is the case in urban society. In the city, symbols of

workers

differentiation in rank are omnipresent; they extend from squalid tenements to magnificent houses. The differences among the mud houses in a village in Lebanon or between the *rancho* and the *casa* in rural Costa Rica are much less obvious. One reason for the importance of class symbols in the city is that everyone in that anonymous society looks for all the clues he can find to assign some sort of identity to the strangers he encounters each day. Because the city dweller's rank is dependent upon achievement, he reveals himself to others through his dress, speech, grooming, and personal possessions. The rural dweller, on the other hand, is known to those among whom he moves, and the rank assigned to him is beyond his power to change. An interesting analogy to the striving of the individual in urban life may be seen in the process by which whole castes in India and Pakistan attempt to rise together by adopting the norms and lifestyles of those above.

Attempts have been made by governments to abolish caste and class. In India, where many hereditary privileges have been outlawed and members of lower castes have been given access to government positions, universities, and civic life, an individual's caste remains one of his most important characteristics. In the Soviet Union, the Communists set out to build a classless society; but Soviet social scientists report "intra-class differences" in the incomes and levels of living of rural workers in state farms and collective farms. Some of the differences are attributable to the income from household plots, which are larger in the collective farms than on the state farms. One of the most reliable indicators of class differences is the number of religious icons displayed in the home, the number decreasing rapidly or vanishing as the class scale is ascended.

The family-owned farm is a vital force in agriculture in many parts of the world. The rank of the rural resident largely depends on his relation to the land. The owner of land, other things being equal, has the highest rank; labourers, especially transient ones, rank lowest; and the various types of tenants rank in between. The once-independent yeoman or farm owner is everywhere becoming less independent as agriculture becomes increasingly industrialized, specialized, and regulated. The ownership of land, however, still retains its importance in rural life. Farmers' and peasants' movements seldom demand that ownership of land be abolished. Even the demands raised in the Mexican Revolution (1911-17) for communal land tenure represented in reality a demand that the *hacendados* (large landowners) return the land to those who had occupied it under a former system. Most rural uprisings demand more, not less, private ownership of property for those revolting.

Organizations. Schools, health services, and adult-training agencies in rural settings tend to be less effective than those of the city, largely because the per-capita cost is always greater in an area of low population density. Also, to the extent that effective service requires highly trained personnel, rural areas find it difficult to attract them from urban areas, where supporting agencies are more available and income greater. To the extent that tradition is hallowed and certain beliefs and procedures are considered sacred, the rural agencies may become instruments for the preservation of custom rather than means of judicious exploration and change.

What rural areas often lack by way of effective formal organization is partly compensated for by the vitality of their informal organizations. The division between the two is not always great. A group that begins by informally purchasing and jointly owning a grain combine may grow into a cooperative buying society. Groups organized informally against horse thievery have been known to grow into formal farmers' organizations with some political power. Work exchange and borrowing is prevalent throughout traditional rural society, and much of it serves a real function without ever becoming formally organized. Cooperative neighbourhood activity, usually work-related, often provides occasion for informal recreation: a barn raising, a harvesting bee, a quilting party are social occasions fully as much as they are work ses-

sions. Harvest celebrations are common in most countries, even in highly modernized societies.

People in traditional rural societies are not good at organizing effective bureaucracies — one of the reasons why the many hundreds of bloody peasant and farmer revolts in the past have failed to bring much improvement in the lot of the agriculturist. Only in recent times, with improved communication and better education, have farmers and peasants begun to play effective political and economic roles. Organizations of rural young people have done much to spread knowledge and social awareness in countries as diverse as Japan, Yugoslavia, and the United States. In addition to socializing and training the youth in practical affairs, these groups often help to modernize their elders.

PROBLEMS OF CHANGE

Large farms versus small. If one examines rural and urban problems from a global point of view, it appears that cities everywhere are in danger of being swamped by a flood of migrants from rural areas. Most cities find it hard to absorb all of the migrants, and the necessary services are more costly and difficult to supply in the largest centres than in the smaller ones. Some students of the problem believe that the trend toward larger and larger agricultural units, with increasingly heavy traffic between farm and city, may have to be reversed. In Japan, the highly mechanized family farm produces most of the agricultural output, as in the United States, but the average Japanese farm is only about three acres (1.2 hectares) as compared with about 400 acres in the U.S. It may be that the future of rural society will conform to the Japanese rather than the American pattern.

In most Communist countries the Marxist predilection for large-scale agriculture has led toward the elimination of rural villages and family farms. Important exceptions are Poland and Yugoslavia, where peasant opposition and the fear of food shortages have prevented collectivization.

The role of planning. Rural and agricultural planning is carried on in most societies, in developed as well as in underdeveloped nations, in countries where agriculture is socialized and in countries where it is not. Denmark, for example, plans for specialization in agricultural exports, India maintains a national ministry for planning, and Yugoslavia plans in order to support its rural cooperatives. In the United States, much planning goes on at the national level in government agencies dealing with farm credit, soil conservation, fish life and wildlife, wood plots, irrigated lands, and rural housing. Very often the planning personnel are not the executive personnel and are not charged with the authority or responsibility for transforming the plans into action programs. For these reasons, planning is not always consistent nor is it undertaken with a sense of urgency.

In India there is great emphasis on the need to plan from the bottom upward and to make planning a two-way process so that the cultivators themselves can play a part in it. A most important Indian planning activity is the establishment between the district centre and the villages of growth centres in which educational, welfare, marketing, and other agencies may be located. This activity is seen as a means of relating the villages to governmental and marketing services. Similar institutions are evolving in many developing societies.

Communist countries make use of the cooperative, the collective, the state farm, the production brigade, and the commune as instruments of rural planning. An important factor in these countries is the power and organization of the centrally directed party apparatus, which cannot be matched in such countries as India.

BIBLIOGRAPHY. HENRI MENDRAS, *La Fin des paysans: changement et innovations dans les sociétés rurales françaises* (1970; Eng. trans., *The Vanishing Peasant: Innovation and Change in French Agriculture*, 1970), deals primarily with French peasants, but the author's concern is not confined to France. T. LYNN SMITH and PAUL E. ZOPF, JR., *Demography: Principles and Methods* (1970), is a useful source of comparative demographic data. JOEL M. OSTROV (ed.), *Town, Country and People* (1969), is a book by Soviet scholars dealing with population trends, rural planning, collectives, state farms, village surveys, religion, rural social structure, and rural sociology in the U.S.S.R. The chapter by Y.V. ARUTYUNYAN on rural social structure is of particular interest. WILLIAM T. LIU (ed.), *Chinese Society Under Communism* (1967), brings together available material on Chinese rural society. D.G. GADGIL, *Planning and Economic Policy in India* (1961), describes the Indian approach to rural planning.

(C.P.L.)

Rush, Benjamin

Benjamin Rush, physician, teacher, patriot, and reformer, was one of the most versatile and influential figures among the founders of the United States. Passing his entire professional life in Philadelphia, then the largest city and the cultural and political centre of the country, Rush knew all of his great contemporaries, corresponded with many of them, and, after the death of his friend Benjamin Franklin, was recognized as the leading citizen of Philadelphia and a major figure in American science and letters. An ardent nationalist, he wrote in 1786 that although the War of Independence had come to an end, the American Revolution had just begun; and he saw it as his mission "to effect a revolution in our principles, opinions, and manners so as to accommodate them" to a truly republican government.

By courtesy of the Independence National Historical Park Collection, Philadelphia, Pa.

Rush, oil painting by Charles Willson Peale (1741-1827), after a painting by Thomas Sully (1783-1872). In the Independence National Historical Park Collection, Philadelphia, Pennsylvania.

Rush was born on December 24, 1745 (new style, January 4, 1746), in Byberry township, now part of Philadelphia, into a pious Presbyterian family. He was sent to a private academy and on to the College of New Jersey at Princeton, from which he graduated in 1760. After a medical apprenticeship of six years, he sailed for Europe. He took a medical degree at the University of Edinburgh in 1768 and then worked in London hospitals and briefly visited Paris.

Returning home to begin medical practice in 1769, he was appointed professor of chemistry in the College of Philadelphia, and in the following year he published his *Syllabus of a Course of Lectures on Chemistry*, the first American textbook in this field. Despite war and political upheavals, Rush's practice grew to substantial proportions, partly owing to his literary output. The standard checklist of early American medical imprints lists 65 publications under his name, not counting scores of commu-

nications to newspapers and magazines. The best known guide to world medical classics (L.T. MORTON, *Garrison and Morton's Medical Bibliography*, 2nd ed., 1954) contains seven entries for Rush, ranging in subject from military hygiene and "breakbone fever" to psychiatry. Another source of Rush's professional prestige was the large number of his private apprentices and students from all over the country. He taught some 3,000 students during his tenure, successively, as professor of chemistry, the theory and practice of medicine, and the institutes of medicine and clinical medicine in the College of Philadelphia and the University of Pennsylvania. After 1790 his lectures were among the leading cultural attractions of the city.

As a physician, Rush was a theorist, and a dogmatic one, rather than a scientific pathologist. Striving for a simple, unitary explanation of disease, he conjectured that all diseases are really one—a fever brought on by overstimulation of the blood vessels—and hence subject to a simple remedy—"depletion" by bloodletting and purges. The worse the fever, he believed, the more "heroic" the treatment it called for; and in the epidemics of yellow fever that afflicted Philadelphia in the 1790s his cures were more dreaded by some than the disease. But in some measure the equally heroic presence of the doctor himself made up for his theories. He refused to flee the city when others did and entered hundreds of sickrooms with a confident air and the reassuring words, "You have nothing but a yellow fever."

In psychiatry Rush's contributions were more enduring. For many years he laboured among the insane patients at the Pennsylvania Hospital, advocating humane treatment for them on the ground that mental disorders were as subject to healing arts as physical ones; indeed, he held that insanity often proceeded from physical causes, an idea that was a long step forward from the old notion that lunatics are possessed by devils. His *Medical Inquiries and Observations upon the Diseases of the Mind* (1812) was the first and for many years the only American treatise on psychiatry.

Rush was an early and active American patriot. As a member of the radical provincial conference in June 1776, he drafted a resolution urging independence and was soon elected to the Continental Congress, signing the Declaration of Independence with other members on August 2. For a year he served in the field as surgeon general and physician general of the Middle Department of the Continental Army, but early in 1778 he resigned because he considered the military hospitals mismanaged by his superior, who was supported by General Washington. Rush went on to question Washington's military judgment, a step that he was to regret and one that clouded his reputation until recent times. He resumed the practice and teaching of medicine and in 1797, by appointment of President John Adams, took on the duties of treasurer of the U.S. Mint. He held this office until his death, of typhus, in Philadelphia on April 19, 1813.

Rush early reflected the humanitarianism of the Enlightenment by publishing antislavery tracts, and after the Revolution he issued a stream of articles and pamphlets attacking tobacco, "spirituous liquors," war, oaths, public punishment of criminals, capital punishment, and the like, while, on the other hand, he espoused free public schools, the education of girls, a national university, and life-saving societies. In later years, however, Rush lost faith in political and social reforms. He kept up his political friendships by writing charming letters, some of which show a capacity to laugh at his own follies. A late triumph of his letter writing was the reconciliation he effected between former Presidents John Adams and Thomas Jefferson. The characterization Rush furnished for himself among his sketches of the signers of the Declaration of Independence was singularly brief and appropriate: "He aimed well."

BIBLIOGRAPHY. The standard biography is NATHAN G. GOODMAN, *Benjamin Rush: Physician and Citizen, 1746-1813* (1934); more recent and very readable is CARL A. BINGER, *Revolutionary Doctor: Benjamin Rush (1746-1813)* (1966). Both contain reference notes and bibliographies. Rush's separately published works are listed in ROBERT B. AUSTIN, *Early*

Medical publications

American Medical Imprints: A Guide to Works Published in the United States, 1668–1820 (1961), which must be supplemented by Rush's nonmedical writings, particularly his *Essays: Literary, Moral & Philosophical* (1798), containing many of his educational and reform proposals. Rush's lively and invaluable *Autobiography* has been admirably edited, with related materials, by GEORGE W. CORNER (1948); and his *Letters*, touching on every aspect of his life, were edited by L.H. BUTTERFIELD, 2 vol. (1951). JOHN H. POWELL, *Bring Out Your Dead* (1949), is a vivid account of the yellow fever epidemic of 1793 and Rush's part therein.

(L.H.Bu.)

Ruskin, John

As a writer, critic, and artist, Ruskin more than anyone else influenced the public taste of Victorian England, and, in economic theory, he did much to inspire the opposition to the philosophy of laissez-faire, or non-interference. He was one of the first to bring the work of art into relation with its creation and with the age in which he lived and one of the first to preach with some effect that a respect for art must be a part of civilization. He inspired the artist and writer William Morris to create the Society for the Protection of Ancient Buildings and preached the necessity for a National Art Collections Fund a generation before one was founded. He included visual training in his educational schemes and made the social condition of the workman a part of the judgment of the work of art and of the products of manufacturing on a larger scale. It is easy and partly true to say that he lost the battle against the doctrines and practice of Manchester and the political economists who followed John Bright in advocating laissez-faire; yet many of his words did not fall on stony ground. No one who has read any of his more important works seriously will ever be quite free from his influence; in what he wrote there was always an element of single-minded nobility. No picture of the Victorian age can be complete without him.

Ruskin, oil painting by Sir John Everett Millais, 1853–54. In a private collection.

Life. Youth. John Ruskin was born in London on February 8, 1819. His grandfather was gifted, a spend-thrift, and a little mad, and he finally killed himself. His parents recognized a dangerous precocity and an unstable genius in their child and sheltered him from contact with reality. At the same time, they checked and restrained him and allowed him little spontaneity of interest or action. The father, John James Ruskin, was a successful wine merchant. He had a liking for pictures, and, when he toured England to solicit orders, he saw the galleries in the great houses, accompanied, in time, by his son. The Ruskins moved to Herne Hill, on the southern outskirts of London, when Ruskin was four, and to nearby Denmark Hill, near Dulwich, when he was 20. His natural appetite for pictures found satisfaction in the Dulwich College Picture Gallery, and the pictures exhib-

ited there remained the basis of his thoughts on art long after he was free to seek wider knowledge.

The Dulwich gallery, constant reading of the Bible with his mother and of the 18th-century classics with his father, and his father's encouragement of his facile talents in writing and drawing were the most valuable part of his education. His father's interest in art secured him drawing lessons from the watercolorist Copley Fielding. When he was 14 the family began a series of tours in Europe, of a conventional kind—northern France, Flanders, the Rhine, the Black Forest, and Switzerland. In the Alps he found the beauty and sublimity that his imagination needed, and he justified his love of the Alps by amateur geologizing and botanizing. Such justification of his enjoyment was made necessary largely by the intense moral preoccupations of his parents, which had left their mark on him.

When he was 17 Ruskin fell in love with Adele Domecq, the daughter of his father's Spanish partner. The frustration of this affair seems to have been the effective cause of a permanent failure to attain emotional maturity, which left him vulnerable and incomplete.

In 1836 Ruskin went up to Christ Church, Oxford, where his studies were desultory and his social life was hampered by his mother's presence in lodgings nearby. Nonetheless, he had gotten away from the suburbs and made friends—chief among them Henry (later Sir Henry) Acland, who became regius professor of medicine—who were permanently to enrich his life. He won the Newdigate prize for poetry in 1839 and, because of a generous allowance from his father, was able to begin to collect pictures by J.M.W. Turner.

First visit to Italy. Ruskin's time at Oxford was interrupted suddenly in the spring of 1840, when he suffered a hemorrhage, which the doctors considered to be of consumptive origin. They advised that he should winter abroad, and the family departed for Italy. Ruskin made many sketches in the course of the long, leisurely journey, but in Rome, where he made friends with the artist George Richmond, he began to have a clearer idea of the difference between amateur and professional work. They went on to Naples, where he had another attack, but on the return journey, by Venice through Switzerland, he regained energy and hope. He found himself able to see natural beauty in all its gamut—from great mountains to minute plants—with a new vividness, and he devoted himself to describing it with artistry.

Ruskin returned to Oxford in the autumn and graduated in the spring of 1842. The Ruskins spent the summer at Chamonix-Mont-Blanc in the French Alps. There John began to plan a book in defense of Turner, whose late style had been exemplified in the pictures that he exhibited in the Royal Academy that year and that had been laughed at by the critics. Returning to a new house on Denmark Hill, he began to work seriously at the National Gallery and at Dulwich and to write the first draft of what was to become the first volume of *Modern Painters*. He set out to examine the "truth to Nature" of the accepted masters of landscape painting, always with the glorification of Turner in mind; and in his description of landscape in Italy and in the Alps he gave rein to his own capacity for word painting. The book appeared in May 1843, when Ruskin was just 24. It had a considerable success, though Turner himself showed nothing but embarrassment. Ruskin immediately set to work on a second volume, which had no such definite scheme as the first and contained even more of the author's sensibility—a sensibility that had by then escaped from Protestant inhibitions in the study of religious painting.

Second visit to Italy; marriage. In April 1845 Ruskin set out on a journey that was to mark a new stage in his development. Together with a valet and an elderly mountaineer guide and without his parents, he set forth to explore northern Italy and found in its medieval architecture and sculpture a romantic beauty he had not known before. The sketches he made were the best he ever achieved, and the things he saw were forever imprinted on his memory; for once he was really happy.

Oxford friendships

Composition of *Modern Painters*

Marriage
to Effie
Gray

When he returned to Denmark Hill it was to complete the second volume of *Modern Painters* in less congenial surroundings. It appeared in April 1846. A subsequent journey to Italy with his parents, to show them the beauties he had lately discovered, was an anticlimax and led to an attack of nervous depression. On their return he began to think of marriage and, with hesitant encouragement from his parents, became engaged to Euphemia Chalmers (Effie) Gray, the pretty daughter of Scottish friends of the family, whom he married in April 1848. He was completely self-centred and very gifted; she was rather demanding, a born social climber, and essentially commonplace. It is not surprising that the marriage (which was never consummated) was not a success.

After a few months in London, where Effie was determinedly social, in August they visited northern France, for Ruskin had it in mind to write a book on the essential qualities of Gothic architecture. By April *The Seven Lamps of Architecture* was finished. The book had a considerable success. It took the fruits of the labours of a generation of medievalists and gave them a generalized basis and a moral flavour; and it was extremely well written. In the autumn of 1849 the young Ruskins went to Venice for the winter. Ruskin wished to apply the general principles of *The Seven Lamps of Architecture* to Venetian architecture and to relate its rise and fall to the working of moral and spiritual forces. He worked hard; the first volume of *The Stones of Venice* duly appeared in 1851. In the course of that year Ruskin was induced to champion the Pre-Raphaelite Brotherhood, a group of young English artists founded in reaction against contemporary academic painting, less because he admired them from the first than because he thought the critics unfair to them. He befriended the painter and poet Dante Gabriel Rossetti, who disliked him; established a lasting and happy friendship with the artist Edward Burne-Jones; and cultivated the company of John Everett Millais, with the result that the artist and Effie fell in love. As soon as Millais had been elected a member of the Royal Academy, with an assured future, Effie left Ruskin. In July 1854 she secured an annulment of her marriage on the ground of her husband's impotence, and a few months later she married Millais.

Return to Denmark Hill. Ruskin was back in the old narrow circle of Denmark Hill. His only escape was to rather futile teaching at the Working Men's College (established in 1854 by the moral philosopher and Christian Socialist J.F.D. Maurice, whom he did not like) and in sitting at the feet of the historian and essayist Thomas Carlyle, who made him waste a good deal of time on causes irrelevant to his real interests. The third and fourth volumes of *Modern Painters* were written on an increasingly authoritarian note, and by the middle of 1855 he felt written out. His chief interest was in the construction of the Oxford Museum of Natural History, under the aegis of his friend Acland and according to his own principles of Gothic beauty. He offered to undertake the sorting and arrangement of the mass of drawings that Turner had left to the National Gallery, and, from February 1857 for about a year, this was his chief occupation. He gave many lectures, less on art pure and simple than on its implications. In those on *The Political Economy of Art* (1857)—later retitled *A Joy for Ever*—he entered economics, with an able and effective disquisition on economy as "the art of managing labour."

In 1858, again alone but for a valet and the old guide, he spent six weeks in Turin, Italy, and recaptured the magic of the mature Renaissance in the paintings of Paolo Veronese. The fifth volume of *Modern Painters* (1860), written in the winter of 1858–59, is largely influenced by these interests. The volume is extremely disconnected; and, indeed, Ruskin's mind was gradually declining into madness. He fell in love with a hysterical young Irish girl of good family, Rose La Touche, who, when he first knew her, was a child of ten; when she was 16 he declared himself to the parents, who were horrified. Soon after, Rose fell mentally and physically ill, and the affair dragged sadly and hectically on until her death in 1875. During these years, Ruskin became a habitué of Miss

Affair with
Rose La
Touche

Bell's girls' school at Winnington, Cheshire, where the company of the children provided a refuge; some of his books—notably *The Ethics of the Dust* (1866)—were developed from talks he gave to her pupils. His only important work at this time was a set of essays on the nature of wealth that he wrote in 1860. His views (based to some extent on those of the reformer and Socialist Robert Owen) included the theory of social justice and were utterly contrary to the laissez-faire doctrines of the time, which derived from the teachings of the Utilitarian philosopher Jeremy Bentham. *The Cornhill Magazine* began to publish the essays, but they roused so much opposition among its readers that, after the fourth essay, William Makepeace Thackeray, the distinguished novelist who was its editor, discontinued them. Ruskin published them as a book under the title *Unto This Last* (1862).

He was near a breakdown and retired for a time to Morne, near Geneva. He returned in time for his father's last illness and death in March 1864 and continued to live with his aging mother at Denmark Hill. His father bequeathed Ruskin £120,000, various properties, and a fine collection of pictures; but he had neither peace of mind nor strength of purpose left. He wrote no more on art, except as a part of his social and economic theories, and when he travelled he was apt to delegate the making of sketches to artists whom he took with him.

Last years. In 1869 Ruskin was elected the first Slade professor of fine art at Oxford University, and he had a great personal success as a lecturer, though his lectures were diffuse and on many subjects other than art. He gave the university a collection of prints, photographs, and drawings for undergraduates to study, and he set up a drawing school for them. He had a need to address himself to those of another intellectual class than himself and, thus, wrote two series of letters to workmen, *Time and Tide* (1867) and a much longer set, *Fors Clavigera* (1871–84). The last was the organ of the Company of St. George, which he founded in 1871 and endowed with a capital of £10,000. It was intended to carry out his economic doctrines; every "companion" was to give it a tenth of his income, and for many years Ruskin did. Its activities were often ill-judged and were usually unfortunate; a museum of art at Sheffield was the most successful. Bouts of illness interrupted work at Oxford and the publication of *Fors*; after his mother's death, in 1871, Ruskin sold the house at Denmark Hill and bought Brantwood, an ugly residence beautifully situated on Coniston Water in the Lake District, where he spent much of his time, with a married cousin to keep house for him. He began to be obsessed with the idea of the "Storm-Cloud and Plague-Wind" that were everywhere defiling natural beauty, and finally in 1878 suffered some months of acute mania. Early in 1879 he resigned his professorship, giving as his excuse that the painter James McNeill Whistler had won a libel action against him for his intemperate criticism of one of the "Nocturnes."

His intellectual life was over. He showed improvement in 1880–81 and even resumed work at Oxford, with grotesque and tragic results. The years that followed were checkered by attacks of mania; yet it was in these years that he wrote the most charming of his works, the autobiography called *Praeterita* (1885–89). It offered escape from the present, and, since he had kept a diary for much of his life, he had materials to work on. It was never finished; after a sixth attack of madness, in the summer of 1889, he was incapable of writing anything but his signature. He died on January 20, 1900, and was buried at Coniston, Lancashire.

Assessment. It is usual to think of Ruskin as a typical public figure of Victorian England, the keeper of the artistic conscience of his country who upheld the pre-eminence of the Gothic style and demanded its employment in building and decoration. Nevertheless, acceptance of Ruskin as a prophet in art was not immediate. Though the substantive part of his pure art criticism was written before he was 35, he was considered to be something of an amateur, a rich dilettante, until after he was 50, in the 1860s. By this time, the Gothic Revival movement, with roots in the late 18th century, had already become estab-

The
Company
of St.
George

lished as a leading current style, independently of his championship of it. By the last quarter of the 19th century, Ruskin's opinions on art were regarded as almost infallible; but from the 1860s onward he himself had lost interest in art criticism for its own sake, and his creative ideas were now active in political and social economy.

Interests and character. His puritanical conscience never let him rest easy in the enjoyment of his unearned wealth: he tried at first to justify his enjoyment of beauty by theorizing about it, and later, when this no longer satisfied him, he turned to the study of economic and social questions.

Ruskin lived an inwardly difficult, lonely life, often pursued and struck at by madness. His interests were wide, embracing art, such branches of natural science as geology, mineralogy, and botany, political science, and economic and social studies. Yet the variety of interest was also symptomatic of a want of concentration that increased with time and caused him, from one hour to the next, to abandon one kind of study for another. His art criticism, too, for all its influence and its breadth, is unsystematic and established on his personal response to works of art; here his apparent limitations are partly those of his time, when art criticism and art history—to which his own writings gave a major impetus—were still only lightly cultivated fields: he had little knowledge or appreciation of French, Dutch, or Spanish art or indeed of any art outside that of Renaissance Italy and of England, and he had no sympathy with the Impressionist movement of his own day.

Style and ideas. Yet John Ruskin was a man of true originality. His literary style, though it has echoes of the King James Version of the Bible and of writers such as Richard Hooker and Dr. Samuel Johnson, is unmistakably his own; although his ideas might owe something to the Greek philosopher Plato and more still to the Bible, he shaped them in his own way. He was a completely honest and curiously innocent man. As a rich man's son, he was free to work at what he liked and generally wrote easily of what interested him. This amateur quality gives a characteristic sparkle and zest to his treatment of all his themes, and they were many. His originality and his intellectual self-indulgence were inextricably mixed with his psychological weakness. He is the archetype of the manic-depressive, swinging from elation to misery, always sensitive and always expressive. The narrow religiosity of his early upbringing, his lack of systematic education, and his mother's overanxious care did nothing to give him the poise and repose that might have helped him to keep a balance; and two frustrated love affairs and an unhappy marriage removed any hope of emotional maturity.

But, in spite of these disabilities (and sometimes because of them), he was able to perceive beauty with an infectious intensity and to express his perception in memorable prose, sometimes made even more cogent by accompanying drawings and sketches, for he was a good amateur draftsman.

What, then, are Ruskin's essential ideas on art and society, and how can they be summarized? It must be remembered first that Ruskin was a follower of the great poet William Wordsworth in his love of nature and of mountain scenery in particular. Ruskin founded his aesthetic principles upon truth to nature in landscape painting and tried to prove his point by contrasting, in *Modern Painters*, the sensitive accuracy in this respect of his hero J.M.W. Turner, the great landscape painter of the first part of the 19th century in England, with the conventional generalizations of Claude Lorrain, the great landscapist of 17th-century France. He went on to find the same truthfulness, but now united with religious feeling, in Gothic architecture. He looked with care at the natural forms of its decoration, carved with delicate reserve by a host of anonymous craftsmen. The gesticulation of the Baroque and its ornaments, such as urns, scrolls, and obelisks—forms not found in nature—seemed artificial and false to him and so, in his view, constituted bad art. His conception of good art as a storehouse of natural truth, which also was its source, led to his ideal view of the workman, whether craftsman or manual labourer, as

a dedicated individual who needed to find fulfillment through doing work with a valid purpose. Social justice required the provision of conditions that would allow all to share with the creative artist the opportunity for work of this kind, but such conditions were not generally to be found in the heedless economic expansion of 19th-century England. Thus, he was led from criticism and exposition of art to a concern with social welfare. Yet one comes back to the fact that he is remembered best in the world of art.

MAJOR WORKS

WRITINGS ON ART: *Modern Painters*, 5 vol. (1843–60, epilogue 1888); *The Seven Lamps of Architecture* (1849); *The Stones of Venice*, 3 vol. (1851–53).

WRITINGS ON SOCIAL AND POLITICAL ECONOMY: *Unto This Last* (1862), four articles first published in *The Cornhill Magazine*, 1860; *Time and Tide* (1867), letters in newspapers of the same year; *Fors Clavigera*, monthly publication, occasionally interrupted, of letters to workmen, 1–96 (1871–84); *Munera Pulveris* (1872), four articles in *Fraser's Magazine*, 1862–63.

OTHER WORKS: *The Two Paths* (1859) and *A Joy for Ever* (1880), both compiled from lectures given in 1856–59; *Sesame and Lilies* (1865) and *The Crown of Wild Olive* (1866), miscellaneous lectures; *The Ethics of the Dust* (1866); *Praeterita*, parts 1–28 (1885–89), an incomplete autobiography.

BIBLIOGRAPHY

Editions: Ruskin's *Works* were edited by E.T. COOK and A. WEDDERBURN, 39 vol. (1903–12). The *Diaries* were edited by JOAN EVANS and J.H. WHITEHOUSE, 3 vol. (1956–59). There are separate editions of *Letters* to various people, of which *Ruskin's Letters from Venice, 1851–1852*, ed. by J.L. BRADLEY (1955), may be noted.

Selections: JOAN EVANS (ed.), *The Lamp of Beauty* (1959), an anthology of his writings on art; also *Ruskin Today*, chosen and annotated by KENNETH CLARK (1964).

Biography and criticism: E.T. COOK, *The Life of John Ruskin*, 2 vol. (1911, reprinted 1968), a classic that now seems overdiscreet; DERRICK LEON, *Ruskin, the Great Victorian* (1949); PETER QUENNELL, *John Ruskin: The Portrait of a Prophet* (1949); JOHN D. ROSENBERG, *The Darkening Glass: A Portrait of Ruskin's Genius* (1961); and R.W. WILENSKI, *John Ruskin: An Introduction to a Further Study of His Life and Work* (1933, reprinted 1967), are good biographies.

More specialized aspects: J.T. FAIN, *Ruskin and the Economists* (1956); W.M. JAMBS (ed.), *The Order of Release: The Story of John Ruskin, Effie Gray and John Everett Millais, Told for the First Time in Their Unpublished Letters* (1947); MARY LUTYENS, *Millais and the Ruskins* (1967); and (ed.), *Effie in Venice: Unpublished Letters of Mrs. John Ruskin Written Between 1849–1852* (1965); H.G. VILJOEN, *Ruskin's Scottish Heritage* (1956); J.H. WHITEHOUSE, *Vindication of Ruskin* (1950).

(J.Ev.)

Russell, Bertrand

Bertrand Russell had one of the most widely varied and persistently influential intellects of the 20th century. During most of his active life, a span of three generations, Russell had at any time more than 40 books in print ranging over philosophy, mathematics, science, ethics, sociology, education, history, religion, politics, and polemic. The extent of his influence resulted partly from his amazing efficiency in applying his intellect (he normally wrote at the rate of 3,000 largely unaltered words a day), his memory, and his aristocratic independence and partly from his deep humanitarian feeling that was the mainspring of his actions. This feeling expressed itself consistently at the frontier of social change through what he himself would have called a liberal anarchistic, left-wing, and skeptical atheist temperament. His first major undertaking in the field of logic and mathematics had a profound influence upon philosophy in the Western world. In his middle years his books on morals, politics, education, pacifism, and other subjects were an illumination and encouragement to the rebellious layman. Finally, during the last decades of his life (just as he felt himself in danger of becoming respectable by sheer weight of years), he became an inspiration to idealistic youth throughout the world in his active opposition to the manufacture of H-bombs and to the war in Vietnam.

Limitations of Ruskin's art criticism

Ruskin's aesthetic principles

Family and education

Early years. Bertrand Arthur William Russell, 3rd Earl Russell, was born at Trelleck in Monmouthshire on May 18, 1872, the second son of Viscount Amberley and his wife Katherine, daughter of the 2nd Baron Stanley of Alderley. Lord Amberley was the third son of Lord John Russell, who was twice prime minister and became the 1st Earl Russell.

Katherine Amberley died of diphtheria in 1874, and Amberley himself died 18 months later. The Amberleys had very advanced views and had intended to place Bertrand and his brother Frank (then aged ten) under the guardianship of friends who were atheists. But the children's grandparents had no difficulty, given the feeling of the time, in upsetting the will and getting the two boys made wards in Chancery, so that they were brought up by their Russell grandmother, a strict yet politically liberal-minded Puritan with a rigid personal conscience and exacting standards. Bertrand Russell was educated privately, had little contact with other children, and developed an intense inner life, full of idealistic feeling and metaphysical profundities (partly a product, he later theorized, of sublimated sexual desires), all imbued with a passionate desire for certainty in knowledge. At the age of 11 he had already begun to have religious doubts, and, eventually, the skeptical cast of his intelligence prevailed over his upbringing. He came to disagree with his family on everything except politics, but he was also able to accept the disillusionment of finding that logical certainty was unattainable in empirical matters and to accept as well the stunning disappointment (when introduced by his brother at the age of 11 to the delightful certainties of mathematics) of being told that the axioms of geometry could not be proved but had to be taken on trust.

This situation set the pattern of Russell's philosophical career. He was determined not to be beguiled by human pretensions to knowledge or by unbacked assumptions either about the foundations of knowledge or about what may be said to exist. Henceforth, one of his primary aims was to inquire, with skeptical and parsimonious intent, "how much we can be said to know and with what degree of certainty or doubtfulness."

He entered Trinity College, Cambridge, in 1890, was at once recognized as intellectually outstanding, and soon became a member of the exclusive Society known to outsiders as "The Apostles." He was winner of first-class honours in the Mathematical Tripos (honours examination) in 1893 and then turned to philosophy, becoming for several years an Idealist under the influence of the Cambridge metaphysician J.M.E. McTaggart, and taking a first-class degree in moral sciences in 1894.

In the same year, against the wishes of his family, he married Alys Pearsall Smith, the sister of Logan Pearsall Smith (the author of *Trivia*) and a Quaker from Philadelphia with advanced views. In the next two years he

lectured in the United States on non-Euclidian geometry, travelled in Germany to study economics, was introduced to Marxism by the Social Democrats there, and, as a result, was appointed first lecturer at the London School of Economics and Political Science. His first published book—written from the orthodox liberal point of view—was *Gerrnan Social Democracy* (1896). He remained a liberal until he joined the Labour Party in 1914. He also won a fellowship at Trinity with a dissertation entitled "An Essay on the Foundations of Geometry."

First philosophical works. In 1898, with Trinity Fellow G.E. Moore leading the way, he rebelled against Idealism and became, broadly, an Empiricist, a Positivist, and what philosophers would call a physical Realist (though in everyday matters he was what the layman would call a Materialist) for the rest of his philosophical career.

His career may be said to have involved three main aims, with an underlying premise that the scientific view of the world is largely the correct view. The most fundamental and pervasive aim was the one already mentioned: that of paring down to a minimum and to their simplest expression the pretensions of human knowledge. This aim manifested itself in such books as *An Inquiry into Meaning and Truth* (1940) and his last major work *Human Knowledge, Its Scope and Limits* (1948), which was intended to be a definitive survey. The second aim involved the linking of logic and mathematics, as in his first major work, *The Principles of Mathematics* (1903), with the object of showing that mathematics can be deduced from a very small number of logical principles. The third aim was analytic: assuming that it is possible to infer something about the world from the language in which it is (correctly) described, Russell analyzed that language down to its minimum requirements—its atomic facts—in order to avoid unnecessarily postulating the existence of the objects denoted by descriptive phrases (such as "The present king of France"). This aim manifested itself in the so-called theory of descriptions, in the philosophy of Logical Atomism, and in such books as *The Analysis of Matter* (1927) and *The Analysis of Mind* (1921), the main thesis of which holds that mind and matter are different "structurings" of the same "neutral" elements.

After an interlude of work on Leibniz (*A Critical Exposition of the Philosophy of Leibniz* [1900]), Russell embarked upon his major work on logic and mathematics, starting with the first draft of *The Principles of Mathematics* (1903) and culminating over a decade later in the publication of the three volumes of *Principia Mathematica* (1910, 1912, and 1913), written in collaboration with his friend and former tutor, the philosopher and mathematician Alfred North Whitehead. This work, together with Russell's ancillary work on logic, was immensely influential among logicians for many years, even though the two authors agreed that they had not completely fulfilled their purpose of deriving mathematics from self-evident logical principles.

At the beginning of this decade of work—the hardest in Russell's whole life—he underwent what he called a "mystic illumination," which in five minutes transformed him into a pacifist (and a pro-Boer in England's war against the Boers of South Africa) and overwhelmed him with "semi-mystical feelings about beauty." It was in 1903 that he suddenly fell out of love with his wife Alys (though the couple did not separate until 1911), Russell in 1910 having met Lady Ottoline Morrell, a prominent literary hostess, with whom he developed a long-lasting relationship.

In 1902 there appeared the popular and, as he later felt, overwritten essay "The Free Man's Worship." In 1907 he stood unsuccessfully for Parliament, campaigning for women's suffrage and free trade. In 1908 he was elected a fellow of the Royal Society. (Russell's travels, lecture tours, professorships, degrees, and prizes, not to mention the books he wrote, are too numerous for complete listing in this article.)

Later political and philosophical works. During World War I his activities as a pacifist resulted in his being fined

Three
aims of his
career

£100 in 1916, being dismissed from his lectureship at Trinity College, and being imprisoned for six months in 1918. While in prison he wrote his *Introduction to Mathematical Philosophy* (1919) and started reading for his work *The Analysis of Mind* (1921).

In 1916 he had met Lady Constance Malletson, a young and beautiful fellow pacifist. In 1919 he met Dora Black, with whom he visited China in 1920 and whom he married as his second wife in 1921. Russell visited the Soviet Union in 1920 and, the same year, published *The Practice and Theory of Bolshevism*, which was markedly critical of the regime, stressing its totalitarian nature and predicting and condemning many of the aspects of what was later to be called Stalinism.

Since the publication of *Principia Mathematica*, Russell's philosophical work had been mainly analytic and as such was one of the inspirations for the Analytic movement in philosophy, with which, however, Russell himself eventually lost sympathy. In working out his philosophy of Logical Atomism, he was influenced to some extent by his pupil Ludwig Wittgenstein, whom he had first met in 1911, and in particular by the basic doctrine of Wittgenstein's *Tractatus Logico-Philosophicus* (1922), which held that a proposition is a picture of the facts that it asserts and must have in a sense the same structure. Russell continued throughout his life to stress the importance of structure and indeed used the notion of similarity of structure in *Human Knowledge, Its Scope and Limits* (1948) as a criterion in inferring causal relationships. But he disagreed with Wittgenstein's later and influential *Philosophical Investigations* (1953).

Works for
the layman

During the 1920s much of his work was written for the layman; some of it was vulgarization in the respectable sense, as in *The ABC of Atoms* (1923) and *The ABC of Relativity* (1925); the rest ranged from *What I Believe* (1925) to *Marriage and Morals* (1929), *The Scientific Outlook* (1931), and *Education and the Social Order* (1932). All of these highly influential books were written with barbed wit from a politically, morally, and intellectually left-wing radical and anti-obscurantist point of view. He also wrote, at the expert's level, on ethics—mainly from a Utilitarian standpoint—and on political, social, and educational philosophy.

In 1927 he and his wife Dora started an experimental school at Telegraph House, near Petersfield, which was carried on by Dora after their divorce (in 1935) until the outbreak of war in 1939 and the permissiveness of which, though advanced for those days, was somewhat exaggerated by public gossip.

On his brother's death in 1931, Russell succeeded to the title as 3rd earl. In 1934 he published *Freedom and Organization, 1814–1914* and, in 1937, *The Amberley Papers*, both written with the help of a research assistant, Patricia Spence, whom he married in 1936.

As a pacifist, he supported British policy at Munich in 1938, though after war broke out he acknowledged that Hitler had to be defeated as "a necessary prelude to anything good." After lectureships in the United States during 1938 and 1939, his appointment to a professorship at City College in New York was annulled by the courts, one of the grounds being that he was an advocate of sexual immorality. (See the appendix to his *Why I Am Not a Christian*, 1927, edited by Paul Edwards.) Russell was temporarily saved from poverty by a five-year contract to lecture at the Barnes Foundation in Pennsylvania, but this was cancelled in 1943. He used his lectures as a basis for his *History of Western Philosophy* (1945), which became an immediate best seller both in Britain and in the United States and was his main source of revenue for many years. In the meantime, on his return to Britain in 1944, Russell had been appointed lecturer and fellow of Trinity College.

The next 15 years saw him attain rapidly increasing fame and respectability, initiated by appearances on the British Broadcasting Corporation (BBC) "Brains Trust" programs and consolidated by the delivery in 1949 of the first BBC Reith Lectures, by the receipt in 1949 of the Order of Merit, and, in 1950, of the Nobel Prize for Literature.

Political activism. When *Human Knowledge, Its Scope and Limits* was published in 1948, it received a respectful but lukewarm reception, partly because the theory of knowledge was at that time out of fashion and partly because, since the war, there had been in any case a turning away from Russell's ideas. This reception was a sharp disappointment to Russell, but he was in any case unsympathetic to the then current linguistic movement in philosophy; and (except for the writing of *My Philosophical Development* [1959] and a few reviews) he began to divert his attention from philosophy to international politics. As a result, from about 1952, when he was divorced from Patricia Spence and married Edith Finch, an American, he became progressively less respectable in the eyes of established authority and more influential in the eyes of the young and left-wing throughout the world. (During the late 1960s he would receive more than 1,000 messages and cards at Christmas, many of them from the Far East.) In 1954 he made his famous "Man's Peril" broadcast on the BBC, condemning the Bikini H-bomb tests; this led to the Russell–Einstein statement of protest by Nobel scientists, to the Pugwash Conferences of scientists from both East and West (Russell was elected president of the first conference in 1957), and, eventually, to the Campaign for Nuclear Disarmament, launched in 1958, again with Russell as president. He resigned, however, in 1960 and formed the more militant Committee of 100 with the overt aim of inciting mass civil disobedience, and he himself with Lady Russell led mass sit-downs in 1961 that brought them a two-month prison sentence, which was reduced to seven days, however, on health grounds.

Attacks on
nuclear
weapons

In 1962, at the age of 90, his energy and strength of purpose were still such that, during the Cuban crisis and the Sino-Indian border conflict, he intervened with heads of state and with U Thant of the United Nations. After the publication of the Warren Report, he chaired the Who Killed Kennedy Committee. In the meantime, in order to systematize his work for peace, he had established, in 1963, the Bertrand Russell Peace Foundation and the Atlantic Trust. During the remainder of the '60s, he vehemently attacked U.S. policies in Vietnam. With the help of the French Existentialist Jean-Paul Sartre, the Yugoslav historian Vladimir Dedijer, the Polish author Isaac Deutscher, and others, he convened the International War Crimes Tribunal.

The last three years of the '60s saw the publication in three volumes of one of Russell's finest works—witty, candid, absorbing, and beautifully written—his own *Autobiography*. He died on February 2, 1970, at Plas Penrhyn, near Penrhyndeudraeth in north Wales, his much-loved home for 15 years.

MAJOR WORKS

MATHEMATICS AND LOGIC: *The Principles of Mathematics* (1903); *Principia Mathematica* (in collaboration with A.N. Whitehead), 3 vol. (1910–13).

PHILOSOPHY: *A Critical Exposition of the Philosophy of Leibniz* (1900); *Philosophical Essays* (1910); *The Problems of Philosophy* (1911); *Our Knowledge of the External World* (1914); *The Philosophy of Pacifism* (1916); *Introduction to Mathematical Philosophy* (1919); *The Analysis of Mind* (1921); *The Analysis of Matter* (1927); *An Outline of Philosophy* (1927); *Why I Am Not a Christian* (1927); *The Conquest of Happiness* (1930); *An Inquiry into Meaning and Truth* (1940); *History of Western Philosophy* (1945); *Human Knowledge, Its Scope and Limits* (1948); *My Philosophical Development* (1959); *Has Man a Future?* (1961).

SOCIAL AND POLITICAL SUBJECTS: *German Social Democracy* (1896); *Principles of Social Reconstruction* (1916); *Roads to Freedom* (1918); *The Practice and Theory of Bolshevism* (1920); *On Education* (1926); *Marriage and Morals* (1929); *Education and the Social Order* (1932); *Freedom and Organization, 1814–1914* (1934); *Power: A New Social Analysis* (1938); *Authority and the Individual* (1949); *New Hopes for a Changing World* (1951); *Human Society in Ethics and Politics* (1954); *Common Sense and Nuclear Warfare* (1959); *Political Ideals* (1963).

SCIENCE: *The ABC of Atoms* (1923); *The ABC of Relativity* (1925); *The Scientific Outlook* (1931).

OTHER WORKS: *In Praise of Idleness, and Other Essays*

(1935); *The Amberley Papers* (1937), an edition of his parents' diaries and letters; *Satan in the Suburbs, and Other Stories* (1953), consisting of five imaginative short stories. The Russell Archives are at McMaster University in Canada.

BIBLIOGRAPHY. ALAN WOOD, *Bertrand Russell: The Passionate Skeptic* (1957), written by a friend and philosophical disciple, with Russell's cooperation; GH HARDY, *Bertrand Russell and Trinity* (1942, reprinted 1970); RUPERT CRAWSHAY-WILLIAMS, *Russell Remembered* (1970), a portrait and memoir of Russell's last 25 years; RALPH SCHOENMAN (ed.), *Bertrand Russell: Philosopher of the Century* (1967), contributions from personal friends and experts; A.J. AYER, *Russell and Moore: The Analytical Heritage* (1971); D.F. PEARS, *Bertrand Russell and the British Tradition in Philosophy* (1967), Russell's philosophy from 1905 to 1919; JOHN WATLING, *Bertrand Russell* (1971), the early philosophy of Russell, with a bibliography of books and articles; HERBERT GOTTSCHALK, *Bertrand Russell* (1962; Eng. trans., 1965), a short biography; JOHN LEWIS, *Bertrand Russell: Philosopher and Humanist* (1968), a Marxist approach; P.A. SCHILPP (ed.), *The Philosophy of Bertrand Russell* (1944).

Russell, Henry Norris

Henry Norris Russell, U.S. astronomer, helped lay the foundations of modern astrophysics (the study of the physics and chemistry of heavenly bodies) and stellar astronomy. In particular, he developed a graphic way of showing a relationship between a star's brightness and its spectrum that led to many ideas about the evolution of stars. Russell also devised a means of computing the distances of binary stars, which are systems of two stars revolving around each other. He exerted considerable influence on the development of 20th-century astronomy, both in the United States and abroad.

Henry Norris Russell.

Early
life
and works

Russell was born on October 25, 1877, in Oyster Bay, New York, the son of a Presbyterian minister. In 1882, at the age of five, Russell was shown a rare phenomenon, the transit of Venus across the Sun's disk, by his parents, and his interest in astronomy began. He was educated at home until the age of 12 and then went to Princeton, first to the preparatory school and later to the university, from which he graduated in 1897 with the highest distinction ever earned to that date by an undergraduate. Russell then entered the university's astronomy department to work under Charles Augustus Young, whom he found to be "a great teacher as well as a great astronomer." He devised a new way of determining the orbits of binary stars around each other and made some planetary studies, obtaining his Ph.D. in 1900.

Russell then left Princeton to work at the university observatories at Cambridge with Arthur Robert Hinks in determining stellar distances by photography, a technique then in its infancy. Maintaining his interest in binary

stars, he published another method of determining orbits, this time for pairs of stars that could not be directly observed as such but that from an analysis of their light by a spectroscope were known to be separate orbiting bodies, now called spectroscopic binaries. In 1905 Russell returned to Princeton as an instructor in astronomy, becoming an assistant professor three years later, when he also married. In 1911 he became professor and director of the university observatory, and from 1921 he held the additional appointment of research associate of the Mount Wilson Observatory. In 1927 his Princeton classmates of 1897 honoured him by endowing the C.A. Young Research Professorship, to which he was appointed.

At Princeton Russell continued his lifelong study of binaries, devising a means of calculating masses from their orbital behaviour and a method of using both orbits and masses for computing distances. He pioneered the study of eclipsing variables—that is, binary stars that appear to move in front of each other as they orbit, thus undergoing periodic eclipses and so displaying characteristic variation in brightness. It is a mark of his lifelong interest that his last scientific paper was on binaries, in this case those in the two small galaxies that are closest to our own and known as the Magellanic Clouds.

In his early works on stellar distances, Russell concluded that there were two main classes of stars, one much brighter than the other. The Danish astronomer Ejnar Hertzsprung, sharing this view, found the two classes to have similar spectra. By plotting luminosity and spectra in a diagram, Russell showed a definite relationship between true brightness and type of spectrum. He announced his results in December 1913, and the important Hertzsprung–Russell diagram was published the next year. This graphical demonstration of relationships stimulated Russell to work out his theory of stellar evolution by emphasizing the changes of spectrum, mass, and luminosity that stars undergo in time. In 1929 he summarized his views in his article "Stellar Evolution" in the 14th edition of the *Encyclopædia Britannica*, suggesting that stars begin as huge cool red bodies and then undergo a continual shrinkage. At first this contraction causes a rise in temperature accompanied by a change in colour from red to yellow, white, and blue; but finally they shrink to become small cool red bodies. The theory was widely accepted, but, in the light of later evidence, it was eventually replaced.

Russell performed extensive research on spectrum analysis, by which he applied laboratory techniques to the study of stellar conditions. This research led him to postulate the composition of stars—the Russell mixture, widely accepted by other astrophysicists—which took account of the great predominance of hydrogen. During World War I, Russell worked on aircraft navigation; but otherwise his professional life was concerned with astronomy, both at Princeton and as consultant to a number of American observatories. His broad interests led him to the wider philosophical problems of cosmic evolution. His *Solar System and Its Origin* (1935) proved to be a pioneering guide for later research. He took seriously the teaching of astronomy. With two colleagues he helped prepare a textbook, volume 2 of *Astronomy* (1927), that, with an extensive coverage of astrophysics and stellar astronomy, changed the whole emphasis of the way the subject was taught. He was also a successful popularizer of science and for over 40 years regularly published articles of high quality on the general progress of astronomy.

Holding to a mechanistic view of nature, Russell did not believe in life after death; but he thought science was really an ally of morals and religion, giving his views in a series of lectures, published as *Fate and Freedom* (1927). His interests ranged from archaeology to botany, from ancient history to boating and travelling. Many honours came to him from universities and academies, both at home and abroad; and he was, as a contemporary said of him, the "Dean of American astronomers." He died in Princeton, New Jersey, on February 18, 1957.

BIBLIOGRAPHY. Most of Russell's work was published in technical periodicals, especially in the *Astronomical Journal* and the *Astrophysical Journal*. The famous and readable

Major
astro-
nomical
work

textbook *Astronomy*, 2 vol., written in conjunction with RAYMOND SMITH DUGAN and JOHN QUINCY STEWART, appeared in 1926–27, with a suppl. to vol. 2 in 1938 and a revision of vol. 1 in 1945. In 1927, his views on science and religion were published as *Fate and Freedom*; and in 1935, his stimulating work, *The Solar System and Its Origin*. Between March 31, 1900, and August 1943, he published monthly articles on astronomy in *Scientific American* and made contributions to *Science*. An almost complete bibliography is given in *Biogr. Mem. Natn. Acad. Sci.*, 32:363–378 (1958), but this should be read in conjunction with that provided in *Biog. Mem. Fellows R. Soc.*, 3:185–191 (1957).

(C.A.R.)

Russell, John Russell, 1st Earl

Twice prime minister of Great Britain (1846–52; 1865–66), Lord John Russell was an aristocratic statesman whose liberalism was ahead of his time. As leader of the Whig Party, he pushed for liberal reforms on a broad front and led the fight for the great Reform Bill of 1832.

The 1st Earl Russell, painting by F. Grant, 1853. In the National Portrait Gallery, London.

Lord John Russell was born in London on August 18, 1792, the third son of John Russell, the 6th duke of Bedford. (As the younger son of a peer, he was known for most of his life as Lord John Russell; he himself was created earl in 1861.) He thus came of a family that had long demonstrated its public spirit. The depth of his liberalism probably owed much to an untypical education. Poor health forbade the rigours of an English public school; and later, his father, who was critical of Oxford and Cambridge, sent him to the University of Edinburgh, where he drank deeply of Scottish philosophy. In 1813 he became a member of Parliament and four years later made his first important speech — characteristically, an attack on the government's suspension of the Habeas Corpus Act. In December 1819 Russell took up the cause of parliamentary reform, making it in the early 1820s not only his own cause but also that of the Whig Party. When the Whigs came to power in 1830, he joined the small ministerial committee that was to draft a reform bill, and on March 31, 1831, he presented it to the House of Commons. Overnight, he had won a national reputation.

In the 1830s and '40s, Russell remained the chief promoter of liberal reform in the Whig Party — although never again, perhaps, was this role so glorious as in the protracted but successful conflict over the passing of the first Reform Bill. As paymaster general under Charles Grey, 2nd Earl Grey, during roughly the first half of the

1830s, Russell championed the cause of religious freedom for both English Dissenters and Irish Catholics. Indeed, he pursued these aims so zealously that in seeking to divert some of the wealth of the established Church of Ireland (which was Protestant) to the Roman Catholics (who formed the bulk of the population) he frightened leading Whigs like Lord Stanley (later earl of Derby) out of the party. In the second half of the 1830s, as home secretary under Lord Melbourne, Russell, among other things, democratized the government of large towns (with the exception of London). He also reduced the number of criminal offenses liable to capital punishment and began the system of state inspection and support of public education.

Even out of office from 1841 to 1846, when he stood in opposition to Sir Robert Peel, Russell left his mark. For in 1845, in advance of his party, he came out in favour of total free trade, a crucial step in forcing Peel to follow him. As a result Peel split his party, the Whigs came to power, and Russell became prime minister.

This administration (1846–52) demonstrated that although Russell's penchant for advanced ideas was as strong as ever, his ability to implement them was now seriously reduced. He was able to establish the ten-hour day in factory labour (1847) and to found a national board of public health (1848). But, largely because of party disunity and weak leadership, he was unable to end the civil disabilities of the Jews, extend the franchise to the workers in the cities, or bring peace to the countryside of Ireland by guaranteeing security of tenure to its farmers.

In the remaining years of his public career, Russell's difficulties increased. Party disunity continued and brought down his second administration (1865–66) when he made his last attempt to extend the franchise. But more significant, in the 1850s the national temper had changed. An age of reform had given way to a mood of self-complacency, even of belligerence. This was already evident in the Ecclesiastical Titles Act of 1851, which Russell's government had passed and which in effect was England's defiance of the papacy. This mood deepened, transformed, on the one hand, into an appetite for foreign war and, on the other, into boredom with social and political reform. In such an atmosphere Russell was inevitably overshadowed by the forceful and popular Lord Palmerston, who seized the forefront of the national stage in the Crimean War (1854–56). Indeed, for four years, from 1855 to 1859, Russell retired from public life and devoted more and more of his time to literature. Private life had always beckoned to him, as had the life of a *littérateur*. Among the English prime ministers, few wrote so copiously — biography, history, poetry — as Russell. He accepted an earldom in 1861, and he died at Pembroke Lodge, Richmond Park, May 28, 1878.

The underlying theme of Russell's career — his long tenure of liberal opinion — is frequently ignored or minimized. But his failings were less evident in the realm of ideas than in the realm of personality. He was neither a gifted administrator nor an efficient and commanding prime minister. More important, he combined in his personality elements of both rashness and timidity. Although he came to liberal ideas sooner and held them longer than did William Ewart Gladstone, he failed where Gladstone succeeded: in building up a Liberal Party firmly based on popular support. His rashness often alienated his followers, and his timidity prevented him from seeking out a massive popularity in the country at large in order to drive home his ideas. In a sense a rebel against aristocracy, he found himself constantly frustrated by the great aristocratic Whigs — remaining in the last analysis, as one historian has said, their prisoner.

Russia and the Soviet Union, History of

The term Russia properly refers only to the empire that occupied approximately the present area of the Soviet Union in the 18th, 19th, and early 20th centuries. In the title of this article, however, it is used very loosely to describe the European part of the Soviet Union from ancient times as well.

The main divisions of the article are as follows:

- I. From the beginnings to c. 1700
 - Prehistory
 - Exploration and the rise of the Rus
 - The Khazars
 - Kiev
 - Rise of Kiev
 - Decline of Kiev
 - Social and political institutions
 - The lands of Rus
 - Novgorod
 - The northwest
 - The northeast
 - The southwest
 - The Mongol period
 - The Mongol invasion
 - Tatar rule
 - The rise of Muscovy
 - Cultural life and the "Tatar influence"
 - The post-Sarai period
 - Rurikid Muscovy
 - Ivan III
 - Vasily III
 - Ivan IV the Terrible
 - Boris Godunov
 - The Time of Troubles
 - Social and economic conditions
 - Cultural trends
 - Romanov Muscovy
 - Michael Fyodorovich
 - Aleksey Mikhaylovich
 - Trends in the 17th century
- II. The 18th century
 - The reign of Peter I (1689–1725)
 - Peter's youth and early reign
 - The Petrine state
 - Assessment of Peter's reign
 - Peter I's successors (1725–62)
 - Anna (1730–40)
 - Elizabeth (1741–62)
 - The reign of Catherine II the Great (1762–96)
 - Expansion of the empire
 - Government administration under Catherine
 - Education and social change in the 18th century
 - The reign of Paul I (1796–1801)
- III. Russia from 1801 to 1917
 - The reigns of Alexander I and Nicholas I
 - General survey
 - Government
 - Social classes
 - Education and intellectual life
 - The Russian Empire
 - Foreign policy
 - From Alexander II to Nicholas II
 - Emancipation and reform
 - Revolutionary activities
 - Economic and social development
 - Education and ideas
 - Russification policies
 - Foreign policy
 - The last years of Tsardom

 - Unbinding the economy
 - Cultural controls
 - Foreign policy
 - Brezhnev's primacy

I. From the beginnings to c. 1700

PREHISTORY

Indo-European and Ural-Altaic peoples have occupied what is now the European territory of the Union of Soviet Socialist Republics (U.S.S.R.) since the second millennium before Christ, but little is known about their ethnic identity, institutions, and activities. In ancient times, Greek and Iranian settlements appeared in the southernmost portions of what is now the Ukrainian S.S.R. Trading empires of that era seem to have known and exploited the northern forests, particularly the Permian triangle formed by the Kama and Volga rivers, but these contacts seem to have had little lasting impact. (See SARMATIANS; SCYTHIANS.) Between the 4th and 9th centuries, the Huns, Avars, Goths, and Magyars passed briefly over the same terrain, but these transitory occupations also had little influence upon the East Slavs, who during this time were spreading south and east from an area between the Elbe River and the Pripyet Marshes. In the 9th century, as a result of penetration into the area from north and south by north European and Middle Eastern merchant adventurers, their society was exposed to new economic, cultural, and political forces.

Exploration and the rise of the Rus. The scanty written records tell little of the processes that ensued, but archaeological evidence—notably, the Oriental coins found in eastern Europe—indicates that the development of the East Slavs passed through several stages.

From about 770 to about 830, commercial explorers began an intensive penetration of the Volga region. From early bases in the estuaries of the rivers of the eastern Baltic region, Germanic commercial-military bands, probably in search of new routes to the East, began to penetrate territory populated by Finnic and Slavic tribes, where they found amber, furs, honey, wax, and timber products, all of which provided generous rewards for the hardy and fortunate. The indigenous population, unlike that of western areas where the Vikings were becoming active, offered little resistance to their incursions, and there was no significant local authority to negotiate the balance among trade, tribute, and plunder. From the south, trading organizations based in northern Iran and North Africa, seeking the same products, particularly slaves, became active in the Lower Volga, the Don, and, to a lesser extent, in the Dnieper region. The history of the Khazar state (see below The Khazars) is intimately connected with these activities.

Around 830 commerce appears to have declined in the Don and Dnieper regions. There was increased activity in the north Volga, where Scandinavian traders who had previously operated from bases on Lakes Ladoga and Onega established a new centre, near Ryazan. Here, in this period, the first nominal ruler of Rus (called, like the Khazar emperor, *khaqan* or kagan) is mentioned by Islamic and Western sources. This Volga Rus kaganate may be considered the first direct political antecedent of the Kievan state.

Within a few decades, these Rus, together with other Scandinavian groups operating farther west, extended their raiding activities down the main river routes toward Baghdad and Constantinople, reaching the latter in 860. The Scandinavians involved in these exploits are known as Varangians; they were adventurers of diverse origins, often led by princes of warring dynastic clans. One of these princes, Rurik of Jutland, is considered the progenitor of the dynasty that ruled in various portions of East Slavic territory until 1598. Evidences of the Varangian expansion are particularly clear in the coin hoards of 900–930. The number of Oriental coins reaching northern regions, especially Scandinavia, indicates a flourishing trade. Written records tell of Rus raids upon Constantinople and the northern Caucasus in the early 10th century.

In the period from about 930 to 1000, the region came under complete control by Varangians from Novgorod. This period saw the development of the trade route from the Baltic to the Black Sea, which established the basis of the economic life of the Kievan principality and determined its political and cultural development.

The degree to which the Varangians may be considered the founders of the Kievan state has been hotly debated since the 18th century. The debate has from the beginning borne nationalistic overtones. Recent works by Russians have generally minimized or ignored the role of the Varangians, while non-Russians have occasionally exaggerated it. Whatever the case, the lifeblood of the sprawling Kievan organism was the commerce organized by the princes. To be sure, these early princes were not "Swedes" or "Norwegians" or "Danes"; they thought in categories not of nation but of clan. But they certainly were not East Slavs. There is little reason to doubt the predominant role of the Varangian Rus in the creation of the state to which they gave their name.

The Khazars. In the mid-7th century, the Khazars, a nomadic confederation of Turkic and Iranian tribes in the North Caucasus, rapidly expanded their power, pressing the Hunnic Bulgars northward and westward and confronting Byzantine and Arab power to the south. Khazar relations with Constantinople became very close (a son of Empel-or Leo III was married to a daughter of the Khazar Kagan in 731) but could not forestall a terrible defeat by the Arabs in the Caucasus in 737, at which time the Khazar capital was destroyed. The centre of Khazar activities shifted north to a new capital at Itil on the Lower Volga, and by the end of the century the Khazars had recovered and surpassed their previous power. The Khazar state was multinational, based upon the military might of Turkic and Iranian nomadic horsemen and the skills of Iranian and Jewish traders. The Khazars seem to have retained their importance through the 9th century, in spite of competition from the Rus and the Hungarians, but were eclipsed in the 10th century.

KIEV

Rise of Kiev. The consecutive history of the first East Slavic state begins with Prince Svyatoslav (died 972), the greatest of the Varangian princes. His victorious campaigns against other Varangian centres, the Khazars, and the Volga Bulgars and his intervention in the Byzantine–Danube Bulgar conflicts of 968–971 mark the full hegemony of his clan in Rus and the emergence of a new political force in eastern Europe, similar in some ways to the princely dynasties of the Piasts in Poland and the Árpáds in Hungary. But Svyatoslav was neither a lawgiver nor an organizer; and on his death he left, in true Varangian style, only his sword and that which had been

gained by it. The role of architect of the Kievan state fell to his son Vladimir (c. 980–1015), who established the dynastic seniority system of his clan as the political structure by which the scattered territories of Rus were to be ruled. He also promulgated the first code of law and invited or permitted the patriarch of Constantinople to establish an episcopal see in Rus in 988. Vladimir's reign inaugurated the golden century of Kievan life, and he has remained in later tradition a figure of heroic stature.

Vladimir extended the realm to its natural limits (the watersheds of the Don, Dnieper, Dniester, Neman, Western Dvina, and Upper Volga), destroyed or incorporated the remnants of competing Varangian organizations, and established regular relations with neighbouring dynasties. The successes of his long reign made it possible for the reign of his son Yaroslav (ruled 1019–54) to produce a flowering of cultural life. But neither Yaroslav, who gained control of Kiev only after a bitter struggle against his brother Svyatopolk (1015–19), nor his successors in Kiev, however, were able to provide lasting political stability within the enormous realm. The political history of Rus is one of clashing separatist and centralizing trends inherent in the contradiction between local settlement and colonization, on the one hand, and the hegemony of the clan elder, ruling from Kiev, on the other. As Vladimir's 12 sons and innumerable grandsons prospered in the rapidly developing territories they inherited, they and their retainers acquired settled interests that conflicted both with one another and with the interests of unity.

Georg Westermann Verlag, Braunschweig

The Kievan Rus in the 10th and 11th centuries

The conflicts were not confined to Slavic lands: the Turkic nomads who moved into the southern steppe in the 11th century (first the Torks, later the Kipchaks—also known as the Polovtsy or Kumans) became involved in the constant internecine rivalries, and Rurikid and Turkic princes often fought on both sides. In 1097 representatives of the leading branches of the dynasty, together with their Turkic allies, met at Liubech, north of Kiev,

and agreed to divide the Kievan territory among themselves and their descendants, although, later, Vladimir Monomakh made a briefly successful attempt (1113–25) to reunite the land of Rus.

Decline of Kiev. The hegemony of the prince of Kiev depended upon the cohesion of the clan of Rurik and the relative importance of the southern trade, both of which began to decline in the late 11th century. The primary reason for this decline was a major shift of trade routes in the eastern Mediterranean, which can conveniently be associated with the First Crusade (1096–99). The re-establishment of the traditional east–west routes, together with other factors, made the route from the Baltic to the Black Sea superfluous and less profitable. Moreover, much of the trade that had followed that route now began moving over land routes through central Europe. At the same time, conflicts among the Rurikid princes acquired a more pronounced regional and separatist nature, reflecting new patterns in export trade along the northern and western periphery. Novgorod, in particular, began to gravitate toward closer relations both with the cities of the Hanseatic League, which controlled the Baltic trade, and with the rapidly developing hinterland in Suzdalia, between the Oka River and the Upper Volga. Smolensk, Polotsk, and Pskov became increasingly involved in trade along western land routes, while Galicia and Volhynia established closer links with Poland and Hungary. The princes of these areas still contested the crown of the "Grand Prince of Kiev and All of Rus," but the title became an empty one; when Andrew Bogolyubsky of Suzdal won Kiev and the title in 1169, he sacked the city and returned to the Upper Volga, apparently seeing no advantage in establishing himself in the erstwhile capital. (Roman Mstislavich of Galicia and Volhynia repeated these actions in 1203.) By the middle of the 12th century, the major principalities, thanks to the prosperity and colonization of the Kievan period, had developed into independent political and economic units, some as large as modern European nation-states.

Social and political institutions. The paucity of evidence about social and political institutions in Kievan Rus suggests that they were rudimentary. The East Slavs had no significant tradition of supratribal political organization before the coming of the Varangians, who themselves, until well into the 10th century, had little interest in institutions more elaborate than those necessary for the exploitation of their rich, new territory. Nor did the Varangians soon acquire any attachment to Rus as a second homeland: archaeology and the sagas agree in portraying the "East" as a theatre of heroic adventure and freebootery, not of colonization. The territory of Rus, moreover, was immense and sparsely settled. The scattered towns, some probably little more than trading posts, were separated by large primeval forests and swamps.

Thus, although the campaigns of Svyatoslav indicate the extent of the political vacuum that his clan filled, he construed his domains as a clan possession rather than as a territorial or national state. His successor Vladimir, however, seems to have been conscious of one political element—organized religion—that distinguished both the contemporary empires and the newly established principalities in Poland and Hungary from his own. The church provided the concepts of territorial and hierarchical organization that made states out of tribal territories; its teachings transformed a charismatic prince into a king possessing the attributes and responsibilities of a national leader, judge, and first Christian of the realm.

Once Vladimir had adopted Christianity in 988, his rule was supported by the propagation of Byzantine notions of imperial authority, and there is ample evidence that Kievan princes after him styled themselves as autocrats in the Byzantine tradition. The political traditions and conditions of Rus, however, required that the actual workings of the political system and some of its style be derived from other sources. The succession system, probably a vestige of the experience of the Rus kaganate in the Upper Volga, was based upon two principles: the indivisibility of the basic territory of Rus (the principalities of

Kiev, Chernigov, and Pereyaslavl) and the sovereignty of a whole generation. Seniority passed through an ascension by stages from elder brother to younger and from the youngest eligible uncle to the eldest eligible nephew. Such a system was admirably suited to the needs of the dynasty, because, by providing a rotating advancement of members of the clan through apprenticeships in the various territories of the realm, it assured control of the key points of the far-flung trading network by princes who were subject to traditional sanctions, and it gave them experience in lands over which they could someday expect to rule from Kiev. This system served well for a century after it was given final form by Vladimir and was revived by Monomakh (Vladimir II, ruled 1113–25), but it could not survive the decline of Kiev's importance.

Each of the princes had a retinue composed of boyars (upper nobility), who gave personal allegiance and military service to the prince in return for grants of income from specified territories. Some of these boyars were originally Scandinavians—perhaps members of dynasties defeated by the Rurikids. Others may have been leading members of local tribal units. The princes and their retinues drew their most significant revenues from the tribute or taxes collected annually in kind from the various territories and disposed of in the export trade.

Some slaves were apparently employed in princely and boyar households, but their number was not large. The main group of dependent peasants consisted of indentured freemen, while most people were apparently free peasants organized in communes, who paid tribute to the prince but not to a landlord.

Very little is known of law in this period; it may be assumed that juridical institutions had not developed on a broad scale. The earliest law code (1016), called the "Russian Law," was one of the "Barbarian" law codes common throughout Germanic Europe. It dealt primarily with princely law—that is, with the fines to be imposed by the prince or his representative in the case of specified offenses; it was later modified by the inclusion of ecclesiastical and moral law from Byzantine and Slavic sources.

Soviet scholars have adhered to a rather literal Marxist view of the nature of the Kievan state, holding that, since law was in the hands of the boyar class, who exploited the labour of slaves and peasants, Kievan society should be termed feudal. The meagre sources indicate, however, that Kiev experienced nothing like the complex and highly regulated legal and economic relationships associated with feudalism in western Europe. Kiev's political system existed primarily for and by international trade in forest products and depended upon a money economy in which the bulk of the population scarcely participated. The rich and powerful doubtless exploited the tillers of the soil. The subsistence agriculture of the forest regions, however, was not the source of Kiev's wealth, nor was it the matrix within which law and politics and history were made.

Formal culture came to Rus, along with Christianity, from the multinational Byzantine synthesis, primarily through South Slavic intermediaries. A native culture, expressed in a now lost pagan ritual folklore and traditions in the arts and crafts, existed before the Kievan period, and then persisted alongside the formal culture, but its influence on the latter is conjectural. Authorities often speak of the imitative nature of Kievan culture, especially of its literature, and of Kiev's "silence." There were no heresies or great disputes in the Kievan church; Christianity came to virgin territory, where there were no native religious or philosophical traditions vital enough to force a confrontation or synthesis such as occurred elsewhere. The Kievan achievement, however, was none the less remarkable: within a few generations, an enormous population was brought within the embrace of Western culture and introduced to the artistic, philosophical, and literary treasures of the contemporary Christian world.

No single one of the regional (or, later, national) cultures, perhaps least of all that of Muscovy, can be called the heir of Kiev, although all shared the inheritance. The strands of continuity were everywhere strained, if not

The boyars

The adoption of Christianity

broken, in the period after Kiev's decline. But "Golden Kiev" was always present, in lore and bookish tradition, as a source of emulation and renaissance.

THE LANDS OF RUS

The decline of Kiev led to the disintegration of Rus into its component principalities. Regional developments are so striking in the subsequent period that it has often been called the Period of Feudal Partition. This is misleading: "feudal" is hardly more applicable to the widely varying institutions of this time than to those of the Kievan period. "Partition" implies a former unity for which there is no historical evidence. The distinct character and historical fortunes of each of the major East Slavic regions is clear even in the Kievan period and has persisted into the 20th century. The following is a brief coverage of the most important states.

Novgorod. The town of Novgorod arose in the 9th century as one of the earliest centres of the exploitation of the forest hinterland and remained the most important commercial centre of the Kievan period. The changes of the latter Kievan period did not diminish Novgorod's importance, for it benefitted both from the increased activity of the Hanseatic League and from the development of the Upper Volga region, for which it was a major trade outlet. Although Novgorod was the first base of the Rurikids, from which Kiev was repeatedly captured and to which Kievan princes often returned to recruit Varangian retinues during their struggles for the Kievan throne, the princely traditions characteristic of Kiev and other post-Kievan centres never developed in Novgorod. During the height of Kiev's power, Novgorod was usually ruled by a son of the grand prince rather than by a member of the "generation of brothers," who held decidedly less important towns. When Kiev declined, Novgorod soon (1136) declared its independence from princely power, and, although it accepted princely protectors from various neighbouring dynasties, it remained, until conquered by Muscovy (Moscow), a sovereign city.

During the 13th century, Novgorod's burghers easily found an accommodation with the invading Mongols. In the Mongol period, its energetic river pirates pushed farther north and east toward the Urals and even down the Volga, and Novgorod's prosperity was generally unbroken until the commercial revolution of the 16th century. Its absorption by the growing principality of Muscovy in 1478 ended its political independence and changed its social structure, but Novgorod's characteristic economic and cultural life did not end with that catastrophe.

Novgorod is notable for its sociopolitical institutions, similar in some ways to those of north European towns but almost unique in East Slavic territory. Novgorod was governed by an oligarchy of great trading boyar families who controlled the exploitation of the hinterland. They chose (from among themselves) a mayor, a military commander, and a council of aldermen, who controlled the affairs of the city and its territories. The town itself was divided into five "ends," which seem to have corresponded to the "fifths" into which the hinterland was divided. There was, in addition, a *veche* ("council"), apparently a kind of town meeting of broad but indeterminate composition, whose decisions, it would appear, were most often controlled by the oligarchy. A major role in politics was played by the archbishop, who after 1156 controlled the lands and incomes previously owned by the Kievan princes and who appears throughout Novgorod's history as a powerful, often independent figure.

The northwest. During this period, much of the territory of the principalities of Smolensk, Polotsk, Turov, and Pinsk was controlled by the grand principality of Lithuania, which was essentially an international or non-national formation, led by a foreign dynasty (of east Lithuanian pagan origins) ruling over predominantly Belorussian and Ukrainian populations. By the 15th century, the dynasty had become Slavic in culture (a version of Belorussian was the official language of the realm), and at its height under Vytautas (1392–1430) it controlled all of the old Kievan territory outside of Great Russia proper—that is, most of the present-day Lithuanian, Belorus-

sian, Moldavian, and Ukrainian Soviet Socialist Republics. In 1385 the grand principality joined the Kingdom of Poland, and the union was sealed shortly thereafter by the marriage of Grand Prince Jogaila (Jagiello) to Jadwiga, the Polish queen.

The northeast. The region bounded by the Oka and Volga rivers, later to be the heartland of the grand principality of Moscow, was settled before the arrival of Slavs from Novgorod and the Baltic area by a Finnic tribe with whom the Slavic newcomers intermingled. Rostov, the earliest princely centre, was from Vladimir's time included in the princely rotation system. In the 12th century, it became the patrimony of the younger branch of Vladimir Monomakh's family (who founded the new princely centre Vladimir in 1108). Under his son Yury Dolgoruky (1125–57) and grandson Andrew Bogolyubsky (1157–74), the principality reached a high political and cultural development, which it retained through much of the succeeding century. Early in the 13th century, the principality of Moscow was created as an appanage (royal grant) within the grand principality of Vladimir, and this new seat grew in importance when Michael Khorobrit, brother of Alexander Nevsky, conquered Vladimir (1248) and made himself prince of both centres. Daniel, Nevsky's son and the progenitor of all the later Rurikid princes of Moscow, had a long and successful reign (1276–1303), but at his death the principality still embraced little more than the territory of the present Moscow *oblast* (an area of 140 miles [225 kilometres] in length and width). The beginning of Moscow's rise to its later pre-eminence came in the reign of Daniel's son Ivan (1328–41), who, by cooperating with Öz Beg, khan of the Golden Horde, and also by his shrewd purchases (probably of tax-farming rights), greatly expanded the influence of his principality.

The southwest. The lands of Galicia and Volhynia were always ethnically and economically distinct from the Kievan region proper, as well as from more distant regions. Agriculture was highly developed, and trade, particularly in the valuable local salt, tended to take westward and overland routes. Galicia, already a separate principality by 1100, grew as Kiev declined. Later, Roman Mstislavich of Volhynia (ruled 1199–1205) conquered Galicia and united the two principalities. Under his son Daniel (1202–64), difficulties with the Galician landed magnates and the interference of the Hungarians weakened the principality, and it was subjugated in 1240 by the Mongol invasion. Eventually, this region came under the domination of Lithuania (Volhynia) and Poland (Galicia).

THE MONGOL PERIOD

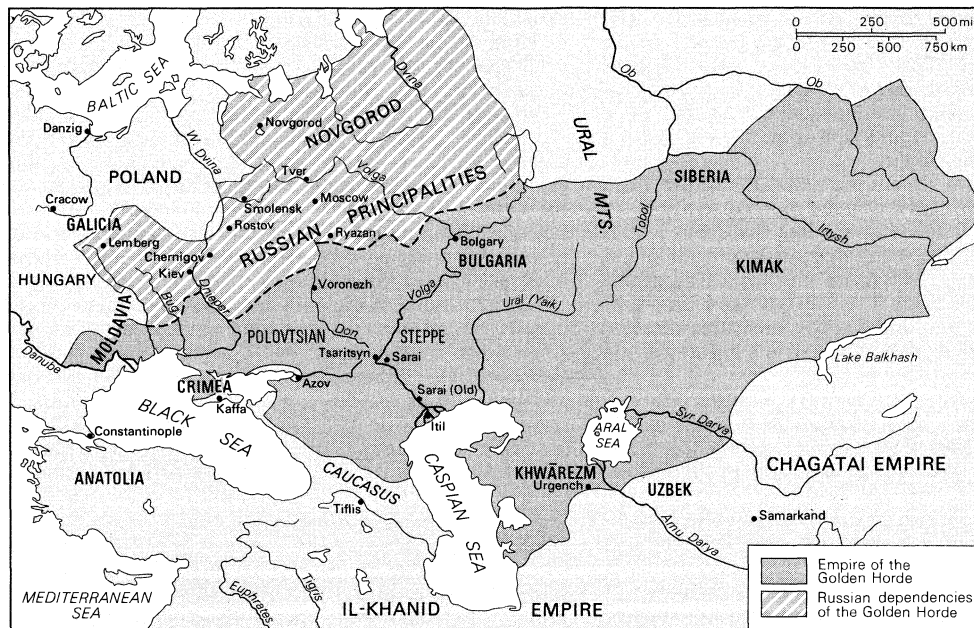

The Mongol invasion. In 1223, when the first Mongol reconnaissance into former Kievan territory led to the disastrous defeat of a Volhynian–Galician–Polovtsian army on the Kalka River, the various Rurikid principalities had for generations been intermittently at war, usually in complex alliances with equally disunited groups of Polovtsian clans. Kiev was in ruins, Novgorod was preoccupied with commerce and with its northern neighbours, Galicia was being torn internally and drawn increasingly into Polish and Hungarian dynastic affairs, and Vladimir-Suzdal, apparently the leading principality, was unable to resist the finely organized and skillful mounted bowmen of the steppe, the greatest military force of the age.

Pious tradition, born of the works of monkish annalists and court panegyrists, has exaggerated both the destructiveness of the first Mongol conquests and the strength of the resistance. The Mongols aimed to revive, under a unified political system, the trade that had traditionally crossed the central Asian steppe and vitalized the economy of the pastoral nomads. As they moved westward, they easily gained the collaboration of groups of Turkic nomads and the predominantly Iranian and Muslim traders in the towns of the old silk route; they encountered the greatest resistance in sedentary political centres and among land-owning elites. The lands of the Rus presented numerous similarities with the central Asian areas the

The empire of the Golden Horde at its greatest extent.
From A. Herrmann, *An Historical Atlas of China*

Mongols had already conquered. Here, too, a former commercial empire had fallen apart into an aggregation of warring principalities. Here, too, ready recruits were to be found in the Polovtsians, who controlled the lower Dnieper and Volga and Don, and in the Muslim merchants, who dealt in the towns of the Crimea and the Upper Volga. These merchants showed the way, first (1223) to the Crimea and up the Volga to the old centre of Bolgary, later (1236) to Bolgary a second time, then to Ryazan, Rostov, and the Suzdalian towns, and still later (1240) to Kiev and Galicia.

Many of the conquered cities made a striking recovery and adjustment to the new relationships. Some towns, such as Kiev, never fully recovered in Mongol times, but the cities of the Vladimir-Suzdal region clearly prospered. New centres, such as Moscow and Tver, hardly mentioned in any source before the Mongol period, arose and flourished in Mongol times.

Thus, the Mongol invasion was not everywhere a catastrophe. The local princely dynasties continued unchanged in their traditional seats; some princes resisted the new authority and were killed in battle, but no alien princes ever became established in Slavic territory. Few Mongols remained west of the Urals after the conquest; political and fiscal administration was entrusted to the same Turkic clan leaders and Islāmic merchants who had for generations operated in the area. The whole of the Novgorodian north remained outside the sphere of direct Tatar control, although the perspicacious burghers maintained correct relations with the khans.

Tatar rule. After a brief attempt to revive the ancient centres of Bolgary and the Crimea, the Jucids (the family of Jochi, son of Genghis Khan, who inherited the western portion of his empire) established a new capital, Itil. (It was moved to "New Sarai," near present Volgograd c. 1260.) These towns became the commercial and administrative centres of what was later to be called the "Golden Horde" (the term is probably a Western invention). Its East Slavic territories were tributaries of an extensive empire, including, at its height, the Crimea, the Polovtsian steppe from the Danube to the Ural River, the former territories of the Bulgar empire (including the fur-rich Moldavian forests and parts of western Siberia), and in Asia the former kingdom of Khwārezm, including Urgench, the cultural capital of the Jucids. Control of the Slavic lands was exercised through the native princes, some of whom spent much of their time at the Mongol capital, and through agents charged with overseeing the activities of the princes and particularly the fiscal levies. The meagre evidence indicates that the Tatar rulers were,

for the first century at least, more interested in developing commerce than in despoiling their subjects.

This multinational commercial empire was unstable. Early in the history of the Horde, the khans of Sarai, who tended to reflect the interests of the Volga tribes, were challenged by the tribal princes of the west, whose control of the Danube, Bug, and Dnieper routes and of the access to the Crimea gave them considerable political and economic power. As early as 1260, Nokhai, one of these western chieftains, showed his independence of Sarai by establishing his own foreign policy, and toward the end of the 13th century he seized control of Sarai itself. At his death, the eastern tribes re-established their control in Sarai, but in the reign of the great Öz Beg (1314–41), the high point of Horde power, the west was again ascendant. Öz Beg based his power upon firm control of the Crimea and had extensive relations with the Genoese and Venetians, who controlled the main ports there. After the death of Öz Beg's son Jani Beg (died 1357), however, the empire began to reveal serious internal strains. The tribes of the west paid little heed to the khans who appeared in dizzying succession in Sarai; the north Russian princes fell to quarrelling and to manoeuvring for their own advantage in the internecine politics of the Horde; the Volga Bulgar region was detached by a dissident Tatar prince; and the lands of the east were drawn into the orbit of the Turkic conqueror Timur (Tamerlane).

The Horde's last cycle of integration and dismemberment was closely linked with events in Timur's domains. Tokhtamysh, son of a minor Tatar prince, had been unsuccessfully involved in the skirmishes around the throne of Sarai in the 1370s and had fled to the court of Timur, with whose aid he returned to Sarai and vanquished the tribal leaders who had opposed him. Having defeated and made peace with them, he now turned to defeat Mamai (1381), who had the previous year been defeated by Prince Dmitry Donskoy ("of the Don"; grand prince of Moscow, 1359–89). Mamai's western tribal allies went over to Tokhtamysh, and, for a brief time, the major components of the tribal structure of the Horde were reunited. Tokhtamysh successfully attacked Moscow (just as Mamai had hoped to do) and set about consolidating his gains. As his power grew, however, Tokhtamysh was drawn into a struggle with Timur, who had conquered much of Iran, the south Caucasus, and eastern Anatolia. After a number of encounters in the northern Caucasus, Timur, who apparently was intent upon diversion of east–west trade through his own Transoxanian and North Iranian territories, set out to destroy Tokhtamysh and the latter's commercial centres. In 1395 and 1396, Timur's armies sys-

tematically annihilated Sarai, Azov, and Kaffa and marched through the Lower Volga to the borders of the Russian principalities. The Horde never recovered; its subsequent history is a record of struggles among its erstwhile subjects for supremacy and attempts to find some new *modus vivendi* that would restore political and commercial stability to the steppe.

The rise of Muscovy. From the beginning of the Tatar period, the Rurikid princes displayed much disunity. During the reign of the Tatar khan Öz Beg there was a shift of alignments. The princes of Moscow and their allies, together with Öz Beg and his Crimean supporters, generally opposed the princes of Tver, Pskov, and, intermittently, Novgorod. The major punitive measures directed by Öz Beg against Tver with Muscovite support were a part of this pattern.

The links forged in the 14th century between Moscow and the Crimea (and Sarai, while Öz Beg controlled it) were crucial to Moscow's later pre-eminence. They not only afforded Moscow a steady and profitable export trade for its furs but (because of contacts between Crimean merchants and Byzantium) also led quite naturally to close relations between the Muscovite hierarchy and the patriarchate of Constantinople. This special relationship was but one of the reasons for the eventual rise of Moscow as leader of the Russian lands. Admirably situated in the northeast, linked with all of the major navigable river systems and with the steppe, close to the major fur-producing regions and to the most intensely settled agricultural lands, served by a succession of shrewd and long-lived princes, Moscow came naturally to a position of pre-eminence during the 14th century and was best equipped to enter the struggle for the political inheritance of the Horde that followed the destruction of its capitals by Timur.

Cultural life and the "Tatar influence." Most traditional scholarship has accepted the notions that (1) the Mongol invasion "destroyed" Kievan culture; (2) the Tatar period was one of "stultification" and "isolation from the West"; (3) "Russian" culture was deeply influenced by Golden Horde culture, in particular by "Oriental" conceptions of despotism. These views do not accord with the evidence and should probably be discarded.

In the first place, it seems incorrect to say that Kievan culture was destroyed. In the shift of the cultural centre of gravity to the numerous regional centres, Kievan traditions were in the main continued and in some cases (*i.e.*, Galician literature, Novgorodian icon painting, Suzdalian architecture) enjoyed remarkable development.

Similarly, the notions of stultification and isolation from the West cannot be supported. The enormous Novgorodian culture sphere, the Upper Dnieper territories that eventually came under Lithuanian control, and the principalities of Volhynia and Galicia all had, if anything, closer contacts with western and central Europe than in the previous period. Each of these areas, in its own way, acted as a repository of the Kievan traditions and produced some features that later were to be incorporated into the new Muscovite culture.

As to "Tatar influence," in the areas of religion and intellectual life, it was practically nonexistent. Control of formal culture by the Orthodox clergy and Muslim divines and limited contact between the Slavic and Turkic populations prevented it. There is no evidence that any single Turkic or Islāmic text of religious, philosophical, literary or scholarly content was translated directly into Slavonic or any East Slavic vernacular during the period.

Concerning the secular culture of the court and counting house, the situation was radically different. These spheres were controlled by very pragmatic princes, merchants, and diplomats. Here, Slavs and Tatars elaborated together an international subculture whose language was Turkic and whose administrative techniques and chancellery culture were essentially those of the Golden Horde. Slavic merchants took full part in this culture, and the princes of Muscovy, in particular, developed their original court culture and chancellery practices within its context. These borrowings, however, were not of a theoretical or ideological nature, and to ascribe later despo-

tism—and its theoretical basis—to "Oriental" influence is to misunderstand the development of Muscovite absolutism. The phenomenon and its justification spring from other sources (see below).

The post-Sarai period. The collapse of the Golden Horde saw a growth in the political power of the old sedentary centres—Muscovy, Lithuania, the Volga Bulgar region (which became the khanate of Kazan), and the Crimea. This growth was accompanied by dynastic struggles. This period of recovery also saw cooperation among the emerging dynasties against their internal enemies and toward the stabilization of the steppe.

Even by the end of the 14th century, Moscow's position was by no means as dominating as the cartographers' conventions or the historians' hindsight make it seem. Other centres—Lithuania, Tver, Novgorod—were as rich and powerful as Moscow; many of the areas nominally subject to the Muscovite princes retained their own dynasties, whose members often broke away and sided with one of Moscow's rivals. Only after a series of dynastic conflicts in the early 15th century did Moscow emerge as the leader of the Great Russian territory.

The struggle began at the death of Vasily I, a son of Dmitry Donskoy, in 1425. The succession of his ten-year-old son Vasily II was challenged by his uncle Yuri, prince of the important Upper Volga commercial town of Galich. Although the ensuing conflict was conducted in the name of the right succession to the grand princely throne, the underlying issues were regional and economic. After many turns of fortune, Vasily II succeeded, with the help of Lithuanian and Tatar allies, in establishing his house permanently as the rulers of Muscovy.

RURIKID MUSCOVY

Ivan III. Ivan III (ruled 1462–1505), known to history as the Great, consolidated from a secure throne the gains his father, Vasily II, had won in the saddle. Although little is known of Ivan, an exceptional intelligence is apparent behind the consistent and brilliantly effective military and diplomatic campaigns of his time.

The "gathering of the Russian lands," as it has traditionally been known, became under Ivan a conscious and irresistible drive by Moscow to annex all East Slavic lands, both the Great Russian territories, which had traditionally had close links with Moscow, and the Belorussian and Ukrainian regions, which had developed under distinctly different historical and cultural circumstances. In 1471 Ivan mounted a simultaneous attack upon Novgorod and its Upper Volga colonies, which capitulated and accepted Moscow's commercial and political demands. The trading republic, however, retained considerable *de facto* independence and became involved with the Lithuanian princes in an attempt to resist Moscow. Ivan, using these dealings as a pretext, attacked again, and in 1478 Novgorod was absorbed by Moscow. A Muscovite governor was installed, and 70 Novgorodian boyar families were deported and assigned estates elsewhere to hold in service tenure, being replaced by members of the Moscow military-service class.

Tver suffered a similar fate. Ivan had agreed with Prince Michael Borisovich of Tver to conduct foreign relations in concert and by consultation, but, when the Tverite complained that Ivan was not consulting him on important matters, Ivan attacked him and annexed his lands (1485). By the end of Ivan's reign, there were no Great Russian princes who dared conduct policies unacceptable to Moscow.

The success of Ivan's expansion was determined by his skillful dealings with the Polish-Lithuanian state, which had expanded down the Dnieper Basin and into Slavic territories on the south flank of Moscow. After 1450 a competition developed for control of the numerous semi-independent principalities of the Dnieper and Upper Donets regions. In the early 1490s, some minor East Slavic princes defected from Lithuania to Moscow. The first phase of the conflict, confined to border skirmishes, ended in 1494 with a treaty ceding Vyazma to Moscow and with the marriage of Ivan's daughter Yelena to Alexander, grand duke of Lithuania. In 1500, on the initiative

The
gathering
of the
Russian
lands

of Lithuanian defectors, Ivan's armies seized a number of important border towns; this began a war that ended somewhat inconclusively in 1503 with a truce that extended Ivan's border considerably to the west.

The third major element of Ivan's foreign policy comprised his relations with the various Tatar confederations. In the 1470s, the Crimean khan Mengli Giray came into increasing conflict with Khan Ahmed of the Horde and became interested in an alliance with Moscow against Ahmed and Lithuania. Ivan, eager to dissolve the connection between Lithuania and the Crimea, but not wanting to alienate Ahmed, stalled for time. In 1481, when Ahmed died, Ivan was able to forge an alliance with the Nogais, Mengli Giray, and Kazan. The security provided by this system became the cornerstone of his later policies. Ivan was the first Muscovite prince to have an integrated foreign policy, but he did not "cast off the Tatar yoke" as he is traditionally supposed to have done. The yoke—if such it was—had long since fallen of itself.

In addition to problems of war and diplomacy, Ivan was faced with a number of challenges from within his own family and court. In 1472 his eldest brother, Yuri, died childless, and Ivan appropriated his entire estate. This action antagonized the two eldest surviving brothers, Andrei and Boris, whose grievances were further increased by Ivan's refusal to give them a share of conquered Novgorod. In 1480 they rebelled, at a time when he was threatened by a Tatar invasion, and only with difficulty were they persuaded to remain loyal. A more serious conflict arose (1497–1502) in the form of an open and murderous struggle among Ivan's relatives for succession to the throne. Ivan had originally named as his heir his grandson Dmitry, son of his deceased son Ivan and the Moldavian princess Yelena, but a group close to Ivan's second wife, Sophia (Zoe) Paleologue, opposed this; her son Vasily threatened and perhaps attempted an insurrection, and Ivan was forced to accept Vasily. Historians have long pondered the causes of this struggle, in which most of the strands of Ivan's politics are brought together, but the motives and actions of the prince and his family remain obscure. For all its obvious achievement, Ivan's reign was nevertheless full of conflict and contradiction.

Ivan made the first effort on the part of a Muscovite ruler to become involved in the diplomacy of western Europe. He and his advisors realized the need for a counterpoise to the Polish–Lithuanian power, while the diplomats of Rome and Vienna were interested in the possibility of flanking the growing empire of the Ottomans with a Muscovite–Tatar force. In the 1470s and 80s, there was an unprecedented traffic between these capitals and Moscow. It was through these channels that Ivan arranged his marriage to Sophia (Zoe) Paleologue, a niece of the last Byzantine emperor. Sophia has been credited with considerable influence over Ivan, in particular with urging him to adopt the Byzantine political style (*e.g.*, autocracy, state domination of the church, etc.), but in fact she probably had little influence over Ivan's policies. His reign ended on a note of failure, with his overtures to the west and his brief rapprochement with Lithuania both disrupted by the intractable territorial and religious conflicts of the Slavic east and by the opportunism of the local magnates. Moscow's situation was worsened after Ivan's death by the collapse of the alliance with the Crimean khan Mengli Giray upon the Khan's death in 1515, opening a new period of chaos and readjustment in the steppe.

A similar appraisal must be made of Ivan's domestic policies. Although his reign was notable for the annexation of the rich Novgorodian provinces, for the establishment of a regular bureaucracy and a land-tenure system, and for certain improvements in agriculture, these achievements created new problems for his successors. The system of land grants to military servitors led to a major struggle over monastic land owning and hastened the enservment of the free peasantry in the central lands. His territorial annexations were to be the seeds of future administrative and political problems.

Vasily III. Ivan's son Vasily, who came to the throne in 1505, greatly strengthened the monarchy. He com-

pleted the annexation of Great Russian territories with the absorption of Pskov (1510) and Ryazan (1521) and began the advance into non-Great Russian territories (Smolensk, 1514). He also undertook to limit the scale of monastic and lay landholdings, as well as the juridical immunities attached to them. In these measures he relied upon the growing crops of bureaucrats and service gentry, rather than upon the great boyars, whose power subsequently declined.

Faced with a continuing Lithuanian war and with the breakdown of his father's Tatar policy, Vasily carefully temporized in order to avoid uniting his enemies. Once he had secured peace in the west, he was able to deal directly with the khan of the Crimean Tatars. In the end, however, much of what Vasily accomplished was undone by his failure as a procreator: divorcing his first wife for her apparent barrenness, he married Yelena Giinskaya, who bore him only two children—the congenitally retarded Yuri and the sickly Ivan, who was three years old at Vasily's death, in 1533.

Ivan IV the Terrible. Vasily had been able to appoint a regency council composed of his most trusted advisors and headed by his wife Yelena. The grievances created by his limitation of landholders' immunities and his antiboyar policies soon found expression in intrigue and opposition. The bureaucracy he had relied upon could not function without firm leadership. Although Yelena continued Vasily's policies with some success, on her death, in 1538, various parties of boyars sought to gain control of the state apparatus; a decade of intrigue followed, during which affairs of state, when managed at all, went forward because of the momentum developed by the bureaucracy. Foreign policy was moribund, in spite of considerable opportunities presented by the continuing decay of the khanate of Kazan, and domestic policy vacillated so wildly that scholars cannot agree upon an appraisal of its main directions.

Toward the end of the 1540s, however, there emerged a strong coalition of bureaucrats, clergy, and old Muscovite boyars. Apparently inspired by a common awareness of the needs of the state, they ended the debilitating intrigues and embarked upon a thoroughgoing program of reform. The first important step was the re-establishment of the monarch (for the first time to be officially designated tsar), accomplished through the coronation of the 16-year-old Ivan in unprecedented solemnity and pomp. Shortly afterward, he was married to Anastasia Romanovna Zakharina, of the leading boyar family.

Although there is a voluminous literature devoted to Ivan, almost nothing is known of his personality, his political views, or his methods of rule. There is little reliable biographical information about him aside from the facts of his six marriages, his lifelong ill health, and his mercurial temper. It is not even known when he began to rule in fact or which of the policies of his reign can be considered his.

Ivan was doubtless a puppet in the hands of the leading politicians long after his coronation. The major reforms of the middle 1550s, which produced a new law code, a new military organization, a reform of local government, and severe restrictions upon the powers of hereditary landowners (including the monasteries), were probably the work of the bureaucrats and clergy, their objective being to modernize and standardize the administration of the growing state. The immediate goal was to strengthen the state and military apparatus in connection with major campaigns (the first undertaken in 1547) against the khanate of Kazan, and to prepare for the major colonization of the new lands that that conquest and others were expected to secure. Toward the end of the 1550s, Ivan seems to have gained the support of certain groups opposed to these policies and to have seized control of the government. The issue was evidently foreign policy. The planned conquest of the Volga and steppe region had been delayed in execution, and the Kazan campaigns had been enormously costly. By 1557, when the campaigns against the Crimea began, there was much opposition in the highest military circles. Ivan took the dissidents' part and for the first time emerged as an independent figure.

Power of
politicians
over Ivan

Ivan was a disastrously bad ruler, in part because no one had ever anticipated that he would rule. His lifelong ill health and the idiocy of his brother made it quite natural for the regency and the politicians to ignore him and to neglect his education. In his adulthood, he contracted a painful and incurable bone disease, from which he sought relief in potions provided by a succession of foreign doctors and quacks and in alcohol. Once he had acquired full power, he set about destroying those who had ruled during the interregnum, as well as the machinery of government they had built up.

Ivan's famous *oprichnina*, an aggregate of territory to be separated from the rest of the realm and put under his immediate control as crown land, established in 1564, was the device through which he expressed his hatred and misunderstanding of the established government. As his private domain, a state within the state, he took into it predominantly northern and commercial territories that had enjoyed a special prosperity in preceding decades. Specific towns and districts all over Russia were included in the *oprichnina*, their revenues being assigned to the maintenance of Ivan's new court and household. He established a new, much simplified officialdom and a court composed of sycophants and mercenaries, prone to rule through terror, accompanied by persecution of precisely those groups that had contributed so much to the modernization of the state. As trained statesmen and administrators were replaced by hirelings and cronies, the central government and military organization began to disintegrate. The destructiveness of the *oprichnina* was heightened by Ivan's involvement in the costly and ultimately disastrous Livonian Wars throughout this period (indeed, some historians have viewed the *oprichnina* as a device for the prosecution of these taxing campaigns). Even before they had ended, Ivan was forced by the utter incompetence of his special *oprichnina* army to reintegrate it (1572) with the regular army and to revert, in theory at least, to the previous institutions of government. By the time he died, in 1584, the state that he had wanted to reclaim from its makers was in ruins.

Boris Godunov. Ivan had murdered his eldest son, Ivan, in a fit of rage in 1581, and his only legitimate heir, Fyodor, was an idiot. Power passed to those who were at Ivan's deathbed, among whom Boris Godunov, who had capped a rapid rise in court circles by the cynical marriage of his sister Irina to the pathetic Fyodor, soon emerged as the leading force. Godunov's judicious combination of chicanery, vision, and force enabled him to disarm his most dangerous enemies and to have himself proclaimed tsar after Fyodor's death in 1598. His policies during Fyodor's reign had been consistently restorative and conciliatory, and he had apparently succeeded in repairing much of the damage done to the state in Ivan's time. He conducted a cautious and generally successful foreign policy: the 20 years of his reign were, except for a short, successful war against Sweden, peaceful. In domestic policy, he returned to the modernizing and standardizing policies of the mid-century. He reorganized the land-tenure system, commerce, and taxation.

For a number of his problems Godunov could find no solution. Chief among these were the depopulation of the central Muscovite lands and the discontent among small landholders in the territories recently acquired in the south and southwest. Added to these problems was the continuing opposition of the boyars.

In spite of these difficulties and widespread famine caused by crop failures in 1601–02, Godunov remained well in control of the situation until the appearance of the so-called first False Dmitry, a defrocked monk who had appeared in Poland in 1601 claiming to be the son of Ivan IV. (The true Dmitry had died during an epileptic seizure in 1591.) The False Dmitry found some supporters in Poland—notably, Jerzy Mniszech, to whose 15-year-old daughter, Maryna, he became engaged. As the impostor moved northeast toward Muscovy, he acquired growing support among the disaffected petty gentry and Cossacks (peasants who had escaped from serfdom to a nomadic life) of the regions through which he passed, and border cities throughout the south opened their gates

to him. Godunov's troops easily defeated the ragtag force, which apparently had many secret supporters among Muscovite boyars, but a few weeks later Godunov died. The boyars staged a coup against Godunov's family and declared Dmitry tsar. The pretender entered Moscow in triumph, was crowned, and married Maryna Mniszczówna.

The Time of Troubles. The events of 1606–13 cannot be captured in a few words. Chaos gripped most of central Muscovy; Muscovite boyars, Polish–Lithuanian–Ukrainian Cossacks, and assorted mobs of adventurers and desperate citizens were among the chief actors. In May 1606, a small-scale revolt supported by popular indignation at the foolishly insulting behaviour of Dmitry and his Polish garrison brought the overthrow and murder of the pretender. The boyars gave the crown to Prince Vasily Shuysky, a leader of the revolt against Dmitry, with the understanding that he would respect the special rights and privileges of the boyars. While the new tsar had the support of most boyars and of the northern merchants, he could not, however, end the disorders in the south or the adventures of the Polish and Swedish kings, who used Muscovy as a battlefield in their continuing conflict with each other. In 1608 a number of boyars, led by the Romanovs, went over to a second False Dmitry, who had ridden a wave of discontent and freebootery from the Cossack south into the centre of Muscovy. A kind of shadow government was formed in the village of Tushino, 14 kilometres west of Moscow, in which the boyars and bureaucrats of the Romanov circle took leading posts. It managed to gain Cossack support and to manipulate Dmitry's pretensions while dealing with the Polish king Sigismund III over terms on which his son Władysław IV might become tsar. Shuysky, in desperation, turned to Sweden for aid, promising territorial concessions along the Swedish–Muscovite border. At this, the Polish king invaded Muscovy and besieged Smolensk (September 1609). The Tushino coalition dissolved, and Dmitry withdrew to the south. The position of the Shuysky government deteriorated, and in 1610 the tsar was deserted by his army and his allies. The boyars formed a seven-man provisional government with the aim of installing a Polish tsar. This government proved unable to settle its affairs and to restore order to the country. A new insurgent army, financed by northern merchants and staffed with Swedish troops, marched on Moscow with the intention of ousting the Polish garrison and of bringing the various Cossack bands under control. It nearly gained Moscow but fell apart because its leadership could make no arrangement with the Cossack leaders. A year later, a second force, raised in the same northern cities and supported by Cossacks who had been part of the Tushino camp, was able to take possession of the Kremlin. A call was issued for the election of a new tsar.

Social and economic conditions. In the flux of social and economic life in the 15th and 16th centuries, three interconnected processes may be observed: a steady economic growth, mainly from colonization and trade but also from the productivity of agriculture; an expansion in the power of the central government; and the encroachment of the nobility upon the lands previously held by the free peasantry, accompanied by the reduction of the bulk of the peasantry to serf status.

In the middle of the 15th century, society and the economy were still organized along traditional lines. The land was sparsely settled. Life for most of the population was simple and probably close to the subsistence level. Serfdom did not yet exist. Most of the peasantry lived on state lands and paid whatever taxes could be extracted from them by their prince or his bailiff.

A number of changes occurred in this pattern in the latter part of the 15th century. Around 1460, measures were taken to bring the peasantry under more regular control of the state and the landlord. Peasant registration appeared at this time, and also the requirement spread that peasants might renounce the tenancy of the land they were working only at the end of the agricultural cycle, in the week of St. Yury's Day (November 26). The growing

The false Dmitry

The struggle for Ivan's succession

controls upon the peasantry received impetus from the large-scale deportations and colonizations that accompanied the annexations of Novgorod, Tver, Pskov, and Ryazan, when the old nobility were replaced with nobility owing service to the prince of Muscovy. The nationwide promulgation of the restriction on movement to St. Yury's Day was contained in the law code of 1497, which added the stipulation that peasants leaving a former situation must pay the landlord all arrears in addition to a departure fee. All of the measures, together with the expansion of the state apparatus for tax gathering and adjudication of disputes over land and peasants, were associated with the growing complexity and power of the central government.

The law code of 1550 repeated the stipulation of 1497 limiting peasant departure, but with much more specific provisions and stronger sanctions. Other reforms put an end to local administration by rotating military governors and limited monastic landholding and the juridical rights of landlords over their peasants. The events and policies of the latter half of the reign of Ivan IV destroyed many of the beneficial results of the reforms. The Livonian Wars imposed unprecedented burdens on the tax-paying population and required such long absences by the landed nobles that their estates fell into ruin. Ivan's *oprichnina* caused the breakup of the great independent boyar holdings, in which the vitality of the peasant commune had been preserved, and replaced them with smaller service estates, often too small to be operated efficiently, whose masters needed to exploit serf and indentured labour in order to meet their obligations of service to the grand prince. These burdens led to the mass flight of the peasantry from the central agricultural regions, resulting in serious economic difficulties and a sharp fiscal crisis. Godunov's government attempted to deal with the problems through remission of taxes, avoidance of war, and harsher measures to keep the peasants on the land; but the country entered the Time of Troubles weakened by decades of economic chaos.

Cultural trends. This period also saw the crystallization of that complex of forms and ideas that can, for the first time, be identified as Great Russian culture. There was a gathering and integration of the Novgorodian, Tverite, and Suzdalian cultural traditions. Moscow began to attract the artists, craftsmen, and learned monks who built the eclectic but "national" churches of Ivan III's otherwise Italianate Kremlin and who wrote the revised national, pro-Muscovite versions of the chronicles that had been kept in Rostov, Ryazan, and Novgorod. The regional traditions were not always easily reconciled. Novgorodian attitudes, in particular, clashed with those of Muscovy.

The reign of Ivan III saw a marked turning toward the West. Ivan surrounded himself with Italian and Greek diplomats and craftsmen. His palace of 1487, his Kremlin with its Latin inscription over the main gate, and his churches, the original aspect of which has been altered by successive russifying restorations, were clearly in the Italian style, as contemporary foreign visitors noted. His marriage to Sophia, the niece of the last Byzantine emperor, Constantine Palaeologus, had, in addition to its diplomatic significance, a symbolic function of bringing Ivan into the circle of Western princes. This was the time of the "Third Rome" theory, when Muscovy supposedly regarded itself as the heir of Byzantium and as the spiritual leader of the Orthodox world. It may be that the church leadership, militantly anti-Roman, thought of itself in this light. Ivan and many around him viewed the Byzantine heritage as Western, by contrast with the Ottoman and Tatar world, and were at pains to associate Muscovy with Western traditions and interprincipely relations. This striving to be accepted in the Western world marked most of the changes in regalia and style of Ivan's reign, although these were later to be buried in the lore of Muscovite Byzantinism.

Three significant causes can be discerned for the evolution of Muscovite culture in the 16th century. The first was the growth and prosperity of the Great Russian population, united under a stable and increasingly centralized

monarchy, which produced the conditions for the rise of a national culture. The second was the diplomatic and cultural isolation in which Muscovy found itself, particularly in the first half of the 16th century, as a result of hostile relations with increasingly powerful Lithuania and Poland, a cause that, more than any other, brought an end to Ivan III's westward turn and to the revolutionary adjustments of the age of exploration. The third cause was the resolution of church-state relations, in the course of which the church submitted to the power of the princes in politics but gained control over the culture, style, and ideology of the dynasty, producing the peculiar amalgam of nationalistic, autocratic, and Orthodox elements that became the official culture of high Muscovy. This new synthesis was reflected in the great undertakings associated with the name of Metropolitan Makary of Moscow: St. Basil's Cathedral in the Kremlin; the encyclopedic *Menolog*, or calendar of months, which contained all of the literature, translated and original, permitted to be read in the churches; and the *Illustrated Codex*, a compilation of East Slavic and Greek chronicles in an official Muscovite version.

ROMANOV MUSCOVY

Michael Fyodorovich. The military drive that finally expelled the Poles from Moscow led to the election of Michael, the sickly 16-year-old son of Fyodor Romanov, as the new tsar. The composition of the coalition that elected him is not clear, but he evidently represented a compromise among the Cossacks, the boyars (especially the Tushino boyars), and the leaders of the northern army. It would be difficult to imagine circumstances less favourable for the beginning of the reign of the adolescent monarch and a new ruling coalition. The military campaigns had left much of the central and southwestern portions of the country in ruins. In many areas, populations had fled, land lay fallow, and administration was in disarray. Significant portions of the Novgorod, Smolensk, and Ryazan regions were occupied by Swedish and Polish armies and by sundry insurrectionary forces, who threatened to renew hostilities.

The Romanov government required more than a decade to establish itself politically and to restore economic and social order. Few had expected the election of a new tsar (the fourth in eight years) to bring an end to the turmoil. But the election of Michael reflected a resolution of political forces that permitted the coalition government to address itself to the problems of reconstruction. Another cause was the survival of the central bureaucracy; the civil servants in Moscow had served all successive governments without much interruption and were ready to restore administrative regularity as soon as political order was established. Fortunately, the new government refrained from involving itself in the Polish-Swedish conflicts, which reached their height at this period. This restraint was a most important element in the success of the 1613 settlement, for the international situation was, if anything, grimmer than the domestic. Polish-Swedish differences permitted Muscovite diplomats to bring the two countries to separate truces (Poland, 1618; Sweden, 1617); although these left substantial territories under the control of Poland and Sweden, they provided a needed interlude of peace. The Romanov government wisely avoided any significant participation in the Thirty Years' War, in which most European states engaged. At the death of the Polish king Sigismund III in 1632, Muscovy made an ill-advised attempt to regain Smolensk that ended in military disaster; but, in 1634, it obtained Władysław's formal abjuration of the Polish king's questionable claim to the title of tsar.

After the failure of the Smolensk campaign, the government refrained from further military involvement with Poland for nearly a generation. It concentrated instead upon the extension and fortification of its southern borders, where the incursions of Crimean Tatars were an impediment to colonization. Moscow, however, was not prepared to go to war with the Ottomans, who were the protectors of the Crimean khan; when in 1637 the Don Cossacks, Muscovy's clients, captured the critical port of

Establishment of the Romanovs

The crystallization of Great Russian culture

Azov and appealed to Moscow for aid in holding off a counterattack, a *zemsky sobor*, or national assembly (see below *Trends in the 17th century*), decided not to intervene, and the port was lost.

Alexis Mikhaylovich. The reign of Michael's son Alexis, whom later generations considered the very model of a benevolent and gentle tsar, began badly. Like his father, Alexis came to the throne a mere boy. Immediately, the boyar who controlled the government, Boris Ivanovich Morozov, embarked upon policies that brought the government to the brink of disaster. Morozov cut government salaries; he also introduced a tax on salt and a state monopoly of tobacco, the first of which caused widespread hardship and discontent, while the second brought the church's condemnation. At the same time, he alienated boyar groups close to the throne by his interference in his ward's marriage.

Morozov's actions exacerbated an already dangerous situation in the country. The city populations and service gentry, in particular, were heavily burdened by taxes and other obligations and were increasingly angry at the growing wealth and power of the ruling clique. During a riot in Moscow in May 1648, a mob surrounded the 19-year-old tsar, demanding the execution of Morozov and the leading officials. Some of the latter were thrown to the mob, and a brief protective exile was arranged for Morozov. Morozov's boyar enemies, who may have abetted the riot, took control of affairs and carried out a series of reforms. The salt tax and tobacco monopoly were ended, and a commission was established for the drafting of a new law code. Serious disorders continued in the cities of the north, particularly in Pskov and Novgorod, where force was required to reimpose authority.

In Novgorod, the principal actor in the government's interest was the metropolitan Nikon, an energetic and authoritarian monk who had made influential friends in Moscow while archimandrite at the Romanov family church and continued assiduously to cultivate the tsar and his relations while in Novgorod. In 1652 his solicitations earned him the *patriarchate*. Tradition has it that, before accepting the position, Nikon demanded a declaration of full obedience in religious and moral matters from the tsar. In the first years of Nikon's tenure, his relations with Alexis and the court were good; the patriarch, with official support, carried out a number of liturgical and organizational reforms; he surrounded himself with an impressive bureaucracy modelled upon the state apparatus. Relations with the tsar became strained in 1658, however, and, after he was publicly snubbed by Alexis, Nikon announced that he was abandoning the patriarchate. He later held that he had simply gone into temporary seclusion, but his effective power and influence were at an end.

The main event of Alexis' reign was the annexation of the eastern Ukraine. His government had continued the previous policy of avoiding entanglements in the West while expanding eastward but could not resist the opportunity offered, in 1654, when the leader of a Cossack revolution against Polish rule in the Ukraine appealed to Moscow for the help he had been unable to obtain from Sweden and the Turks. Moscow accepted his allegiance in return for military assistance and thus became involved in a protracted struggle with Poland and Sweden for the Ukrainian, Belorussian, and Baltic territories. At first, the war went well, but the differing objectives of the Ukrainian and Muscovite allies soon revealed themselves; when Charles X of Sweden entered the fray against Poland, Alexis made peace, in 1656; he feared a strong Sweden as much as a strong Poland. Muscovite forces plunged into war with Sweden for the Estonian, Livonian, and Karelian territories along the Baltic coast. The situation in the Ukraine became increasingly confused and dangerous for Moscow, and it was necessary to end the war with Sweden in 1661, even at the cost of yielding, once again, the Baltic coast.

In the Ukraine, the war took on a new aspect when, in 1664, Peter Doroshenko, a new leader, put himself under the protection of the Ottomans. The Turks joined in a number of major military operations, alarming both Po-

land and Moscow sufficiently to bring them to a truce at Andrusovo (1667). Poland recognized Moscow's control over eastern Ukraine and Kiev, while Moscow yielded most of Belorussia and the Ukraine west of the Dnieper.

The peace did not greatly improve the government's position, for the same year saw the beginning of a threatening movement among the Don Cossacks and peasants of the Volga region, led by Stenka Razin, and a political battle within the inner circles at court, caused by the death of Alexis' wife. After two years, Alexis was married to Nataliya Naryshkina. In 1676, however, Alexis himself died, and Fyodor, a sickly son of his first wife, Mariya Miloslavskaya, succeeded him. A struggle began between the rival Naryshkin and Miloslavsky families. The Naryshkins were exiled, and the Miloslavskys, with their clients and supporters, took over. In 1682, however, Fyodor died, and the Naryshkin faction sought to place his half-brother Peter on the throne instead of Fyodor's full brother, the ailing Ivan. The elite corps of *streltsy* (a hereditary military caste) revolted and established Ivan's elder sister Sophia as regent. (For the accession and reign of Peter the Great, see below *II. The 18th century: The reign of Peter I [1689–1725]*.)

Trends in the 17th century. Economic reconstruction was slow, particularly in agriculture and in the old central lands, but it was accompanied by a growth of trade and manufacturing. The state revenues profited from the expansion eastward beyond the Urals and southward into the black-soil region. In the north, the port of Archangel handled the export of forest products and semimanufactures (naval stores, potash) to the English and Dutch, and its merchants took a leading role in the early exploitation of Siberia. The government itself became deeply involved in the development of trade and commerce, both through its monopolistic control of certain areas and commodities and by its efforts to build up such strategic industries as metallurgy. The economy grew at unprecedented speed during the 17th century. By 1700 Russia was a leading producer of pig iron and potash, and the economic base upon which Peter's military successes were to depend had been firmly established.

The political recovery of the Russian state after the Time of Troubles was due largely to the survival of the central bureaucracy and ruling oligarchy. The lines of subsequent development were determined by the growth, consolidation, and almost unimpeded self-aggrandizement of these groups in the 17th century. The expansion of the bureaucratic apparatus can be measured in various ways. In 1613 there were 22 *prikazes*, or departments; by mid-century there were 80. At the beginning of the period, the jurisdiction of the bureaucracy included primarily fiscal, judicial, and military matters; by the end of the century, it also covered industrial, religious, and cultural life. At the close of the Time of Troubles, the bureaucracy's functions were exercised by leading boyars and professional administrators; by Peter's time, the mercantile class, the whole of the nobility, and the clergy had become part of its ubiquitous network. This bureaucracy was the buttress—indeed, the substance—of an absolute monarchy whose prerogatives knew no internal bounds.

The ease with which the extension of central authority overwhelmed all other political and social forces is to be explained by the frailty of local institutions and by the absence of independent ecclesiastical or social authority. The Muscovite administration was extended first into the devastated areas, where local institutions had been swept away, and then into new territories that had no significant political institutions, until it became a standardized and centralized mechanism powered by the colossal wealth generated by its own expansion.

These processes were reflected in the great law code of 1649, the first general codification since 1550, which was to remain the basis of Russian law until 1833. Its articles make clear the realities of Muscovite political practice: the rule of the bureaucrats and the extension of the powers of the state into all spheres of human activity. It was based in large measure upon the accumulated *ad hoc* decisions of the officials and was intended for their guidance. It made ecclesiastical affairs a matter of state juris-

Domination of Morozov

Territorial expansion in the 17th century

The expansion of central authority

diction; it gave legal expression to the practice of serfdom; and, in an important new article, it enumerated crimes "of word and deed" against the "Sovereign"—by which were to be understood the state and all its agents.

Social development paralleled and was determined by the developments just described. The great families of hereditary princes, still rich and powerful at the turn of the century, were systematically reduced, first through direct repression by the Romanovs, who feared them, and later through fiscal and administrative measures. By the end of the century, only those families that had made new careers in the state apparatus through service as generals, ministers, and ambassadors remained at the apex of society; they were joined by numerous parvenu families that had risen in government service. Particularly striking was the prosperity of the dyak class of professional administrators, which had become a closed hereditary estate by a decree of 1640; this class had become a new and powerful "nobility of the seal" that was to survive into modern times.

During much of the 17th century, the government was run, for all practical purposes, by high officials in cooperation with relatives and cronies of the reigning tsar. Nineteenth-century historians, eager to find constitutional traditions in Russia's past, have stressed the role of the zemsky sobor—an assembly of dignitaries that from the time of Ivan IV had been called together when matters of crucial importance had to be decided. In the period after 1613, it was in almost continuous session for some years. After 1619, however, the services of these assemblies were no longer required. It is questionable whether they ever had, in law or in fact, any power beyond that of a crowd of military and administrative leaders. They were summoned by the government, and their composition was determined by the government.

Cultural life. No period of Russia's cultural history has been as full of change, turmoil, creativity, failure, and sheer destructiveness as the 17th century. Russian society emerged from the Time of Troubles shattered and unsure of itself, disoriented and impoverished. This shaken society was then subject to wrenching social and economic change and strong external influences.

The old culture, in its formal aspects, had been the culture of the monasteries. Art, literature, architecture, and music remained, until the end of the 16th century, traditional, canonical, and orthodox.

The 17th century produced, first among the officials and boyars, later among the merchants and middle classes, a new elite that was increasingly interested in European culture and that had mainly secular interests. Yet the government of these same officials and boyars worked to stifle native cultural development, and many of these merchants and nobles were drawn into movements opposed to westernization.

The reasons for this paradoxical development were three. First, Western culture had reached Muscovy largely through Polish and Roman Catholic mediation, which rendered it unacceptable to all but those sophisticated enough to take a very broad view of the events of the Time of Troubles. In the Ukrainian and Belorussian territories, the Polish counter-reformation had brought a national cultural revival. The books and ideas and men flowing from these lands into Muscovy in the 17th century, however, were hardly less suspect than those of Catholic Poland, and, as these "aliens" acquired a dominant position in Muscovite cultural affairs, resentment was added to suspicion.

A second reason for the character of Muscovite cultural development in the 17th century was the preponderant role of the church and, later, of the state, which took over at last the assets, liabilities, and responsibilities of the ecclesiastical establishment. From 1620, when the patriarch Philaret pronounced an anathema upon "books of Lithuanian imprint" (in effect the only secular books in print for the Russian reader) until the end of the century, when the government turned to imposing Greek and "Lithuanian" (*i.e.*, Ukrainian and Belorussian) views upon a resisting populace, the state and its ecclesiastical adjunct had a repressive and stultifying influence.

Finally, indigenous cultural forces were, for various reasons, unable to assert themselves. They were physically dispersed, socially diverse, and set at odds by cultural and political disaffection. The development of a vernacular literature, which can be seen in the synthetic "folk songs," pamphlets, tales, and imitations produced for and by the growing educated class, remained an underground phenomenon; they were unpublished because of the ecclesiastical monopoly of the press, and they were anonymous out of fear. The promising experiments of a group of noble writers who worked within the formal Slavonic tradition were ended by exile and repression. The gay and expressive architecture and painting of the northern regions, which continued certain Novgorod traditions, fell victim to official discrimination against this region and its predominantly Old Believer population.

Despite these negative influences, the court, especially in the time of Alexis, was a centre of literary and artistic innovation, and many of the leading men of the realm were considered cultured and cosmopolitan by Westerners who knew them.

The great schism. The contradictions of the age were reflected in the great schism within the Russian church. The doctrinal debate began over obscure and petty matters of ritual, but larger, unarticulated issues were at stake. Religion in the Time of Troubles had taken two directions, which were at first closely associated: the reformation of religious life, (with stress on the pastoral functions of the clergy and the simplification of the liturgy) and the correction and standardization of the canonical books (which had, over centuries of regional mutation and textual degradation, come to vary widely from the Greek originals). The government had at first supported these linked objectives, but the supporters of "Old Russian piety" fell into opposition to the reforms as they were officially promulgated. When, in the 1650s, the patriarch Nikon began to enforce the reforms in the parishes, where they had been generally ignored, the discontent developed into a massive religious and regional insurrection. Towns and parishes of the north were riven by warring "old" and "new" bishops. The Old Believers were either crushed by government force, driven to self-destruction, or reduced to silent resistance.

In the end, the Western secular culture fostered at the court and the new religious culture and education, spread by Ukrainians and Belorussians, who came to dominate church life, submerged and displaced the disparate beginnings of a modern synthesis within native matrices and cleared the way for Peter's cultural policies, which erected a Western facade over the ruins of the native culture.

(E.L.K.)

II. The 18th century

THE REIGN OF PETER I (1689–1725)

Peter's youth and early reign. The accession of Peter I ushered in and established the social, institutional, and intellectual trends that were to dominate Russia for the next two centuries. Both Russian and Western historians, whatever their evaluation of Peter's reign, have seen it as one of the most formative periods of Russia's history. The seminal nature of the reign owes much to Peter's own personality and youth. The child of his father's second marriage, Peter was pushed into the background by his half brother Fyodor and exiled from the Kremlin during the turbulent years of the regency (1682–89) of his half sister Sophia. He grew up among children of lesser birth, unfettered by court etiquette. Playing at war and organizing his young friends into an effective military force, he could manifest his energy, vitality, and curiosity almost untrammelled. He also came into close contact with the western Europeans who lived in Moscow; the association kindled his interest in navigation and the mechanical arts—at which he became a skilled practitioner—and gave him the experience of a socially freer and intellectually more stimulating atmosphere than he might otherwise have had. He resolved to introduce this more dynamic and "open" style of life into Russia, a goal he pursued after the overthrow of Sophia in 1689 and that he erected into a policy of state after he became sole ruler following

Enforcement of religious reforms

The emergence of a new elite

the death of his mother in 1694. (His half-witted half brother, Ivan V, remained co-tsar but played no role and died in 1696.)

Peter's first political aim was to secure Muscovy's southern borders against the threat of raids by Crimean Tatars supported by the Ottoman Empire. For lack of adequate sea power, his initial attempt in 1695 failed to gain a foothold on the Sea of Azov. Undaunted, Peter built up a navy—the first Russian ruler since early Kievan times to do so—and succeeded in capturing Azov a year later. The experience convinced him of the necessity of extending his own technical knowledge and of securing tools and personnel from the West. To this end Peter travelled to western Europe, something no Muscovite tsar had ever done; he spent almost a year in Holland and England acquiring mechanical and maritime skills, hiring experts in various fields, purchasing books and scientific curiosities, and carrying on diplomatic negotiations for a crusade against the Turks. In the course of negotiations with Poland-Saxony and Denmark, an alliance was formed, not against Turkey but against Sweden. The alliance led to the Great Northern War (1700–21), which became Peter's major concern for almost the remainder of his reign.

Not only did the war absorb the country's resources and energies, but the war's requirements—defensive at first, and offensive after Peter's decisive victory over Charles XII at Poltava in 1709—determined most domestic policy measures as well. Only when victory was well in sight could Peter devote more of his attention to a systematic overhaul of Russia's institutions. The hastiness and brutality of steps taken under the stress of war had an effect on subsequent history. Historians have debated whether Peter's legislation was informed by an overall plan based on more or less clearly formulated theoretical considerations, or whether it was merely a series of ad hoc measures taken to meet emergencies as they occurred. Pragmatic elements predominated, no doubt, over theoretical principles. Yet the struggle against Sweden's modern military machine, together with the prevailing intellectual climate and administrative practices of Europe, contributed to orient Peter's thinking.

The Petrine state. Formally, Peter changed the tsardom of Muscovy into the Empire of All Russias, and he himself received the title of "emperor" from the Senate at the conclusion of the peace with Sweden (Treaty of Nystad, 1721). The title not only aimed at identifying the new Russia with European political tradition, it also bespoke the new conception of rulership and of political authority that Peter wanted to implant: that the sovereign emperor was the head of the state and its first servant, not the patrimonial owner of the land and "father" of his subjects (as the tsar had been). Peter stressed the function of his office rather than that of his person and laid the groundwork of a modern system of administration. Institutions and officials were to operate on the basis of set rules, keep regular hours and records, apply laws and regulations dispassionately, and have individual and collective responsibility for their acts. Reality, of course, fell far short of this ideal, because Muscovite traditions and conditions could not be eradicated so rapidly. Furthermore, there was a great shortage of educated and reliable persons imbued with such rationality and efficiency (a problem that bedevilled the imperial government until its end). They were mainly to be found in the military establishment, where officer and noncommissioned ranks acquired the requisite outlook, experience, and values in the army and navy established by Peter. The Russian bureaucracy thus acquired a preference for uniformity and militarism that did not foster respect or concern for the individual needs of the various regions and peoples of the far-flung empire.

In the new administration, performance was to be the major criterion for appointment and promotion. Peter wanted this principle to apply to the highest offices, starting with that of the emperor himself. As a result of his bad experience with his own son, Alexis (who fled abroad, was brought back, and died in prison), Peter decreed in 1722 that every ruler would appoint his own successor. He did not have the opportunity to avail him-

self of this right, however, and the matter of regular succession remained a source of conflict and instability throughout the 18th century. Peter's concern for performance lay at the basis of the Table of Ranks (1722), which served as the framework for the careers of all state servants (military, civil, court) until the second half of the 19th century. In it, the hierarchy was divided into 14 categories, or ranks; theoretically one had to begin at the bottom (14th rank) and proceed upward according to merit and seniority. Throughout the 18th century the 8th rank (1st commissioned officer grade) automatically conferred hereditary nobility on those who were not noble by birth. In a sense, therefore, the Table of Ranks opened all offices to merit and thus democratized the service class; but because service was contingent on good preparation (*i.e.*, education), it was accessible only to the few—nobility and clergy—until later in the 18th century.

The same need for qualified personnel that had brought about the Table of Ranks also determined Peter's policies toward the several social classes of his realm. The traditional obligation of members of all estates to perform service to the state, each according to his way of life (*i.e.*, the nobleman by serving in the army and administration, the peasantry and merchants by paying taxes, the clergy by prayer), was given a modern, rational form by Peter. Paradoxically, the reform helped to transform the traditional estates into caste-like groups from which—except in rare instances of clergy and rich merchants—it became impossible to escape. The nobility was most directly affected by the change, not only in Peter's lifetime but under his successors as well. The nobleman's service obligation became lifelong, regular, and permanent. The staffs of military and government institutions were no longer recruited on the basis of regional origin or family ties, but strictly according to the need of the state and the fitness of the individual for the specific task at hand. The serviceman was transferred from one assignment, branch, or locality to another as the state saw fit. The office of heraldry within the Senate kept the service rosters up to date and decided on appointments and transfers. Peter also introduced single inheritance of real estate (1714), attempting in this way to break the traditional inheritance pattern that had led to the splintering of estates. In so doing he hoped to create a professional service nobility unconnected with the land and totally devoted to the state; but the resistance the law met in its application forced its revocation in 1731. He also required the nobility to be educated as a prerequisite for service. Schooling, whether at home or in an institution, became a feature of the nobleman's way of life. Until the late 18th century, a nobleman was not considered to have attained his majority and did not have the right to marry unless he had passed a government examination in basic subjects. Schooling was a radical innovation, at first resented and resisted; but within a generation it was accepted as a matter of course and became the decisive element in the status and self-image of the nobility.

The peasantry had been ensnared during the 17th century, but the individual peasant had retained his traditional ties to the village commune and to the land that he worked. To prevent tax evasion through the formation of artificial households, Peter introduced a new unit of taxation, the "soul"—*i.e.*, a male peasant of working age—and the lords were made responsible for the collection of the tax assessed on each of their souls. The peasant thus became a mere item on the tax roll who could be moved, sold, or exchanged according to the needs and whims of his master—whether a private landlord, the church, or the state. The serf became practically indistinguishable from a slave. The noble landlord, on the other hand, was turned into an agent of the state; he stood in the path of the peasantry's traditional personal relationship with the sovereign and thereby contributed to the sense of alienation that the ordinary Russian felt toward the new, rational, but remote, Petrine state.

As befitted a secular-minded autocrat who saw his main task as enlightening and leading his people to "modernity," Peter had little regard for the church. He recognized its value only as an instrument of control and as an agent

Reform of the church

of modern education. When the patriarch died in 1700, Peter appointed no successor; finally in 1721 he gave the church a bureaucratic organization: a Holy Synod composed of several appointed hierarchs and a lay representative of the emperor; the latter, called the chief procurator, came to play the dominant role. Ecclesiastic schools turned into closed institutions with a narrowly scholastic curriculum. Membership in the clerical estate became strictly hereditary; the priesthood was transformed into a closed caste of government religious servants cut off from the new secular culture being introduced in Russia and deprived of their traditional moral authority. One of the priests' main tasks was to assist the state in enforcing its laws, in particular those directed against the Old Believers, so that the clergy became an instrument of persecution and oppression. Both on economic and religious grounds, therefore, the reign of Peter I appeared particularly oppressive to the common people. It seemed unnatural and contrary to tradition; for many it clearly was the reign of Antichrist from which one escaped only through self-immolation (practised by some of the Old Believers), open rebellion, or flight to the borderlands of the empire.

Resistance and flight were made possible by Peter's failure, despite all his modernizing and rationalizing, to endow the government with effective means of control on the local level. The noble landlords might have acted as police agents; but Peter removed them from the local scene by forcing them into permanent and lifelong service. Regular officials were short in number and experience and could not be easily spared for local administration. Peter tried to have the officers of the regiments that were garrisoned in the provinces double as local officials; but the experiment failed because of the necessities of war and because regular officers proved incompetent to administer peasants. The attempts at copying Western models were also unsuccessful, for the Russian nobility lacked (and was not allowed to develop) a local corporate organization that could serve as the foundation for local self-government.

Peter concentrated his attention almost entirely on the central administration, an area in which his reforms provided the basic framework within which the imperial government was to operate until its fall in 1917. To prosecute the war, the Petrine state had to mobilize all the resources of the country and to supervise practically every aspect of national life. This required that the central executive apparatus be extended and organized along functional lines. Peter hoped to accomplish this by replacing the numerous haphazard *prikazy* (administrative departments) with a coherent system of functional and well-ordered colleges (their number fluctuating around 12 in the course of the century). Each college was headed by a board for more effective control; it had authority in a specific area such as foreign affairs, the army, the navy, commerce, mining, finances, justice, etc. The major problems of this form of organization proved to be the coordination, planning, and supervision of the colleges. Peter endeavoured to cope with these defects pragmatically through the creation of a Senate, which came to serve as a privy council as well as an institution of supervision and control. In addition, he set up a network of espionage agents (*fiskaly*), who acted as tax inspectors, investigators, and personal representatives of the emperor. Internal security was vested in 1689 in the chancery of the Preobrazhensky Guards, the tsar's own military group, which became a much dreaded organ of political police and repression. Under different names the police apparatus remained a permanent feature of the imperial regime. The police were also the instrument of the ruler's personal intervention, an essential function for the preservation of the autocracy as a viable political system.

The needs of war, as well as the desire to modernize Russia, led Peter to promote and expand industry, particularly mining, naval construction, foundries, glass, and textiles. The Emperor aimed at maximizing the use of all potential resources of the country to heighten its power and further its people's welfare; these goals were pursued in mercantilist fashion through discriminatory tariffs,

state subsidies, and regulation of manufactures. Peter hoped to involve the rich merchants and the nobility in economic enterprise and expansion. As a class, however, the merchants failed to follow his lead; many were Old Believers who refused to work for the Antichrist. Nor did Peter's urban legislation provide the townspeople with the incentives and freedom necessary to change them into an entrepreneurial class; as a matter of fact, the municipal reforms were simply means to collect taxes and dues in kind. As to the nobility, only a few had the necessary capital to become entrepreneurs, and their time and energies were completely taken up by their service obligations. The shortage of capital could be, and in some specific cases was, overcome by direct government grants. But the equally serious shortage of labour was not so easily resolved. Peter permitted the use of servile labour in mines and manufactures, with the result that thousands of peasants were moved and forced to work under unfamiliar conditions, in new places, at very difficult tasks. Resentment ran high and the productivity of this forced labour was very low. Most of the enterprises established in Peter's lifetime did not survive him. But the impetus he had given to Russian industrial development was not altogether lost; it revived with new vigour—under different policies—in the middle of the 18th century.

Among the important factors in Russia's economic development under Peter was the building of St. Petersburg (now Leningrad) on the then inhospitable shores of the Gulf of Finland. Its construction cost an estimated 30,000 lives (lost from disease, undernourishment, and drowning) and engulfed vast sums of public and private monies. Nobles who served in the central administration and at court were required to settle in the new city and to build townhouses.

The location of the new capital symbolized the shift in the empire's political, economic, and cultural centre of gravity toward western Europe. After two decades of war, during which the survival of Russia seemed at times to hang in the balance, Peter emerged victorious. The Treaty of Nystad gave him control of the Gulf of Finland and of the eastern shore of the Baltic Sea and put under his sceptre several provinces having Western constitutions, social structures, and cultural traditions. This acquisition was to create constitutional and administrative problems for the multinational empire; but in the meantime trade and social intercourse with western Europe became easier, and the icebound peripheral ports of what is now Murmansk and Archangel were abandoned for the more convenient harbours of Riga, Revel (now Tallinn), and the new St. Petersburg. Secure on the Baltic, Russia could now take an active part in the diplomatic and military affairs of the comity of European states, although sometimes this was to its disadvantage because it became embroiled in dynastic and political conflicts not involving its own interests. After 1721 Peter also extended the borders of the empire in the south along the Caspian Sea as a result of a successful war against Persia (Treaty of St. Petersburg, 1732).

The changes that made Peter's reign the most seminal in Russian history were not the administration reforms and the military conquests, significant as those were, but the transformation in the country's culture and style of life, at least among the service nobility. Foreign observers made much of Peter's requirement that the nobility shave off their beards, wear Western clothes, go to dances and parties, and learn to drink coffee. These were only the external marks of more profound changes that in a generation or so were to make the educated Russian nobleman a member of European polite society. The common people, especially the peasantry, were not so immediately and positively affected, although by the end of the 18th century most peasants, and all inhabitants of towns, had moved a considerable distance from the values and habits of their 16th- and 17th-century forebears.

Most important of all, perhaps, the reign of Peter I marked the beginning of a new period in Russian educational and cultural life. Peter was the first to introduce secular education on a significant scale and to make it compulsory for all state servants. (More significant than

Change in Russia's culture and life-style

Petrine economy

the limited quantitative results during Peter's lifetime was the fact that education eventually became indispensable to membership in the upper class.) First, Peter tried to use the church to establish a network of primary schools for all children of the free classes; this plan failed largely because the clergy were unable to finance and staff schools for secular learning. But the specialized technical schools Peter founded, such as the Naval Academy, struck roots and provided generations of young men with the skills necessary for leadership in a modern army and navy. Although he did not live to see its formal inauguration, Peter also organized the Academy of Sciences as an institution for scholarship, research, and instruction at the higher level. The Academy's beginnings were quite modest—German professors lectured in Latin to a handful or poorly prepared students—and its development was not free from difficulties; but at the end of the 18th century it was a leading European centre of science and enlightenment, preparing and guiding Russia's scientific and technological flowering in the 19th century.

Russia as
a major
European
power

Assessment of Peter's reign. Contemporaries as well as later historians have given first place among Peter's accomplishments to his conquest of the Baltic provinces and areas on the Caspian Sea. More important was the fact that during his reign Russia became a major European power, in regular intercourse with the major trading powers and especially with Holland and Great Britain. This status of European power, however, burdened Russia with the maintenance of a large and up-to-date military establishment, which became involved in many costly conflicts. The weakening of Poland during the Northern War with Sweden led ultimately to Poland's partitioning, which proved a heavy burden for the Russian body social. Finally, the cultural, religious, and linguistic diversity of the empire was increased by the incorporation of national and social groups that were not easily assimilated. The new institutional forms that Peter introduced helped to shape a less personal and more modern (*i.e.*, routinized and bureaucratized) political authority. This led to an ambiguous relationship between the autocratic ruler and his noble servants and also to a sense of alienation between the common people and the ruler.

Contemporaries and later generations alike shared the feeling that Peter's reign had been revolutionary—a radical and violent break with the centuries old traditions of Muscovy. To some extent this was the consequence of Peter's ruthless manner, his dynamism, his harsh suppression of all opposition, and his obstinate imposition of his will. From a historical perspective, Peter's reign may appear to have been only the culmination of 17th-century trends rather than a radical break with the past. But men are more conscious of changes in manners and customs than of deeper transformations that require a long time for their working out. Thus Russia's cultural Europeanization in the early 18th century produced works of literature in a new manner, using foreign styles and techniques, such as the treatises and sermons of Feofan Prokopovich, Peter's main assistant in church matters, and the satires and translations of Prince Antiokh Kantemir, the first modern Russian poet. These writers, and many anonymous ones, praised Peter's work, stressing its innovative and necessary character; and the educated elite, reared on the cultural elements introduced by Peter, perceived his reign as the birth of modern Russia. This fact in itself became the source of critical thought and raised the question of whether the break, with the past was desirable or a betrayal of the genuinely national patterns of development of Russian culture. It appeared that forcible imposition of foreign elements had led to an alienation between the elite and the Russian people. This debate as to the nature and value of the reign of Peter I served as the main stimulus to a definition of Russian national culture and to the elaboration of competing political and social philosophies in the 19th century (*e.g.*, those of the Slavophiles and the westernizers). Peter's reign has been at the centre of all debates over Russian history, since any attempt to define its periods and to assess Russia's development in modern times requires a prior judgment of the reign and work of Peter I.

PETER I'S SUCCESSORS (1725–62)

Peter's unexpected death in 1725 at the age of 52 left unresolved two major institutional problems. The first was the succession to the throne, which remained unsettled not only because Peter did not choose his own successor but also because during the remainder of the century almost any powerful individual or group could disregard the choice of the preceding ruler. The second problem was the lack of firm central direction, planning, and control of imperial policy; closely related to it was the question of who would have the determining role in shaping policy (*i.e.*, what would be the nature of the "ruling circle" and its relationship to the autocrat). The failure to solve these problems produced a climate of instability and led to a succession of crises in St. Petersburg and Moscow that made it difficult to give unity and meaning to the period from 1725 until the accession of Catherine the Great in 1762.

Instability
and crisis

Normal and peaceful succession to the throne was thwarted by a combination of biological accidents and palace coups. At Peter's death his chief collaborators, headed by Prince A.D. Menshikov and with the help of the guard regiments (the offshoots of the play regiments of Peter's youth), put on the throne Peter's widow—his second wife, Catherine I, the daughter of a Latvian peasant. Quite naturally, Menshikov ruled in her name. Soon, however, he was forced to share his power with other dignitaries of Peter's reign. A Supreme Privy Council was established as the central governing body, displacing the Senate in political influence and administrative significance. Catherine I's death in 1727 reopened the question of succession; Peter's grandson (the son of Alexis who had perished in prison) was proclaimed emperor Peter II by the Council. An immature youngster, Peter II fell under the influence of his chamberlain, Prince I. Dolgoruky, whose family obtained a dominant position in the Supreme Privy Council and brought about the disgrace and exile of Menshikov. It looked as if the Dolgorukys would rule in fact because Peter II was affianced to the chamberlain's sister; but Peter's sudden death in January 1730 crossed the plans of that ambitious family.

Anna (1730–40). Under the leadership of Prince Dmitry Golitsyn—scion of an old Muscovite boyar family and himself a prominent official under Peter I—the Supreme Privy Council elected to the throne Anna, dowager duchess of Courland and niece of Peter I (daughter of his co-tsar, Ivan V). At the same time, Golitsyn tried to circumscribe Anna's power by having her accept a set of conditions that left to the council the decisive voice in all important matters. This move toward oligarchy was foiled by top level officials (the *generalitet*; *i.e.*, those with the service rank of general or its equivalent), in alliance with the rank-and-file service nobility. While the former wanted to be included in the ruling oligarchy (and Golitsyn seemed to have been ready to concede them this right), the latter opposed any limitation on the autocratic power of the sovereign. Indeed, the ordinary service nobles feared that an oligarchy, however broad its membership, would shut them off from access to the ruler and thus limit their opportunity to rise in the hierarchy of the Table of Ranks.

Anna left most of her authority to be exercised by her Baltic German favourite, Ernst Johann Biron, who acquired a reputation for corruption, cruelty, tyranny, and exploitation and who was felt to have set up a police terror that benefitted the Germans in Russia at the expense of all loyal and patriotic Russians. Recent scholarship has modified this image and shown that Biron's bad reputation rested on his inflexibility in applying the law and collecting taxes, rather than on malevolence. The Supreme Privy Council was abolished upon Anna's accession in 1730, and the functions of coordination, supervision, and policy planning were vested in a cabinet of ministers composed of three experienced high officials, all Russians.

Role of
Ernst
Biron

Elizabeth (1741–62). Anna was childless; she appointed as successor her infant nephew, Ivan Antonovich, under the regency of his mother, Anna Leopoldovna. Biron, who had at first retained his influence, was over-

thrown by Burkhard Christoph, Graf von Miinnich, who had made his fortune in Russia. The continuing domination of a few favourites—many of whom were Germans—much displeased the high officials, whose position was threatened by the personal caprices of ruler or favourite, and incensed even more the rank and file of the service nobility, who could not obtain rewards or favours from the sovereign without the approval and help of the favourites. The malcontents banded together around Peter I's daughter, Elizabeth, whose easygoing and open ways had gained her many friends; she was also popular because of her Russian outlook, which she emphasized, and because she shared the aura of her great father. With the help of the guard regiments and high officers, and with the financial support of foreign diplomats (in particular the French envoy), Elizabeth overthrew the infant Ivan VI and the regent Anna Leopoldovna in 1741. Her 20-year reign saw the rise of certain trends and patterns in public life, society, and culture that were to reach their culmination under Catherine the Great. On the political plane, the most significant development was the restoration of the Senate to its earlier function of chief policy-making and supervising body. At the end of her reign Elizabeth also established a kind of permanent council or cabinet for planning and coordination—the Special Conference at the Imperial Court.

Stabili-
zation
under
Elizabeth

During this period Peter's administrative reforms began to bear fruit. The Table of Ranks became the framework for a class of servicemen whose lives were devoted to the interests of the state. In principle, entry to this class of officials was open to anyone with the required ability and education, including the sons of priests and non-Russian landowners. In fact, however, promotion in the Table of Ranks was possible only if the individual's merit and performance were recognized by the ruler or, more likely, by high officials and dignitaries who had access to the ruler. The personal element, bolstered by family and marriage ties, came to play an important role in the formal system of promotion; most significantly, it determined the makeup of the very top echelon of the administrative and military hierarchies (which were interchangeable), the so-called *generalitet*. This group constituted an almost permanent ruling elite, co-opting its own membership and promoting the interests of the families most directly connected with it; in order to solidify its influence and function it aimed at bringing as many routine government operations as possible under a system of regulations that would make appeal to the ruler unnecessary. The latter's autocratic power could not be infringed however, because his authority was needed not only to settle special cases but to promote, protect, and reward members of the ruling group and their clients. The greatest threat to the system was the interference or interposition of favourites—"accidental people"—and to guard against this, the oligarchy entered into an alliance with the rank-and-file service nobles who wanted to join its ranks and could hope to do so with the help of the dignitaries' patronage; this alliance permitted successful palace coups against favourites. The system benefitted both the high and low nobility; but it worked only with the help of a strong autocracy in which the ruler could easily fend off any attempt at limiting his power, as Anna had demonstrated in 1730. The system worked well enough to allow the consolidation of Peter's reforms, some success in foreign policy, and a general increase in the power and wealth of the state, despite the low calibre of the rulers and the mismanagement of favourites.

The system rested on the availability to all nobles of the minimum education necessary for entrance and promotion in service; this created a desire to go through rapidly, or omit altogether, the most arduous and tedious lower echelons of the Table of Ranks. As a consequence, cultural policy became a major concern of the government and the nobility alike; the members of the service class demanded that institutions of learning be set up to prepare the nobility for better careers, skipping the lowest ranks. The demand was fulfilled in 1731 with the creation of the Corps of Cadets. In the course of the following decades, the original corps was expanded and other special institu-

The
service
nobleman

tions for training the nobility were added. General education became accessible to a large stratum of the rank-and-file nobility with the founding of the University of Moscow in 1755, although the lack of automatic preferment for its graduates kept it from being popular among the wealthier nobles until the end of the century. The Corps of Cadets and similar public and private institutions also acted as substitutes for the local and family bonds that had formerly given cohesion to the Muscovite service class but which Petrine practices had destroyed; these schools were also the seedbeds for an active intellectual life, and their students played a leading role in spreading the literature and ideas of western Europe in court circles and in the high society of the capitals.

The service nobleman was a landlord and serf owner; he was very poor for a number of reasons, chief among which were the low productivity of Russian agriculture and the continual splintering of estates through inheritance. As a rule his estates provided him only with the minimum necessary for his maintenance in service. But as long as he remained in service and away from his estates, he could do little to improve his property. He thus depended on the ruler for additional income, either in the form of a salary or as grants of land (and serfs) in reward for service. The salary was not very large, it was often in kind (furs), and it was paid out rather irregularly; lands and serfs could be obtained only from the ruler, and most went to favourites, courtiers, or high dignitaries. Service, it is true, provided the nobleman with some extras such as uniforms, sometimes lodgings, and—most important—greater accessibility to court, cultural life, and education for his children. Thus, he remained in service, took less and less direct interest in his estates and serfs, and became almost a rootless, permanent serviceman.

Elizabeth's chief advisor, Pyotr Shuvalov, had the government grant exclusive privileges and monopolies to some of the nobility, hoping to involve them in the development of mining and manufacturing. Shuvalov also initiated a gradual loosening of state controls over economic life in general. He began to dismantle the system of internal tariffs, so that local trade could develop; he strengthened the landlord's control over all the resources on his estate; and he gave the nobles the right to distill alcohol.

Shuvalov's
gifts to
the
nobility

At the same time, the landlords were obtaining still greater power over their serfs. The full weight of these powers fell on the household serfs, whose number increased because their masters used them as domestics and craftsmen in their town houses to make Western-style objects with which they surrounded themselves. When noblemen established factories or secured estates in newly conquered border areas, they transferred their serfs to them without regard for family or village ties. The operation of most estates was, in the absence of the landlord, left to the peasants. This only perpetuated the traditional patterns of agriculture and made the modernization and improvement of agricultural productivity impossible.

THE REIGN OF CATHERINE II THE GREAT (1762-96)

Elizabeth, too, was childless, and the throne passed to the heir she had selected—her nephew the Duke of Holstein, who became Peter III. Intellectually and temperamentally unfit to rule, Peter III made himself personally unpopular with St. Petersburg society; in addition, he allowed his entourage (mainly his Holstein relatives and German officers) to take control of the government. The regular hierarchy of officials—particularly the Senate—was pushed into the background; power passed into the hands of the emperor's favourites, while a modernized police, under the personal control of a general who was one of the emperor's minions, spread its net over the empire. The pro-Prussian foreign and military policy pursued by Peter III (who abruptly ended Russia's victorious involvement in the Seven Years' War) and his treatment of his wife Catherine provoked much resentment. As a result, the Emperor lost all support in society. It was easy for Catherine, with the help of the senators, high officials, and officers of the guard regiments (led by her lover

Grigory Orlov and his brothers) to overthrow Peter III on July 9 (June 28, old style), 1762. Thus began the long and important reign of Catherine II, whom her admiring contemporaries named "the Great."

The daughter of a poor German princeling, Catherine had come to Russia at the age of 15 to be the bride of the heir presumptive, Peter. She matured in an atmosphere of intrigue and struggle for power. She developed her mind by reading contemporary literature, especially the works of the French Encyclopaedists and of German jurists and cameralists. When she seized power at the age of 33 she was intellectually and experientially prepared, as the more than 30 years of her reign were to show.

The historiography of Catherine's reign has been dominated by two main approaches: a dramatization and romanticization of her personal life, which was indeed colourful for the number and variety of her lovers; and the viewpoint of 19th-century liberalism, which took literally her self-description as a "philosophe on the throne." Marxist and Soviet historians, to the extent that they have dealt with her reign at all, see it primarily in terms of the pressures put on the state by the serf-owning nobility faced with the demands of an expanding market economy. In recent years, scholars have come to think of Catherine's government as working to further the formation of a modern civil society in which social classes and groups pursue their own interests rather than serving the needs of the state exclusively.

Even before she seized power, Catherine wrote that the task of good government was to promote the general welfare of the nation by providing for the security of person and property; to that end, government should operate in a legal and orderly fashion, furthering the interests of individual subjects and giving groups and classes as much autonomy in the pursuit of their normal activities as possible. All the same, Catherine believed that the autocratic state had important functions; she had no intention of relinquishing or limiting her authority, even though she was willing to withdraw from those areas of national life that could be safely administered by an educated elite.

Expansion of the empire. Catherine's reign was notable for imperial expansion. The expansion had been prepared by military and political efforts since the reign of Peter I; in particular, an important process of incorporating and settling empty land (especially in the south, corresponding roughly to the modern Ukraine) had been initiated in the reign of Elizabeth. This continued with the partitions of Poland, in which Catherine played a leading role, with the result that all eastern Poland and the former Grand Duchy of Lithuania came under Russian rule. A disadvantage of this was that Russia became a partner in the alliance of the three partitioning powers and had to mind its common border with Prussia. An additional source of difficulty was that the Roman Catholic Poles, proud of their cultural and political traditions and resentful of their loss of independence, proved less easy to assimilate and draw into Russian society than had the Baltic Germans. Also, the large number of Jews in the formerly Polish and Lithuanian provinces created special problems for the imperial government.

Of greater immediate importance for the empire were the securing of the northern shore of the Black Sea (Treaty of Küçük Kaynarca, 1774), the annexation of the Crimea (1783), and the expansion into the steppes beyond the Urals and along the Caspian Sea. This permitted the adequate protection of Russian agricultural settlements in the south and southeast and the establishment of trade routes through the Black Sea and up the Danube. On the other hand, these gains involved Russia more and more in the political and military struggle over the crumbling Ottoman Empire in the Balkans (the Treaty of Küçük Kaynarca, for example, allowed intervention on the pretext of protecting the Christian populations under Turkish rule). Russian sovereignty was extended over these territories through traditional means of war and diplomacy, but their incorporation into the Russian polity and their economic integration showed the hand of Catherine.

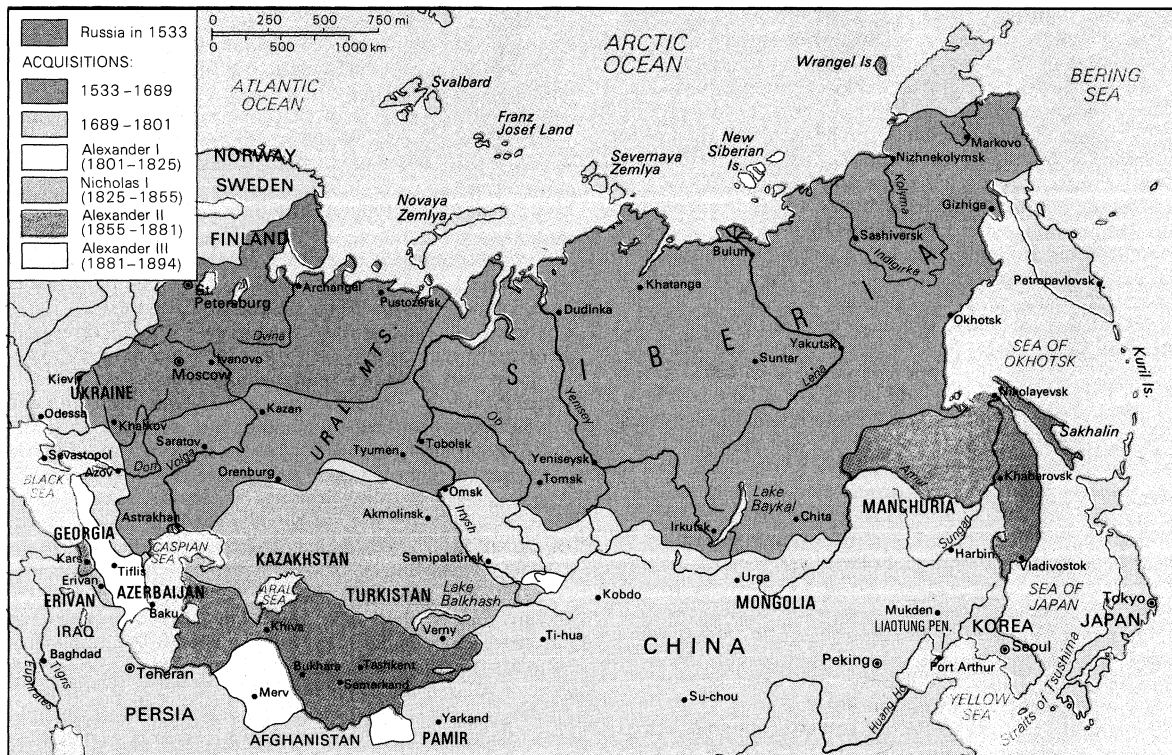

G.A. Potemkin, Catherine's favourite in the 1770s, may be considered the chief architect of her imperial policy. He promoted large-scale foreign colonization and peasant resettlement in the south - with only mediocre success so far as agricultural settlements went but with great success in the foundation and rapid growth of such towns and ports as Odessa, Kherson, Nikolayev, Taganrog, and Mariupol (now Zhdanov). Within a generation or two these became lively cultural centres and major commercial cities for all of southern Russia, contributing to the reorientation of Russia's pattern of trade with the development of agricultural exports from the Ukraine. Local society was transformed on the Russian pattern: the landlords became imperial service nobles with full control over their peasants; vast new lands were parcelled out to prominent officials and made available for purchase by wealthy Russian nobles, who also received the right to resettle their own serfs from the central regions. Thus, serfdom, along with elements of the plantation system, was extended to still more people and over whole new provinces. If this expansion benefitted the state and a small and already wealthy part of the Russian nobility, it increased the misery and exploitation of the Ukrainian and Russian peasantries. The traditional military democracies of the Cossack hosts on the Dnieper, Don, Ural, Kuban, and Volga rivers lost their autonomy and special privileges; the wealthier officers became Russian service nobles, receiving the right to own and settle serfs on their own lands, while the rank-and-file Cossacks sank to the level of state peasants with special military obligations.

Integration of the new territories required the absorption of a large number of non-Russian, non-Christian, nomadic peoples. The approach of Catherine's ministers, which prevailed until the late 19th century, was based on the idea, taken from Enlightenment writings, that there is a natural progress of society from primitive hunting and fishing groups through the stage of nomadism to settled agriculture, trade, and urbanization. Accordingly, the government sought to bring the nomadic peoples up to what it considered to be the Russian peasantry's higher way of life; this policy had the advantage also of producing uniformity in administrative and legal structures. Catherine's government was quite willing to let religious, cultural, or linguistic differences stand, although it did not feel committed to protect them actively. Inevitably, however, its effort to change the ways of the nomads affected their culture and religion and, through these, their social equilibrium and sense of national identity. While Catherine's policy led some peoples to accept (more or less under duress) changes in their way of life, thus facilitating the extension of Russian agricultural settlements onto the open steppes, it also gave rise to a new national self-consciousness and to a growing sense of identity based on cultural, linguistic, and religious traditions. These nationalistic sentiments clashed with the outlook and practices of officials accustomed to thinking in universal categories. The government found it difficult to rely upon native elites to operate the institutions it imposed on the new territories. Russian officials had to be sent in, strengthening uniformity and centralization in contradiction to the professed aim of furthering autonomy in local affairs. The policy thus defeated its own aims: it handicapped the economic development of the empire's border regions (e.g., in Siberia) and worked against the social and cultural integration of the natives into the fold of the dominant Russian culture (although russification did take place on a significant scale in the case of some native elites, as in the Caucasus and the Crimea).

Government administration under Catherine. The reforms of local government carried out by Catherine also contained contradictions. The successors of Peter I had not solved the problem of local administration. St. Petersburg relied on appointed officials, too few in number and much given to abuse and corruption, and on the informal control exercised by individual landowners and village communes; but a great peasant rebellion, led by Ye.I. Pugachov in 1773-74, demonstrated the inadequacy of this system. Taking up suggestions of various officials and mindful of the information and complaints offered by the

deputies to the Legislative Commission (1767–68), Catherine shaped the local administration into a structure that remained in force until the middle of the 19th century and also served as a foundation for the *zemstvos* (local elected councils), established in 1864. The basic pattern was established by the statute on the provinces of 1775 and complemented by the organization of corporate self-administration contained in the charters to the nobility and the towns (1785). Essentially, the reforms divided the empire's territory into provinces of roughly equal population, disregarding historical traditions and economic ties; each of these units (*guberniya*) was put under the supervision and responsibility of a governor or governor general acting in the name of the ruler, with the right of direct communication with him. A governor's chancery was set up along functional lines (paralleling the system of colleges) and subordinated to and supervised by the Senate. The regular provincial administration was assisted by officials who were elected from among the nobility for the countryside and from the higher ranks of townspeople for the cities; these elected officials took care of routine police matters in their jurisdictions, helped to enforce orders received from the central authorities, and assisted in the maintenance of law and the collection of taxes. Other elected personalities (marshals of the nobility and heads of city councils) protected the interests of their respective classes and helped to settle minor conflicts without recourse to regular tribunals. This delegation of some administrative functions to the local level (albeit under the strict control of St. Petersburg) not only relieved the bureaucracy of much burdensome detail and multiplied the number of its agents on the local level but also fostered a sense of responsibility among the active and cultured members of the local upper classes. On the other hand, the serfs and the lower classes in the towns found themselves without anyone to protect their interests.

Catherine made no fundamental changes in the administration of the central government. The system of colleges was retained; but the authority of the presidents increased at the expense of the boards, initiating an evolution that culminated in the establishment of monocratic ministries in 1802. The Senate supervised all branches of administration, regulating the orderly flow of business. The Senate was also involved—albeit indirectly—in coordina-

tion, mainly because its procurator general, Prince A. Vyazemsky, held the office for a quarter of a century with the full trust of the empress. At the same time, the judicial functions of the Senate as a high court of appeal and administrative review were widened.

The major institutional weakness of the Petrine system remained—namely, the lack of a body to coordinate the jurisdictions and resolve the conflicts of the colleges and to plan policies and control their implementation. A ruler as energetic, hard-working, and intelligent as Catherine could perform these tasks almost single-handedly, as had Peter I; but with the growing complexity of administration even Catherine felt the need for such a body, if only to reduce her involvement in every small detail or contested matter and to provide a wider scope for government by permanent laws and uniform regulations. Eventually, she set up a council of state as a kind of cabinet but without giving it any specific authority or jurisdiction.

A major need of the empire was an up-to-date code of laws. The last code, issued in 1649, had become largely inoperative as a result of Peter's reforms and the transformation of society. Peter and his successors had recognized this need by appointing commissions to prepare a new code; none of the several efforts having reached a successful conclusion, Catherine tried to tackle the job again, but in a different manner. In 1767 she convoked a commission of representatives elected by all classes except private serfs. For their guidance she drafted an instruction largely inspired by Western political thinkers; but, far from providing a blueprint for a liberal code, it emphasized the need for autocracy and strong central institutions. In its civil part the instruction owed much to German political philosophy and natural-law jurisprudence, putting the individual's duties before his rights emphasizing the state's responsibility for the welfare of the nation, and encouraging the pursuit of material self-interest within the established order. Although not implemented by the commission (which was dissolved in 1768), the instruction stimulated the modernization of Russian political and legal thought in the early 19th century.

In her social policy Catherine aimed at steering the nobility toward cultural interests and economic activity so as to reduce their dependence on state service. (They already had been freed from its compulsory character by

Catherine's social policy

Peter III [February 18, 1762].) To this end she made a general land survey that fixed clearly and permanently the boundaries of individual estates, and she granted the nobility the exclusive right to exploit both the subsoil and surface resources of their land and to market the products of their estates and of their serfs' labour. The nobles also obtained a monopoly of ownership of inhabited estates, which, in fact, restricted ownership of agricultural serfs to the noble class. Catherine hoped to stimulate agricultural expansion and modernization by providing easy credit and by disseminating the latest techniques and achievements of Western agriculture through the Free Economic Society founded in 1765. She also fostered the nobility's corporate organization. The Charter to the Nobility, 1785, gave the corps of nobles in every province the status of a legal entity. The corporation's members gathered periodically, in the provincial and district capitals, to elect a marshal of the nobility, who represented their interests before the governor and the ruler himself; they also elected a number of officials to administer welfare institutions for the nobility (schools, orphanages, etc.), to help settle disputes, and to provide guardianships for orphans. The corporate life of the nobles did not develop as well as expected, however, and the nobility never became the class it was in Prussia or England; but the charter did foster a sense of class consciousness and afforded legal security to the members and their property. The periodic electoral meetings stimulated social intercourse, led to a livelier cultural life in the provinces, and helped to involve the nobility in local concerns.

Turning the nobility's interests toward economic activity brought the return home of many landowners to supervise the operation of their estates. Interested in obtaining greater income, they not only intensified the exploitation of serf labour but also interfered in the traditional routine of the village by attempting to introduce new agricultural techniques. In most cases this meant increased regimentation of the serfs. The secularization of the monasteries and episcopal sees in 1764 had brought a considerable amount of land into the possession of the state. To reward her favourites and to encourage the nobles to economic activity, Catherine gave away large tracts with many peasants, who now had to work for ambitious and capricious masters.

Serfdom had never been acceptable to the Russian peasant; it now became particularly burdensome and unjust, the more so since the lord's extensive police powers removed his serfs from the state's protection, and the new local officials enforced strictly the prohibition against appealing for relief to the sovereign. There were also the specific grievances of the Cossacks, whose traditional liberties had been sharply curtailed and their social organization undermined, and the discontent of the nomadic peoples forced to accept a new way of life. Peasant misery erupted in rebellion that engulfed all of eastern European Russia in 1773–74, led by the Cossack Yemelyan Pugachov. The peasant forces captured a number of towns and cities before they were finally defeated by government armies. The revolt demonstrated the inadequacy of local controls and was thus partly responsible for the reform of provincial administration mentioned above. It also brought the educated elite to a new awareness of the profound alienation of the peasantry from the culture of St. Petersburg.

The reign of Catherine II was a period of active town planning and building. The number and size of the urban centres grew slowly but steadily. Along with new cities in the south, many old towns were rebuilt and developed. The renaissance of the old provincial centres was in part due to the administrative reforms of 1775 and 1785, which brought an influx of officials and nobles. Along with them came craftsmen, artisans, and merchants. An act of Peter III, which permitted peasants to trade in neighbouring towns without passports or controls at the gates, gave impetus to the emergence of a class of small merchants from among the peasantry. This trend received support from the administrative reorganization of the towns and the limited degree of corporate self-administration granted by the Charter of 1785.

EDUCATION AND SOCIAL CHANGE IN THE 18TH CENTURY

Secular education had been actively propagated by Peter I. At first it focussed on technical subjects—those directly related to the prosecution of a war, the building of a navy, and the running of the government. This was also the original emphasis of the Academy of Sciences and the school connected with it. But as education became the prerequisite for advancement in service and as Western ways of life spread among the upper classes, the focus of education gradually broadened. A class of nobles grew up who were interested in culture for the sake of their own development, as well as for cutting a good figure in society. Beginning in the 1760s the demand for western European artistic and cultural works grew in the salons of St. Petersburg increasingly. By the 1780s the major classics of European literature had become easily available in translation to any educated person. Private boarding and day schools proliferated, as did the number of tutors hired by wealthy nobles for their children (and for less fortunate neighbours and relatives). The Academy of Sciences took its place among the major academies of Europe. The University of Moscow and the chief schools of the military, naval, and civil services had become regular institutions.

There were also ecclesiastical schools. Paradoxically, the instruction they gave was almost irrelevant for the future priest but quite useful for the future official or scholar; it emphasized the rhetorical arts and logic and gave a solid foundation in scholastic philosophy, natural-law doctrine, the classical languages, and mathematics. The seminaries and theological academies not only trained future members of the episcopate and officials of the Holy Synod but also staffed government bureaus on the middle and higher levels and produced the first native Russian academics, scholars, and scientists. Russia's lack of professional experts in such fields as jurisprudence, civil and military engineering, astronomy, and geophysics brought a great influx of foreigners. Peter I imported large numbers of engineers and technicians from Holland and England, and the practice continued on a reduced scale after his death, so that foreign scholars, scientists, and experts staffed the Academy of Sciences and the University of Moscow and supplied the requirements of the state for such purposes as geological surveys. They brought with them French and German philosophy: the metaphysics and epistemology of René Descartes and the natural-law doctrines of the German school of Gottfried Leibniz, Samuel von Pufendorf, and Christian Wolff. These emphasized social obligation and the individual's dependence on the community. Stressing his duties to the group, they laid the foundation for a critique of society. The critique was at first directed against the moral inadequacies of individuals—the vain courtier, the superficially westernized fop, the corrupt official—but it soon broadened into the view that the educated man had an obligation to help his fellowmen improve themselves. In the Russian context the class most obviously in need of improvement was the peasantry. Moral progress, it was quickly realized, was not possible without material progress, and this led quite naturally to an advocacy of practical philanthropy and social action.

German natural-law doctrines furthered the dissemination of German Pietism, with its emphasis on spiritual progress and on the need to serve man and the community. Similar tendencies underlay the most influential branch of Freemasonry; the Freemasons devoted themselves to disseminating knowledge, relieving hunger, and caring for orphans and other destitutes. The publisher Nikolay Novikov carried the Pietist and Masonic messages to the public in his satirical journals and periodicals for women and children. All would-be reformers were concerned about the serf, especially since the Pugachov revolt had shown the degree of the peasantry's alienation. The major writers of Catherine II's reign (including the empress herself, who dabbled in journalism and drama) produced satires, fables, and comedies of manners attuned to the belief that moral and spiritual progress would lead to social improvements. A similar approach was noticeable in education, which stressed the develop-

Western intellectual influences

Town planning and building

ment of moral feeling in the conviction that a good heart would guide the well-filled head in the proper direction. This was the context in which the writings of the French philosophes (e.g., Jean-Jacques Rousseau, Guillaume Raynal, Claude *Helvétius*, Paul-Henri Holbach) struck a response in the Russian educated elite. The Russians had been prepared by natural-law teachings, Pietism, and Freemasonry for a more radical criticism of contemporary society looking to the perfectibility of man through education and social change.

Growth of
national
pride

All of these intellectual currents combined to awaken among educated Russians a sense of national pride and a feeling that, thanks to the impetus given by Peter I, Russia had managed to lift itself to the cultural and political level of a great European state. The educated Russian was no longer a servile and mute slave of the tsars; he had made himself into a gentleman, a man of heart and honour, a "true son of the fatherland," concerned about his fellow men. Nor was this regarded simply as imitation of the West; it was the fruit of Russian history, which was not to be scorned or neglected. A revived interest in Russian history led to the first important native works of modern Russian historiography.

The response of the empress and her entourage to these intellectual developments was ambivalent. The new sense of national pride and personal dignity enhanced the government's prestige and was in line with Catherine's own aspirations for the nobility. But the spread of these new interests and ideas was also dangerous, for the moral criticism of abuses could easily turn into criticism of Russia's social and political system. The outbreak of the French Revolution made Catherine II particularly anxious. She felt that large-scale private philanthropic and educational activities without government guidance and control were trespassing on her own prerogatives as an enlightened autocrat. By the end of the 18th century the ideal of service to the state, which had underlain the Russian nobility's value system, had been transformed into one of service to the people; this meant the elite's separation from the state, which Catherine II could not accept. A dramatic illustration of Catherine's concern occurred after the appearance in 1790 of Aleksandr Radishchev's *Journey from St. Petersburg to Moscow*. A member of the nobility, Radishchev had returned from Germany to rise to a prominent position in the government service. He depicted social conditions as he saw them, particularly the dehumanization of the serfs and the corruption of their masters, warning that these threatened not only the stability of the existing order but also Russia's survival as a nation. Incensed by the book, Catherine had Radishchev arrested and banished to Siberia. He became the first political martyr of the Russian elite; his book and his fate foreshadowed the antagonism between the intelligentsia and the government that was to dominate Russia's history in the 19th century.

THE REIGN OF PAUL I (1796–1801)

Catherine died in 1796 and was succeeded by her son Paul. A capricious, somewhat unstable individual, Paul had a passion for military order that conflicted with the basic values of the developing civil society; he felt that the nobility should again become a service class (or withdraw completely into agriculture) and help the ruler in implementing his reform program, even at the expense of its private interests. In trying to re-establish compulsory state service, he made it more rigid, harsh, and militaristic. He sought to promote the welfare of the serfs, but the manner of his approach—a decree permitting a maximum of three days of labour service a week—was clumsy and high-handed; it did nothing to help the serfs and angered their lords. Paul also made the same mistake as his father, Peter III: he wanted to govern with his own minions, disregarding both tradition and the administrative patterns that had developed during his mother's 30-year reign. Paul's hatred of the French Revolution and of everything connected with it led him to impose tight censorship on travel abroad and to prohibit foreign books, fashions, music, etc. He thereby earned the enmity of upper society in St. Petersburg. On March 23 (March 11,

O.S.), 1801, he was murdered by conspirators drawn from high officials, favourites of Catherine, his own military entourage, and officers of the guard regiments. The accession of his son, Alexander I, inaugurated a new century and a new period in the history of imperial Russia. (M.Ra.)

III. Russia from 1801 to 1917

THE REIGNS OF ALEXANDER I AND NICHOLAS I

General survey. When Alexander I came to the throne in March 1801, Russia was in a state of hostility with most of Europe, though its armies were not actually fighting; its only ally was its traditional enemy, Turkey. The new emperor quickly made peace with both France and Britain and restored normal relations with Austria. His hope that he would then be able to concentrate on internal reform was frustrated by the reopening of war with Napoleon in 1805. Defeated at Austerlitz, the Russian armies fought Napoleon in Poland in 1806 and 1807, with Prussia as an ineffective ally. After the Treaty of Tilsit (1807), there were five years of peace, ended by Napoleon's invasion of Russia in 1812. For further information see FRENCH REVOLUTIONARY AND NAPOLEONIC WARS: *The Napoleonic Wars, 1801–15*. From the westward progress of its arms in the next two years of heavy fighting, Russia emerged as Europe's greatest land power and the first among the continental victors over Napoleon. The immense prestige achieved in these campaigns was maintained until mid-century. During that period, Russian armies fought only against weaker enemies: Persia in 1826, Turkey in 1828–29, Poland in 1830–31, and the mountaineers of the Caucasus during the 1830s and 1840s. When Europe was convulsed by revolution in 1848, Russia alone among the Great Powers was unaffected; and in the summer of 1849 the Tsar sent troops to crush the Hungarians in Transylvania. Russia was not loved, but it was admired and feared. To the upper classes in central Europe, Nicholas I was the stern defender of monarchical legitimacy; to democrats all over the world, he was "the gendarme of Europe" and the chief enemy of liberty. But the Crimean War (1853–56) showed that this giant had feet of clay. The vast empire was unable to mobilize, equip, and transport enough troops to defeat the medium-sized French and English forces under very mediocre command. Nicholas died in the bitter knowledge of general failure.

Alexander I as a young man had longed to reform his empire and benefit his subjects. His hopes were disappointed, partly by the sheer inertia, backwardness, and vastness of his domains but chiefly because Napoleon's aggressive enterprises diverted Alexander's attention to diplomacy and defense. Russia's abundant manpower and scanty financial resources were both consumed in war. The early years of his reign saw two short periods of attempted reform. During the first, from 1801 to 1803, the Tsar took counsel with four intimate friends, who formed his so-called Unofficial Committee, with the intention of drafting ambitious reforms. In the period from 1807 to 1812, he had as his chief adviser the liberal Mikhail Speransky (q.v.). Both periods produced some valuable administrative innovations, but neither initiated any basic reform. After 1815 Alexander was mainly concerned with grandiose plans for international peace; his motivation was not merely political but also religious, for the years of war and national danger had aroused in him an interest in matters of faith to which, as a pupil of the 18th-century Enlightenment, he had previously been indifferent. While he was thus preoccupied with diplomacy and religion, Russia was ruled by conservatives, among whom the brutal but honest Gen. Aleksey Arakcheyev was outstanding. Victory in war had strengthened those who upheld the established order, serfdom and all. The mood was one of intense national pride: Holy Russia had defeated Napoleon, the Corsican Antichrist, and therefore it was not only foolish but also impious to copy foreign models. Educated young Russians, who had served in the army and seen Europe, who read and spoke French and German and knew contemporary European literature, felt otherwise. Masonic lodges and secret societies flour-

Russian
victories
against
weak
enemies

ished in the early 1820s. From their deliberations emerged a conspiracy to overthrow the government, inspired by a variety of ideas: some men looked for a model to the United States, others to Jacobin France. The conspirators, known as the Decembrists because they tried to act in December 1825 when the news of Alexander I's death became known and there was uncertainty about his successor, were defeated and arrested; five were executed and many more sentenced to various terms of imprisonment in Siberia. Nicholas I, who succeeded after his elder brother Constantine had finally refused the throne, was deeply affected by these events and set himself against any major political change, though he did not reject the idea of administrative reform. After the revolutions of 1848 in Europe, his opposition to all change, his suspicion of even mildly liberal ideas, and his insistence on an obscurantist censorship reached their climax.

The sections that follow cover the development, under Alexander I and Nicholas I, of the machinery of government; of social classes and economic forces; of education and political ideas; of the relations between Russians and other peoples within the empire; and of Russian foreign policy.

Government. The discussions of Alexander I's Unofficial Committee were part of an ongoing debate that was to remain important until the end of the imperial regime. This may be called the debate between enlightened oligarchy and enlightened autocracy. The proponents of oligarchy looked back to a somewhat idealized model of the reign of Catherine II. They wished greater power to be placed in the hands of the aristocracy for the purpose of achieving a certain balance between the monarch and the social elite, believing that both together were capable of pursuing policies that would benefit the people as a whole. Their opponents, of whom the most talented was the young Count Pavel Stroganov, were against any limitation on the power of the tsar. Whereas the oligarchs wished to make the Senate an important centre of power and to have it elected by senior officials and country nobility, Stroganov maintained that, if this were done, the sovereign would have "his arms tied, so that he would no longer be able to carry out the plans which he had in favour of the nation." In the event, neither enlightened oligarchs nor enlightened absolutists had their way: Russia's government remained autocratic but reactionary. Alexander, however, never quite abandoned the idea of representative institutions. He encouraged Speransky to prepare in 1809 a draft constitution that included a pyramid of consultative elected bodies and a national assembly with some slight powers of legislation. In 1819 he asked Nikolay Novosiltsev, a former member of the Unofficial Committee who had made a brilliant career as a bureaucrat, to prepare another constitution, which turned out to be rather similar. Neither was ever implemented, though Alexander took some features of the first and used them out of their intended context.

In 1802 Alexander instituted eight government departments, or ministries, of which five were essentially new. The organization of the departments was substantially improved in 1811 by Speransky. In the 1820s, the ministry of the interior became responsible for public order, public health, stocks of food, and the development of industry and agriculture. Inadequate funds and personnel and the dominant position of the serf-owning nobility in the countryside greatly limited the effective power of this ministry. There was no question of a formal council of ministers, or of anything corresponding to a cabinet, and there was no prime minister. A committee of ministers coordinated to some extent the affairs of the different departments, but its importance depended on circumstances and on individuals. When the tsar was abroad, the committee was in charge of internal affairs. Aleksey Arakcheyev was for a time secretary of the committee, but he did not cease to be the strongest man in Russia under the tsar when he ceased to hold this formal office. The committee had a president, but this office did not confer any significant power or prestige.

Under Nicholas I the committee of ministers continued to operate, but the individual ministers were responsible

only to the emperor. The centre of power to some extent shifted into the emperor's personal chancery, which was built up into a formidable apparatus. The Third Department of the chancery, under Count Aleksandr Benckendorff, was responsible for the security police. Its head was also chief of gendarmes, and the two offices were later formally united. The task of the security force was to obtain information on the state of political opinion and to track down and repress all political activity that might be considered dangerous to the regime. The Third Department was also considered by the tsar as an instrument of justice in a broad sense, the defender of all those unjustly treated by the powerful and rich. Some of the department's reports show that there were officials who took these duties seriously, but as a whole it showed more talent for repressing opposition and stifling opinion than for redressing the grievances of the powerless. This was the case notwithstanding the fact that the department was often on the worst of terms with other branches of the public service.

Russia under Alexander I and Nicholas I was ruled by its bureaucracy. The efforts of successive sovereigns after Peter the Great to establish a government service of the European type had had partial success. The Russian bureaucracy of 1850 combined some features of a central European bureaucracy of 1750 with some features of pre-Petrine Russia. One may speak of a "service ethos" and trace this back to 16th-century Muscovy. But the foundation of this ethos was, for the great majority of Russian officials, servile obedience to the tsar and not service to the state as that phrase was understood in a country such as Prussia. The notion of the state as something distinct from and superior to both ruler and ruled was incomprehensible to most government servants. Russian bureaucrats were obsessed with rank and status. Indeed, this was the only incentive that the government could give, as salaries were very meagre. Rank was not so much a reward for efficient service as a privilege to be grasped and jealously guarded. In order to prevent able persons, especially of humble origin, from rising too quickly, great emphasis was laid on seniority. There were exceptions, and outstandingly able, cultured, and humane men did reach the top under Nicholas I, but they were few.

The rank and file of the bureaucracy was mediocre, but its numbers steadily increased, perhaps trebling in the first half of the century. It remained poorly paid. The government's poverty was caused by the backward state of the economy, by the fact that no taxes could be asked of the nobility, and by the cost of waging wars—not only the great wars but also the long colonial campaigns in the Caucasus. Government officials were badly educated. They lacked not only precise knowledge but also the sort of basic ethical training that competent officials need. They were reluctant to make decisions: responsibility was pushed higher and higher up the hierarchy, until thousands of minor matters ended on the emperor's desk. Centralization of responsibility meant slowness of decision, and delays of many years were not unusual; death often provided the answer. There were also many antiquated, discriminatory, and contradictory laws. Large categories of the population, such as Jews and members of heretical Christian sects, suffered from various legal disabilities. Since not all of those discriminated against were poor and since many small officials were unable to support their families, bending or evasion of the law had its market price, and the needy official had a supplementary source of income. Corruption of this sort existed on a mass scale. To a certain extent it was a redeeming feature of the regime: if there had been less corruption the government would have been even slower, less efficient, and more oppressive than it was.

Social classes. No significant changes were made in the condition of the serfs in the first half of the century. Alexander I, perhaps from fear of the nobility and with the memory of his father's fate in mind, approached the problem with caution, though with a desire for reform, but first war and then diplomacy diverted him. His successor, Nicholas, disliked serfdom, but there were politi-

and
autocracy

cal hazards in eliminating it. The power of the central government extended down to the provincial governors and, more tenuously, down to the *ispravnik*, or chief official of the district, of which each province had about three or four. The *ispravnik* was elected by the local nobility. Below the level of the district, the administration virtually ceased to operate: the sole authority was the serf owner. If serfdom were to be abolished, some other authority would have to be put in its place, and the existing bureaucratic apparatus was plainly inadequate. The Decembrist conspiracy in 1825 had greatly increased the tsar's distrust of the nobility. He was determined to avoid public discussion of reform, even within the upper class.

The one important exception to the general picture of bureaucratic stagnation was the creation of the Ministry of State Domains, under Gen. Pavel Kiselev. This became an embryonic ministry of agriculture, with authority over peasants who lived on state lands. These were a little less than half the rural population: in 1858 there were 19,000,000 state peasants and 22,500,000 private serfs. Kiselev set up a system of government administration down to the village level and provided for a measure of self-government under which the mayor of the *volost* (a district grouping several villages or peasant communes) was elected by male householders. There was also to be a *volost* court for judging disputes between peasants. Kiselev planned to improve medical services, build schools, establish warehouses for stocks of food in case of crop failure, and give instruction in methods of farming. Something was done in all these fields, even if less than intended and often in a manner that provoked hostility or even violent riots; the personnel of the new ministry was no more competent than the bureaucracy as a whole.

Opposition
to serfdom

Only minor measures were taken to benefit the serfs on private estates. Opposition to serfdom grew steadily, however, not only among persons of European outlook and independent thought, but also among high officials. It seemed not only unjust but intolerable that in a great nation men and women could be owned. Serfdom was also obviously an obstacle to economic development. Whether serfdom was contrary to the interests of serf owners is a more complex question. Those who wished to abolish it argued that it was, since their best hope of getting the nobility to accept abolition lay in convincing them that their self-interest required it. Certainly in parts of southern Russia where the soil was fertile, labour was plentiful, and potential profits in the grain trade with Europe were high, a landowner would do better if he could replace his serfs by paid agricultural labour and be rid of obligations to those peasants whom he did not need to employ. In other regions, where the population was scanty, serfdom provided the landowner with an assured labour supply; if it were abolished, he would have to pay more for his labour force or see it melt away. In large parts of northern Russia where the land was poor, many serfs made a living from various crafts—in cottage industry or even in factories—and from their wages had to pay dues to their masters. The abolition of serfdom would deprive the serf owner of this large income and leave him with only what he could make from farming and from tenants with rather poor economic prospects. On balance, it seems likely that the short-term interests of the great majority of serf owners favoured the maintenance of serfdom, and, in any case, there is no doubt that this is what most serf owners believed.

Industry and trade made slow progress during these years. In the latter part of the 18th century, Russia had been, thanks to its Urals mines, one of the main producers of pig iron. In the next 50 years, it was left far behind by Great Britain, Germany, and the United States. In cotton textiles and sugar refining, Russia was more successful. Count Ye.F. Kankrin, minister of finance from 1823 to 1844, tried to encourage Russian industry by high protective tariffs. He also set up schools and specialized institutes for the advancement of commerce, engineering, and forestry. Russia's exports of grain increased substan-

tially, though its share of total world trade remained about the same in 1850 as in 1800. The first railways also appeared; rail traffic between St. Petersburg (now Leningrad) and Moscow was opened in 1851. The road system remained extremely inadequate, as was demonstrated in the Crimean War.

The urban population grew significantly. There were a few prosperous merchants, well protected by the government. Some centres, such as Ivanovo, in central Russia, with its textile industry, had the beginnings of an industrial working class. The rest of the inhabitants of the cities consisted of small tradesmen and artisans, together with serfs living in town with their owners' permission as household servants or casual labourers.

Education and intellectual life. Alexander I's School Statute (1804) provided for a four-tier system of schools from the primary to the university level, intended to be open to persons of all classes. Under its provisions, several new universities were founded, and gymnasiums (pre-university schools) were established in most provincial capitals. Less was done at the lower levels, for the usual reason of inadequate funds. In the latter part of Alexander's reign, education was supervised by Prince A.N. Golitsyn, head of the ministry of education and spiritual affairs. In an effort to combat what he believed to be dangerous irreligious doctrines emanating from western Europe, Golitsyn encouraged university students to spy on their professors and on each other; those who taught unacceptable ideas were frequently dismissed or threatened with prison. Under Nicholas I there was some improvement. Count Sergey Uvarov, minister of education from 1833 to 1849, permitted a much freer intellectual atmosphere, but he also began the practice of deliberately excluding children of the lower classes from the gymnasiums and universities, which was continued under his successors.

Nevertheless, in increasing numbers the children of minor officials, small tradesmen, and especially priests, were acquiring education. Together with the already Europeanized nobility, they began to form a new cultural elite. Direct political criticism was prevented by the censorship of books and periodicals. Petty police interference made life disagreeable even for writers who were not much concerned with politics. Aleksandr Pushkin, Russia's greatest poet, got into trouble with the police for his opinions in 1824; he was also a friend of some leading Decembrists. After 1826 he lived an unhappy life in St. Petersburg, tolerated but distrusted by the authorities, producing magnificent poetry until he met his death in a duel in 1837. The writers Mikhail Lermontov and Nikolay Gogol were also objects of suspicion to the bureaucrats.

The censorship was not always efficient, and some of the censors were liberal. It became possible to express political ideas in the form of philosophical arguments and literary criticism. Thus, it was partly in intellectual periodicals and partly in discussions in the private houses of Moscow noblemen that the controversy between "westernizers" and "Slavophiles" developed. It began with the publication of a "philosophical letter" by Pyotr Chaadayev in the periodical *Teleskop* in 1836. One of the most penetrating essays ever written about Russia's historical heritage, it argued that Russia belonged neither to West nor to East, neither to Europe nor to Asia:

Standing alone in the world, we have given nothing to the world, we have learnt nothing from the world, we have not added a single idea to the mass of human ideas; we have made no contribution to the progress of the human spirit, and everything that has come to us from that spirit, we have disfigured. . . . Today we form a gap in the intellectual order.

Nicholas declared that Chaadayev must be mad and gave orders that he should be confined to his house and regularly visited by a doctor. This humiliating but relatively mild treatment silenced him.

It is misleading to represent the westernizers as wishing slavishly to copy all things Western or the Slavophiles as repudiating Europe and rejecting reform. The chief Slavophiles—Aleksy S. Khomyakov, the brothers Ivan and Pyotr Kireyevsky, and the brothers Konstantin and Ivan

Western-
izers and
Slavophiles

Aksakov — were men of deep European culture and bitter opponents of serfdom. Indeed, as landowners they knew more about the problems and sufferings of the serfs than many westernizers. The leading westernizers — Aleksandr Herzen, Vissarion Belinsky, and Mikhail Bakunin — were for their part profoundly Russian. Belinsky was ill at ease with foreigners, and Herzen and Bakunin, despite many years' residence in France, Germany, England, and Italy, remained not only hostile to the world of European bourgeois liberalism and democracy but also strangely ignorant of it.

The difference between westernizers and Slavophiles was essentially that between doctrinaire radicals and empirical conservatives, a familiar theme in the history of most European nations. It was the difference between those who wished to pull the whole political structure down and replace it by a new building, according to their own admirable blueprints, and those who preferred to knock down some parts and repair and refurnish others, bit by bit. Another basic difference was that the Slavophiles were Orthodox Christians and the westernizers either atheists or, like the historian T.N. Granovsky, deists with their own personal faith. Belinsky described the Orthodox Church, in his famous "Letter to Gogol" (1847) as "the bulwark of the whip and the handmaid of despotism." He maintained that the Russian people was "by its nature a profoundly atheistic people," and that they viewed the priesthood with contempt. These were but half-truths: the church was indeed subject to the government and upheld autocracy, and priests were often unpopular; but this did not mean that the peasants and a large part of the upper and middle classes were not devoted to the Orthodox faith.

The Slavophiles idealized early Russian history. They believed that there had once been a happy partnership between tsar and people: the tsar had consulted the people through their elected spokesmen in the *zemsky sobor*. This had been changed by Peter the Great when he sought to copy foreign models and interposed an alien bureaucracy, staffed largely by Germans, between himself and his people. The Slavophiles held that Russia should return to the way from which it had strayed under Peter. They asked not for a legislative body of the Western type, still less for parliamentary government, but for a consultative assembly to advise the emperor. This was quite unacceptable to Nicholas, who was proud of Peter the Great and believed himself his political heir. To the westernizers, on the other hand, Peter the Great was a symbol of radical change, not of autocracy.

The Russian Empire. Russia in the 19th century was both a multilingual and a multireligious empire. Only about half the population were at the same time Russian by language and Orthodox by religion. The Orthodox were to some extent privileged in comparison with the other Christians; all Christians enjoyed a higher status than Muslims; and the latter were not so disadvantaged as the Jews. The basis of legitimacy was obedience to the tsar: Nicholas expected all his subjects to obey him, but he did not expect non-Russians to become Russians. Admittedly, he detested the Poles, but that was because they had been disloyal subjects and revolted against him.

The idea that Russians, as such, should have a status superior to that of other peoples of the empire was distasteful to Nicholas. Russian nationalism nevertheless received some support from Count Uvarov, who, in his famous report to the tsar in 1832, proclaimed three principles as "truly Russian": autocracy, Orthodoxy, and the national principle (*narodnost*). In 1833 Uvarov set up a new university in Kiev, to be the centre for a policy of spreading Russian language and culture through the schools in the western provinces, at the expense of the Polish. Nicholas approved of this, for the Poles had been guilty of rebellion. But when the attempt was made to russify the Germans of the Baltic provinces, he objected. The Baltic Germans were loyal subjects and provided admirable officers and officials: they must be allowed to preserve their German culture and to maintain their cultural and social domination over the Estonians and Latvians. The young Slavophile and landowning nobleman

Yury Samarin, a junior official in Riga, was severely reprimanded by the Emperor for his anti-German activities.

The most revolutionary of the Decembrist leaders, Pavel Pestel, had insisted that all non-Russian peoples of the empire except the Poles should "completely fuse their nationality with the nationality of the dominant people." Another group of Decembrists, however, the Society of United Slavs, believed in a federation of free Slav peoples, including some of those living under Austrian and Turkish rule. In 1846 this idea was put forward in a different form in the Brotherhood of Cyril and Methodius, in Kiev. This group, among whose members was the Ukrainian poet Taras Shevchenko, believed that a federation of Slav peoples should include the Ukrainians, whom they claimed were not a part of the Russian nation but a distinct nationality. The society was crushed by the police, and Shevchenko was sent as a private soldier to the Urals; Nicholas himself gave orders that the great poet should be forbidden to write or draw. But Ukrainian national consciousness, though still confined to an educated minority, was growing; and nothing did more to crystallize Ukrainian as a literary language than Shevchenko's poetry.

During the first half of the century Russia made substantial conquests in Asia. In the Caucasus, the kingdom of Georgia united voluntarily with Russia in 1801, and other small Georgian principalities were conquered in the next years. Persia ceded northern Azerbaijan, including the peninsula of Baku, in 1813 and the Armenian province of Erivan (Yerevan) in 1828. The mountain peoples of the northern Caucasus, however, proved more redoubtable. The Chechens, led by the Shaykh Shāmil, resisted Russian expeditions from 1834 until 1859, and the Circassians were not finally crushed until 1864. In the 1840s, Russian rule was established over the pastoral peoples of Kazakhstan. In the Far East, Russian ships explored the lower course of the Amur River and discovered the straits between Sakhalin and the mainland of Asia in 1849. The Russian-American Company, founded in 1799, controlled part of the coast and islands of Alaska.

Foreign policy. At the beginning of the 19th century, Russian foreign policy was essentially concentrated on the three western neighbour countries with which it had been preoccupied since the 16th: Sweden, Poland, and Turkey. The policy toward these countries also determined Russian relations with France, Austria, and Great Britain.

Russo-Swedish relations were settled during the Napoleonic era. When Napoleon met with Alexander at Tilsit, he gave the latter a free hand to proceed against Sweden. After two years of war, in which the Russians did not always fare well, the Swedish government ceded Finland to the Tsar in 1809. Alexander became grand duke of Finland, but Finland was not incorporated into the Russian Empire, and its institutions were fully respected. In 1810, when Napoleon's former marshal, Bernadotte, was elected heir to the Swedish throne, he showed no hostility to Russia. In 1812 he made an agreement recognizing the Tsar's position in Finland in return for the promise of Russian support in his aim to annex Norway from Denmark. Bernadotte achieved this in the Treaty of Kiel of 1814, and thereafter the relations between Russia and Sweden, now a small and peaceful state, were not seriously troubled.

Alexander I, influenced by his Polish friend Prince Adam Czartoryski, had plans for the liberation and unity of Poland, which had ceased to exist as a state in the 18th century, when it had been partitioned among Russia, Prussia, and Austria. After his defeat by Napoleon in 1805, he abandoned those plans in favour of an alliance with Prussia. In 1807 Napoleon established a dependency called the Grand Duchy of Warsaw and in 1809 increased its territory at the expense of Austria. Alexander's attempts to win the Poles to his side in 1811 and to persuade Austria to make concessions to them failed; when Napoleon invaded Russia in 1812, he had 100,000 first-class Polish troops fighting for him. After Napoleon's defeat Alexander was not vindictive. He protected the Poles against the demands of Russian nationalists who

wanted revenge, and sought once more to create a large Polish kingdom comprising the territories annexed by Russia and Prussia in the partitions of the 18th century. He was opposed at the Congress of Vienna in 1814–15 by Austria and Britain, and the ensuing kingdom of Poland, which, though nominally autonomous, was to be in permanent union with the Russian Empire, consisted of only part of the Prussian and Russian conquests. Alexander was popular in Poland for a time after 1815. But real reconciliation between Poles and Russians was made impossible by their competing claims for the borderlands, which had belonged to the former Grand Duchy of Lithuania. The majority of the population of this region was Belorussian, Ukrainian, or Lithuanian; its commercial class was Jewish; and its upper classes and culture were Polish. Neither Russians nor Poles considered Belorussians, Ukrainians, or Lithuanians to be nations, entitled to decide their own fates: the question was whether Lithuania was to be Polish or Russian. Russians could argue that most of it had been part of "the Russian land" until the 14th century, and the Poles that it had been Polish since the 16th. Alexander had some sympathy for the Polish point of view and allowed the Poles to hope that he would reunite these lands with Poland, but the effective political forces in Russia were strongly opposed to any change. The disappointment of Polish hopes for Lithuania was probably the most important single cause of the growing tension between Warsaw and St. Petersburg in the late 1820s, which culminated in the revolt of the Poles in November 1830 and the war of 1831 between Polish and Russian armies. It ended in the defeat of the Poles and the exile of thousands of political leaders and soldiers to western Europe. Poland's constitution and, thus, its autonomy were abrogated; and there began the policy of russification of Poland.

International reactions to the Russo-Polish war were of some importance. There was much public sympathy for the Poles in France and Britain, but this had no influence on Russian actions. On the other hand, the governments of Prussia and Austria strongly supported Russia. It is arguable that the cooperation among the three monarchies, which continued over the next two decades and was revived from time to time later in the century, had less to do with their eloquently proclaimed loyalty to monarchical government than with their common interest in suppressing the Poles.

Balkan problems

Turkey had long been the main object of Russian territorial expansion; through a certain inertia of tradition, the Turkish policy had become almost automatic. It was to some extent reinforced by religious motives—by the romantic desire to liberate Constantinople, the holy city of Orthodoxy—but more important in the mid-19th century was the desire to assure the exit of Russian grain exports through the Black Sea. During certain periods, Russia sought to dominate Turkey as a powerful ally: this was its policy from 1798 to 1806 and again from 1832 to 1853. When this policy was successful, Russia supported the integrity of the Ottoman Empire and made no territorial demands. When it was not successful, Russia sought to undermine Turkey by supporting rebellious Balkan peoples or, more directly, by war: this was the case from 1806 to 1812, from 1828 to 1829, and from 1853 to 1856.

The periods of cooperation were more profitable for Russia than those of conflict. In the first period, a promising foothold was established in the Ionian Islands, which had to be abandoned after the Treaty of Tilsit. In the second period, Russia achieved a great success with the 1833 Treaty of Hünkâr iskelesi, which in effect opened the Black Sea Straits to Russian warships. It achieved a more limited but more durable gain by the Straits Convention of 1841, signed by all the Great Powers and by Turkey, which forbade the passage of foreign warships through either the Dardanelles or the Bosphorus as long as Turkey was at peace, thus protecting Russia's position in the Black Sea unless it was itself at war with Turkey.

In the periods of hostility between Russia and Turkey, the main object of Russian expansion was the area later known as Romania—the Danubian principalities of

Moldavia and Walachia. In 1812 Moldavia was partitioned between Russia and Turkey: the eastern half, under the name of Bessarabia, was annexed to Russia. In the war of 1828–29, Russian armies marched through the principalities and afterward remained in occupation until 1834. In 1848 the Russians returned, with Turkish approval, to suppress the revolution that had broken out in Bucharest. It appeared to be only a matter of time before the two Romanian principalities were wholly annexed to Russia. This did not occur, however, because of Russia's defeat in the Crimean War.

The Crimean War (1853–56) pitted Russia against Great Britain, France, and Turkey. It arose from a series of misunderstandings and diplomatic errors among the powers in their conflict of interests in the Near East, particularly over Turkish affairs. It has been called "the unnecessary war." The fact that it was fought in the Crimea was due to Austrian diplomacy. In June 1854 the Russian government accepted the Austrian demand that Russian troops be withdrawn from the Danubian principalities, and in August Austrian troops entered. It is arguable whether, on balance, the presence of Austrian troops benefitted Russia by preventing French and British forces from marching on the Ukraine or whether it damaged Russia by preventing its troops from marching on Constantinople. The tsar resented the Austrian action as showing ingratitude toward the power that had saved Austria from the Hungarian rebels in 1849. When the British and French were unable to attack in the principalities, they decided to send an expedition to the Crimea to destroy the Russian naval base at Sevastopol. It was here that the war dragged out its course. The war showed the inefficiency of Russia's top military command and of its system of transport and supply. The Russian armies, nevertheless, won victories over the Turks in the Caucasus; and the defense of Sevastopol for nearly a year was a brilliant achievement.

FROM ALEXANDER II TO NICHOLAS II

Emancipation and reform. Defeat in the Crimea made Russia's backwardness clear, and the first step toward modernization was the abolition of serfdom. It seemed to the new tsar Alexander II (reigned 1855–81) that the dangers to public order of dismantling the existing system, which had deterred Nicholas I from action, were less than the dangers of leaving things as they were. As the Tsar said to the nobility of Moscow in March 1856, "it is better to abolish serfdom from above than to wait until the serfs begin to liberate themselves from below." The main work of reform was carried out in the ministry of the interior, where the most able officials, headed by the deputy minister Nikolay Milyutin, were resolved to get the best possible terms for the peasants. In this they were assisted by a few progressive landowners, chief among whom was the Slavophile Yuri Samarin; but the bulk of the landowning class was determined, if it could not prevent abolition of serfdom, to give the freed peasants as little as possible. The settlement, proclaimed on March 3 (February 19, old style), 1861, was a compromise. Peasants were freed from servile status, and a procedure was laid down by which they could become owners of land. The government paid the landowners compensation and recovered the cost in annual "redemption payments" from the peasants. The terms were unfavourable to the peasants in many, probably most, cases. In the north, where land was poor, the price of land on which the compensation was based was unduly high: in effect this served to compensate the landowners for the loss of their serfs and also for the loss of the share that they had previously enjoyed of the peasants' earnings from nonagricultural labour. In the south, where land was more valuable, the plots given to the peasants were very small, often less than they had had for their use when they were serfs.

The emancipation of the serfs

It is arguable that the main beneficiary of the reform was neither peasant nor landowner, but the state. A new apparatus of government was established to replace the authority of the serf owner. From the *ispravnik*, the chief official of the district, who in 1862 ceased to be elected by

the nobility and became an appointed official of the ministry of the interior, the official hierarchy now stretched down to the village notary, the most powerful person at this level, who was assisted by an elder elected by an assembly of householders. The lowest effective centre of power was the village commune (*obshchina*), an institution of uncertain origin but great antiquity, which had long had the power to redistribute land for the use of its members and to determine the crop cycle, but which now also became responsible for collecting taxes on behalf of the government.

Further important reforms followed the emancipation. A new system of elected assemblies at the provincial and county levels was introduced in 1864. These assemblies, known as *zemstvos*, were elected by all classes including the peasants, although the landowning nobility had a disproportionately large share of both the votes and the seats. The *zemstvos* were empowered to levy taxes and to spend their funds on schools, public health, roads, and other social services, but their scope was limited by the fact that they also had to spend money on some of the tasks of the central government. In 1864 a major judicial reform was completed. Russia received a system of law courts based on European models, with irremovable judges and a proper system of courts of appeal. Justices of the peace were instituted for minor offenses; they were elected by the county *zemstvos*. A properly organized, modern legal profession now arose, and it soon achieved very high standards. The old system of endless delays and judicial corruption rapidly disappeared. There were, however, two important gaps in the system: one was that the ministry of the interior had power, regardless of the courts, to banish persons whom it regarded as politically dangerous; the other was that the courts for settling disputes between peasants were maintained and operated on the basis of peasant custom. Their institution by Kiselev in the 1840s had been a well-intentioned reform, but their continuation after emancipation meant that the peasants were still regarded as something less than full citizens.

During the first years of Alexander II's reign there was some demand from a liberal section of the nobility for representative government at the national level—not for full parliamentary rule, still less for a democratic suffrage, but for some sort of consultative assembly in which public issues could be debated and which could put before the Emperor the views of at least the educated section of the Russian people. The tsar and his bureaucrats refused to consider this. The principle of autocracy must remain sacred. Such was the view not only of bureaucrats but of such men as Nikolay Milyutin and Yuri Samarin, both of whom rested their hopes for the progressive reforms they so ardently desired on the unfettered power of the Emperor. Their attitude was essentially that of Pavel Stroganov at the beginning of the century, that the sovereign must not have "his arms tied" and so be prevented from realizing "the plans which he had in favour of the nation." The decision against a national assembly in the early 1860s was a negative event of the greatest importance: it deprived Russia of the possibility of public political education such as that which existed, for example, in contemporary Prussia, and it deprived the government of the services of hundreds of talented men.

Revolutionary activities. The emancipation was received with bitter disappointment by many peasants as well as by the radical intellectuals. The serfs' view of their relationship to the landowners had been traditionally summed up in the phrase: "We are yours, but the land is ours." Now they were being asked to pay for land that they felt was theirs by right. During the 1860s small revolutionary groups began to appear. The outstanding figure was the socialist writer N.G. Chernyshevsky; the extent of his involvement in revolutionary action remains a subject of controversy, but of his influence on generations of young Russians there can be no doubt. In 1861 and 1862 revolutionary leaflets were distributed in St. Petersburg, ranging from the demand for a constituent assembly to a passionate appeal for insurrection. The Polish uprising of 1863 strengthened the forces of repression. An unsuccessful attempt on the tsar's life in 1866

led to a certain predominance, among Alexander's advisers, of extreme conservatives. Nevertheless, there were still some valuable reforms to come. In 1870 the main cities of Russia were given elected municipal government (on a very narrow franchise), and in 1874 a series of military reforms was completed by the establishment of universal military service. This was the work of Dmitry Milyutin, the brother of Nikolay and like him a liberal, who was minister of war from 1861 to 1881.

In the 1870s revolutionary activity revived. Its centre was the university youth, who were increasingly influenced by a variety of socialist ideas derived from Europe but adapted to Russian conditions. These young people saw in the peasantry the main potential for revolutionary action. In 1873 and 1874 hundreds of the youth, including women, "went to the people," invading the countryside and seeking to rouse the peasants with their speeches. The peasants did not understand, and the police arrested the young revolutionaries. Some were sentenced to prison, and hundreds were deported to remote provinces or to Siberia. It became clear that no progress could be expected from overt action: conspiratorial action was the only hope. In 1876 a new party was founded that took the title of Land and Freedom. Some of its members favoured assassination of prominent officials in reprisal for the maltreatment of their comrades and also as a means to pressure the government in order to extract Western-type political liberties. Experience also had shown them that while the peasants were physically too scattered to be an effective force, and in any case too apathetic, the workers in the new industrial cities offered a more promising audience. This faction was opposed by others in the party who deprecated assassination, continued to pay more attention to peasants than to workers, and were indifferent to the attainment of political liberties. In 1879 the party split. The politically minded and terrorist wing took the name People's Will and made its aim the assassination of Alexander II. After several unsuccessful attempts it achieved its aim on March 13 (March 1, O.S.), 1881, when the tsar was fatally wounded by a bomb while driving through the capital. All the main leaders of the group were caught by the police, and five of them were hanged.

Shortly before his death the Tsar had been considering reforms that would have introduced a few elected representatives into the apparatus of government. His successor, Alexander III (reigned 1881–94), considered these plans. Under the influence of his former tutor, Konstantin Pobedonostsev (*q.v.*), the procurator of the Holy Synod, he decided to reject them and to reaffirm the principle of autocracy without change. In 1882 he appointed Dmitry Tolstoy minister of interior. Tolstoy and Pobedonostsev were the moving spirits of the deliberately reactionary policies that followed. Education was further restricted, the work of the *zemstvos* was hampered, and the village communes were brought under closer control in 1889 by the institution of the "land commandant" (*zemsky nachalnik*)—an official appointed by the ministry of interior, usually a former officer or a local landowner, who interfered in all aspects of peasant affairs. The office of elected justice of the peace was abolished, and the government was authorized to assume emergency powers when public order was said to be in danger. By this time Russian public officials were better paid and educated, and less addicted to crude corruption, than they had been in the reign of Nicholas I, but they retained their arrogant contempt for the public and especially for the poorer classes. The discriminatory laws against Jews and members of dissenting Christian sects remained a source of widespread injustice, hardship, and resentment.

The repressive policies of Dmitry Tolstoy worked for a time. But the economic development of the following decades created new social tensions and brought into existence new social groups, from whom active opposition once more developed. The *zemstvos* were in growing conflict with the central authorities. Even their efforts at social improvement of a quite unpolitical type met with obstruction. The ministry of the interior, once the centre of Russia's best reformers, now became a stronghold of

Introduction of the *zemstvos*

Attempts at repression

From reform to terrorism

resistance. In the obscurantist view of its leading officials, only the central government had the right to care for the public welfare, and *zemstvo* initiatives were undesirable usurpations of power. Better that nothing should be done at all than that it should be done through the wrong channels. This attitude was manifested in 1891, when crop failures led to widespread famine and relief work by *zemstvo* officials met with government obstruction. The revival of political activity may be dated from this year. It was accelerated by the death of Alexander III in 1894 and the succession of his son Nicholas II (reigned 1894–1917), who commanded less fear or respect but nevertheless at once antagonized the *zemstvo* liberals by publicly describing their aspirations for reforms as "senseless dreams." In the late 1890s moderate liberalism, aiming at the establishment of a consultative national assembly, was strong among elected *zemstvo* members who were largely members of the landowning class. A more radical attitude, combining elements of liberalism and socialism, was to be found in the professional classes of the cities, including many persons employed by the *zemstvos* as teachers, doctors, engineers, or statisticians. The growth of an industrial working class provided a mass basis for socialist movements, and by the end of the century some interest in politics was beginning to penetrate even to the peasantry, especially in parts of the Middle Volga Valley.

Economic and social development. Liberation from serfdom was a benefit for the peasants that should not be underrated. The decades that followed brought a growth of prosperity and self-reliance to at least a substantial minority. In 1877, when about four-fifths of the land due to be transferred to the former serfs was actually in their possession, this "allotment land" constituted about half of the arable land in 50 provinces of European Russia. A further one-third of the arable land was still owned by the nobility, and the rest belonged to a variety of individual or collective owners. In 1905 substantially more than half the arable land was in allotment land and another 10 percent belonged to individual peasants or to peasant associations; the nobility's share of arable land had fallen to a little more than 20 percent. Peasant land had increased by more than 40,000,000 hectares between 1877 and 1905, of which more than half had been obtained by purchase from landowners and the remainder by the completion of the transfer of allotment land. Peasant purchases had been assisted by loans from the Peasants' Land Bank, set up by the government in 1882. The Nobles' Land Bank, set up in 1885, made loans to landowners at more favourable rates of interests; it may have retarded, but did not prevent, the passage of land from landowners to peasants. In 1894 the rate of interest charged by the two banks was equalized.

Though many peasants improved their position, agriculture remained backward, and poverty increased more rapidly than prosperity. One of the main reasons for this was the indifference of the government to agriculture. The government's economic policy was motivated by the desire for national and military power. This required the growth of industry, and great efforts were made to encourage it. Agriculture was regarded mainly as a source of revenue to pay for industry and the armed forces. Exports of grain made possible imports of raw materials, and taxes paid by peasants filled the state's coffers. The redemption payments were a heavy charge on the peasants' resources, though a gradual fall in the value of money appreciably reduced it with the passage of years. Consumption taxes, especially on sugar, tobacco, matches, and oil, affected the peasants, and so did import duties. In 1894 the government introduced a liquor monopoly that drew enormous revenues from the peasants, to whom vodka was a principal solace in a hard life. The techniques and tools of agriculture remained extremely primitive, and farm output low; virtually nothing was done to instruct peasants in modern methods.

The second main cause of peasant poverty was overpopulation. The vast landmass of Russia was, of course, sparsely populated, but the number of persons employed in agriculture per unit of arable land, and relative to

output, was extremely high as compared to western Europe. There was a vast and increasing surplus of labour in the Russian villages. Outlets were available in seasonal migration to the southern provinces, where labour was needed on the great estates that produced the grain that Russia exported; and peasants could move permanently to new land in Siberia, which at the end of the century was absorbing a yearly influx of 200,000; or they could find seasonal work in the cities or seek permanent employment in the growing industrial sector. These alternatives were not enough to absorb the growing labour surplus, which was most acute in the southern part of central Russia and in the northern Ukraine, in the provinces of Kursk and Poltava. Peasants competed with each other to lease land from the landlords' estates; this drove rents up; the existence of the large estates became more and more resented; and class feeling began to take the form of political demands for further redistribution of land.

The difficulties of agriculture were also increased by the inefficiency of the peasant commune, which had the power to redistribute holdings according to the needs of families and to dictate the rotation of crops to all members. In doing so, it tended to hamper enterprising farmers and protect the incompetent. In defense of the commune it was argued that it ensured a living to everyone and stood for values of solidarity and cooperation that were more important than mere profit and loss. Russian officials also found it useful as a means of collecting taxes and keeping the peasants in order. The 1861 settlement did provide a procedure by which peasants could leave the commune, but it was very complicated and was little used. In practice, the communal system predominated in northern and central Russia, and individual peasant ownership was widespread in the Ukraine and in the Polish borderlands. In 1898, in 50 provinces of European Russia, about 80,000,000 hectares of land were under communal tenure, and about 22,000,000 were under individual tenure.

The dispute over the peasant commune divided the ranks both of officialdom and of the government's revolutionary enemies. The ministry of the interior, which stood for paternalism and public security at all costs, favoured the commune in the belief that it was a bulwark of conservatism, of traditional Russian social values, and of loyalty to the tsar. The Socialist Revolutionaries favoured it because they took the view that the commune was, at least potentially, the natural unit of a future socialist republic. The ministry of finance, concerned to develop capitalism in town and country, objected to the commune as an obstacle to economic progress; it hoped to see a prosperous minority of individual farmers as a basis of a new and more modern type of Russian conservatism. The Social Democrats agreed that the commune must and should be replaced by capitalist ownership, but they saw this only as the next stage in the progress toward a socialist revolution led by urban workers.

The emancipation of the serfs undoubtedly helped capitalist development, though this began rather slowly. A rapid growth of railways came in the 1870s, and in the same decade the exploitation of petroleum began at Baku in Azerbaijan. There was also progress in the textile and sugar industries. Only in the 1890s did the demand for iron and steel, created by the railway program and by military needs in general, begin to be satisfied on a large scale within Russia. By the end of the century there was a massive metallurgical industry in the Ukraine, based on the iron ore of Krivoy Rog and the coal of the Donets Basin. The iron industry of the Urals, which lost a large part of its labour force when the serfs became free to leave, lagged far behind. Poland was also an important metallurgical centre. Textiles were concentrated in the central provinces of Moscow and Vladimir; by the end of the century they were drawing much of their raw cotton from the newly conquered lands of Central Asia. Baku was also booming, especially as a supplier of petroleum to the Moscow region. St. Petersburg had begun to develop important engineering and electrical industries. Count Sergey Witte (*q.v.*), minister of finance from 1892 to 1903, was able to put Russia on the gold standard in 1897 and to encourage foreign investors. French and Bel-

Difficulties

Industrial
growth

gian capital was invested mainly in the southern metallurgical industry, British in petroleum, and German in electricity.

Industrial growth began to produce an urban working class, which seemed fated to repeat the history of workers in the early stages of industrial capitalism in Western countries. The workers were unskilled, badly paid, overworked, and miserably housed. Uprooted from the village communities in which they had at least had a recognized place, the peasants' sons who flocked into the new industrial agglomerations suffered both physical and moral privation. This was especially true of central Russia, where the surplus of labour kept wages down to the minimum. It was in St. Petersburg, where employers found it less easy to recruit workers, that the transformation of the amorphous mass of urban poor into a modern working class made the most progress. St. Petersburg employers were also less hostile to government legislation on behalf of the workers. In 1882, Finance Minister N.Kh. Bunge introduced an inspectorate of labour conditions, and limited hours of work for children. In 1897, Count Witte introduced a maximum working day of 11½ hours for all workers, male or female, and of ten hours for those engaged in any night work. Trade unions were not permitted, though several attempts were made to organize them illegally. The ministry of the interior, being more interested in public order than in businessmen's profits, occasionally showed some concern for the workers. In 1901 the head of the Moscow branch of the security police, Col. S.V. Zubatov, encouraged the formation of a workers' society intended to rally the workers behind the autocracy; but it became largely infiltrated by Social Democrats. Strikes were strictly forbidden but occurred anyway, especially in 1885, 1896, 1902, and 1903.

A Russian business class also developed rapidly under the umbrella of government policy, benefitting especially from the high protective tariffs and the very high prices paid for government purchases from the metallurgical industry. Russia's industrial progress took place under private capitalism, but it differed from classical Western capitalism in that the motivation of Russian industrial growth was political and military, and the driving force was government policy. Russian and foreign capitalists provided the resources and the organizing skill, and they were richly rewarded. The richness of their rewards accounted for a second difference from classical capitalism: Russian capitalists were completely satisfied with the political system as it was. English and French capitalists had material and ideological reasons to fight against absolute monarchs and aristocratic upper classes; Russian businessmen accepted the principle and the practice of autocracy.

Education and ideas. At the time of the first modern census in Russia, in 1897, there were 104,000 persons who had attended or were attending a university—less than 0.1 percent of the population—and 73 percent of these were children of nobles or officials. The number who had studied or were studying in any sort of secondary school was 1,072,977, or less than 1 percent of the population, and 40 percent of these were children of nobles and officials. In 1904 primary schools managed by the ministry of education had rather more than 3,000,000 pupils, and those managed by the Orthodox Church not quite 2,000,000. The combined figure represented only 27 percent of the children of school age in the empire at that time. Persistent neglect of education could no longer be explained by sheer backwardness and lack of funds: the Russian empire of 1900 could have afforded a modern school system if its rulers had thought it important.

In the last half of the 19th century the word *intelligentsia* came into use in Russia. This word is not precisely definable, for it described both a social group and a state of mind. Essentially the *intelligentsia* consisted of persons with a good modern education and a passionate preoccupation with general political and social ideas. An uneducated or stupid man could not be a member of the *intelligentsia*, but not all educated and intelligent men could belong to it either; for example, a brilliant scientist devoted solely to his science would not be reckoned a member

of the *intelligentsia*. Its nucleus was to be found in the liberal professions of law, medicine, teaching, and engineering, which grew in numbers and social prestige as the economy became more complex; yet it also included individuals from outside those professions—private landowners, bureaucrats, and even army officers. The *intelligentsia* was by its very nature opposed to the existing political and social system, and this opposition coloured its attitude to culture in general. In particular, the value of works of literature was judged by the *intelligentsia* according to whether they furthered the cause of social progress. This tradition of social utilitarianism was initiated by the critic Vissarion Belinsky and carried further by N.A. Dobrolyubov in the late 1850s. Its most extreme exponent was Dmitry I. Pisarev, who held that all art was useless and that the only aim of thinking people should be "to solve forever the unavoidable question of hungry and naked people." In the last decades of the century the chief spokesman of social utilitarianism was the sociological writer Nikolay K. Mikhaylovsky, a former supporter of the terrorist group People's Will. It is hardly an exaggeration to say that Russian literature was faced with two censorships—that of the official servants of the autocracy and that of the social utilitarian radicals. Yet the great writers of this period—Leo Tolstoy, Fyodor Dostoyevsky, Aleksandr Blok, and the symbolist poets of the early 20th century—though profoundly concerned with social issues, did not conform to these criteria.

The *intelligentsia* did not consist of active revolutionaries, although it preferred the revolutionaries to the government; but it was from the *intelligentsia* that the professional revolutionaries were largely recruited. The lack of civil liberties and the prohibition of political parties made it necessary for socialists to use conspiratorial methods. Illegal parties had to have rigid centralized discipline. Yet the emergence of the professional revolutionary, imagined in romantically diabolical terms in the "Revolutionary Catechism" of Mikhail Bakunin and Sergey Nechayev in 1869 and sketched more realistically in *What Is To Be Done?* by Vladimir Ilyich Ulyanov, better known as Lenin, in 1902, was not entirely due to the circumstances of the underground political struggle. The revolutionaries were formed also by their sense of mission, by their absolute conviction that they knew best the interests of the masses. For these men and women, revolution was not just a political aim; it was also a substitute for religion. It is worth noting that a remarkably high proportion of the young revolutionaries of the late 19th century were children of Orthodox priests or persons associated with religious sects. It is also worth noting that the traditional Russian belief in autocracy, the desire for an all-powerful political saviour, and the contempt for legal formalities and processes had left its mark on them. The autocracy of Nicholas II was, of course, odious to them, but this did not mean that autocratic government should be abolished; rather, it should be replaced by the autocracy of the virtuous.

Russian revolutionary socialism at the end of the century was divided into two main streams, each of these being subdivided into a section that favoured conspiratorial tactics and one that aimed at a mass movement to be controlled by its members. The Socialist Revolutionaries (founded in 1901 from a number of groups more or less derived from People's Will) first hoped that Russia could bypass capitalism, and when it became clear that this could not be done, they aimed to limit its operation and build a socialist order based on village communes. The land was to be socialized but worked by peasants on the principle of "labour ownership." The Social Democrats (founded in 1898 from a number of illegal working-class groups) believed that the future lay with industrialization and a socialist order based on the working class. The Socialist Revolutionaries were divided between their extreme terrorist wing, the "Fighting Organization," and a broader and looser membership that at one end merged imperceptibly with radical middle-class liberalism. The Social Democrats were divided between Lenin's group, which took the name Bolshevik (derived from the Russian word for "majority," after a majority won by his

The
socialists

The
Russian
intelli-
gentsia

group at one particular vote during the second congress of the party, held in Brussels and London in 1903), and a number of other groups that were by no means united but that came to be collectively known as Menshevik (derived from the word for "minority"). The personal, ideological, and programmatic issues involved in their quarrels were extremely complex, but it is a permissible oversimplification to say that Lenin favoured rigid discipline while the Mensheviks aimed at creating a mass labour movement of the west European type; that the Mensheviks were much more willing to cooperate with nonsocialist liberals than were the Bolsheviks; and that Lenin paid much more attention to the peasants as a potential revolutionary force than did the Mensheviks.

Russification policies. After the Crimean War the Russian government made some attempt to introduce in Poland a new system acceptable to the Polish population. The leading figure on the Polish side was the nobleman Aleksander Wielopolski. His pro-Russian program proved unacceptable to the Poles. Tension increased and in January 1863 armed rebellion broke out. This was put down, being suppressed with special severity in the Lithuanian and Ukrainian borderlands. In order to punish the Polish country gentry for their part in the insurrection, the Russian authorities carried out a land reform on terms exceptionally favourable to the Polish peasants. Its authors were Nikolay Milyutin and Yury Samarin, who genuinely desired to benefit the peasants. The reform was followed, however, by a policy of russification intended to separate the Polish peasants from their own culture. In the 1880s this went so far that the language of instruction even in primary schools in areas of purely Polish population was Russian. At first, all classes of Poles passively accepted their defeat, while clinging to their language and national consciousness; but in the 1890s two strong, though of course illegal, political parties appeared—the National Democrats and the Polish Socialist Party, both fundamentally anti-Russian.

After 1863 the authorities also severely repressed all signs of Ukrainian nationalist activity. In 1876 all publications in Ukrainian, other than historical documents, were prohibited. In Eastern Galicia, however, which lay just across the Austrian border and had a population of several million Ukrainians, not only the language but political activity flourished. Here the great Ukrainian historian Mikhail Hrushevsky and the socialist writer Mikhail Drahomanov published their works; Ukrainian political literature was smuggled across the border. In the 1890s small illegal groups of Ukrainian democrats and socialists existed on Russian soil.

In the 1890s the government began to adopt a general policy of russification. It was no longer enough that the subjects of the tsar should obey him loyally: they were required to become Russians. The social driving force behind this policy was the growing bureaucracy, comprised mainly of children of landowning families who no longer owned estates. The Orthodox Church played an active part, since russification and imposition of Orthodoxy went naturally together. It must be recognized that russification had considerable support among all classes of the Russian population except the intelligentsia. Part of the large-circulation conservative press in particular was intensely nationalistic.

The main victims of russification were the very peoples that had shown consistent loyalty to the empire and now found themselves rewarded by being pressed to abandon their own culture. The Germans of the Baltic provinces were deprived of their university and their ancient secondary schools were russified. The Latvians and Estonians did not object to action by the government against the Germans, whom they had reason to dislike as landowners and rich burghers; but the prospect of the German language being replaced by the Russian had no attraction for them, and they strongly resented the pressure to abandon their Lutheran faith for Orthodoxy. The attempt to absorb and russify Finland united the Finns in opposition to St. Petersburg in the 1890s. In 1904 a Finnish terrorist murdered the Russian governor-general, and passive resistance to Russian policies was almost universal. Effec-

tive and widespread passive resistance also occurred among the traditionally Russophile Armenians of the Caucasus when the Russian authorities began to interfere with the organization of the Armenian church, and to close the schools maintained from its funds.

Of the Muslim peoples of the empire, those who suffered most from russification were the most economically and culturally advanced, the Tatars of the Volga Valley. Attempts by the Orthodox Church to convert Muslims, and the rivalry between Muslims and Orthodox to convert small national groups of Finno-Ugrian speech who were still pagans, caused growing mutual hostility. The Tatars had developed a substantial merchant class by the end of the century and the beginnings of a national intelligentsia. Modern schools, maintained from merchants' funds, were creating a new Tatar educated elite that was increasingly accessible to modern democratic ideas. In Central Asia, on the other hand, modern influences had barely made themselves felt. In those newly conquered lands, Russian colonial administration was paternalistic and limited: like the methods of "indirect rule" in the British and French empires, it made no systematic attempt to change old ways. Here there was no russification.

The position of the Jews was hardest of all. As a result of their history and religious traditions, as well as of centuries of social and economic discrimination, the Jews were overwhelmingly concentrated in commercial and intellectual professions. They were thus prominent both as businessmen and as political radicals, hateful to the bureaucrats as socialists and to the lower classes as capitalists. In the 1880s legal discrimination against them became more severe both in education and in economic life. It was at this time that the police began the practice of pogroms, or officially sponsored riots that led to the destruction of Jewish shops and to physical assaults on Jews—in some cases to killings. These were deliberately used by the authorities as a means of diverting popular discontent to a convenient scapegoat in order to diminish popular hostility to the government.

Foreign policy. During the second half of the 19th century, Russian foreign policy gave about equal emphasis to the Balkans and the Far East. The friendship with Germany and Austria weakened; and in the 1890s the Triple Alliance of Germany, Austria-Hungary, and Italy stood face to face with a dual alliance of France and Russia.

The demilitarization of the Black Sea coast that had resulted from the Crimean War was ended by the London Conference of 1871, which allowed Russia to rebuild its naval forces. In 1876 the Serbo-Turkish War produced an outburst of Pan-Slav feeling in Russia. Partly under its influence, but mainly in pursuit of traditional strategic aims, Russia declared war on Turkey in April 1877. After overpowering heavy Turkish resistance at the fortress of Plevna in Bulgaria, the Russian forces advanced almost to Constantinople. By the Treaty of San Stefano of March 1878 the Turks accepted the creation of a large independent Bulgarian state. Fearing that this would be a Russian vassal, giving Russia mastery over all the Balkans and the straits, Britain and Austria-Hungary opposed the treaty. At the international Congress of Berlin, held in June 1878, Russia had to accept a much smaller Bulgaria. This was regarded by Russian public opinion as a bitter humiliation, for which the German chancellor Bismarck was blamed. In 1885–87 a new international crisis was caused by Russian interference in Bulgarian affairs, with Britain and Austria-Hungary once more opposing Russia. Once more, Russia suffered a political reverse. In the 1890s, despite the pro-Russian sentiment of many Serbs and Bulgarians, neither country's government was much subject to Russian influence. In the crises that arose in connection with the Turkish Armenians and over Crete and Macedonia, Russian policy was extremely cautious and on the whole tended to support the Turkish government. In 1897 an Austro-Russian agreement was made on spheres of influence in the Balkans.

The attempt of Bismarck to restore Russo-German friendship through the Reinsurance Treaty of 1887, with

The repression of nationalities

The Balkans

a view to an ultimate restoration of the alliance of Russia, Germany, and Austria, did not survive Bismarck's fall from power in 1890. The Russian government, alarmed by indications of a closer cooperation between the Triple Alliance and Britain and by some signs of a pro-Polish attitude in Berlin, reluctantly turned toward France. The French needed an ally against both Germany and Britain; the Russians needed French capital, in the form both of loans to the Russian government and of investment in Russian industry. The Franco-Russian alliance was signed in August 1891 and was supplemented by a military convention. Essentially the alliance was directed against Germany, for it was only in a war with Germany that each could help the other.

Russia established diplomatic and commercial relations with Japan by three treaties between 1855 and 1858. In 1860, by the Treaty of Peking, Russia acquired from China a long strip of Pacific coastline south of the mouth of the Amur and began to build the naval base of Vladivostok. In 1867 the Russian government sold Alaska to the United States for \$7,200,000. The Treaty of St. Petersburg between Russia and Japan in 1875 gave Russia sole control over all of Sakhalin and Japan all the Kuril Islands.

The systematic Russian conquest of Turkistan, the region of settled population and ancient culture lying to the south of the Kazakh steppes, began in the 1860s. This was watched with distrust by the British authorities in India, and fear of Russian interference in Afghanistan led to the Anglo-Afghan War of 1878–80. In the 1880s, Russian expansion extended to the Turkmen lands on the east coast of the Caspian, whose people offered much stiffer military resistance. The Russian conquest of Merv in 1884 caused alarm in Calcutta, and in March 1885 a clash between Russian and Afghan troops produced a major diplomatic crisis between Britain and Russia. An agreement on frontier delimitation was reached in September 1885, and for the next decades Central Asian affairs did not have a major effect on Anglo-Russian relations.

War with
Japan

Much more serious was the situation in the Far East. In 1894–95 the long-standing rivalry between the Japanese and Chinese in Korea led to a war between the two Oriental empires, which the Japanese won decisively. Russia faced the choice between collaborating with Japan (with which relations had been fairly good for some years) at the expense of China, or assuming the role of protector of China against Japan. The tsar chose the second policy, largely under the influence of Count Witte. Together with the French and German governments, the Russians demanded that the Japanese return to China the Liaotung Peninsula, which they had taken in the treaty of peace. Russia then concluded an alliance with China in 1896, which included the establishment of a Russian-owned Chinese Eastern Railway to cross northern Manchuria from west to east, linking Siberia with Vladivostok, and administered by Russian personnel and a Russian police force with extraterritorial rights. In 1898 the Russian government went still further and acquired from China the same Liaotung Peninsula of which it had deprived the Japanese three years earlier. Here the Russians built a naval base in ice-free waters at Port Arthur. They also obtained extraterritorial rights of ownership and management of a South Manchurian railroad that was to stretch from north to south, linking Port Arthur with the Chinese Eastern Railway at the junction of Harbin. When in 1900 the European powers sent armed forces to relieve their diplomatic missions in Peking, besieged by the Boxer Rebellion, the Russian government used this as an opportunity to bring substantial military units into Manchuria. All of this bitterly antagonized the Japanese. They might have been willing, nonetheless, to write off Manchuria as a Russian sphere of influence provided that Russia recognize Japanese priority in Korea, but the Russian government would not do this. It was not so much that the tsar himself wished to dominate the whole Far East; it was rather that he was beset by advisers with several rival schemes and could not bring himself to reject any of them. The British government, fearing that

Russia would be able to establish domination over the Chinese government and so interfere with the interests of Britain in other parts of China, made an alliance with Japan in January 1902. Negotiations between Russia and Japan continued, but they were insincere on both sides. On the night of February 8/9, 1904, Japanese forces made a surprise attack on Russian warships in Port Arthur, and the Russo-Japanese War began.

THE LAST YEARS OF TSARDOM

Defeat and disorder. The Russo-Japanese War brought a series of Russian defeats on land and sea, culminating in the destruction of the Russian Baltic fleet in the Straits of Tsushima. Political discontent grew steadily at home. The efforts of the moderate *zemstvo* liberals to organize help for the war effort were discouraged by the authorities, and criticism of the government in the press and at public banquets grew bolder. On Sunday, January 22 (January 9, O.S.), 1905, a large crowd of workers, led by a priest named Georgy Gapon, who was active in one of the officially sponsored workers' societies, marched to the square in front of the Winter Palace. Troops opened fire and several hundred were killed or injured.

Bloody Sunday was followed by disorders in gathering momentum. There were strikes, workers' demonstrations, street fighting, peasant insurrections, and mutinies in both the army and navy. The disorders were especially violent in regions inhabited by non-Russians: in Poland, Latvia, Georgia, and parts of the Ukraine. There were also numerous pogroms, not only of Ukrainians and Russians against Jews but also of Tatars in Azerbaijan against Armenians. Armed bands of townsmen of various social origin, led by men of the extreme right, in many cases by policemen or priests, formed to fight against left-wing bands. These groups, known as Black Hundreds, were a prototype of the fascist gangs of central Europe in the 1930s. The revolutionary movement of 1905 reached its climax in October with a nationwide railway strike and the formation in St. Petersburg of a Soviet (council) of Workers' Deputies. Faced by the threat of collapse, the Tsar issued a manifesto promising to convoke a national Parliament. Count Witte, who had just successfully conducted peace negotiations at Portsmouth (New Hampshire), saving for Russia the northern half of Sakhalin and the Chinese Eastern Railway but ceding Port Arthur and the South Manchurian Railway, became Russia's first prime minister. In the following weeks a series of laws established the powers of the Parliament, called the State Duma, and the procedure for its election.

The Dumas. The election, held in April 1906 on a rather broad franchise, produced a Duma with a left-wing majority even though the Social Democrats and Socialist Revolutionaries had for the most part boycotted the election. The largest party, the Constitutional Democrats (Kadets), were the heirs to the earlier Union of Liberation (a group of nonsocialist radicals formed in 1903). The second largest, the Labour Group (*Trudoviki*), may be described as moderate socialists. The non-Russian peoples returned a large number of deputies, among them 40 Ukrainians and 30 Muslims. Russian conservatives were a tiny minority. Cooperation proved impossible between this assembly and the tsar's ministers, who were responsible to him only and could not be overthrown by Duma majorities. The reforms demanded by the Duma—redistribution of landowners' estates to peasants with or without compensation, amnesty for political prisoners, equal rights for Jews and for religious dissenters, autonomy for Poland—were unacceptable to the government. After two months of deadlock the tsar dissolved the Duma in July. For the next eight months the new premier, Pyotr Stolypin, ruled by decree. Peasant riots were ruthlessly suppressed, with hundreds executed by specially established courts-martial. By the beginning of 1907 the last stirrings of revolution were over; the discipline of the armed forces was restored, and the police functioned effectively. In February 1907 elections were held for a second Duma. This time the Social Democrats put up official candidates and won 65 seats, giving them the third largest representation after the *Trudoviki*

Revolutionary
disturbances of
1905

Popular
sentiment
and the
Dumas

(101) and the Kadets (92). Conservative groups had 63 seats, and the Octobrists, heirs to the moderate *zemstvo* liberals of the 1890s, had 32. The political centre of gravity thus lay still further to the left than it had in the first Duma. Cooperation again proved impossible. In June 1907 the tsar dissolved the second Duma and Stolypin changed the electoral law, restricting the franchise in favour of the upper classes against the peasants and in favour of the Russians as against the other nationalities.

The third and fourth Dumas were accordingly more conservative in their composition; the Kadets, the Socialists, and the non-Russians had a total of about a quarter of the seats. The regime that followed from 1907 to 1914 was, however, substantially different from that before 1905. On the one hand, the principle of autocracy was officially upheld: the tsar had complete control over military affairs and over the appointment of ministers; while many bureaucrats, from provincial governors down to local police officials, continued to treat the public with contempt, and even flouted the laws that they were supposed to administer. On the other hand, political parties now existed, with public meetings and open political debate in the Duma. The press was relatively free. Workers were able to form trade unions, although strikes were illegal. The central government no longer obstructed local governments; it even made substantial money grants to them for social services. Primary education was improving in quantity and quality. The government was less positive in its attitude toward the universities, and there were massive disorders accompanied by resignations of teachers in the University of Moscow in 1911. Though conditions and prospects did improve, there was still plenty for educated men and women to resent; and the alienation of the intelligentsia from the regime was only marginally reduced.

Stolypin's
reforms

Stolypin's main concern, apart from restoring order, was to improve agriculture. He introduced measures facilitating the dissolution of peasant communes and the formation of individual farms, with scattered strips consolidated in economically viable holdings. The events of 1905–06 had shattered the view, formerly held by ministry of interior officials, that the commune was a bulwark of conservative feeling. Since the political arguments in favour of the commune were no longer considered valid, the economic arguments against it carried more weight. The extent to which Stolypin's reforms benefitted the Russian peasants, or would have done so if the war had not come, is debatable. The Stolypin policy was, however, a recognition that it was worthwhile to put money, effort, and education into agriculture and that the countryside could no longer simply be milked for the benefit of other parts of the economy. The assassination of Stolypin in September 1911 deprived the regime of its one outstanding leader; thereafter the government reverted to the old pattern of a weak and irresolute tsar surrounded by intriguing bureaucrats and flatterers. In these years the religious adventurer Grigory Rasputin obtained great influence over the empress through his ability to check by some hypnotic power the hemophilia that afflicted her only son Aleksey.

These years also saw continued progress in industry and a marked tendency toward the formation of large concentrations of capital. In June 1912 the Duma introduced health insurance for industrial workers. In Siberia land of first quality was brought under cultivation, and a self-reliant farmer class began to grow up using modern machinery and efficient marketing cooperatives.

While the non-Russian peoples had made political and cultural gains in 1905 and 1906, these were reversed after 1907. Russification was one of the most important features of the policy of Stolypin and his successors. The Finns and the Volga Tatars suffered especially, though they resisted stubbornly. Ukrainian nationalism gained ground despite the efforts to repress it, and extended from its nucleus in the intelligentsia to embrace a growing section of both peasants and workers. In Central Asia the increasing colonization of the lands of the Turkic peoples by immigrants from European Russia caused bitter resentment.

War and the fall of the monarchy. After 1906 Russia pursued a policy of cooperation with Japan in the Far East. Conflicts with Great Britain in Persia, Afghanistan, and Tibet were mitigated by the Anglo-Russian Convention of 1907. The alliance with France was reaffirmed after massive French loans had been received in return for Russian diplomatic support to France in its conflict with Germany over Morocco. Russian policy became absorbed by Balkan affairs after the Bosnian crisis of 1908–09, in which Russia was publicly humiliated by Germany and forced to abandon its support for Serbia. In the ensuing years Russian diplomacy tried to organize an anti-Austrian block of Balkan states, including Turkey. This failed, but the organization of the Serbian–Greek–Bulgarian alliance against Turkey in 1912 was a success for Russia. The second Balkan War of 1913 again placed Bulgaria in the Austrian camp. When Austria made demands upon Serbia in the summer of 1914, Russia was faced by a terrible dilemma. If it abandoned Serbia, it would lose the whole of the Balkans, raising doubt as to its usefulness as an ally of France; in that event Russia would be likely to drift into the status of a satellite of Germany. The alternative was to escalate the Balkan conflict. By the conventional wisdom of 1914, Russia's choice of the second alternative must be considered reasonable; but it destroyed the imperial regime.

In 1914 the Franco-Russian alliance proved its value. The German Army could have crushed either France or Russia alone, but not both together. The Russian invasion of East Prussia was a failure, and in two unsuccessful battles the Russians lost nearly 150,000 as prisoners. It did, however, enable the French to win the First Battle of the Marne. In Galicia the Russian armies advanced far into Austrian territory. The entry of Turkey into the war as an ally of Germany was a major disaster, since it not only created a new front in the Caucasus (where the Russian armies did rather well), but, by closing the straits, enormously reduced the amount of supplies the allies could deliver to Russia. The Russian armies were seriously short of munitions. The failure of the British and French campaign in the Dardanelles and the entry of Bulgaria into the war on the German side meant that no relief could come from the south. In May 1915 the central powers launched their offensive in Poland and made enormous gains of territory. By the autumn Russia had lost more than 1,000,000 men.

These disasters aroused bitter discontent. A demand was raised, both in the Duma and in the press, for a "government commanding the confidence of the nation." The tsar ignored the demand; he insisted on assuming the supreme command of the armies in the field and left in the capital a collection of ministers of second-rate ability that could hardly be said to constitute a government at all. Economic conditions deteriorated. The mobilization of manpower disorganized both industry and agriculture; transport was overloaded; the military authorities interfered arbitrarily with civilian needs; prices rose much faster than wages; and there were serious shortages of goods, even of food. Working class discontent grew.

During 1916 the military situation improved. Gen. A.A. Brusilov advanced in Galicia and captured nearly 400,000 Austrian prisoners. Public discontent, however, increased. The official bureaucracy and the leaders of the *zemstvos* and municipalities wasted much energy in fighting each other. The ministers chosen by the tsar—in some cases probably on the advice of the empress and Rasputin—were exceptionally incompetent and unpopular. The murder of Rasputin in December 1916 probably made matters still worse by further demoralizing the emperor. In January 1917 the food supply in the capital worsened. At the beginning of March (February, O.S.) strikes, demonstrations, and food lines filled the streets with aimless crowds. Mutinies took place in some barracks—their origin remains obscure—and it became clear that the troops were not going to fire on crowds. The tsar refused for several days to appoint a "government of public confidence." In Petrograd (formerly St. Petersburg), a Soviet of Workers' and Soldiers' Deputies was formed; a standing committee was also set up by the

Out-
break of
First

War

Political
collapse

Duma, which the tsar had prorogued. By agreement between the Soviet and the Duma committee, a Provisional Government was formed, composed principally of Kadets and Octobrists, headed by Prince G.Ye. Lvov. On March 15 its emissaries reached Pskov, where the tsar had been held up in a vain attempt to return from military headquarters to Petrograd. Here he handed to them his abdication: the thousand-year-old Russian monarchy had come to its end. (H.S.-W.)

IV. The U.S.S.R. from 1917 to 1939

THE GOVERNMENTS OF 1917

Results of the February (March) Revolution. To fill the vacuum left by the collapse of the ancient Russian monarchy, the leaders of the recently dissolved Duma set up a Provisional Committee to maintain order and establish democratic reforms. The same day, March 12 (February 27, old style), leaders of the Petrograd workers and the rebellious garrison created the Petrograd Soviet of Workers' and Soldiers' Deputies, an unofficial but representative body elected by the factories and regiments and dominated at the outset by the Menshevik and Socialist Revolutionary parties. Similar soviets were quickly set up all over Russia on the Petrograd model. Unsure of their strength and convinced that Russia was still in the stage of the bourgeois revolution, the leaders of the soviet refrained from any claim to exercise governmental power.

Prodded by the potential challenge of the soviet, the Duma Committee on March 15 (March 2, O.S.) established the Provisional Government. Prince Georgy Lvov was designated prime minister; Pavel Milyukov, leader of the Constitutional Democratic Party, was foreign minister and the strong man of the Cabinet; Aleksandr Guchkov, leader of the conservative Octobrist Party, became war minister. Aleksandr Kerensky, a Duma deputy of the moderately socialist Labour Group, became minister of justice and the unofficial liaison man with the soviet.

The Provisional Government. The Provisional Government was faced with a series of difficult and controversial problems. The food shortages and worsening economic crisis that led to the fall of the tsar were no nearer solution. Russia's participation in World War I, underlying these difficulties, raised agonizing questions — whether to fight or make peace and on what terms. Above all, the circumstances of the revolutionary overthrow of the monarchy released the latent grievances and demands of every sector of a frustrated population. As the year wore on, the political mood of the masses grew more and more radical, with the increasingly insistent demands of the peasants for land, of the workers for food and for control of the factories, of the soldiers for an end to the war, and of the national minorities for independence.

The first serious crisis of the Provisional Government was occasioned by foreign policy. Foreign Minister Milyukov wanted to continue the war for the territorial gains promised by the Allies, despite growing popular sentiment for a "democratic peace without annexation or indemnities." The release of a note from Milyukov promising Russian solidarity with Britain and France precipitated the mass demonstrations of the "April Days." Milyukov and Guchkov were compelled to resign, and the Cabinet was reshuffled to strengthen its popular base. Kerensky took over the war ministry, and Mikhail Tereshchenko, a businessman of moderate persuasion, became foreign minister. Several leaders from the soviet were brought in, including the Socialist Revolutionary Viktor Chernov as minister of agriculture and the Menshevik Irakly Tsereteli as minister of posts and telegraphs.

This first coalition cabinet made no more progress than its predecessor toward solving the country's fundamental problems, despite the convening in June of the First All-Russian Congress of Soviets, designed to permit the delegates from the local soviets all over the country to define their program. Major decisions were postponed until a Constituent Assembly could be elected to draft a democratic constitution for Russia. (The election was finally scheduled in September and held in November, after the Bolshevik Revolution.) Meanwhile, at the prodding of

War Minister Kerensky, the Provisional Government turned to the prosecution of the war, which had been more or less dormant on the eastern front since the outbreak of the revolution. In June, Kerensky ordered an offensive; at first, the Russians were successful, but in July they were routed by the counterattacking Germans. Russian discipline and morale then began to disintegrate rapidly, desertions mounted, and, by the time of the Bolshevik Revolution, the army was scarcely a fighting force.

The rise of the Bolsheviks and the crisis of the Provisional Government. At the time of the March Revolution, the Bolshevik Party was small (fewer than 30,000 members) and disoriented. Most of its leaders, including Lenin, were in exile abroad or in Siberia. Initially, the Bolsheviks in Petrograd were hostile to the Provisional Government; then, higher ranking leaders returning from Siberia, including Lev Kamenev and Joseph Stalin, endorsed the Soviet's conditional acceptance of the Provisional Government. Lenin, in Switzerland, denounced the Provisional Government as a bourgeois, imperialist regime, and was independently echoed by Leon Trotsky in New York (though he was not yet a member of the Bolshevik Party). Refused passage by the Allied powers, Lenin secured permission to travel across Germany (and thence, via Sweden and Finland, to Petrograd) in the famous "sealed train" (actually one car to which Lenin and his party were confined while in transit).

There has been much controversy over Lenin's relations with the German government. It seems certain from the German archives that the Germans facilitated Lenin's journey in the hope that he would help undermine the war effort of the Provisional Government and that they also made funds available to the Bolsheviks and other extremist groups for the same purpose. On the other hand, the allegations that Lenin was literally a German agent, after, as well as before, the Bolshevik Revolution, are without foundation. Documents published to this effect have proved to be forgeries.

Upon his arrival in Petrograd at the Finland Station on April 16 (April 3, O.S.), 1917, Lenin issued an open call for the overthrow of the Provisional Government and "All Power to the Soviets" (his so-called April Theses). He quickly brought the Bolshevik Party around to this position and launched it on a campaign of organization and propaganda to win the allegiance of the increasingly radical Russian masses. He was joined in this by Trotsky and a number of other people formerly in the left wing of the Menshevik Party. Rank and file Bolshevik membership grew rapidly, until, on the eve of the Revolution, it stood at around 200,000. The party rapidly attracted popular support at the expense of the Mensheviks and Socialist Revolutionaries, reflected in increasing Bolshevik representation in the soviets.

The first test of strength between the Bolsheviks and the Provisional Government came in the violent mass demonstrations of the "July Days" in Petrograd. Sparked by sailors from the Kronstadt naval base, the Petrograd mob started to act on the Bolshevik appeal for a new revolution. The Bolshevik leadership drew back, however, and the Provisional Government was able to restore order with loyal troops and outlaw the Bolshevik Party. Trotsky was arrested, and Lenin went into hiding in Finland, where he composed his principal theoretical work, *The State and Revolution*. In the aftermath of this setback for the Bolsheviks, Kerensky replaced Prince Lvov as prime minister in the second coalition cabinet.

The next two months witnessed a temporary swing toward the right. Conservatives, rallying around the appeal for discipline and the war effort, looked to Kerensky's chief of staff, Gen. Lavr Kornilov, as the man who could restore order and check the course of the revolution. The State Conference held by Kerensky in Moscow in August only underscored the gulf between the right and the moderate left. Finally, late in August, on the pretext of supporting the government against the soviet, General Kornilov ordered troops to march on Petrograd in what Kerensky, at least, perceived to be a right-wing plot to overthrow him. Kerensky turned at this point to the forces of the left, even relaxing the ban on the Bol-

Establishment of the soviets

Lenin's return to Russia

The "April Days": demonstrations against the war

The "July Days": the abortive revolt and the new Kerensky government

sheviks. Kornilov's troops deserted him, and the attempted counter-revolutionary coup collapsed. The consequence of the attempt was to drive the country further to the left and imbue it with an acute fear of counter-revolution.

The October (November) Revolution. Following the Kornilov affair, popular support for the Provisional Government dissipated rapidly, as the country polarized toward the extremes of left and right. The revolutionary mood of the masses, accentuated by rampant inflation and worsening shortages of goods, reached the stage of direct action. Peasants, impatient with the legal delays of the government, began seizing and plundering the landlords' estates. Strikes mounted, and workers began imposing "Workers' Control" in the factories through elected factory committees. Nationalist leaders in Kiev and Helsinki made the Ukraine and Finland virtually independent. The army began to crumble as peasant troops deserted to return home and share in the land seizures. The reserve units in the cities, fearful of being sent to the front, came under increasing Bolshevik influence.

Against this setting of growing turmoil, the Bolsheviks, with their slogan "Peace, Land, and Bread," were the only party (along with their allies, The Left Socialist Revolutionaries) ready to acknowledge the most extreme popular demands. They scored a series of political victories in the soviets, winning control of the key Petrograd and Moscow soviets by mid-September. Trotsky, released from jail at the time of the Kornilov affair, was elected chairman of the Petrograd Soviet.

At this juncture, Lenin (still hiding in Finland) concluded that the time had come for the Bolshevik Party to attempt the armed seizure of power, overthrow the Kerensky government, and make the soviets the official organs of power. He so instructed the Bolshevik leaders in Petrograd, but the latter, convinced that power was coming to the party more or less democratically, at first resisted his instructions. Against Lenin's wishes, they participated in the Democratic Conference convoked by the Provisional Government to speed consideration of Russia's political future.

The conference merely registered the deepening political cleavages in Russia, between Kerensky and the moderate left, as well as among the government, the right, and the far left. To continue its work until the Constituent Assembly could be convoked, the conference authorized the establishment of a provisional parliament, the Council of the Republic, or Pre-Parliament, composed, like the Democratic Conference, of representatives nominated by the various parties and interest groups. When the Pre-Parliament convened early in October, the Bolsheviks walked out in a gesture of revolutionary defiance. The Second Congress of Soviets had been scheduled for later on in the month, and the Bolsheviks made it clear that they expected this body to resolve the question of power.

This was not sufficient for Lenin. On October 20 (October 7, O.S.) he returned secretly to Petrograd to urge the policy of armed insurrection, and on October 23 (October 10, O.S.) the Bolshevik Central Committee voted in principle (with only Kamenev and Grigory Zinoviev in opposition) to "place armed insurrection on the agenda." Meanwhile plans by the government to move the capital to Moscow stirred up rumours that Kerensky meant to surrender Petrograd to the Germans in order to defuse the revolution. Utilizing the consequent state of panic, the Bolsheviks persuaded the soviet to assert emergency authority over the garrison through the Military Revolutionary Committee, finally activated on November 2 (October 20, O.S.). Although it is generally believed (and asserted by the official Soviet historians) that by this time the Bolsheviks were actively planning an armed uprising to coincide with the Congress of Soviets on November 7 (October 25, O.S.), there is no documentation of such planning, and the preponderance of evidence indicates that the Bolshevik leaders were concentrating on defensive measures to prevent another Kornilov-style coup and to protect the Congress of Soviets while it voted itself into

power. This was contrary to Lenin's demands, but he was sidetracked by polemics against the more openly expressed opposition of Zinoviev and Kamenev.

The actual revolution was precipitated by an abortive government crackdown. Angered by the soviets' claim to control the garrison, Kerensky sent troops on the morning of November 6 (October 24, O.S.) to close the Bolshevik newspapers. This was seen by the Bolsheviks as the opening of the expected counter-revolutionary coup. They called out sympathetic troops and the workers' Red Guards to defend the soviet, only to find that effective government forces were almost nonexistent. With most of the city in their hands by evening, the Bolshevik leaders then began a more deliberate take-over of public utilities and government buildings. It is not clear from the evidence whether this preceded or followed Lenin's midnight return from his hiding place to soviet headquarters in the Smolny Institute. On the morning of November 7 (October 25, O.S.), the Bolsheviks proclaimed the overthrow of the Provisional Government. The virtually bloodless siege and capture of the Cabinet members in the Winter Palace that night came as an anticlimax.

The circumstances of the Bolsheviks' armed insurrection turned out, in part by accident, to be close to the strategy Lenin had demanded. Retrospectively, the Bolsheviks' victory can be attributed to a combination of factors—superior organization, skillful manipulation of the mood of the masses, and Lenin's single-minded leadership—but, on balance, their success was more a matter of good fortune and of default, thanks to the dissension and mistakes on the government side.

The Bolshevik coup was quickly ratified by the Second Congress of Soviets, where the Bolsheviks and their allies, the Left Socialist Revolutionaries, had a substantial majority. The soviets were proclaimed to be the ruling organs in Russia, headed by the Soviet Central Executive Committee as a quasi-parliament and by the Council of People's Commissars as the Cabinet. Lenin was designated chairman of the Council of People's Commissars—in effect, prime minister; Trotsky took the post of commissar of foreign affairs; Stalin, in line with his Georgian origin, was made commissar of nationalities. An abortive attempt by Kerensky to return to power with loyal troops and military cadets was quickly put down, and the new Soviet government of the Bolsheviks proceeded to consolidate its hold. Kerensky went into hiding and the following year fled to England and thence to the United States.

The consolidation of the Soviet government. The revolutionary seizure of power by the Bolsheviks in Petrograd in the name of the soviet was quickly followed by similar moves on the part of the local soviets in most other parts of Russia. In Moscow alone there was serious fighting for about a week, before the Soviet forces prevailed over conservative military units. The Soviet take-over was resisted in southern Russia, where the Ukrainian nationalists and the Don Cossacks under General Kaledin established autonomous regimes. Thus, a state of civil war existed from the outset of Soviet rule. As to Finland, its independence was recognized by the Soviet regime in December 1917, in anticipation of a take-over by pro-Bolshevik Finnish revolutionaries.

The Soviet government lost no time in proclaiming its revolutionary intentions in a series of sweeping decrees. The decree on land abolished private property and ordered the distribution of the land to those who worked it, thus ratifying the peasants' land seizures. The decree on peace called for an immediate armistice and a peace "without annexations or indemnities" among all the warring powers, on pain of unleashing the forces of world revolution. These two basic steps were soon followed by decrees legitimizing workers' control in industry; nationalizing the banks; abolishing the old courts and police in favour of revolutionary tribunals and a workers' militia; removing legal class privileges and titles and abolishing inheritance; separating church and state; and establishing the legal equality of the sexes. Calendar reform was proclaimed in order to bring Russia into line with the new-style Western dates in February 1918.

Aside from these initial steps, there arose a basic dis-

revolu-
tionary
decrees

Lenin's
advocacy
of armed
insurrec-
tion

agreement among the Bolshevik leaders over the future shape of the regime. A hard-line faction headed by Lenin and Trotsky insisted on one-party Bolshevik rule, representing the dictatorship of the proletariat. Zinoviev and Kamenev, joined by several of the new people's commissars and seconded by the Left Socialist Revolutionaries, argued for a coalition government in order to avoid violence and defeat. Negotiations among the parties broke down, and only the Left Socialist Revolutionaries joined the Council of People's Commissars.

Suppression of
opposition

Meanwhile, the Soviet government was suppressing the Constitutional Democrats and other conservative groups. In December the Cheka (All-Russian Extraordinary Commission for Combatting Counterrevolution and Sabotage—or secret police) was established to root out opposition to the government. The elections to the Constituent Assembly, held as scheduled in November, were disappointing for the Bolsheviks: they won around 25 percent of the seats against an absolute majority for the Right Socialist Revolutionaries, with the rest scattered among the other moderate socialist and conservative groups. The Soviet government allowed the Assembly to convene in January 1918 for one day only; it was then closed down as a counter-revolutionary body.

The appeal for peace by the new Soviet government was rejected by the Allied powers as a betrayal of the war effort. On the other hand, Germany and its allies quickly took advantage of the Soviet proposal, agreed to an armistice on the eastern front, and commenced peace negotiations in the city of Brest–Litovsk in Russian Poland. Confronted with a Soviet determination to turn the negotiations into a forum for revolutionary propaganda, the Germans broke off the talks and resumed their offensive in February 1918, meeting virtually no resistance. Lenin, faced with an imminent threat to his regime, called for acceptance of the German peace terms, assuming that a proletarian revolution was due soon in Germany anyway. He was bitterly resisted by the left wing of the Bolshevik Party, led by Nikolay Bukharin, and by the Left Socialist Revolutionaries, who called for guerrilla war against the Germans as an example to inspire revolutionaries elsewhere. Trotsky took the position "No war, no peace" and abstained on the final vote in the Central Committee, which backed Lenin by a narrow margin. The Soviet delegates thereupon signed the Treaty of Brest–Litovsk on March 3, surrendering the Baltic provinces, Poland, the Ukraine, Finland, and the Caucasus to German, Austrian, and Turkish occupation. At the cost of a major part of Russia's population and economic resources, Lenin had won a "breathing space" for the consolidation of his rule.

Treaty of
Brest–
Litovsk

WAR COMMUNISM

The Civil War and intervention. The period of relatively peaceful consolidation for the Soviet government was ended by the outbreak of civil war in May 1918, triggered by a clash between Soviet forces and the troops of the Czechoslovak Legion who were being evacuated from Russia via the Trans-Siberian Railway. Anti-Communist Russians, called the "Whites" and led by officers of the old army, seized this opportunity to take control of most of the country from the Volga River to the Pacific Ocean. Bitter fighting ensued between White units and the Red Army, newly organized by Trotsky (as Commissar of Military Affairs since Brest–Litovsk), and a White thrust on Moscow was barely turned back in August.

Meanwhile, the Allied powers had begun to intervene militarily in Russia. With the original aim of keeping Allied munitions shipments out of German hands, British forces had landed in Murmansk in March by arrangement with the Soviet government. Following the Czech revolt, Great Britain, France, and the United States landed troops in northern Russia, while the U.S. and Japan landed forces in eastern Siberia, all in support of the Whites. The Allied motives were mixed, with Britain and France impelled by the hope both of getting Russia back into the war against Germany and of suppressing the Communist Revolution. Japan was interested in annexing Russian territory, and the United States was concerned

mainly to restrain the Japanese and help rescue the Czechoslovaks.

The collapse of Germany and the end of World War I in November 1918 terminated the original excuse for intervention and, at the same time, appeared to herald the world revolution anticipated by the Communists. Intervention now assumed an avowedly counterrevolutionary aim. U.S. Pres. Woodrow Wilson proposed a peace conference on Russia to be held on the Turkish island of Prinkipo (Biiyiikada), but the Whites, backed by French Premier Georges Clemenceau and British War Secretary Winston Churchill, rejected the idea. The British and French landed additional forces and stepped up their logistical support of the White armies, despite sharp cleavages of opinion at home over the Russian Revolution.

Stiffened by their foreign backing, the Whites launched a series of determined offensives toward Moscow in 1919—from Siberia under Adm. Aleksandr Kolchak, from the Don region under Gen. Anton Denikin, and from the Baltic region under Gen. Nikolay Yudenich toward Petrograd. Though militarily formidable, the White cause was weakened politically by its authoritarian tendencies, its unwillingness to leave the peasants in possession of the land, and its harsh treatment of non-Russian minorities, particularly the Jews. The Communists had the advantage of interior communications and a spirit of national resistance against foreign intervention. Allied intervention was not sufficiently massive or resolute to be decisive. One by one, the White thrusts were turned back, and, by early 1920, with the capture and execution of Kolchak, the serious challenge of counterrevolution was at an end. Acknowledging the futility of intervention, all the Allied powers, except the Japanese, now withdrew their forces.

In the course of its victories, the Red Army reoccupied much of the territory that had been lost under the Treaty of Brest–Litovsk. Where independent states had been set up under the aegis of the Central Powers—in the Ukraine and in Georgia, Armenia, and Azerbaijan in the Caucasus—local Communists were installed in power to form new soviet republics, linked to Russia by treaty. A similar republic was set up for the area of Belorussia ("White Russia," as distinguished by language, not to be confused with the White Russians in the political sense). In the Baltic region, the Communists were not able to take power; and the republics of Estonia, Latvia, and Lithuania, which had proclaimed their independence when the Armistice ended the German occupation, survived with Allied backing.

Reoccupation of
lost
territories

Poland, which had similarly proclaimed independence, uniting Polish-speaking territory formerly under German or Austrian rule with German-occupied Russian Poland, was soon at odds with Soviet Russia over the undefined frontier between them. The Poles rejected the Curzon Line proposed by British Foreign Secretary Lord Curzon as Poland's eastern frontier and attacked in the Ukraine in the spring of 1920. The Russians pushed back and very nearly took Warsaw, before a Polish counter-offensive with French staff and logistical support routed the Red Army. In the Treaty of Riga of March 18, 1921, the Russians accepted a frontier leaving considerable Belorussian- and Ukrainian-speaking territory under Polish rule. This region was the object of Soviet annexation in 1939 and again at the close of World War II.

The last White offensive against the Soviet regime was led by Baron Ferdinand von Wrangel from his base in the Crimea in mid-1920. The Red Army, once a settlement with the Poles was in prospect, turned its full force against Wrangel and easily drove him and his army into exile. There remained only the Japanese and White Russian forces in eastern Siberia, with which Moscow dealt through a nominally independent government known as the Far Eastern Republic. In the fall of 1922, the Japanese finally withdrew, the Whites went into exile (mainly in Manchuria), and the Far Eastern Republic was absorbed into Soviet Russia.

The Communist dictatorship. The passions and desperation of the Russian Civil War rapidly transformed

the Communist regime into a terroristic one-party dictatorship. With the dissolution of the Constituent Assembly and the suppression of the conservative parties, it was clear that the Bolsheviks (renamed Communists at the Seventh Party Congress in March 1918) would brook no serious challenge to their own power. The Left Socialist Revolutionaries resigned from the Council of People's Commissars in protest against the Treaty of Brest-Litovsk, thus leaving a one-party Communist executive. For a time, along with the Mensheviks and Right Socialist Revolutionaries, they continued to function as opposition parties in the local soviets and in the Central Executive Committee (both of which were given legal sanction as the official organs of government by the first constitution of the Russian Socialist Federated Soviet Republic in July 1918). The outbreak of civil war and the sympathy of the Right Socialist Revolutionaries for the anti-Communist cause led to the prompt outlawing of that party. The Left Socialist Revolutionaries sealed their own doom by an abortive uprising against the Soviet government in July 1918 (intended mainly to provoke a resumption of war with Germany by assassinating the German ambassador). Only the Mensheviks remained, sharply curtailed despite their neutrality in the civil war, until they were finally suppressed and their leaders exiled in 1920. By this time, Lenin had made one-party rule by the Communists a cardinal principle in his doctrine of the dictatorship of the proletariat.

The Civil War and the suppression of opposition parties were accompanied by a rising tide of political violence. Socialist Revolutionaries, true to their terrorist tradition, assassinated a number of Communist leaders and wounded Lenin in August 1918. The Communists replied with an avowed campaign of Red Terror, designed to extirpate or terrorize any opposition to the regime within the territory they held. Among both Reds and Whites, the murder of hostages and prisoners and the execution of suspected enemies without trial became the rule. The number of victims probably reached a figure of 100,000 on the two sides. A far greater number of persons, perhaps 2,000,000, mainly of the educated upper and middle classes, were lost to Russia by emigration to escape Communist rule. Russian social life has never recovered the element of sophistication and westernization that these groups represented.

The suppression of opposition parties was paralleled by the development of progressively more authoritarian practices within the Communist Party itself. Though formally democratic in structure and reasonably so in practice in 1917, the party rapidly tightened its internal organization in order to wage civil war and deal with the staggering problems of the Soviet government. The leadership structure was more sharply delineated in 1919 by the creation, in addition to the Central Committee, of a political bureau (Politburo) for policy decision making, an organizational bureau (Orgburo) to supervise the party organization, and a Secretariat to superintend the assignments of individual party members. At the same time, Lenin's principle of "democratic centralism" was affirmed—that party decisions once arrived at had to be obeyed with "iron discipline" by the members and that the decisions of higher party organizations were automatically binding on the local organizations. Utilizing this authority, the party Secretariat commenced the practice of transferring dissidents out of positions of influence and of appointing the secretaries of local organizations to impose party discipline. The stage was thus set for the development of personal control over the party organization by Joseph Stalin after he became general secretary in 1922.

The experiment of War Communism. With the onset of civil war and the emergence of the one-party dictatorship in mid-1918, the Communists abandoned the relatively gradual approach that they had taken in economic and social matters since the October Revolution, an approach characterized by Lenin as "one foot in socialism." Beginning with the sweeping nationalization of large-scale industry in June 1918, an attempt was made to transform Russian society directly into the classless com-

munist ideal. At the same time, a pattern of centralization and coercion was adopted to channel the country's efforts and resources into victory in the civil war. Economic conditions deteriorated rapidly, and by 1921, amid a crisis of opposition within the Communist Party as well as outside, the experiment of War Communism had to be admitted a failure.

Nationalization, initiated ostensibly to forestall German influence, was eventually extended to practically every enterprise of consequence, including small-scale as well as large-scale industry and trading and service enterprises. Workers' control was now rejected by Lenin as an impediment to production; instead, he pressed for one-man management by paid experts, with the tight centralization of overall administration of each industry in the *glavki* ("chief administrations") in Moscow. Nevertheless, industrial production, already declining in 1917 as a result of the disruptions of war and revolution, continued to sag. Transportation (mainly the railroads) was in a critical state, which contributed further to the paralysis of industry. Steel production, for example, fell from a level of 4,200,000 tons in 1913 to a mere 200,000 tons in 1920.

To finance the costs of government and the Civil War, the Soviet regime relied mainly on the printing press (a practice already begun by the tsarist government during the war years), with the inevitable consequence of accelerating inflation. By 1922 the ruble was worth approximately 1/200,000 of its prewar value. Some Communists welcomed the result as a victory over the capitalist economic system, and increasingly the government relied on measures of a "natural economy," rewarding workers with rations in kind, free streetcar tickets, confiscated apartments, and so forth, in place of the depreciated currency. The breakup of the large landholdings and the propensity of the peasants to consume their produce or curtail production rather than sell it for worthless money caused a catastrophic drop in the food available for the urban sector and the army. The Soviet government responded by having grain "requisitioned" by armed detachments, aided by "committees of the Village poor." The consequence was further disruption of food production and a severe alienation of the majority of the peasants, to the point of armed insurrection against the Soviet authorities in some districts of central Russia.

The practices of War Communism—above all the centralizing trend in political life and in industry—evoked within the Communist Party a series of protests by left-wing idealists. These included the "Democratic Centralist" group led by Valerian Osinsky and the "Workers' Opposition" group led by Aleksandra Kollontay and Aleksandr Shlyapnikov (commissars of welfare and of labour, respectively, in 1917–18). With the end of the pressure of civil war in 1920, these groups temporarily made considerable headway.

Soviet Russia experienced its most severe internal crisis after the cessation of civil war. By the end of 1920, the experiment of War Communism, coupled with the wartime disruptions, had brought industry almost to a standstill. The countryside was seething with unrest over the requisitioning of food. Strikes, though outlawed by the Soviet government, erupted in the major cities.

Within the Communist Party, bitter controversy broke out in the winter of 1920–21 over the future of Soviet society, focussed on the test issue of the trade unions. In this controversy, the ultraleft groups, with a goal of democratic communism in mind, called for control of industry by the unions; Trotsky and Bukharin and their followers wanted to absorb the unions into the government and press toward communism by strict discipline and central authority; Lenin, backed by Zinoviev, Kamenev, and Stalin, took the less ambitious stand that industry should be run by qualified managers and that the function of the unions was only to protect the workers. This was a harbinger of the retreat from communism soon to be announced in the New Economic Policy (NEP).

As the delegates of the Communist Party were assembling in March 1921 to resolve their deep disagreements at the Tenth Party Congress, the Soviet regime was confronted by armed challenge in the mutiny of the sailors

Nationalization and centralization

The Red Terror

The
Kronstadt
mutiny

and garrison at the Kronstadt naval base. The Kronstadt Rebellion was bloodily put down, though it professed to represent the true goals of the revolution. Kronstadt made it clear to Lenin and most of the Communist leadership that a continuation of War Communism would endanger the existence of the Soviet regime. There was virtually no opposition when Lenin called a halt to War Communism and, as a "strategic retreat" of the revolution, introduced the New Economic Policy.

THE NEW ECONOMIC POLICY

The decisive step marking the end of War Communism and the beginning of the era of the New Economic Policy was the suspension of food requisitioning and the introduction of a tax in kind specifying the amounts that each peasant had to contribute. From this there followed a series of measures putting the government on a more legal and orderly basis, while temporarily sacrificing the collectivist and equalitarian goals of the Communist Party. In the perspective of the history of revolution, the NEP had many of the characteristics of a Thermidorean reaction on the model of France in 1794 after the overthrow of the Jacobins. Although the revolutionary party remained in power in the Soviet case, there was a marked psychological relaxation and a turning away from revolutionary extremism.

State
capitalism:
denational-
ization
and
decentral-
ization

The policies of the NEP. The NEP was described frankly by Lenin as a retreat from the momentarily unattainable goal of Communism to state capitalism. The monetary system and the market economy were restored. The peasants were allowed to dispose of their produce freely after meeting their tax obligations. Most trading enterprises and much small-scale industry were denationalized, permitting the rise of a new class of small businessmen, the Nepmen. On the other hand, large-scale industry, transportation, public utilities, the financial system, and major natural resources—the so-called "commanding heights"—were kept under state ownership.

Within the state-owned sector, there were further steps back toward capitalistic economic arrangements. Individual, professional management became the rule, and profit-and-loss accounting was restored. State-owned enterprises traded with each other and sought to grow by earning profits. Wages and salaries were set to reflect effort and responsibility, an acknowledged reversion from the Marxist goal of equality. Economic planning was reduced to a modest effort at forecasting resources, rehabilitating war-torn plants, and building up the infrastructure, particularly electric power.

The NEP quickly achieved a recovery in both agricultural and industrial production, although a drought in 1921 on top of the ravages of War Communism caused a devastating famine in the Volga region in 1921–22 (the occasion of a major international relief effort headed by the U.S. relief administrator Herbert Hoover). By the mid-1920s, most branches of the economy reached pre-war levels. A major issue then developed over the manner of future development—an issue between the proponents of gradual growth in the pattern of market socialism, on the one hand, and the advocates of more deliberate planning for a high tempo of industrialization, on the other. The issue was ultimately decided by the political succession struggle that characterized the years of the NEP.

The politics of succession. The leadership of the Communist Party was nominally collective, although Lenin enjoyed such personal force and prestige that his will was seldom resisted successfully by his colleagues. Lenin's illness and then his death, on January 21, 1924, which invited a contest for ultimate control of Soviet Russia, put the system of collective leadership to a test that it could not withstand. By 1928, when the period of the NEP came to an end, the Soviet Union was well on the way to the unrestricted personal dictatorship of Joseph Stalin.

A critical step toward a monolithic system of rule within the Communist party was taken at the Tenth Party Congress in 1921, when it was resolving the crisis of War Communism. At Lenin's behest, the congress condemned the ultraleft factions of the Democratic Centralists and

the Workers' Opposition as "petty-bourgeois deviations" and banned any further existence of organized factions within the party. Thus, while Lenin was making economic concessions to the general public on the right and curtailing secret-police terror (the Cheka was curbed and renamed State Political Administration, or GPU), he was cracking down on idealistic sentiment within the party of the left. To underscore this shift of emphasis, the party Secretariat, composed of ideologically oriented friends of Trotsky, was replaced by a more discipline-oriented group (including Vyacheslav Molotov) under the influence of Stalin. A systematic purge of the party membership was instituted in the fall of 1921, expelling individuals guilty of such sins as corruption, incompetence, alcoholism, or opposition; the membership was cut from some 700,000 before the purge to around 400,000 in 1922. Finally, to tighten the organization further, Lenin decided to install Stalin in the new post of General Secretary of the party in April 1922.

In May 1922, Lenin fell ill with the first of a series of cerebral hemorrhages. Although Trotsky was clearly the party's second-ranking figure in terms of prestige, he was opposed by all the other members of the Politburo and most of the Central Committee, who backed instead a temporary troika, or triumvirate, of Zinoviev, Kamenev, and Stalin. Recovering briefly in the fall of 1922, Lenin found serious fault with the leadership of the troika, particularly Stalin. In a series of articles and letters, Lenin attacked the reappearance of traditional bureaucratic habits and the lack of systematic economic policy (particularly in the foreign-trade area). He took Stalin particularly to task for his heavy-handed approach in forcing the non-Russian soviet republics to accept formal federation with the Russian Republic in the Union of Soviet Socialist Republics (established in December 1922). Finally, in his so-called "Testament" written December 23–26, 1922, Lenin recognized the personal power that Stalin was accumulating through the party Secretariat and concluded,

Stalin is too rude, and this deficiency, fully tolerable in the milieu and dealings among us Communists, becomes intolerable in the office of General Secretary. Therefore I propose to the comrades to think up a means of transferring Stalin from that position.

Felled by new attacks of arteriosclerosis in December 1922, Lenin turned to Trotsky to lead the attack on Stalin. Trotsky temporized, possibly hoping that he could enlist Stalin against Zinoviev, until then his chief personal antagonist. Stalin continued to tighten his control through the appointment of local party secretaries and the handpicking of congress delegates, and at the Twelfth Party Congress in April 1923 he had effective control of the selection of new members for the expanded Central Committee. By this time, a final stroke had rendered Lenin speechless and removed him from the political scene altogether.

In the fall of 1923, a coalition of Trotsky supporters and former Democratic Centralists launched an open attack on the leadership of the troika, charging economic mismanagement, neglect of the industrial workers, and violation of the principle of democracy within the party. In this "New Course" controversy (so termed from a pamphlet by Trotsky), the opposition was overwhelmed by the organizational machinery of the party and was condemned in January 1924 for factionalism and anti-Marxist deviation. Lenin's death a few days afterward came as an anticlimax; Stalin's leading role at the funeral was symbolic of the advantage that he had already won in the contest for power.

In December 1925 the succession struggle took a new turn, when Zinoviev and Kamenev, alarmed at Stalin's accretion of power, tried to unseat him at the Fourteenth Party Congress. Stalin easily turned back the challenge and removed the Zinoviev supporters from their Lenin-grad power base.

Early in 1926, Zinoviev and Trotsky finally joined forces in the "United Opposition," waging a desperate battle of polemics with the party leadership for a year and a half. They re-echoed the themes of party democra-

cy and economic mismanagement, criticized the trend toward "State capitalism" and favouritism for the peasants as against the workers, and called for the institution of vigorous planned industrial development to strengthen the proletarian base of Communist rule. In foreign policy, they alleged that the leadership was abandoning the world revolution.

To defend himself from these charges, Stalin appealed to the theory of "Socialism in one country," which he had first suggested in 1924. This was the argument, based on a statement made by Lenin in 1915 and taken out of context, that the Soviet Union could build socialism by itself without waiting, as the Communists had earlier assumed, for the victory of the proletarian revolution in the more advanced countries of the West. The "Socialism in one country" issue is often interpreted to mean that Trotsky and Zinoviev believed in promoting world revolution, whereas Stalin was a Russian nationalist, but in practice there was little difference between the two groups. The significance of "Socialism in one country" lay first of all in the attempt of the opposition to argue that the Party leadership was deviating in an unsocialist direction because of the isolation of the revolution and should therefore be removed. Secondly, the controversy represented a landmark in the manipulation of party doctrine and history by Stalin, who was able to make a palpably false interpretation of Lenin and compel the party to accept this by organizational pressure. This manoeuvre established the pattern, still followed, of ideological reinterpretations imposed by the party leadership to suit the political needs of the moment, with the consequent necessity of strict control over all ideological discussion within the party.

Beginning in the fall of 1926, Trotsky, Zinoviev, and their followers were progressively stripped of their party and governmental positions, with the vacancies going to Stalin's followers. At the Fifteenth Party Congress in December 1927, the entire opposition group was expelled from the Communist Party. The Zinoviev-Kamenev group recanted and shortly afterward won temporary readmission to the party. Trotsky and his supporters were exiled, tsarist fashion, to remote parts of the country, Trotsky himself being sent to Alma Ata in Central Asia. A year later, in January 1929, Trotsky was deported from the Soviet Union altogether. After periods of residence in Turkey, France, and Norway, during which he organized the "Fourth International" of anti-Stalinist splinter groups from numerous Communist parties around the world, Trotsky settled in Mexico. He was assassinated in 1940, most probably on orders from Stalin.

Foreign policy during the NEP. Along with their relinquishment of utopian goals in internal affairs, the Soviet leaders were compelled to recognize that the forces of international revolution had subsided. By 1921 Lenin had made it clear that the survival of the Soviet state—if necessary, through accommodation with the major capitalist powers—took precedence over any momentary gains for international revolution.

In 1921 the Soviet Union concluded treaties of peace or nonaggression with its immediate neighbours Poland, the Baltic states, and the Middle Eastern tier of Turkey, Persia, and Afghanistan, where the Soviets endeavoured to align themselves with nationalist sentiment against the European powers. Also in 1921, a trade agreement with Great Britain opened the way to normalization of commercial relations with most of the world.

On April 16, 1922, the U.S.S.R. scored a major diplomatic breakthrough by concluding the Treaty of Rapallo with the Weimar Republic of Germany, providing for diplomatic recognition and secret military collaboration, despite the fact that the German Communists were still attempting revolution. As a sequel to Rapallo the Soviet Union secured diplomatic recognition by Great Britain early in 1924 (by the first Labour government), and soon afterward by most other countries. The United States remained the major holdout—over the issue of repudiated tsarist debts and Communist propaganda—until the advent of the Franklin D. Roosevelt administration in 1933; commercial relations, including the award of busi-

ness concessions to U.S. firms, nevertheless became active in the 1920s.

Following the achievement of recognition, the U.S.S.R. continued its quest for allies, particularly in the European labour movement and among Asian anti-Western nationalists. In Europe, the Communist parties were brought under tight Soviet control but were directed to curtail revolutionary activity in the interest of collaboration with reformist groups. In Asia, the Soviets vested their hopes in the Chinese Nationalist Party (Kuomintang) of Sun Yat-sen and Chiang Kai-shek, then struggling to extend its power from Canton to the whole of China. The U.S.S.R. supplied advisors, directed the small Chinese Communist Party to work within the Nationalist movement, and helped Chiang organize a Leninist-style one-party system of political controls. Nevertheless, as soon as Chiang had achieved national power in 1927, he purged the Communists from his ranks and abandoned the Soviet alliance. The end of the NEP period saw the U.S.S.R. almost as bereft of allies as the beginning of the era.

Society and culture during the NEP. As in the "Thermidorean" periods of earlier revolutions, Soviet social and intellectual life during the NEP swung back substantially toward the pre-revolutionary norm, far more so than during War Communism or after 1928. In literary and cultural matters the regime was generally content to suppress overt political opposition, allowing a variety of artistic schools to work out their ideas. The same held true for social thought—economic, educational, and philosophical—among representatives of the regime itself. No attempt was made to control the conclusions of scientists. Strictly speaking, the Soviet regime, while dictatorial, was not yet totalitarian; nonpolitical areas were not subjected to the positive and exclusive dictates of official controllers.

Literature and the arts during the NEP were distinguished by the emergence of a variety of extreme leftist groups, experimenting radically in their respective media and contending for the right to represent the proletariat and the new society. Most notable were the poets Sergey A. Yesenin and Vladimir V. Mayakovsky (both suicides after official controls began to close in), the theatrical directors Konstantin Stanislavsky and Vsevolod Meyerhold (the latter purged in 1938), and the film director Sergey M. Eisenstein. The "proletarian culture" movement of Aleksandr Bogdanov was suppressed, however, in favour of the doctrine that former bourgeois artists and writers could be induced to create in the service of the proletarian state. Overall, Russia's leading role in the international artistic revolution of modernism, begun in the decade before World War I, was sustained.

In education as well as in the arts, a doctrine of service to the proletariat was combined with serious attempts at experimentation. Radical educators, encouraged by Anatoly Lunacharsky, the commissar of education, borrowed from American theories of progressive education and pressed further, in their reaction against discipline, to the doctrine of the "withering away of the school." At the same time, great strides were made in expanding the basic primary and secondary school system, creating the machinery that, by the end of the following decade, substantially wiped out illiteracy among the younger Soviet generation. In higher education, class principles required admission preference for children of workers and peasants, regardless of preparation, to the great detriment of the universities. Much was achieved, however, in the education of the working class (and of many future Soviet leaders) through the so-called *rabfak*, or workers' night courses.

A liberating attitude toward social mores generally prevailed. The family was regarded as a bourgeois anachronism by many Communist leaders (notably Aleksandra Kollontay, an outspoken exponent of free love). Abortion was legalized and divorce made a matter of request (the so-called postcard divorce). Children were encouraged to inform on anti-Soviet parents. The effect of social change among the mass of the population, however, was probably not as great as during the industrialization era that followed.

Religion continued to be actively discouraged, though not persecuted violently as it had been before 1922. Patriarch Tikhon of the Russian Orthodox Church, elected in 1917 when the office was restored, was arrested in 1922 and thereupon abandoned political opposition to the Soviet regime. After his death in 1925, however, the government kept the office vacant until World War II.

THE STALIN REVOLUTION

In 1928 the relatively relaxed and pluralistic character of Soviet life came abruptly to an end. Joseph Stalin, having made himself to all intents and purposes the unchallenged ruler of the Communist Party, proceeded to impose the controls of the Party on every aspect of life in the Soviet Union, and to use those controls to drive the country through an unprecedented experience of violent economic transformation.

The Stalin revolution had its origins in the circumstances of internal political struggle within the Communist Party. After Stalin had destroyed the Left Opposition of Trotsky and Zinoviev, his next concern was to isolate and discredit the people with whom he had shared the leadership during the NEP—particularly Nikolay Bukharin (editor of the official Party newspaper *Pravda* and chairman of the Comintern, or Third International of Communist parties), Aleksey Rykov (chairman of the Council of People's Commissars after Lenin's death), and Mikhail Tomsy (chairman of the trade unions). In an adroit series of political manoeuvres, Stalin shifted to leftist lines of policy that his colleagues were bound to oppose. Then he brought into play the organizational machinery of party discipline to condemn them for factionalism and deviation.

Stalin's "left turn" began early in 1928, with moves for a more militant stance by the Comintern and with pressure on the peasantry who were failing to sell their grain in the needed amounts. By virtue of Stalin's shift and his evident determination to get rid of them, Bukharin, Rykov, and Tomsy found themselves the leaders of the Right Opposition. There was an open rupture in the Central Committee in July, followed by a decisive battle in the Moscow provincial party organization in the fall, when Stalin's control of the central Secretariat proved decisive. In 1929 and 1930, after they had lost effective power, Bukharin, Rykov, and Tomsy were removed from their posts and relegated to minor jobs. Rykov yielded the chairmanship of the Council of People's Commissars to Molotov in 1930. Tomsy was replaced by Nikolay Shvernik, who served as trade union chief (with an interruption as chief of state after World War II) until 1956. Meanwhile, the policies that Stalin had adopted as a political vantage point for fighting the Right Opposition became permanent commitments, the foundations for a violent and profound transformation of Soviet society.

The Five-Year Plans. The concept of a planned economy—in particular, planned industrial development through investment of governmental funds—was not new with Stalin, though, on the other hand, there was little clear background for it in Marxist or pre-revolutionary Russian thought. Mainly it had its origins in the improvised central industrial administration of War Communism, encouraged by Lenin's admiration for the "war socialism" of German economic controls during World War I. The first substantial steps toward economic planning had been the creation of the State Commission for the Electrification of Russia (Goelro) in 1920 and the State Planning Commission (Gosplan) in 1921.

During the NEP, Gosplan built a highly competent staff of economists studying various planning approaches, some relying more on market mechanisms (the "geneticists") and some stressing the role of deliberate governmental action (the "teleologists"). The planning controversy became deeply involved in the factional struggle within the Communist Party, as the Trotskyists called for an aggressive industrialization drive, while the Stalin-Bukharin leadership held to the virtues of gradualness. Nevertheless, the leadership accepted the concept of comprehensive planning, and the Fifteenth Party Congress in 1927 directed Gosplan to prepare a five-year plan.

During 1928 Stalin repeatedly raised his expectations for the targets of the plan and resorted to the Supreme Economic Council under Valerian Kuibyshev to prepare a more ambitious version. Bukharin vainly supported the caution expressed in the work of Gosplan, which was purged and restaffed early in 1929. In April 1929 the Central Committee adopted the most optimistic variant of the plan, backdated to October 1928. The plan called for more than quadrupling the output of heavy industry and at the same time substantially increasing the output of agriculture and consumer-goods industries.

Implementation of the five-year plan entailed the imposition of much tighter controls over the Soviet economy. The managers of state-owned enterprises lost most of their autonomy; rather than produce for the market as they saw it, they were placed under intense pressure to fulfill specific output plans. The relative autonomy of the trade unions was brought to an end, and their function was redefined from the protection of the workers to the promotion of productivity. All small-scale industry and trade that had been left in private hands during the NEP were renationalized and subjected to the same system of central planning.

The manner in which the five-year plan was adopted precluded the practice of careful, scientific planning. The five-year plan was rather a set of politically prescribed targets, demanding maximum effort. Given the limitations of existing resources and trained manpower, the plan as a whole was unrealizable. As shortages appeared, decisions were made according to the implicit primacy of heavy industry, sacrificing consumer goods and agriculture. Although money incomes rose, particularly with the influx of peasants into industrial jobs, a very substantial inflation caused a serious net decline in consumer real income. To absorb excess purchasing power, the "Turn-over" tax—actually a sales tax with high rates depending on the supply of each item—was instituted and still remains the basic Soviet governmental revenue. While the industrialization drive stimulated rapid urbanization all over the country, inadequate provision was made for housing, a chronic Soviet problem ever since.

In December 1932, Stalin proclaimed the First Five-Year Plan completed. Actually it had been in effect only three years and eight months. In the area of heavy industrial construction the results were impressive: steel output up 40 percent, electrical power up 150 percent, machinery output multiplied significantly. On the other hand, the targets for consumer goods production were far under-realized, and agricultural production was woefully inadequate, thanks to collectivization. Statistically, the achievements of the plan were exaggerated by the tabulation of new products at higher prices, a practice that has distorted Soviet economic claims ever since.

The Second Five-Year Plan, initiated in January 1933, ran full term. Consumer needs were more favourably reflected than in the actual conduct of the First Five-Year Plan, and the standard of living recovered appreciably. At the same time, many of the new plants begun in 1929–32 only now went into production, so that output of certain commodities such as steel scored their most spectacular increases during this period. With the Third Five-Year Plan, begun in 1938, the rate of increase sagged again—partly because of the shift of expenditures to armaments and partly because of the impact of the Great Purge (see below) on industrial management. Nevertheless, with all their defects, the five-year plans had accomplished their purpose of turning the Soviet Union into a first-class industrial power and providing the technological foundation for modern war.

Collectivization. The forcible reorganization of the Soviet peasantry into collective farms was the second great accomplishment of the Stalin revolution, closely related to the first, as the economic foundation on which the industrialization drive was based. Like forced-tempo industrialization, compulsory collectivization was hit upon by Stalin as a political expedient, but it answered his economic need for a guaranteed farm surplus and became a permanent commitment of his regime, regardless of cost.

The character and origins of Stalinism

Gosplan and the growth of centralized economic controls

The Second Five-Year Plan

Marxism offered little guidance for the organization of the peasants under socialism, having assumed that capitalism would already have converted them into proletarians or hired labourers. Non-Marxist Russian revolutionary thought stressed the maintenance of the peasant commune as well as the distribution of all land to those who tilled it. This was the program accepted by Lenin in 1917. During the NEP the Soviet peasants were fully individual proprietors, not altogether equal; the class of kulaks—those peasants with above average landholdings and hired labour—grew distinctly stronger. Only a few voluntary communal experiments and a few large-scale state-owned demonstration farms were maintained.

Until 1928 the government induced the peasantry to join cooperatives voluntarily, while meanwhile satisfying their economic needs in return for the sale of food for the urban market. This approach was inherently unsatisfactory, largely because of the propensity of the peasants to consume the produce of confiscated estates that had been the source of a major part of the marketable food supply before the Revolution. There was still enough surplus to feed the cities, but the prospects for supplying a growing industrial labour force were uncertain, and the prewar grain surplus for export and earning foreign exchange had been lost altogether. Faced with this problem, the Trotskyists called openly for exploitive taxation of the peasants to finance the "primary socialist accumulation" of capital for industrial construction.

In the course of his struggle with the Right Opposition in 1928–29, Stalin opted for a more and more ambitious program of collectivization, first couched in voluntary terms, but by the fall of 1929 implemented by force in many parts of the country. The program called for the complete socialization of the peasants' land, tools, and animals. Actual residence was not affected, since the new collective farms were generally based on the villages in which most of the peasantry were concentrated. Legally, each collective farm (kolkhoz) was regarded as a co-operative, using land allotted to it by the state, and in return paying taxes and meeting obligatory deliveries of food at prices favourable to the state. Peasants were to be remunerated with a share of the produce in proportion to the amount and skill of their work. Mechanization was supposed to accompany collectivization and to constitute one of its major advantages; in fact, the availability of tractors fell far short of meeting the loss in horses eaten by the peasants. Machinery was not assigned to the *kolkhozy* but was concentrated in "machine-tractor stations" (MTS), which also functioned as centres of political indoctrination and control in the countryside. For special crops and agricultural experiments, the state-owned-and-managed farms (sovkhozy) were retained, with labour paid on an industrial basis.

There was widespread peasant resistance to collectivization, not only among kulaks but also among "middle" (that is, self-sufficient) peasants. A significant element in the passive resistance that followed was the slaughter and consumption of livestock rather than surrendering it to the collective; in consequence, over half the national livestock resources were lost in most categories. Resistance was most severe in the major grain-surplus-producing regions (the Ukraine, the Volga region, and the North Caucasus), where the peasants were more prosperous and traditionally more independent, and where the government pushed collectivization earliest and most vigorously to get control of the grain surplus. Active resisters were branded as kulaks; kulaks were denied membership in the collectives and were subjected to "liquidation as a class," that is, deportation en masse to Siberia and central Asia. The toll is unknown, but probably some millions of lives were lost in the deportation process and in the labour camps, where many were incarcerated.

Early in 1930 Stalin criticized the excesses of collectivization and permitted partial decollectivization. The following winter, however, the drive was resumed again and pursued steadily, until by 1936 virtually 100 percent of peasant households were incorporated in some form of collective enterprise. The cost in terms of disruption to agriculture was a serious decline in production, although

at the same time the farms proved their efficacy as a tax-collecting device for the government by delivering steadily larger amounts of grain to the state. The peasants, doubly pinched, were stricken further by the disastrous drought and famine of 1932–33 in the Ukraine and Volga regions. Unlike the famine of 1921–22, the government now refused to admit the existence of the famine and allowed no disaster relief for the suffering areas. As in the dekulakization, the exact loss of life is not known, but it probably reached several million.

The famine crisis prompted the government to make certain concessions in the collective farm system. Each peasant household was allotted a small plot with the right to raise vegetables and livestock for its own use and to sell the surplus in the free *kolkhoz* markets established for this purpose. Certain chronic limitations remained in the system: investments of machinery and fertilizer were inadequate; centralized instructions were inappropriate to the local requirements of farming; and the peasants lacked incentive to work more than a minimum on the collective fields. Collective agriculture remains the weakest single aspect of the Soviet economic system, though it does represent a system of effective political control over the peasantry, and it has assured a minimum grain supply for the cities and the troops in time of war or famine.

Social and cultural policies. The Stalin revolution embodied as its third major aspect, along with industrialization and collectivization, the imposition of totalitarian regimentation in practically all realms of life. With the rise of Stalin, the Communist Party had been subjected to strict centralization of authority within its ranks; after 1928, using the party as his primary agent of control, Stalin extended this pattern to most aspects of Soviet social, cultural, and intellectual life.

The social pattern of the period of the Stalin revolution was based above all on the subordination of the individual to the collective organization. This was most apparent in the elimination of individual economic enterprise among Nepmen and peasants, but it also became the rule among writers, scholars, and scientists. At the same time, the old revolutionary impulse toward collective equality was suspended. Stalin put heavy emphasis on the development of individual responsibility, on the strengthening of the authority of organizers and managers, and on the expansion of wage and salary differentials on the basis of skill and effort. This was no longer represented as a postponement of the Marxian ideal but as a permanent aspect of it.

The educational experimentation of the 1920s was abruptly suspended in 1929 with the replacement of Lunacharsky by Aleksey Bubnov as commissar of education. The new emphasis, under the label "polytechnicism," was heavily toward practical industrial skills. In this realm, the challenge of training uneducated peasants for the tasks and responsibilities of industrial life was a monumental one, but, through a complex network of technical schools and institutes and on-the-job training, the Soviet government made a substantial breakthrough in the modernization of its population.

In 1929 the power of the party was turned on Soviet intellectual life, until then the freest aspect of the system. Beginning with crackdowns on the philosophers and historians, every academic and artistic field was subjected to the dictates of extreme Marxism and the imposition of strict party controls. Typically, the party found a leader in each particular field who represented the doctrinaire Marxist view—notably, the historian Mikhail Pokrovsky and the literary critic Leopold Averbakh—and gave them authority to impose the party line on their colleagues. "Bourgeois" (that is, nonconformist) thinkers and artists were silenced or, in many cases, imprisoned. Immediate technological or propaganda contributions to production were the overriding demand. Few artistic works of merit were produced, with the notable exception of Mikhail Sholokhov's novels. Overall, the doctrine of *partiinost*—party spirit—was stressed, entailing party judgments in every field as to the ultimate truth and the appropriateness of any piece of work. Party judgment, in turn, ultimately meant Stalin's personal judgment.

Chronic problems in agriculture

Forced collectivization: the kolkhozy and sovkhozy

Suppression of freedom in the arts and sciences

Foreign policy in the "third period." During War Communism, Soviet foreign policy had been characterized by defiance of the outside world; during the NEP it had involved a search for allies. During the period of the Stalin revolution Soviet foreign policy took still another turn in consonance with the domestic radicalism of the period. Essentially, the years 1928–34 witnessed a resumption of revolutionary rhetoric and a tendency in practice to withdraw into diplomatic isolation, although trade with the West and the solicitation of Western engineering services were pursued vigorously in support of the Five-Year Plan.

Commencing in 1928, the so-called left turn was enjoined on the parties of the Comintern, with emphasis (particularly in Germany) on hostility toward the Social Democrats and reformist governments (labelled "Social Fascism"). In consequence, the Soviet Union did nothing to prevent the rise of Hitler, hoping he would pave the way for Communist revolution in Germany. Hitler's victory and his avowed plans to expand eastward soon made it clear that the U.S.S.R. needed a new diplomatic approach.

In Soviet–Far Eastern relations much the same crisis developed even earlier. Relations with China had degenerated to the point of armed clashes in Manchuria in 1929. In 1931, with the rise of Japanese militarism and the Japanese occupation of Manchuria, a new and more serious threat emerged. By 1933, the Soviet Union was confronted with the spectre of aggressive enemies both to the West and to the East and an absence of any allies at all. The stage was thus set for the fundamental change in Soviet foreign policy characteristic of the period of collective security.

THE PURGES AND THE CONSOLIDATION OF STALINISM

The Great Purge. By 1934 the essential framework of Stalinist society had been laid down in the economic and political structure of the Soviet Union. The country was nevertheless in a state of severe tension and unrest, not only among the masses who had experienced the privations of collectivization, famine, and forced industrialization, and among the intellectuals newly subjected to severe regimentation, but within the party hierarchy as well, where misgivings about the rigours of Stalin's approach had never been entirely overcome. These were the circumstances in which Stalin launched the Great Purge, involving the arrest, exile, or liquidation of some millions of persons, mainly Communists and officials in Soviet government and industry.

Although the Right Opposition had been hopelessly defeated by 1929, occasional manifestations of opposition by small groups in the party continued, mainly over the issue of collectivization. These critics were uniformly denounced as counter-revolutionary, expelled from the party, and turned over to the police. The rank and file of the party were subjected to a purge in 1929 similar to the purge of 1921, directed officially at personal inadequacies but also at opposition sympathies. In 1933 the purge was renewed, in the course of re-issuing party cards. Meanwhile, the practice of staging show trials with elaborate confessions was begun with a series of groups accused of "wrecking" and sabotage. In all cases, the culprits—mainly managers and economists of bourgeois background—were found guilty and sentenced to long terms.

The critical event signalling the advent of the Great Purge was the assassination of Sergey Kirov, Leningrad party secretary and Politburo member, in December 1934. Kirov was thought to be Stalin's chosen second-in-command, but he had recently become associated with the protests against collectivization; he apparently figured in moves to alleviate the lot of the peasants and consumers. There is some evidence that Stalin had the secret police (absorbed into the Commissariat of Internal Affairs, or NKVD, under Genrikh Yagoda in 1934) arrange or allow the assassination of Kirov in order to eliminate a potential challenger.

In any event, Kirov's murder was taken as the pretext for a sweeping roundup of old oppositionists in Leningrad, including Zinoviev and Kamenev and most of their known sympathizers. Zinoviev and Kamenev were put on

trial in 1935 on charges of abetting the assassination and were sentenced to long terms. The following year, in the first of the "Moscow trials," Zinoviev and Kamenev and their principal followers were tried again for conspiring to assassinate the entire Soviet leadership; they confessed to the charge, were condemned to death, and shot.

The Zinoviev–Kamenev trials opened the most familiar aspect of the purges—namely, the show trials of the old Communist oppositionists. The 1936 trial was followed early in 1937 by the trial of the principal supporters of Trotsky, including Karl Radek and Grigory Pyatakov. The charges were extended to include conspiring with Germany and Japan to partition the U.S.S.R. Again the defendants confessed and were condemned to death or long prison terms.

The third trial, in 1938, was the most bizarre. The leaders of the Right Opposition, including Bukharin and Rykov, were accused along with additional Trotskyists and physicians and with Yagoda, who as head of the NKVD had prepared the first trial. The charges included the medical murders of Maksim Gorky and others, and a plot in 1918 to depose and assassinate Lenin. All confessed again (with the exception of the former Trotskyist party secretary Nikolay Krestinsky), and most were shot.

There has been much speculation over the reasons for the uniform confessions to clearly absurd charges. Most probably it was a combination of torture, psychological pressure, and promises of leniency for the accused or their families. A number of former oppositionists were not brought to trial but simply liquidated without publicity, and it can be presumed that this was the fate of individuals who could not be induced to confess.

Alongside the spectacular liquidation of the old opposition leaders, a sweeping, though unpublicized purge of the newer, Stalinist party leaders was conducted in 1937 and 1938. The reasons are generally obscure, but, in any event, members of almost the entire party hierarchy below the rank of the Politburo and over the age of 35 were secretly arrested and executed; two members of the Politburo, five of the six candidate members, and over two-thirds of the Central Committee elected at the Seventeenth Party Congress in 1934 were liquidated. The purge was particularly severe in the non-Russian Soviet republics, where virtually the entire party and government leadership were liquidated on the charge of "bourgeois nationalism."

Simultaneously with the purge of the party hierarchy, the "Yezhovshchina" (the "Yezhov business," named for the new head of the NKVD) extended down into the government bureaucracy, industrial management, cultural circles, and the army. The chief of staff, Marshal Mikhail Tukhachevsky, and seven other Red Army commanders were brought to trial in June 1937 on charges of conspiring with Germany and were executed. Most of the upper-grade officers of the army were likewise liquidated or committed to labour camps (from which many returned in the hour of need in 1941). Numerous intellectual figures who had incurred Stalin's ire also perished, usually without mention. Altogether, in the dragnet of forced confessions and fabricated incriminations, some millions of Soviet officials, high and low, with members of their families, were caught up and executed, jailed, or exiled.

The reasons for the Great Purge remain obscure and controversial. The official charges of wrecking, espionage, and counter-revolutionary activity were repudiated by Nikita S. Khrushchev in 1956, when he "rehabilitated" all the victims except those accused in the Moscow trials. Some authorities hold that periodic mass purging is inherent in the maintenance of totalitarian personal control over the bureaucracy. Others believe that the purges of the late 1930s were a distinct aberration, as the secret police instrument got temporarily out of hand. Still others see the period as the manifestation of a psychotic state of paranoid suspicion on the part of Stalin himself. It does seem clear, in view of the damage done to Soviet administration, industry, and the army, that the purge was an irrational phenomenon, detracting from, rather than adding to, the strength of the dictatorship. No further purge

Purges of the newer party leaders

The purges of 1929 and 1933

of similar scale has occurred, although lesser purges of the same nature continued, particularly in the late 1940s.

The Stalin constitution. Simultaneously with the onset of the purges, Stalin took steps to improve the democratic appearances of his regime, notably by introducing the Stalin Constitution in 1936. Reportedly drafted by Bukharin shortly before he was arrested, the constitution abolished the structure of local soviets, indirectly elected and class-based, which had constituted the formal basis of government since 1917. The new soviets were directly elected by universal suffrage, culminating at the top in the Supreme Soviet, a directly elected, parliamentary-style body, bicameral in composition (the Soviet of the Union and the Soviet of Nationalities). Nominally, the Council of People's Commissars was responsible to the Supreme Soviet. The chairman of the Presidium of the Supreme Soviet functioned as ceremonial chief of state (Mikhail Kalinin, from 1919 to 1946). The individual rights traditional in democracies were guaranteed, along with the right to work and other economic rights. In practice, the constitution was vitiated by the de facto power of the Communist Party, which controlled all nominations, and the practice of treating any manifestation of opposition as a criminal and anti-Soviet act.

The constitution continued the formal federal structure of the U.S.S.R. and even accorded union republics the right of secession. Five new republics had meanwhile been added, for a total of 11, by partitioning the Turkic and Iranian-speaking areas of Central Asia from the Russian Republic—the Uzbek, Turkmen, and Tadzhik republics in 1929, and the Kazakh and Kirghiz republics in 1936. On the other hand, the actual autonomy of the union republics was strictly limited by the centralized authority of the Communist Party, which subordinated all of them to Moscow. Cultural and linguistic autonomy of the non-Russian nationalities had been encouraged in the 1920s, but in the purge period it yielded to a renewed Russification effort in many regions. Accompanying this was the severe shake-up of the republic governments and Communist Party organizations in the purge itself.

In line with the more conventional appearances of the Stalin constitution, Soviet legal doctrine and political theory were fundamentally revised during the later 1930s. Older revolutionary notions, expressed in the formulas, "the withering away of the state" and "the withering away of law"—conceiving government and law as essentially transitional devices to combat the remnants of capitalism—were rejected in favour of emphasizing the permanent or very long-term functions of the state and law in the development and protection of the communist society. The legal theoreticians of the old school were purged, and Andrey Vyshinsky, prosecutor at the Moscow trials, became the chief spokesman for the new "socialist law." Subsequently, a reasonably orderly legal procedure, both civil and criminal, has prevailed, except in the case of political crimes. In political theory Stalin himself made the basic pronouncements at the Eighteenth Party Congress in 1939, stressing the positive role of the state, the armed forces, and the police even after the presumed attainment of the communist society.

The culture of Stalinism. A remarkably consistent shift, analogous to Stalin's new legal and political interpretations, characterized most fields of Soviet thought and culture after 1934. Using the machinery of Communist Party control imposed on Soviet cultural life in the service of extreme Marxist doctrines during the period of the First Five-Year Plan, Stalin and his lieutenants now ordered a shift in the party line in one field after another, away from the revolutionary mode and toward traditional and conservative models, though all in the name of Marxism. Writers, artists and scholars who attempted to adhere to earlier, more obviously Marxist ideas were swept away in the purges. By 1939 Soviet cultural life was cast in the mold that has essentially contained it ever since—restrictive in form, conservative in substance, revolutionary in labels.

The writers were the first to feel the new strictures, beginning as early as 1932 with the manifest failure of proletarian propagandistic writing. The Russian Associa-

tion of Proletarian Writers (RAPP), which had controlled the field since 1929, was dissolved and replaced by the Union of Soviet Writers. The new line was enunciated in 1934—Socialist Realism, meaning in practice artistic work that was traditional in form, accessible to the masses, hortatory, and optimistic. Similar standards were enjoined on all other fields of artistic creation during the next few years. Modern art and literary experimentation were condemned as "bourgeois formalism," and their dissemination was altogether banned.

The sciences were affected less severely and somewhat later. Work in the physical sciences generally proceeded without interference, except when philosophical issues were involved. The theory of relativity, for example, was condemned as a bourgeois idealist doctrine. Biology, and particularly genetics, was subjected to increasingly severe political interference, as the party gave official sanction to Trofim Lysenko (*q.v.*) and his theory of acquired characteristics. The eminent Soviet geneticist Nikolay Vavilov was purged and perished in a labour camp.

In historical teaching and research, ultra-Marxism was condemned in 1934 in favour of a more conventional approach stressing nationalism and great leaders, though still couched in Marxist language. A related reversal was imposed on the behavioral sciences, dismissing modern deterministic and analytical approaches to the study of man and emphasizing the traditional model of rationality, will power, and incentives. Freudian psychology was condemned as "reactionary idealism."

Soviet educational policies shifted similarly. Beginning in 1934, traditional discipline, examinations, and the like were restored. The polytechnic approach was dropped in favour of a classical secondary school curriculum, heavily oriented toward language and science, for those who could master it. Educational preference for children of proletarians was abandoned in the late 1930s in favour of a combination of merit and political reliability.

Changes in the area of social policy reflected the Stalin regime's paramount concern with order and discipline. The loose family legislation of the 1920s was abolished; in 1936, new laws banned abortion and made divorce difficult and expensive. Leniency toward crimes on the part of juveniles and the insane yielded to much stricter definitions of responsibility. Labour regulations put a premium on discipline, punctuality, and incentives. In 1935 there was launched the "Stakhanovite" movement (named after a Donets coal miner, Aleksey Stakhanov, whose team had speeded up output remarkably); it rewarded "shock brigades" and "innovators" with higher pay and other privileges and dramatized the stress on individual productive effort in the service of the state. Overall, the regime acquired an aura of grim puritanism, compared by some commentators with the Protestant ethic that earlier spurred the forces of industrial revolution in the West.

Soviet foreign policy in the era of collective security. The external threats that Soviet Russia faced by 1933 as a diplomatically isolated and internally hard-pressed power were sufficient to compel a basically new approach in foreign policy. The architect of this shift was Maksim Litvinov, commissar of foreign affairs from 1931 to 1939. Under Litvinov, and with Stalin's implicit backing, the Soviet Union commenced a pragmatic search for allies and supporters, in the Comintern in the form of the Popular Front and diplomatically in the policy of collective security.

In the international Communist movement, by 1934, the ultraleft stance of the "third period" had given way to the quest for political accommodation with socialist, reformist, or nationalist groups and governments. The new strategy was formalized by the Seventh (and last) Congress of the Communist International in 1935, with the doctrine of the Popular Front allying Communists with any other anti-Fascist elements.

In 1936 the Popular Front tactic succeeded in bringing Communist-supported governments to power in France and Spain. The ensuing Spanish Civil War constituted a severe test of collective security, as the Soviets endeavoured to expand their influence in Spain while restrain-

ing the extremist revolutionaries so as not to alarm the potential allies of the Soviet Union.

Meanwhile, the Soviet Union concluded an agreement for diplomatic recognition by the United States in 1933, joined the League of Nations in 1934, and entered into defensive military alliances of the traditional type with France and Czechoslovakia in 1935. Litvinov became a familiar figure in the League of Nations, espousing disarmament and collective security against aggression. Collective security finally collapsed in 1938, however, when Britain and France came to terms with Nazi Germany at Munich. Stalin apparently interpreted the Munich agreement as a free hand for Hitler in the East. He thereupon replaced Litvinov with Molotov early in 1939 and began to explore possibilities of accommodation with the Germans. (R.V.D.)

V. The U.S.S.R. since 1939

PRELUDE TO WAR

As the year 1939 opened, the storm clouds of an impending war cast their shadow over Soviet life. The rising power of Hitler's Germany posed dangers that could not be ignored. During the Second Five-Year Plan (1933–37), Soviet defense industries expanded about two and a half times as rapidly as industry as a whole. The military and naval budget rose from 1,420,700,000 rubles in 1933 to 23,200,000,000 rubles in 1938, and by 1940 it had reached 56,800,000,000 rubles. New industrial centres were erected beyond the Urals, and military industries were dispersed with the contingency of war in mind. The size of the standing army was greatly increased; the Universal Military Service Act of 1939 made service in the armed forces obligatory for all citizens of the U.S.S.R. The draft age was lowered to 19, the age limits for reservists increased from 40 to 50, and the terms of service substantially lengthened in the air force, the navy, and other branches with special technical requirements.

Despite these intensive military preparations, the state of the Soviet armed forces left much to be desired. The purge of the officer corps following the execution of Marshal Mikhail Tukhachevsky and other high-ranking generals in 1937 for alleged "treason to the Fatherland and Stalin's decision to keep the army under the closest political supervision weakened the authority of the military command structure and deprived it of some of its most professional and experienced leadership. The damaging effects of the Great Purge were also registered in a slowing up in the rate of industrial growth and in a lag in technical innovation in weaponry. Although desperate efforts were made to modernize the military equipment of the Soviet Army during the middle and late '30s—advanced designs in tanks and aircraft were on the drawing board and in prototype—the existing stock, except for artillery, did not compare in quality or performance with the equipment the Nazis already had available in 1939.

Clearly the Soviet leaders were not ready for war, though this did not deter them from proclaiming their invincibility. Hitler, after disposing of Austria and Czechoslovakia, turned his energies eastward, hurling threats against Poland. If Poland succumbed, or joined with Germany, and if the Western powers stood aside, the Soviet Union would be left alone. The British declaration of March 31, 1939, concurred in by the French, that they would "lend the Polish government all support in their power" in the event of a Nazi attack, gave Moscow room to manoeuvre. If it joined in the British–French guarantee and concerted its military plans with the western Allies, there was the possibility that Hitler might be deterred; but there remained the great risk that Hitler would persevere in his invasion plans and that the Soviet Union would then find itself embroiled in a war in which it would receive the main brunt of Nazi military action. If, on the other hand, it held off from participation in the British–French guarantee, with its implicit commitment to join in a war against Hitler, and banked on the possibility that Hitler wished to avoid a two-front war, it might extract concessions from the Nazis as the price of Soviet neutrality. In the event, Hitler proved ready to

bargain. The result was the German–Soviet Nonaggression Pact of August 23, 1939, with its secret protocol providing for the partition of Poland between Germany and the Soviet Union, reserving Lithuania to the German sphere of influence and giving the Soviet Union a free hand in Estonia, Latvia, Finland, and Bessarabia. On September 1 the German armies marched into Poland, and two days later France and Britain declared war on Germany.

WORLD WAR II

Consolidation in eastern Europe. The outbreak of World War II seemed at first to represent a triumph of Soviet diplomacy. Vast territorial gains were achieved with virtually no effort. The expectation that Germany and the western Allies would wear each other out in a bloody and prolonged war of attrition opened up the prospect that the Soviet Union would emerge as the arbiter of Europe's destinies. But unfolding events betrayed Stalin's calculations. The quick collapse of Polish resistance and the decision of the French high command not to advance against the Germans aroused the most acute apprehensions in Moscow. Stalin undertook to ease possible friction with Germany in Poland by yielding the provinces of Lublin and Warsaw to Hitler in exchange for most of Lithuania. Meanwhile, Moscow moved swiftly to consolidate its new-found gains and improve its defensive posture. The Polish territories assigned to it were occupied by the Soviet Army and absorbed into the White Russian and Ukrainian Soviet republics. The fate of the three Baltic states was settled, first by military occupation and then, in August 1940, by annexation to the Soviet Union. Finland proved more difficult. When the Finns refused to cede territories and yield naval bases that the Soviets deemed vital to the defense of Leningrad, the Soviet Army invaded Finland. The so-called Winter War, which lasted from the end of November 1939 to March 1940, proved costly to the Russians. The Finns offered fierce resistance, attracting worldwide sympathy and support for their cause. Although the Soviet Army finally succeeded in breaching the Mannerheim line, Soviet casualties were large and the army's performance was unimpressive. Hitler concluded that the U.S.S.R. was militarily weak and that he could afford to press his aggressive designs without much concern for Soviet reactions.

The German occupation of Denmark and Norway in April 1940, and the crushing defeat of the Anglo-French armies in June, reinforced Soviet fears and apprehensions. All Europe appeared to be at Hitler's feet. The question was no longer who would win a war of attrition in western Europe but rather which way the Nazi juggernaut would turn next—against Britain or the Soviet Union. The Soviet response was fourfold. First, it accelerated its efforts to strengthen its armaments industry, modernize its military equipment, and prepare its armed forces for war. Second, it sought to expand its borders, particularly at the expense of Romania, and to limit Nazi penetration into Finland, eastern Europe, and the Balkans. Third, it undertook to protect its Far Eastern flank by concluding a neutrality and nonaggression pact with Japan. Finally, it did what it could to placate Hitler by giving trade concessions and abstaining from anti-German propaganda or other provocative gestures.

The Soviet seizure of the Romanian territories of Bessarabia and Bukovina in late June 1940 exacerbated Nazi–Soviet relations. Hitler's reply was to move German troops into what remained of Romania. By late July, Hitler had reached a tentative decision to invade the Soviet Union, though the official directive for "Operation Barbarossa" was not signed until December 18, 1940. Other preparatory moves were made. German armed forces were granted the right of passage through Finnish territory. On September 27, 1940, Germany, Italy, and Japan concluded a Tripartite Pact proclaiming the "leadership of Germany and Italy in the establishment of a new order in Europe" and according a similar status to Japan in Greater East Asia. In November Vyacheslav M. Molotov, then head of government as well as foreign

The uneasy truce with Hitler

Military and diplomatic preparations for war

commissar, was invited to Berlin, where Hitler offered the Soviet Union a chance to share in the spoils of the "bankrupt" British Empire by expanding in the direction of the Indian Ocean. The Soviet reply was to accept the offer, provided German troops were withdrawn from Finland and the Soviet Union was permitted to establish military bases in Bulgaria. Hitler's response was to move troops into Bulgaria and later into Yugoslavia and Greece. His determination to consolidate his hold on the Balkans and strengthen his ties with Finland foreshadowed the coming invasion. In this increasingly ominous situation Stalin scored at least one diplomatic coup. The negotiation of the Soviet-Japanese Neutrality Pact of April 13, 1941, held out the hope that Japan would not join in a strike against the Soviet Union.

By late spring German preparations for the onslaught on the U.S.S.R. became so obvious that it seemed impossible to ignore them: German troops were massing on the Soviet frontier; German overflights of Soviet territory were virtually a daily occurrence; intelligence reports testified to Nazi intentions. Yet Stalin persisted in behaving as if war could be averted. Large-scale shipments of Soviet materials to Germany continued. The Soviet press derided the idea that there might be a war with Germany. Soviet frontiers were poorly defended. Front-line troops were ordered not to respond to Nazi provocations. There seems to have been no carefully drawn plan of defense against a surprise attack. One can only speculate that Stalin believed to the end that Hitler would not march, or that he could be appeased by concessions. Hitler made no demands. In the early dawn of June 22, 1941, the German divisions crossed the borders and advanced rapidly, meeting little resistance.

The German offensive. The first phase of the war was a Soviet disaster. The Luftwaffe dominated the air, destroying some 2,000 Soviet planes in the first two days of the war and subjecting the retreating troops to incessant bombing and machine-gunning. German tank columns contributed to the disorganization of the Soviet Army. Hundreds of thousands of Soviet soldiers were killed during the early days of the war, and many more hundreds of thousands were encircled and taken prisoner. By mid-November the German army was at the gates of Leningrad, had penetrated into the suburbs of Moscow, had captured Kiev, and was in occupation of the whole of the eastern Ukraine and most of the Crimean Peninsula.

As the Germans began to outrun their supply lines, Soviet resistance stiffened. Leningrad held firm. In early December the Soviet command, with the aid of fresh troops hurriedly brought from Siberia, launched a counteroffensive on the Moscow front that pushed the Germans back as much as 200 miles in some areas. Soviet forces also recaptured the Kerch Peninsula in the Crimea.

By the end of 1941 it was already clear that the quick victory on which Hitler was counting had eluded him. Soviet losses had been huge, but German casualties were also heavy (1,250,000 in the first 12 months). The Russian winter was hard on German troops and equipment. Supplying them was becoming increasingly difficult because of long lines of communications, poor roads, shortages of railway rolling stock, and guerrilla attacks in rear areas. The Soviets had recovered from their early panic and were beginning systematically to rebuild their army, reorganize their armaments industries, and gird their forces for a long war. Over 1,500 factories, including 1,360 armaments plants, were evacuated with their workers from European U.S.S.R. to the east. During the next years they were to contribute significantly to the mounting supply of planes, tanks, and munitions; together with British and American Lend-Lease aid, they helped turn the tide of battle.

Stalingrad. After the grim winter of 1941-42 the Germans returned to the attack. In May they recaptured the Kerch Peninsula and routed three Soviet armies that sought to liberate Kharkov; in early June they completed their occupation of the Crimea by overwhelming the defenders of Sevastopol. Toward the end of June they launched a major offensive in the direction of Voronezh. Halted there, they turned south toward Stalingrad (now

Volgograd), where they again met stubborn resistance. Farther to the south they scored a series of victories, occupying the rich Donets Basin, capturing Rostov, and overrunning the Kuban granary. Turning in the direction of the Caucasus, they seized the Maykop oil fields and drove toward Baku, but they were finally stopped in the mountains that stood between them and their objective. By this time the German armies were dangerously dispersed, and the Soviet high command began preparations for a new counteroffensive. Hitler's insistence that the Battle of Stalingrad be fought to a successful finish and that no retreat be tolerated provided the Russians with their opportunity. Marshalling fresh reserves, the Soviet forces under the command of Gen. Georgy Zhukov encircled the German 6th Army in Stalingrad and barred the way to German columns sent to relieve it. In Stalingrad more than 200,000 German soldiers perished. On February 2, 1943, the remaining 91,000 men of the 6th Army surrendered after their commanding general, Friedrich Paulus, and 23 other generals had been taken prisoner. The German defeat at Stalingrad marked the turning point of the war. Although many bitter battles remained to be fought, the U.S.S.R. had reason to be confident that it would emerge victorious.

In the aftermath of Stalingrad the German armies began to yield ground. Fearing that their forces in the Caucasus would be cut off, they managed an orderly withdrawal, but with the Soviet Army in hot pursuit they abandoned Rostov and retreated into the Ukraine. In mid-February Soviet troops fought their way into Kharkov, but the German general Erich von Manstein staged a successful counterattack, pushing the Soviets back across the Donets River and reoccupying Kharkov on March 12, 1943. Meanwhile, however, the Germans were forced to withdraw from the Vyazma salient near Moscow; and Soviet forces in the Leningrad area broke through the blockade lines over a seven-mile front and established a precarious railway link with the rest of the U.S.S.R. Hitler's final bid for victory—the July battle for the Kursk salient, in which he hoped to trap and annihilate four Soviet armies—proved a fiasco. The Germans were thrown back with heavy losses, and the Soviet Army advanced on a wide front, recapturing Kharkov, Kiev, and Smolensk. By the end of 1943 the Soviet Army had liberated nearly two-thirds of the vast areas seized by the Nazis.

The advance into Europe. Soviet military historians describe 1944 as the "Year of the Ten Blows." The first, which came in January, freed Leningrad from encirclement. The second, struck in the Ukraine in February and March, forced a German retreat to the old Polish and Romanian borders. The third, in April and May, resulted in the recapture of the Crimea. The fourth was directed against the Karelian Isthmus and forced the Finns out of the war. The fifth, in June-July, was aimed at German Army Group Centre and resulted in the capture of 30 German divisions, the seizure of Minsk and Vilnius, and the clearing of the road to the Vistula and Warsaw. The sixth hammered German forces in Galicia and resulted in the capture of Lvov on July 25 and a march to the San and Vistula rivers and the Carpathian passes. The seventh was directed against the German and Romanian armies along the Dnestr River. It produced the unconditional surrender of Romania on August 23 and opened the road to Hungary and the Balkans. The eighth carried the Red Army to Yugoslavia and Hungary. The ninth cleared the Baltic states, cutting off a number of German divisions in Courland. The final blow was directed against the Petsamo region and northern Norway.

By January 1945, when the Soviet Army launched its final drive toward Berlin, it possessed a decisive superiority in troops, aircraft, tanks, artillery, and munitions. The Soviet advance was rapid. In the north, two army groups invaded East Prussia. In the centre, General Zhukov drove from the Vistula directly toward Berlin. To the south, I.S. Konev's armies cleared Upper Silesia. Farther south, Gen. R.Ya. Malinovsky and Gen. F.I. Tolbukhin occupied Austria and Slovakia. In early March, Soviet forces established bridgeheads across the Oder, and by April 25 Berlin was completely surrounded. On April 30

Hitler committed suicide. By May 2 the last pockets of Nazi resistance in Berlin were eliminated, and a joyful Soviet nation celebrated victory.

The war had entailed bitter sacrifices for the Soviet people. Some 15,000,000 to 20,000,000 soldiers and civilians were killed, and many millions more were maimed, wounded, or weakened by malnutrition. The material losses were equally staggering. Officially estimated at 679,000,000,000 rubles, they spelled destruction on so vast a scale as to pose a colossal task of reconstruction. The stoicism with which the Soviet populace endured its suffering had few parallels in history. After the panic and disorganization of the first phase of the war, the will to resist stiffened. Stories of brutal treatment of Soviet prisoners of war and Nazi atrocities in occupied areas contributed to a deep hatred for the German invaders. As the armed forces drained factories and farms of manpower, the women, old men, and children who replaced them worked all the harder because they were bound to the front by the knowledge that the fate of husbands, brothers, and sons depended on them. The reservoirs of patriotic sacrifice on which the regime was able to draw helped to ensure its survival.

Stalin, in his first broadcast to the nation on July 3, 1941, was wise enough to identify himself with this patriotic upsurge and to exploit it to the full. The war became the Great Patriotic War, the Great Fatherland War, and a National War of Liberation. The cult of

Stalin fused with the new patriotism. Slogans of class struggle were put aside, at least temporarily. Anti-religious propaganda was subdued, church leaders were wooed, the patriarchy was restored, and the church faithful joined in defense of their country. A new national anthem replaced the "Internationale." The Army was glorified, and patriotic slogans dominated the mass media. The nationalist revival that Stalin led was an important key to victory.

Perhaps equally significant was the ruthless determination of the Soviet leadership to gear the economy to the needs of the front. Beginning in 1942, the industries evacuated to the east and new factories and mines began to lift the tempo of production. In 1943 tank production totalled 19,500 and included such advanced models as the T-34, one of the best medium tanks used in the war. In the same year, 35,000 planes were produced, an increase of 37 percent over 1942. During the next years, production of all types of arms continued to increase. Soviet production was supplemented by a mounting flow of supplies from Britain and the United States. By the end of the war, U.S. Lend-Lease aid to the Soviet Union totalled \$9,100,000,000; U.S. trucks and Jeeps had contributed significantly to the mobility of the Soviet Army.

The war alliance. The Soviet–British–U.S. alliance during the war proved a troubled partnership. Relations were poisoned by Stalin's deep-seated suspicion that the delay in opening a second front in the west represented a

The sacrifices of the war

deliberate effort to bleed and weaken the Soviet Union. Once the tide of battle had turned and victory appeared inevitable, the conflicting interests of the Allies came more sharply into focus. The initial clashes centred on the future of Poland. For Stalin, security considerations dictated the installation of a "friendly" regime in Poland, and in his eyes the only friendly regime was a Communist-dominated one. The British and Americans pressed instead for a freely elected Polish government. The disposition of the Soviet forces at the end of the war made certain that Stalin would have his way, but at the price of the war alliance. His diplomatic moves at the conferences of Teheran, Yalta, and Potsdam, and his actions in the closing days of the war and in the immediate postwar period, revealed that he was determined to assume a dominant position in eastern Europe and to regain the Far Eastern territories lost in the Russo-Japanese War of 1904–05. But his claims extended farther. They included a military base on the Turkish straits, which would enable the Soviet Union to control access to the Black Sea; trusteeship of one of the former Italian North African colonies, which would establish the Soviet Union as a Mediterranean power; participation in control of Germany's industrial Ruhr area as well as unilateral control of the eastern occupation zone of the country; and a continued Soviet occupation of Iranian territory. These demands met increasing resistance from the United States and Britain, who became determined to contain what they regarded as Soviet expansionist tendencies.

By the end of the war the Soviet Union could justly claim that its military triumph over Germany entitled it to the status of one of the world's two great powers. To the territories it had seized during the German-Soviet pact were now added a slice of East Prussia taken from Germany, the Western Ukraine taken from Poland, the Carpatho-Ukraine taken from Czechoslovakia, and the Far Eastern outposts yielded by Japan. Soviet armies of occupation extended from Germany and Poland through Czechoslovakia and the eastern section of Austria to Hungary, Romania, and Bulgaria. But the imposing military establishment also concealed serious internal weaknesses: the economic base on which it rested had been ravaged by the war, and Soviet industry and agriculture were in a sorry condition.

POSTWAR POLICY TO STALIN'S DEATH

Reconstruction. With the end of hostilities, the Soviet Union faced difficult problems of demobilization, reconversion, and reconstruction. The pattern of industrial location had shifted to the east during the war, and areas nearer the front lines had been neglected. In the war-devastated areas of European U.S.S.R., enormous tasks of rehabilitation presented themselves. As early as 1943, a special committee attached to the Council of People's Commissars was established to work on the restoration of the economy in regions liberated from the Germans. The first of the postwar five-year plans was announced early in 1946. Its proclaimed objective was to reach and surpass the prewar levels of output in industry and agriculture. Because of the deterioration of relations with the United States, Stalin could no longer count on American aid in postwar reconstruction. He exploited to the utmost such war booty and reparations as were available to him.

Table 1: Total Livestock in the Soviet Union (000,000)

	cows	cattle (including cows)	hogs	sheep and goats	horses
1916	28.8	58.4	23.0	96.3	38.2

The Five-Year Plan gave priority to heavy industry, and in this area its goals were by and large reached and even exceeded. The first Soviet atomic bomb was exploded in September 1949, much sooner than many knowledgeable Western scientists had anticipated. If the progress made in heavy industry and military technology was impressive, the same could not be said of consumer goods and agriculture. In these low-priority areas even the relatively modest targets set by the plan were not met. The situation was particularly critical in agriculture. In 1946 a devastating drought in the Ukraine and other grain-producing areas resulted in a famine of major proportions. Despite Stalin's efforts to force the collective farms to increase their production, Soviet agriculture remained backward and stagnant. Inadequate incentives and meagre capital investment contributed to low agricultural productivity. The full dimensions of the agricultural crisis were not publicly revealed until after his death. Tables 1 and 2, based on official data, show how little progress agriculture had made.

Table 2: Gross Physical Output for Selected Food Items*

year	grain	potatoes	vegetables	milk	meat (dressed weight)	eggs

The return to Stalinism. The postwar years were also marked by intensive political mobilization. During the war the party leadership had sought to broaden its appeal to the army and the nation by muting its Marxist-Leninist ideology and stressing the great unifying theme of patriotism. Early in the war, when the army was undergoing vast expansion, the party also expanded its ranks to include many members of the armed forces, particularly front-line fighters. Glorification of the army and the high command formed part of the wartime pattern, but as the war drew to a close the party reasserted its ascendancy. The organs of mass communication put increasing emphasis on the role of Stalin and the party as the major architects of victory; the heroic exploits of Soviet marshals were painted in more subdued colours. When there were signs at the end of the war that Marshal Zhukov was becoming too prominent, he was removed from the limelight and relegated to a less conspicuous military command in the Ukraine. Ideological indoctrination of the army, which had been relaxed during the war, was revived and intensified. The ranks of the party were purged.

A series of authoritative pronouncements by party leaders at the end of the war reasserted the historical perspectives of Marxism-Leninism. Stalin's election speech of February 9, 1946, restated the basic Communist analysis of capitalism and imperialism, as well as the dangers they posed for the Soviet Union. The increasingly strong Western resistance to Soviet expansion aroused an equally strong Soviet reaction. Gen. Andrey A. Zhdanov's blunt speech at the organizing conference of the Cominform in September 1947 allowed no doubt as to the Soviet position. The world, Zhdanov declared, was divided into two camps, the imperialist camp led by the United States and the anti-imperialist camp led by the Soviet Union. The Communists of the world were summoned to join in the battle against the "imperialist aggressors." All Soviet party members were called upon to alert the population to its peril and to discipline the masses for new sacrifices.

Soviet patriotism, as Stalin propounded it in the postwar years, fused Russian nationalism with an ideological commitment to Marxism-Leninism. In one of its aspects, it stressed the leading position of the Great Russian people in the Soviet family of nations. In another aspect, it

Stalin's
harsh
postwar
policies

The
task of
rehabilita-
tion

proclaimed the superiority of the Soviet social and political order over capitalism.

Under the cover of Soviet patriotism, Stalin also attempted to ignite a xenophobic hatred for the capitalist world. By making "cosmopolitanism" equivalent to treason, he sought to destroy pro-Western sentiment among the people; in doing so he virtually sealed off the Soviet populace from contact with the outside world. History, literature, drama, music, and art were purged of every trace of "bourgeois objectivism" and noncommitment. Partynost (devotion to the party) became the new watchword; in fact, it meant complete subservience to Stalin.

The cult of Stalin reached its apogee in the postwar period. In theory, the party ruled the state. In practice, Stalin ruled the party and through it dominated every other sector of Soviet life. His colleagues in the party's Politburo functioned as administrative henchmen and assistants on a high level; the Central Committee of the party went into a shadowy eclipse, meeting rarely; no party congress was held between 1939 and 1952. The party ranks (members and candidates) expanded from 3,876,885 in February 1941 to 6,882,145 on October 1, 1952, but as the party grew its influence diminished because of the undisputed personal authority that Stalin exercised. His method of governance was shaped to a very considerable extent by his own personality—his paranoiac suspicion, his fear of rivals, his distrust of those around him, and his insistence on holding all the strings of power in his own hands. In his drive to safeguard his own authority, he evolved a system of competing and overlapping bureaucratic hierarchies in which he depended on the party apparatus and the security police to penetrate and watch each other and made use of both to control the administrative organs of government as well as all other parts of Soviet life. The same pattern of rule was imposed on his East European Communist partners, at least as far as his power could reach. In the postwar years Poland, Czechoslovakia, Hungary, Romania, Albania, and Bulgaria were all transformed into Soviet satellites, completely subservient to Stalin's will. Only Tito's Yugoslavia managed a successful resistance; leaders elsewhere in eastern Europe who might have sought to imitate Tito were executed or purged.

The system of calculated insecurity in which Stalin enveloped his henchmen carried over to the postwar years. At the end of the war the two chief rivals for Stalin's favour were Georgy M. Malenkov and Andrey A. Zhdanov. Malenkov's primary area of jurisdiction was the party apparatus. Immediately after the war his prestige suffered a temporary eclipse, and in 1946 he ceased to be listed as a party secretary. Meanwhile, Zhdanov, who had been recalled to Moscow from his post as Leningrad first party secretary, occupied the limelight as the ideological spokesman of the party and exercised his influence to promote members of his Leningrad entourage to leading party and governmental posts. If Nikita S. Khrushchev's later testimony is to be believed, Malenkov conspired with Lavrenty P. Beria, who had charge of the security police, to curb Zhdanov and to fan Stalin's distrust of the Leningraders. On July 21, 1948, the party newspaper *Pravda* revealed that Malenkov had been restored to his secretarial authority. The death of Zhdanov on August 31, 1948, was followed by a ruthless purge of his dependents in the apparatus, most of whom were executed for their alleged involvement in a conspiracy called the Leningrad Affair. According to Khrushchev, the case was fabricated from beginning to end. Among its victims were N.A. Voznesensky, a Politburo member; A.A. Kuznetsov, the Central Committee secretary who had been entrusted by Stalin himself with the supervision of state security organs; P.S. Popkov, first secretary of the Leningrad party organization; and many others. Malenkov seized the opportunity to fill many of the vacancies with his supporters, although after 1949 his own authority was somewhat diluted by Stalin's appointment of Khrushchev as Central Committee secretary with some jurisdiction over party organizational affairs. Until Khrushchev's transfer from the Ukraine to Moscow in 1949, A.A. Andreyev had served as the chief Politburo spokesman on

agricultural policy. Khrushchev replaced him in that role in the following year, when Andreyev was publicly attacked and discredited for championing the link, or small team, method of organizing agricultural production in preference to reliance on the larger brigade unit then coming into favour. Khrushchev in turn soon found himself in troubled waters because of the radical and overambitious character of his proposals for the limitation of peasants' private plots and for the resettlement of the rural population in large agrogorods, or rural towns. But Khrushchev, unlike Andreyev, remained a member of Stalin's inner circle.

During the last years of Stalin's life, according to Khrushchev, "Stalin became even more capricious, irritable and brutal"; his distrust extended even to his closest associates. A mass purge of the party organization in the republic of Georgia was apparently directed against Beria. The anti-Semitic campaign of the years 1948–52, which began with a sweeping denunciation of rootless cosmopolitans and culminated in the execution of several dozen Jewish writers, even extended into the Kremlin: Foreign Minister Vyacheslav Molotov's Jewish wife was sent to Siberia to live. The 19th Party Congress (1952), with its reiterated call for vigilance, suggested that there were still more purges to come. According to Khrushchev, Stalin had plans "to finish off the old members of the politburo." Andreyev was expelled from it. Marshal Kliment Ye. Voroshilov was forbidden to attend meetings, was spied upon, and was accused by Stalin of being an English agent. Molotov and Anastasy I. Mikoyan, then a deputy prime minister, were under suspicion, and the decision after the 19th Congress to create a Presidium of 25 members and 11 alternates to replace the Politburo was intended, according to Khrushchev, as a cover "for the future annihilation of the old Politburo members." The arrest of the Kremlin doctors (a majority of them Jews) for allegedly having cut short the lives of Zhdanov and Politburo member Aleksandr S. Shcherbakov and having conspired to destroy the health of leading Soviet military personnel, evoked grim memories of the earlier "doctors' plot" during the great purge of the late 1930s and seemed to portend its repetition on a mass scale. If Khrushchev's testimony is to be credited, only Stalin's death averted a blood-bath reaching into the very highest Kremlin circles. Indeed, the cloud of fear that Stalin projected cast its shadow over the whole of Soviet society.

The Cold War. The fear and tension evident inside the Soviet Union were reflected in its foreign policy. Deeply suspicious of his wartime capitalist partners, Stalin failed to utilize the goodwill that the Soviet Union had acquired in the West. Instead, he chose to pursue the most brutal policies of power, assuming that the withdrawal of U.S. military forces would leave the Soviet Union dominant in Europe. At the same time he did not overestimate his strength and sought to avoid confrontations that might lead to war. Urged by Tito to help drive the Anglo-Americans out of Trieste, he gave the Yugoslavs diplomatic support but stopped short of military action. In a revealing exchange with the Yugoslavs, he declared: Since all other methods were exhausted, the Soviet Union had only one other method left for gaining Trieste for Yugoslavia—to start war with the Anglo-Americans over Trieste and take it by force. The Yugoslav comrades could not fail to realize that after such a hard war the U.S.S.R. could not enter another.

Stalin did not hesitate to press hard where he thought substantial Soviet interests were at stake. The U.S. atomic monopoly in the immediate postwar years did not deter him from consolidating his position in eastern Europe. But stiffening Anglo-U.S. resistance led him to withdraw his troops from Iran in 1946, and he did not challenge the program of U.S. military and economic aid to Greece and Turkey that began in March 1947. Another barrier to the expansion of Soviet influence arose in western Europe, where the economic assistance program known as the Marshall Plan, put forward by the United States in June 1947, succeeded in restoring those countries to economic viability.

The main battlefield between the Soviets and the West

The
intrigues
of the
leaders

The
struggle
with the
West

in the postwar years lay in Germany. The breakdown of cooperation over the matter of reparations, the transformation of the eastern zone of occupied Germany into a Soviet satellite, the decision of the Western powers to unify the three western zones, and their introduction of a currency reform in 1948 set the stage for the Berlin crisis of 1948–49. Berlin had been divided into sectors by the occupying powers, and it lay far within the Soviet-occupied part of Germany. The Soviet blockade of West Berlin, which appeared primarily designed to prevent a West German state from coming into being, was answered by an Anglo-U.S. airlift. The blockade was finally lifted in May 1949. Its de facto result was the division of Germany into two states: the Federal Republic of Germany, aligned with the West; and the German Democratic Republic, incorporated into the Soviet satellite system. Stalin then sought unsuccessfully to prevent or impede the rearmament of West Germany.

Difficulties
in Yugo-
slavia
and Korea

Meanwhile, Stalin was encountering problems with Tito. Not only did Tito seem to have his own expansionist plans in the Balkans, but he also insisted on running the affairs of his party and state without interference. When Tito refused to subordinate himself to Stalin's dictates and showed himself powerful enough to make his defiance effective, he and his party were expelled from the Cominform and denounced as counterrevolutionary agents of American imperialism. Facing the possibility of Soviet invasion, Tito turned to the West for aid and demonstrated that a Communist regime could survive without Moscow's support or approval. Tito's successful assertion of national independence opened the first crack in the international Communist monolith. Stalin moved to tighten his hold over the rest of eastern Europe by purging some of the leading Communists in Poland, Bulgaria, Hungary, and Czechoslovakia.

Far Eastern problems. While Stalin sought to contain Titoism in eastern Europe, a far more formidable threat was beginning to take shape in Asia. The victory of the Chinese Communists in 1949 was saluted as a great triumph for the world Communist movement, but friction between Peking and Moscow began almost at once. The Chinese leader, Mao Tse-tung, proved a hard bargainer. A treaty concluded between the Soviet Union and China on February 14, 1950, provided for the return to China of the Manchurian Railway and the Soviet-held base of Port Arthur no later than 1952. The ultimate disposition of Dairen was to be settled after the conclusion of a peace treaty with Japan; meanwhile, its administration was transferred to China.

There was also Korea. At the end of World War II Soviet troops had occupied Korea north of the 38th parallel of latitude, the area south of the parallel being occupied by U.S. forces. The withdrawal of Soviet and U.S. troops in early 1949 set the stage for conflict between the Soviet-sponsored Korean National Democratic Republic in the north and a regime established in the south with the help of the Americans. Both claimed to represent the Korean nation. Stalin, perhaps impressed by the American failure to intervene on behalf of Chiang Kai-shek on the Chinese mainland and misled by authoritative U.S. pronouncements that South Korea was outside the sphere of U.S. defense commitments, either allowed or encouraged the North Koreans to invade the south on June 25, 1950, and apparently counted on a quick victory. Operating under United Nations auspices, U.S. forces intervened to aid the South Koreans and in their march north threatened for a time to eliminate Stalin's North Korean satellite altogether. The intervention of Chinese "volunteers" drove the Americans back to the 38th parallel, where the front remained more or less stabilized. Negotiations for a truce began in July 1951, but sporadic fighting continued over the next two years, and the conclusion of an armistice had to await Stalin's death. While the Soviet Union managed to avoid direct involvement in the conflict, the Korean War set off a formidable American rearmament drive and hardened American attitudes, in Europe as well as in Asia. As a direct result of the Korean conflict, the United States concluded a peace treaty and security pact with Japan in September 1951.

Stalin's legacy. The patrimony that Stalin handed on to his successors was in many respects impressive. The territorial gains achieved as a result of World War II, and the consolidation of control in eastern Europe, testified to the Soviet Union's status as a major power. The industrialization drive launched by Stalin had made the Soviet Union second only to the United States in heavy industry and military power. To this end Stalin invested heavily in elementary and higher education; pushed the training of engineers, technicians, and scientists; reorganized the incentive system to reward skills essential to the production process; and assigned great prestige to the new industrial elite in Soviet society. But forced-draft industrialization had exacted its toll. Its cost could be measured in the millions Stalin consigned to forced-labour camps or killed in mass purges, and in the chronic shortages of food, consumer goods, and housing that resulted from the priority accorded to heavy industry.

Heavy
investment
in
education

Stalin left a legacy of suppressed aspirations with which his successors had to reckon. First, there was a widespread desire for improvement in the standard of living. The most disadvantaged groups were the collective farmers and the unskilled and semiskilled workers, but the pressure for improvement extended well beyond these groups into the middle and even relatively privileged strata of Soviet society.

Second, there was an equally widespread yearning for greater personal security, for a life of stable expectations free from the numbing uncertainties of arbitrary arrest, police surveillance, denunciation by one's associates, or sentencing to forced labour.

Third, there was the desire for greater freedom—not necessarily freedom in the Western political sense, but freedom to use one's talents and capacities without fearing the consequences. These aspirations found their sharpest focus in the new Soviet intelligentsia. Their dreams of greater autonomy did not necessarily involve an overt challenge to the ruling ideology; many of those who harboured thoughts of greater independence and authority operated within a framework of loyalty to the Soviet system and envisaged such developments as strengthening a regime of which, after all, they were an integral part.

THE KHRUSHCHEVERA

Stalin's successors had to deal with these aspirations. The first response of Stalin's lieutenants upon his death on March 5, 1953, was to submerge their differences. Two facts quickly became apparent: first, that none of Stalin's former colleagues had the strength immediately to assume the position of undisputed leadership that Stalin had commanded; second, that all of them were at least temporarily agreed on the necessity of presenting a united front to the nation and the world. Faced with the uncertainties of the transitional period and the necessity of stabilizing their authority, they embarked on a policy of concessions and relaxation of tensions at home and abroad. Amnesties, reductions in the prices of consumer goods, and promises to raise living standards showed a new disposition to seek popular support. The ending of the Korean War helped to ease tensions with the West.

The transition. But the issue of the succession remained to be resolved. The leading figures were Georgy M. Malenkov, who served as head of government; Lavrenty P. Beria, who had the formidable police weapon in his hands; Vyacheslav M. Molotov, who headed the foreign ministry; Nikita S. Khrushchev, who had succeeded Malenkov as the senior party secretary; and Nikolay A. Bulganin, the minister of defense. The threat posed by Beria's control of the police was eliminated with his arrest in July and execution in December 1953.

At the September 1953 session of the Central Committee, Khrushchev was elected first secretary of the party, and his star began to rise. His report on the agricultural situation contained a remarkable acknowledgment of the seriousness of the agricultural crisis and initiated a series of measures to raise production, particularly by offering the collective farmers a higher return for their efforts. His propensity for bold and daring ventures was

The
rise of
Khrushchev

manifest in early 1954, when he obtained Central Committee approval for his virgin lands program. This sought to bring new areas into cultivation, mainly in western Siberia and northern Kazakhstan. The hope was to obtain a vast increase in grain output with minimal capital investment, but success depended on favourable weather in areas that were climatically marginal and subject to drought. Khrushchev was gambling his political future on harvests that might not materialize. Fortune favoured him in the early years, but later there were failures that contributed to his downfall.

Except for the innovations that Khrushchev sponsored in agriculture, his first public pronouncements followed a conservative course. There was a settlement of accounts with various Beria henchman, and a number of Stalin's victims were discreetly rehabilitated. Friction with Malenkov became evident. Khrushchev's militant speech at Prague on June 12, 1954, with its boast of Soviet leadership in developing the hydrogen bomb and its declaration that a nuclear war would spell the end of capitalism, contrasted sharply with Malenkov's earlier declaration that nuclear war would mean the destruction of civilization. In a series of speeches he clearly dissociated himself from Malenkov's alleged "consumerism" and reasserted the priority of heavy industry over light industry. The denouement came on February 8, 1955, when Malenkov resigned as head of government and was replaced by Bulganin.

It is not clear whether the positions taken by Khrushchev at this time represented his deep convictions or whether they were designed to undercut Malenkov among the more conservative elements in the party. Subsequently, however, Khrushchev adopted Malenkov's formulation on the danger of nuclear warfare, wavered on the issue of heavy versus light industry, and became a strong partisan of the consumer.

With the downgrading of Malenkov, Khrushchev's field of manoeuvre widened and he began to place his personal stamp on foreign as well as on domestic policy. One of his most dramatic initiatives was the effort to woo Tito back into the fold by flying to Belgrade in May 1955. The expedition, undertaken against the opposition of Molotov, was apparently inspired by Khrushchev's faith that shared ideological commitments would serve to transcend all past difficulties. Although the visit did result in improved relations, Tito wrung heavy concessions from the Soviet leadership, including recognition of Yugoslavia's independence in both domestic and international affairs. The ultimate consequences for the unity of the Soviet bloc were to be less than happy.

At the same time, Khrushchev moved toward an easing of relations with the West. The conclusion of the Austrian State Treaty with the Western powers in May 1955 put an end to the occupation of Austria and neutralized that country, marking the first significant withdrawal of Soviet power in Europe. Against this background of a negotiated settlement, Khrushchev met with U.S. Pres. Dwight D. Eisenhower in July 1955 in Geneva. No agreements of substance emerged from the conference, but the very fact that the sessions took place in an atmosphere of relative cordiality raised hopes for peace throughout the world. The "spirit of Geneva," as it came to be called, provided Khrushchev with a useful theme for his peace-seeking stance.

Khrushchev also undertook to strengthen Soviet influence among the new nations of Asia and Africa. Abandoning Stalin's postwar policy of encouraging local Communists to struggle for power in these countries, Khrushchev wooed their nationalist leaders with offers of aid and trade, sought to weaken their ties with the West, and tried to influence them to adopt a policy of positive neutrality favourable to Soviet interests. The campaign began with Khrushchev's and Bulganin's trip to India toward the end of 1955. A more ominous note was struck by an agreement to supply large quantities of arms to Egypt, thus aligning the Soviet Union with the anti-Israeli and anti-Western forces of Arab nationalism.

The 20th Party Congress. While the new dynamism thus introduced into Soviet foreign policy reflected a de-

parture from the Stalinist legacy, it remained for the 20th Congress of the party, held in February 1956, to define the content of what has since come to be described as de-Stalinization. Khrushchev made a "secret speech" to the delegates in which he combined a wide-ranging condemnation of Stalin's methods of rule with sensational disclosures of his crimes. Khrushchev's motivation in making the speech is not known, but it can be seen as a bold manoeuvre in the struggle for the succession, freeing him to pursue new policies of his own. In repudiating Stalin's terrorist excesses, he in effect offered his personal guarantee that they would not be repeated.

The Congress also brought a number of ideological innovations designed to make Communism more attractive abroad. The doctrine that Lenin had formulated and Stalin had often reiterated—that war between the Soviet Union and the so-called imperialist states was inevitable—was now amended to read that war was not "fatalistically inevitable." This new formulation laid the groundwork for a reaffirmation of the theory of peaceful coexistence, this time without the usual qualification as to its temporary character. Khrushchev's effort to present communism in a more attractive guise was particularly evident in his theses on ways of building socialism. In defending the proposition that there were different roads to socialism, he went so far as to include the Yugoslav road in his approved list. Even more startling was his statement that the parliamentary road to power was now open to the working class "in many capitalist countries," though he added that victory would be possible only under Communist leadership and that the use or non-use of violence would depend on the resistance offered by the capitalists.

The de-Stalinization campaign and the ideological reformulations announced at the 20th Congress were intended both to broaden the appeal of the Communist movement and to strengthen Khrushchev's own position within it. In the event, they came close to destroying Khrushchev, and they released divisive forces within the Communist world that have not yet run their full course. In the Soviet Union, the ferment stirred up by Khrushchev's secret speech—which did not long remain secret—infected wide circles of the intelligentsia and the youth and inspired a protest literature that went beyond denunciation of Stalin to criticism of the Soviet system itself. The demoralization elsewhere assumed proportions serious enough to threaten the Soviet hold over eastern Europe. The gathering unrest came to a climax in October 1956, when large contingents of Soviet troops had to be rushed into Hungary to suppress a revolution in which native Communists were leading workers into battle against the Soviet Union. In Poland, direct military intervention was narrowly averted when a last-minute *modus vivendi* was worked out with Władysław Gomułka, who had reassumed leadership in the Polish party over Soviet objections. The bloody repression in Hungary and the reimposition of cultural curbs within the Soviet Union tarnished the image of Khrushchev as a liberalizer. In the aftermath of Hungary, his prestige declined sharply. His handling of Hungarian events also exacerbated relations with Yugoslavia. The Chinese party leaders gave him public support, but subsequent disclosures showed that they were privately highly critical of his de-Stalinization campaign, of his ideological initiatives, and above all of his failure to consult with them. Within the Soviet party leadership his opponents began to organize a *cabal* to unseat him, and by May 1957 they were able to mobilize a seven-to-four majority against him in the Presidium, where they confronted him with a demand for his resignation.

It is a measure of the power concentrated in the office of the first secretary, as well as of Khrushchev's capacity to turn adverse developments to his own advantage, that he was able to triumph even in these circumstances. By appealing from the 11-member Presidium to the several-hundred-member Central Committee, in which his followers were strongly installed, he turned the tables on his opponents and emerged victorious. Molotov, Malenkov, and L.M. Kaganovich were expelled from both the Pre-

Khrushchev's denunciation of Stalin

Overtures toward Tito

Decline of Khrushchev's prestige

sidium and the Central Committee. In October of the same year he further consolidated his position by removing his erstwhile supporter Zhukov from the Presidium. (M.F.)

Khrushchev's position as party leader appeared unsailable. He had surmounted the crisis in eastern Europe, where the political structure seemed to have been stabilized. The world now saw a startling demonstration of Soviet accomplishments in rocketry. On August 26, 1957, the Soviet government announced the successful firing of an intercontinental ballistic missile. On October 4 the Soviet Union launched the first space satellite, Sputnik 1, followed on November 3 by Sputnik 2, with the dog Laika aboard as passenger. These developments lifted the Soviet Union's world prestige to new heights. They also enhanced the prestige of its political leadership. The space ventures had obvious military implications, and Khrushchev was not slow to claim that they indicated a significant shift in the balance of power. He initiated a drive to translate Soviet rocket superiority into diplomatic gains, and in a militant speech on November 10, 1958, ignited a new Berlin crisis by demanding that the occupation regime in West Berlin be terminated.

There were limits to the pressure that Moscow could apply on the West. The United States was still a formidable thermonuclear power with larger resources than the Soviet Union, and any confrontation that imperilled vital American interests might have disastrous consequences for both sides. As long as relations remained tense and difficult, they fostered an expensive "arms race" that diverted resources from domestic development and required continual sacrifices from the Soviet people. Easing of relations with the United States, by contrast, would offer hope of more rapid economic development and better living standards. But obstacles to even a partial détente remained formidable. Khrushchev's visit to the United States in the autumn of 1959 was made in the hope both of relaxing tensions and of winning concessions, but no concessions were forthcoming. On May 1, 1960, a U.S. high-altitude reconnaissance airplane, a U-2, crashed deep in Soviet territory and its pilot was captured. This was followed by the collapse of a Paris summit conference scheduled for that month. Further deterioration in Soviet-American relations was manifest in connection with the civil war in the Congo in the early 1960s, the building of the Berlin Wall in 1961, and finally the Cuban Missile Crisis in October 1962.

The Cuban Missile Crisis seemed to bring the two great nuclear powers to the brink of war. Under the guise of providing Cuba with defensive weapons, the Soviet government was found to be trying to establish launching sites on the island for medium- and intermediate-range missiles. The U.S. government's rapid deployment of a naval blockade around Cuba and an exchange of letters between Pres. John F. Kennedy and Khrushchev resulted in the latter's agreement to withdraw the "aggressive" weapons.

The rift with China. Khrushchev also faced increasing difficulties in his relations with China. At the root of the Sino-Soviet dispute lay the fact that the Soviet Union and China were two great nations with different destinies, each with its own defined set of interests. Khrushchev saw as his main tasks the building up of Soviet power, minimizing the risks of thermonuclear war, demonstrating the superiority of the Soviet system, and at the same time exploiting the vulnerabilities of the non-Communist world by means of nuclear stalemate. For the Chinese leaders, termination of the Kuomintang regime in Taiwan was a prime objective. Involved with this, however, and going well beyond it, was the need for Soviet military and economic support to help overcome Chinese backwardness.

Khrushchev's reluctance to challenge the U.S., as well as his insistence on giving priority to Soviet interests, became evident as the Sino-Soviet dispute developed. Faced with a choice between providing broad economic and military assistance to the Chinese or concentrating on the homeland, he chose the latter. Fearing that the Chinese might embroil him in a war with the West, he

denied them nuclear weapons and gave them only token support in their campaign to win Taiwan. He imposed more and more severe sanctions on the People's Republic, reducing trade and military and economic assistance, withdrawing specialists, and demanding the repayment of debts. His attempt to persuade the Chinese to desist from attacks on the Soviet leadership, however, failed. Faced with defiance and with Chinese efforts to mobilize support within the international Communist movement, he moved to close up his own ranks and to expel the Chinese and their allies from the movement as heretics who had broken away from the true faith of Communist internationalism.

In the wake of the Cuban Missile Crisis of 1962, with its sobering reminder of how close the world had come to thermonuclear warfare, Khrushchev demonstrated renewed eagerness to improve his relations with the United States and the West. He signed, with the U.S. and the U.K., the Nuclear Test-Ban Treaty (August 1963); joined in establishing better communications between Moscow and Washington; undertook in cooperation with the United States to prohibit missiles in orbit and to cut back the production of fissionable material; pressed restraints on the regime of Fidel Castro in Cuba; and relaxed tension over Berlin and undertook to improve relations with West Germany. All these efforts to "normalize" relations with the West were received by the Chinese as additional confirmations of Khrushchev's apostasy from true Marxism-Leninism. The rift was rapidly becoming unbridgeable.

Economic problems. Khrushchev's decision to seize the "peace issue," even at the cost of further alienating China, won support among Communists as well as non-Communists who feared nuclear war. But perhaps the most compelling reasons for seeking détente with the West were domestic strains and difficulties. The efforts of the post-Stalin leadership to raise the low living standards in the Soviet Union had whetted the appetite of the people but failed to satisfy it. Their deeply felt need for more and better food, clothing, and housing could not be met without diversion of investment from armaments and heavy industry to light industry and agriculture. The situation in agriculture was particularly troublesome. The good harvest of 1958, largely attributable to uniformly favourable weather, was followed by a series of mediocre harvests. Disaster struck in 1963, when bad weather and widespread drought combined to cause a greatly reduced output and compelled the government to purchase abroad approximately 12,000,000 tons of grain to meet consumer needs. While there were several reasons for the decline in agricultural output, one important factor was the failure to invest adequate capital in agriculture.

In a belated effort to meet the problem, Khrushchev announced a program to expand the chemical industry (including fertilizer production), increase output of agricultural machinery, extend irrigation, and other measures that required substantial new capital investment. This would mean less rapid expansion in heavy industry, as well as reduced funds in other sectors, including the military. The proposed shift in priority, of course, met resistance from others in the leadership.

Nor were Khrushchev's problems limited to agriculture. Industrial progress also lagged. The industrial slowdown and the fall in agricultural output combined to produce a serious decline in the overall economic growth rate in 1962-63.

Khrushchev's efforts to cope with these problems by periodic reorganizations of the state and party machinery created more confusion. His division of the party organization into separate industrial and agricultural branches in November 1962 antagonized many regional leaders and eroded his support in that section of the party apparatus where he had previously commanded the strongest loyalty. His increasing disposition to announce important changes in policy without consulting his colleagues in the Politburo tended to antagonize them. These domestic developments, taken together with his unsuccessful efforts to dislodge the Western

Domestic strains and difficulties

Cuban Missile Crisis

Growing dissension with China

powers from Berlin and the rebuff he received during the Cuban Missile Crisis, helped set the stage for his removal.

THE BREZHNEV–KOSYGIN ERA

Collective leadership. On October 16, 1964, the Soviet press announced that the Central Committee had met two days earlier and granted Khrushchev's request that he be released from his responsibilities "in view of his advanced age and deterioration in the state of his health." Pravda the next day charged him with:

harebrained schemes, halfbaked conclusions and hasty decisions and actions divorced from reality; bragging and bluster; attraction to rule by fiat; unwillingness to take into account what science and experience have already discovered.

The new collective leadership was led by Leonid I. Brezhnev, the new first secretary of the CPSU, and Aleksey N. Kosygin, who succeeded to the chairmanship of the Council of Ministers (*i.e.*, head of government). Public polemics with Peking ceased. The parallel industrial and agricultural hierarchies that Khrushchev had introduced into the party and governmental structure were combined. The new leaders announced the removal of "unwarranted limitations" on the size of household plots of land in the collective farms and on private livestock holdings by collective farmers. The party apparatus was assured that it could count on stability; the industrial managers were told that more rational economic policies would be pursued.

The style of the new Brezhnev–Kosygin leadership was much less dramatic than that of Khrushchev, and there was renewed emphasis on collective leadership. De-Stalinization was arrested, and indeed reversed, despite sharp opposition from liberal intellectual circles. Brezhnev took the lead by stressing Stalin's leadership during World War II and his achievements as an industrializer and builder of Soviet power. Khrushchev vanished from the public eye.

Within the new collective leadership, Brezhnev became increasingly prominent. His position was strengthened when in December 1965 N.V. Podgorny, one of the party secretaries, was elevated to the largely ceremonial post of chairman of the Presidium of the Supreme Soviet (*i.e.*, head of state) in place of Anastas I. Mikoyan. Another potential rival was eliminated when A.N. Shelepin lost his post as deputy premier and secretary of the Central Committee of the CPSU. At the 23rd Party Congress in March–April 1966, Brezhnev's title of first secretary was changed to general secretary, a title that had last been used by Stalin. During the next years Brezhnev's became the most authoritative voice on issues of domestic and foreign policy.

Unbinding the economy. Among the economic problems inherited by Khrushchev's successors, the most serious were in agriculture. In March 1965 Brezhnev promised relief to the collective and state farmers: higher prices for grain and livestock; stable delivery quotas; decreased tax burden on collective farms; and doubling of investments in farm machinery, trucks, tractors, fertilizer, and land improvement. The promises came too late to prevent a poor harvest in 1965, but the harvest in 1966 was very good, apparently confirming the measures Brezhnev had taken. That year the prices of trucks, tractors, and agricultural machinery were reduced for collective and state farms, rural electricity rates were reduced, and retail prices on certain consumer items in rural stores were lowered to the level of prices in the cities. Collective farms were authorized to introduce guaranteed monthly pay for their members based on rates of corresponding categories of state farm workers.

Poor harvests in 1967 and 1969 alternated with good harvests in 1968 and 1970. But even the harvest of 1970, estimated at more than 160,000,000 tons of grain, fell short of the projected goal for that year of 190,000,000–200,000,000 tons. If the overall performance of agriculture in the period 1966–70 compared favourably with that of the preceding five-year period, it was still far from satisfactory.

Khrushchev's successors also confronted difficult problems in industry. While space and weapons technology

and the iron and steel industry matched the best that the West had to offer, technological progress in such new industrial fields as automation, computers, petrochemicals, and industrial research and management techniques lagged well behind that of the United States, Japan, and western Europe. Many industries, particularly those producing consumer goods, also were far less developed technologically. The slowing of the industrial growth rate and the difficulty of resolving increasingly intricate and complex planning and management problems aroused deep concern in the party and government leadership.

Industrial reforms announced in September 1965 represented an effort to come to grips with the management problem by giving managers of enterprises greater discretion in decision making and by establishing an incentive system designed to reward the efficient use of resources. Hand in hand with these changes went complete repudiation of Khrushchev's administrative reforms. The whole system of regional, republican, and all-Soviet economic councils was abolished, and the ministerial system that had prevailed before 1957 was re-established. Each ministry was made responsible for a sector of the economy, while central planning functions were concentrated in the State Planning Committee (Gosplan), and responsibility for the allocation and distribution of supplies was entrusted to a new State Committee for Material and Technical Supplies.

These industrial changes were hailed by economic reformers as a modest step in the right direction, but enterprise managers complained that they were still hemmed in by rigid supply restrictions. The economy continued to function much as it had earlier—the bureaucratic machinery resisted change and innovation.

The Five-Year Plan for 1966–70, which was presented at the 23rd Party Congress in April 1966, represented a considerable reduction of the targets Khrushchev had originally set for 1970. Even the relatively modest new goals for 1970, however, turned out in many cases to be impossible of fulfillment.

Cultural controls. In cultural affairs the Brezhnev–Kosygin regime, after some tentative liberalization, became increasingly conservative and regressive. Innovations in the arts and literature had been greatly stimulated by Khrushchev's de-Stalinization program. The problem for Stalin's heirs was that of defining the limits of cultural freedom. It was perhaps inevitable that Khrushchev should find himself increasingly out of sympathy with the bolder spirits who wanted greater freedom of expression and found his cultural outlook oppressive. Nevertheless, his experiments in controlled relaxation provided the liberals with a field of manoeuvre, and it was Khrushchev himself who authorized the publication of Aleksandr I. Solzhenitsyn's powerful concentration-camp novel, *One Day in the Life of Ivan Denisovich*.

Khrushchev's successors were less tolerant. The arrests on September 13, 1965, of Andrey Sinyavsky and Yuly Daniel, for publishing abroad (under the pseudonyms Abram Tertz and Nikolay Arzhak, respectively) works allegedly slandering the Soviet Union, introduced a period of increased repression. Over the next years many other dissident writers and their sympathizers were also arrested, imprisoned, or consigned to forced-labour camps. After the Arab defeat by Israel in the Six-Day War of 1967, attacks on Israel and Zionism took on anti-Semitic overtones. The events in Czechoslovakia in 1968 (see below) also had repercussions within the Soviet Union. After the invasion of Czechoslovakia, Soviet cultural policy hardened. The treatment of Solzhenitsyn was symbolic: even before Czechoslovakia the police had seized all his unpublished manuscripts and withdrawn his few published works from circulation; in November 1969 he was expelled from the Writers' Union, and the Nobel Prize for Literature that was awarded to him the next year only intensified the attacks on him. Even such a moderate party spokesman as Aleksandr T. Tvardovsky, editor of the literary magazine *Novy Mir*, found himself deprived of his seat as an

alternate member of the Central Committee in 1966; he was subjected to increasing harassment culminating in a purge of the staff of the journal in 1970 that forced him to relinquish his editorship.

The repressive measures did not go unchallenged. After the sentencing of Sinyavsky and Daniel to seven and five years' hard labour, respectively, 63 well-known Moscow writers joined in an appeal for their release. On the eve of the 23rd Party Congress, 25 distinguished figures in Soviet public life, including some leading nuclear physicists, signed an open letter to Brezhnev registering their opposition to Stalin's rehabilitation.

Participants in the protest movement that began to take form in the years after Khrushchev's deposition thus ranged from prominent representatives of the scientific and creative intelligentsia, who confined their activities chiefly to signing occasional statements, to groups of dedicated activists, mostly students and younger intellectuals, who engaged in illegal public demonstrations, circulated underground literature, and constantly risked arrest and imprisonment. Their common bond was their dissatisfaction with the regime's repressive policy and their commitment to civil rights, greater intellectual freedom, and democratization.

Foreign policy. The Brezhnev-Kosygin regime also had to contend with difficult problems in foreign affairs. The most troublesome was that of relations with China. After an initial effort to lower tensions, the quarrel flared into violence, culminating in clashes along the Ussuri River (which for a considerable distance forms the border between the two countries) in March 1969 and along the Soviet-Sinkiang border in August. Subsequently the two sides agreed to negotiate their differences, but friction persisted. The Soviet Union strengthened its military formations along the Chinese border in the Far East, Central Asia, and the Mongolian People's Republic. It continued to provide military aid to India as well as to Pakistan in an effort to counter Chinese influence in those countries.

Indeed, even the extensive military and economic aid the Soviet government supplied to North Vietnam during the period of the Indochina war could be viewed not only as a demonstration of its willingness to come to the assistance of a fellow Communist state but also as an effort to decrease North Vietnamese dependence on China and to reinforce historic Vietnamese resistance to Chinese domination.

In eastern Europe, Khrushchev's successors found an increasing spirit of independence. Romania had begun to take an increasingly nationalist position, proceeding with plans for all-around industrialization despite Soviet insistence that Romania's economic role should be based on division of labour with other countries in eastern Europe. Over the next years Romania continued to display independence by maintaining friendly relations with China, reorienting its foreign trade away from the Soviet bloc, concluding a trade treaty with the United States (1964), expanding contacts with the West, opposing Soviet attempts to strengthen the Warsaw military pact (1966), establishing diplomatic relations with West Germany (January 1967), and adopting a neutral position in the Arab-Israeli War (June 1967).

Czechoslovakia was less fortunate. The downfall of the party leader, Antonín Novotný, and his replacement by Alexander Dubček in January 1968 was followed by the "Prague Spring," a period of remarkably free political expression. Past abuses were attacked, and demands for democratization of the system were made. Fearful that the Dubček leadership had lost control of the situation and that the challenge to party authority might spread to other Communist countries, the Soviet leaders decided on military intervention. On August 20, 1968, Soviet forces, aided by token military contingents from East Germany, Poland, Hungary, and Bulgaria, occupied Czechoslovakia. The invasion was justified by what later came to be called the Brezhnev doctrine: in essence, that the Soviet Union reserved the right to intervene militarily in the affairs of any of its east European Communist neighbours whenever it believed that its interests or the security interests

of its allies were significantly threatened. The effect of Soviet intervention was to force Czechoslovakia back on a more orthodox Communist course and to warn other Communist states in eastern Europe that there were limits to the degree of autonomy Moscow would tolerate.

Soviet policy in the Middle East was directed toward protecting the interests of its Arab clients, expanding Soviet influence, and eliminating residual Western influence. While the failure of the Soviet Union to come to the aid of the Arabs in the Six-Day War in 1967 tarnished its prestige, the Soviet decision to rearm its Arab clients won it renewed favour.

The primary objective of Soviet policy in western Europe continued to be to weaken U.S. influence. A special relationship was cultivated with France, which had withdrawn its forces from the North Atlantic Treaty Organization. A substantial increase in trade with several west European countries emphasized mutual needs and dependencies. At the same time, the Soviet Union remained determined to keep Germany divided and to press for general recognition of East German sovereignty. The decision of West Germany to sign the Treaty on the Non-proliferation of Nuclear Weapons on November 28, 1969, eased tensions on the nuclear armaments issue and helped prepare the way for an effort to normalize relations.

Soviet attacks on "American imperialism" became increasingly vigorous following the U.S. bombing attacks on North Vietnam in February 1965. The cooling of relations did not, however, prevent agreement on specific questions of mutual interest. In March 1966 a cultural agreement between the two countries was renewed; in September arrangements were made to exchange weather information; and in November agreement was reached to inaugurate direct commercial air flights between New York and Moscow. On January 27, 1967, both the U.S. and the Soviet Union became parties to the International Treaty on the Peaceful Uses of Outer Space, which prohibits the orbiting of nuclear weapons and provides, among other things, for assistance to astronauts or cosmonauts landed accidentally in either country. The ending of the India-Pakistan war in early 1966, as a result of Kosygin's successful mediation, was supported by parallel American efforts and stemmed from a common desire to contain Chinese penetration into southern Asia. The Middle East crisis of May 1967, which culminated in the Six-Day War in June, brought a new clash of Soviet and U.S. interests; but both sides joined in efforts to stop the fighting in order to prevent the war from broadening into a direct Soviet-American military confrontation. (M.F./Ed.)

Space
treaty

Brezhnev's primacy. The Soviet invasion of Czechoslovakia blighted the hopes of détente in Europe that since the mid-1960s had been the main objective of Soviet diplomacy. For a few years Western governments chose to ignore Soviet overtures, but in April 1969 the North Atlantic Treaty Organization (NATO) powers proposed to explore with the Soviet Union and its allies the concrete issues between them that best lent themselves to fruitful negotiations. In October Willy Brandt became chancellor of West Germany, an event that in this respect was helpful because he declared his readiness to establish good relations, on a realistic basis, with the Soviet Union, Poland, and East Germany. On August 12, 1970, in Moscow and on December 7 in Warsaw Brandt initialled with the Soviet and Polish premiers, respectively, separate treaties by which West Germany recognized the inviolability of the existing frontiers. On May 26, 1972, Pres. Richard M. Nixon and Brezhnev signed in Moscow the first SALT (Strategic Arms Limitation Talks) agreement, a document embodying acceptance on both sides that nuclear war had ceased to be a reasonable option. On June 3, 1972, in a quadripartite agreement, the foreign ministers of the U.S., the U.K., France, and the Soviet Union declared that West Berlin was not a constituent part of West Germany but that the existing links between that city and West Germany must be maintained and developed. Finally, on December 21, in East Berlin, the two German states concluded a basic

treaty establishing formal relations between them that cleared the way for the entry of both into the United Nations.

Ratification by the West German Bundestag of the Moscow and Warsaw treaties and of the basic inter-German treaty created a good atmosphere for Brezhnev's visit to Bonn—the first by a Soviet statesman of his rank to the capital city of West Germany—in May 1973. In June, Brezhnev travelled to Washington, where he signed with Nixon a series of relatively minor executive agreements and an agreement designed to avert nuclear war between the U.S. and the U.S.S.R. or between one of them and any other country. Brezhnev expressed his conviction that Soviet-U.S. relations were assuming "maximum stability of irreversible character."

The Helsinki Conference

On July 30, 1975, the heads of the 33 European governments and those of the U.S. and Canada met at Helsinki in the Conference on Security and Cooperation in Europe; on August 1 they signed the Final Act that brought the conference to its solemn conclusion. The participating states recognized as inviolable the existing frontiers of all states in Europe. The Soviet Union and its allies had to make substantial concessions in the field of human rights, but the Helsinki Conference was hailed in Moscow as a major success for the detente policy in Europe, since the frontiers of its eastern European satellites were now secured. Brezhnev, however, in his report of February 24, 1976, to the 25th Party Congress of the CPSU, warned that ideological confrontation between the capitalist and socialist camps would continue. "We do not conceal our views [he said]. In the developing countries, as everywhere else, we are on the side of the forces of progress, democracy and national independence, and regard them as friends and comrades in struggle."

In October 1977, deputy foreign ministers of the 35 governments assembled in Belgrade to review the working of the Helsinki agreement of 1975, but the delegates of the Soviet Union and its allies refused to discuss issues concerning the basic human rights of their citizens. The chief Soviet representative affirmed that, though the Soviet Union was fulfilling all the provisions of the Helsinki Accord, it refused to submit to outside scrutiny matters that fell within the competence of the Soviet state. In March 1978 the Belgrade meeting ended in deadlock, its only decision being that another post-Helsinki meeting would be held in 1979.

Dissidence within the Soviet Union over the denial of basic human rights caused increasing anxiety to the Soviet authorities. By May 1976 the security police had begun to put pressure on the members of the Public Group to Promote the Fulfillment of the Helsinki Accord. Later the Soviet press attacked Pres. Jimmy Carter of the U.S. for introducing the human rights theme in his inaugural address (January 20, 1977) and the U.S. Department of State for its warning to Moscow against trying to silence Andrey Sakharov, a leading critic of political repression. On March 21, 1977, Brezhnev denounced the "interference in our internal affairs" and added that "A normal development of relations on such a basis is unthinkable." A new SALT meeting between the U.S. and Soviet delegations, however, opened in August 1978.

In his speech of February 24, 1976, Brezhnev announced that since the 24th Party Congress (April 1971) nearly 2,600,000 men and women had been admitted to membership in the CPSU, which now numbered 15,694,000. The 25th congress elected a new 287-member Central Committee, which appointed a new Politburo of 16 members with an average age of 66. Including the candidate members and secretaries, the membership of the party's leadership rose from 25 (1971) to 28.

On March 24, 1977, Brezhnev submitted to the Central Committee the draft of a new Soviet constitution. In his speech he included the following frank statement:

We know, Comrades, that some years after the adoption of the current constitution were darkened by illegal repressions, violations of the principles of socialist democracy and Leninist standards of party and state life. . . . The party has resolutely condemned this practice and it must never be repeated.

The new constitution, which showed no basic differences from the Stalin Constitution of 1936, was approved by the Supreme Soviet on October 7, 1977.

Reporting to the 25th Party Congress on main economic guidelines for the tenth Five-Year Plan (1976–80), Aleksey Kosygin stated that during the 1971–75 plan total industrial output had increased by 43 percent, and announced the targets for 1980. On May 6, 1978, at Bonn, Brezhnev and Chancellor Helmut Schmidt of West Germany signed a declaration confirming that the Soviet-West German treaty of August 12, 1970, will "continue to determine the direction of relations between the two states." At the beginning of 1979, rumours that the Soviet Union would favour the "neutralization" of a reunited Germany appeared in some Western newspapers; Piotr Abrasimov, the Soviet ambassador to East Germany, however, described these reports as "calumnious."

After six and a half years of arduous negotiations, the United States and the Soviet Union by May 1979 reached agreement on a new treaty limiting their strategic nuclear armaments. Presidents Jimmy Carter and Leonid Brezhnev met in Vienna and on June 18 signed the SALT II, which limited each country to a ceiling of 2,250 strategic missiles by 1981. Confirmation of the treaty by the U.S. Senate was delayed, however, when a serious crisis in U.S.-Soviet relations arose six months later, centring on Afghanistan. In 1978–79, that country suffered a series of bloody coups in which three successive Marxist leaders took power. The third, Babrak Karmal, took the presidency on December 27, 1979, with the support of a massive invasion of Soviet armed forces. President Carter condemned the Soviet military intervention as being "in blatant violation of accepted international rules of behavior" and as a serious threat to world peace. Ronald Reagan, elected to the U.S. presidency in November 1980, took a strong stance vis-a-vis the Soviet Union during the first months of his administration.

By 1980 Brezhnev's political career appeared to be coming to a close. He was the first Soviet statesman to hold simultaneously the posts of party leader (general secretary of the CPSU, from 1964) and head of state (chairman of the Presidium of the Supreme Soviet, from 1977); and as a marshal of the Soviet Union (from 1976) he wore the highest decorations. Under his rule the Soviet Union, the last colonial empire in the world, became stronger on land, in the air, and especially on the seas. But the rulers of this multinational agglomeration, where Russians make up a little more than half of the population, are convinced that it can survive only as a totalitarian police state. And this is its weakness. (K.M.S.)

Invasion of Afghanistan

BIBLIOGRAPHY

Russia to c. 1700: The best brief survey of early Russian history in English is SERGEI F. PLATONOV, *History of Russia* (1925; orig. pub. in Russian, 1910; French trans., 1929). Other useful surveys include V.O. KLIUCHEVSKY, *A History of Russia*, 5 vol. (1911–31; new trans. of vol. 3–4, 1961–68; orig. pub. in Russian, 1904–10); and PAVEL N. MILIUKOV, *Outlines of Russian Culture*, 3 vol. (1942; orig. pub. in Russian, 1898–1903). For the history of Muscovy, see JOHN L.I. FENNELL, *The Emergence of Moscow, 1304–1359* (1968) and *Ivan the Great of Moscow* (1961); GEORGE VERNADSKY, *The Tsardom of Muscovy, 1547–1682*, 2 vol. (1969).

1700–1801: A topical interpretive synthesis, with a comprehensive bibliographical guide, is MARC RAEFF, *Imperial Russia 1682–1825: The Coming of Age of Modern Russia* (1971). For imperial institutions, see the indispensable ERIK AMBURGER, *Geschichte der Behördenorganisation Russlands von Peter dem Grossen bis 1917* (1966). For the reforms and reign of Peter the Great, a very brief summary is B.H. SUMNER, *Peter the Great and the Emergence of Russia* (1950); while the only comprehensive survey is REINHARD WITTRAM, *Peter I, Czar and Kaiser*, 2 vol. (1964). The standard economic history of Russia is PETER I. LYASHCHENKO, *History of the National Economy of Russia to the 1917 Revolution* (1949, reprinted 1970; orig. pub. in Russian, 2 vol., 1947–48). For an introduction to a history of the nobility, both as social class and matrix of the intelligentsia, see MARC RAEFF, *Origins of the Russian Intelligentsia: The Eighteenth-Century Nobility* (1966). For the Russian Church, see JAMES CRACRAFT, *The Church Reform of Peter the Great* (1971). For the Old Believers, see ROBERT O. CRUMMEY, *The Old Believers and the World of*

Antichrist: The Vyg Community and the Russian State, 1694-1855 (1970). On education, cultural life, and the emergence of radical thought among the intelligentsia, see HAROLD B. SEGEL (comp.), *The Literature of Eighteenth-Century Russia*, 2 vol. (1967). Sources of philosophy and social thought may be found in JAMES M. EDIE, JAMES P. SCANLAN, and MARY-BARBARA ZELDIN (eds.), *Russian Philosophy*, 3 vol. (1965); and MARC RAEFF (ed.), *Russian Intellectual History: An Anthology* (1966). For a comprehensive survey of philosophical trends, see V.V. ZENKOVSKY, *A History of Russian Philosophy*, 2 vol. (1953; orig. pub. in Russian, 1948-50). On educational and scientific institutions, see A.S. VUCINICH, *Science in Russian Culture*, vol. 1, *A History to 1860* (1963); the seminal revolt of Radishchev is discussed by ALLEN MCCONNELL in *A Russian Philosopher: Alexander Radishchev* (1964), and in RADISHCHEV'S *Journey from St. Petersburg to Moscow*, trans. and ed. by LEO WIENER and RODERICK PAGE THALER (1958). On the influence of the German Enlightenment and Russia's relations with the West, see MARC RAEFF, "Les Slaves, les Allemands, et les 'Lumières,'" *Revue Canadienne d'Études Slaves*, 1:521-551 (1967).

1801-1917: General surveys of Russian history in the 19th century include: MICHAEL T. FLORINSKY, *Russia: A History and an Interpretation*, 2 vol. (1953-54); and HUGH SETON-WATSON, *The Russian Empire, 1801-1917* (1967). The best work in English on the reign of Alexander I is MARC RAEFF, *Michael Speransky, Statesman of Imperial Russia, 1772-1839* (1957). The best work on the reign of Nicholas I is NICHOLAS V. RIASANOVSKY, *Nicholas I and Official Nationality in Russia, 1825-1855* (1959). A useful addition is JOHN S. CURTISS, *The Russian Army Under Nicholas I, 1825-1855* (1965). In *Black Night, White Snow: Russia's Revolutions, 1905-1917* (1978), HARRISON E. SALISBURY grapples with a large subject and emerges on top. For the general economic development of Russia in the 19th century, see G.T. ROBINSON, *Rural Russia Under the Old Régime* (1932). The industrialization drive of the 1890s is treated in THEODORE VON LAUE, *Sergei Witte and the Industrialization of Russia* (1963). Economic and political trends at the turn of the century are discussed in D.W. TREADGOLD, *The Great Siberian Migration* (1957). Two biographical studies that do much to explain the interplay of cultural and political factors in the 19th century are M. MALIA, *Alexander Herzen and the Birth of Russian Socialism, 1812-1855* (1961); and RICHARD PIPES, *Struve: Liberal on the Left*, vol. 1, *1870-1905* (1961). For the earlier revolutionary movement and the development of so-called Populism, the classical description and interpretation is FRANCO VENTURI, *Il populismo russo* (1952; Eng. trans., *Roots of Revolution*, 1960). An absolutely essential source for the history of revolutionary activity up to 1917 are the earlier volumes of LENIN'S *Works* (available in English in many editions). Three useful books on individual non-Russian peoples in this period are MICHAEL HRUSHEVSKY, *A History of the Ukraine* (1954, reprinted 1970; orig. pub. in Russian, 1918); S.A. ZENKOVSKY, *Pan-Turkism and Islam in Russia* (1960); and GEOFFREY WHEELER, *The Modern History of Soviet Central Asia* (1964). Four studies of important moments and problems in Russian foreign policy, which thoroughly examine the Russian point of view, are MARIAN KUKIEL, *Czaryński and European Unity, 1770-1861* (1955); MICHAEL B. PETROVICH, *The Emergence of Russian Pan-Slavism, 1856-1870* (1956); B.H. SUMNER, *Russia and the Balkans, 1870-1880* (1937); and A. MALOZEMOFF, *Russian Far Eastern Policy, 1881-1904* (1958). On the final collapse of tsardom, MICHAEL T. FLORINSKY, *The End of the Russian Empire* (1931), remains the best general survey.

1917-1939: General works on the period include: GEORG VON RAUCH, *Geschichte des bolschewistischen Russland* (1955; Eng. trans., *A History of Soviet Russia*, 5th rev. ed., 1967), a critical survey; EDWARD HALLETT CARR, *A History of Soviet Russia*, 20 vol. (1950-79), a detailed history of the years 1917-29; RAPHAEL R. ABRAMOVICH, *The Soviet Revolution, 1917-1939* (1962), the Menshevik viewpoint; B.N. PONOMAREV et al. (eds.), *History of the Communist Party of the Soviet Union*, 2nd rev. ed. (1963), translation of an official Soviet textbook; and MAURICE DOBB, *Soviet Economic Development Since 1917* (1948), sympathetic though critical. Biographies of the Bolshevik leaders include: ADAM B. ULAM, *The Bolsheviks* (1955), on Lenin; ISAAC DEUTSCHER, *The Prophet Armed: Trotsky 1879-1921* (1954), *The Prophet Unarmed . . . 1921-1929* (1959), and *The Prophet Outcast . . . 1929-1940* (1965); BORIS SOUVARINE, *Stalin* (1935; Eng. trans., 1939); and ROBERT CONQUEST, *The Great Terror* (1968), an exhaustive account of the purges of the 1930s. Outstanding works on Soviet foreign relations include: MAX BELOFF, *The Foreign Policy of Soviet Russia, 1929-1941*, 2

vol. (1947-49); LOUIS FISCHER, *The Soviets in World Affairs*, 2 vol. (1930); GEORGE F. KENNAN, *Russia and the West Under Lenin and Stalin* (1961), a critical analysis of the period 1917-45; and ADAM B. ULAM, *Expansion and Coexistence: The History of Soviet Foreign Policy, 1917-67* (1968).

1940 to the present. (Domestic politics): JOHN A. ARMSTRONG, *The Politics of Totalitarianism* (1961), a history of the Communist Party from 1934 to 1960; ABRAHAM BRUMBERG (comp.), *In Quest of Justice* (1970), commentaries and documents of protest and dissent in the Soviet Union; ALEXANDER DALLIN and T.B. Russian Soviet Federated Socialist Republic

In terms of territory, population, and economic development, the Russian Soviet Federated Socialist Republic is pre-eminent among the 15 republics that make up the

The
character
of the
R.S.F.S.R.

Soviet Union. It covers 76 percent of that nation's area and—following it—is the second largest political unit in the world; with 6,592,800 square miles (17,075,400 square kilometres), it is almost twice the size of either China or the United States. Its population in 1975, 133,700,000, places it fifth among the political units of the world, exceeded only by China, India, the Soviet Union itself, and the United States. The "Russian" of its title (often abbreviated R.S.F.S.R., otherwise known as the Russian Federation, or simply Russia) derives not from *ruskaya*—"pertaining to the Russian nationality"—but from *rossiyskaya*—"pertaining to the country Russia," and the vast territory is in fact the home of some 60 nationalities. This situation is reflected in the republic's complex system of administrative subdivisions.

Extending halfway round the northern portion of the globe and covering much of eastern and northeastern Europe and all of northern Asia, the Russian S.F.S.R. displays an enormous variety of landforms and environments. These form great bands across its territory: Arctic deserts lie to the north, giving way toward the south to the wastes of tundra and the forest that covers two-thirds of the entire republic and accounts for much of its character. In the far south, beyond belts of open steppes, portions of the land assume a subtropical and even a hot semidesert character. The republic's position, in latitudes in which evaporation can scarcely keep pace with the accumulation of moisture, engenders abundant rivers (including a number of the world's largest), lakes, and swamps.

Most of the people are found in a great triangle in the western, or European, portion of the republic, but since World War II there has been a great flow of population to the Siberian Basin of the east, where deposits of minerals are being exploited.

The republic itself was set up immediately after the October Revolution of 1917 and became a union republic on December 31, 1922, when the federal state of the Soviet Union was created. Its capital, Moscow, is also the capital of the Soviet Union.

The Russian S.F.S.R.'s maritime border, longer than the Equator, meets the Arctic and Pacific oceans. The land borders touch Norway, Finland, and Poland on the northwest and west and the People's Republic of China, the Mongolian People's Republic, and North Korea on the south. They also touch eight constituent Soviet republics: to the west Estonia, Latvia, Lithuania, and Belorussia, to the south the Ukraine, Georgia, Azerbaijan, and Kazakhstan.

Historically, the republic was the core of the expanding Russian state and suffered onslaughts ranging from that of the Mongol hordes in the 13th century to the Nazi invasion of World War II. This heritage, together with a vast area and great natural wealth, has given Russia a unique place among the Soviet republics. Its brooding landscapes and the complexities of the old society have been celebrated in prose and in music by such giants of world culture as Pushkin, Tolstoy, and Tchaikovsky, while the October Revolution and enormous transformations engendered in the Soviet period have been recorded by such people as the novelists Maxim Gorky and Mikhail Sholokhov, the poet Vladimir Mayakovsky, and the composers Dmitry Shostakovich and Sergey Prokofiev.

This article describes the land and peoples of the contemporary republic and the specific contribution it makes to the overall Soviet economy, society, and culture. For historical treatment, see *RUSSIA AND THE SOVIET UNION, HISTORY OF*. There are also separate articles on the major cities and physical features of the republic.

THE LAND

The natural regions. The Russian S.F.S.R. is divided basically into plains and mountains and, using these and other natural characteristics as criteria, may be subdivided into nine physical regions.

The Kola-Karelian region. The Kola-Karelian region lies in the northwest of the European Russian S.F.S.R. To the west, beyond the Finnish (and, in the north, a

small portion of the Norwegian) frontier, it continues as Scandinavia. Karelia is a plateau marked by ridges and knolls and dotted with many lakes, the largest being Ladoga, Onega, Segozero, Pyaozero, Imandra, Umbozero, and Lovozero (ozero, "lake"). Ancient glaciation is evident everywhere, both in the scoured landscape of the glaciers' advance and in the mask of drift left on their retreat.

Taiga and swamps cover the southern part. The Kola Peninsula is mainly hills and plateaus, though Mt. Khibini rises to 3,907 feet (1,191 metres).

Despite the Arctic location, the climate here is temperate continental, averaging 12° F (−11° C) in January and 57° F (14° C) in July, with annual precipitation of 14–20 inches (350–500 millimetres). The principal rivers are the Ponoy, Vodla, Kem, and Suna. There is a narrow band of tundra in the northern Kola Peninsula and a zone of taiga forests on rocky podzolic soil in the south.

The Kola region has deposits of nickel, copper, iron, valuable types of mica, apatite, and nepheline as well as raw materials for the construction industry and peat.

Animal life depends on the character of the natural zones. The Arctic fox, northern reindeer, and snowy owl are characteristic of the tundra; elk, wolverine, brown bear, lynx, hare, and fox are found in the taiga and forest zones.

The Russian Plain. The Russian Plain, one of the great lowland areas of the world, extends east from the western border to the Ural Mountains and from the Arctic Ocean south to the Caucasus and the Caspian Sea. The topography is varied; there are elevations of up to 1,300 feet (400 metres) in the Valdai Hills west of Moscow, in central Russia stretching south of Moscow, and in the Volga Hills (just west of the Volga, southeast of Moscow), alternating with the vast lowlands of the Oka-Don and the Caspian littoral, part of which lies below sea level. The Oka-Don lowland, passing imperceptibly into the Volga Hills, ends sharply at the Volga, where the Zhiguli Mountains begin, sometimes rising to 1,200 feet.

The climate is mainly temperate continental, with January temperatures varying from 29° F (−1.5° C) in the southwest to −8° F (−22° C) in the northeast. July temperatures average 48° F (9° C) in the north and 77° F (25° C) in the southeast. Annual precipitation ranges from around 24 inches (600 millimetres) in the west to five inches (125 millimetres) in the southeast. Many great rivers flow across the plain, most of them—for instance, the Volga, Dnepr, Don, and Western Dvina—originating in the centre. They are fed mainly by snow and freeze for about two months in the south and seven in the northeast. The Volga is the principal river, its basin encompassing nearly half the Russian Plain. In the north there are many lakes and swamps.

The European triangle is nearly devoid of exploitable natural resources. The soil is very thin podzol, which historically has yielded poor crops and much of which has been allowed to return to forest, where the Russians like to hunt mushrooms. The situation for the homeland of the Great Russians is desperate in regard to underground minerals, for there are none. Prior to the 18th century, iron, copper, and more precious metals had to be imported into Muscovy. The situation changed when the Russians began to exploit the Urals during the reign of Peter the Great and subsequently moved to develop Siberia, the Ukraine, and other regions outside their homeland. The absence of local natural resources explains much of Russia's geopolitics for the past quarter millennium.

A significant part of the Russian Plain is covered with forests: taiga (spruce, fir, and Siberian spruce), mixed, and broad-leaved (oak, birch, beech, and linden). In the north of the plain are tundras; on the southeast fringes, steppes and semideserts.

Animal life varies: Arctic fox, northern reindeer, snowy owl, and willow ptarmigan are found in the tundras; white elk, brown bear, lynx, wolverine, squirrel, sable, hare, and fox in the forests. In the forest steppes and steppes are rodents—suslik (ground squirrels, genus

Karelian
lakes

Absence of
natural
resources

Spermophilus), jerboa, and marmot—and birds—bustard, eagle, and *strepit* (related to the bustard).

The Caucasus. The Russian S.F.S.R. includes the northern part of the Great Caucasus (Bolshoy Kavkaz), extending north-northwest to south-southeast from the Black Sea to the Caspian, containing the Kuban–Azov and Terek–Kuma lowlands, separated by the Stavropol Upland, about 2,300 feet high. Alpine and moderate-altitude relief prevails, and the region's climate is temperately continental; January temperatures average 21° F (–6° C) and July 76° F (24.5° C). In parts of the east the climate is arid. Maximum annual precipitation is 15.7 inches (400 millimetres). The mountaintops have permanent snow and glaciers, feeding the numerous rivers, which can flood for up to six months in warm years. Tundra vegetation and, on the lower slopes, alpine meadows are found. Pine, spruce, and fir grow to elevations of 6,500 feet (2,000 metres), and oak, hornbeam, ash, beech, and wild fruit trees are found to 5,000 feet (1,500 metres).

The foothills form sloping plateaus, sometimes intersected by spurs rising 5,000 feet. Fields, vineyards, and orchards are numerous, and in the subtropical southwest are laurel, palm, bamboo, and boxtree. The seaward slopes of the Caucasus Mountains, with their extremely fertile *zheltozem* (yellow-earth) soils, luxuriant vegetation, and subtropical climate, make good sites for health resorts, rest homes, Pioneer camps, and tourist centres.

Mountain
animals
of the
Caucasus

Mountain animals include species from temperate forests, semideserts, and high mountains: tur (wild goat), chamois, stag (red deer), brown bear, lynx, fox, and leopard, and, among the birds, eagle, Caucasian grouse, and pheasant. (See also CAUCASUS MOUNTAINS.)

The Urals and Novaya Zemlya. The great north–south spine of the Urals and of their continuation, Novaya Zemlya (a group of islands in the Arctic Ocean), separates Europe from Asia. The Urals extend about 1,250 miles north–south and are extended an additional 600 miles into the Arctic Ocean by Novaya Zemlya; their landscapes vary from tundra to steppes. Tundra and forest tundra cover Novaya Zemlya and the Polar and Nether-Polar Urals, culminating in Mt. Narodnaya at 6,214 feet (1,894 metres). Shrubs are the commonest vegetation, but there are leaf-bearing trees in the south. The animal life is sparse, mostly reindeer, Arctic fox, willow ptarmigan, duck, and goose. An extremely harsh climate and permafrost inhibit the development of this northernmost area.

The Northern Urals and the northern part of the Central Urals form a taiga zone, rich in forests and potash minerals, predominantly carnallite and sylvite. The Central Urals and much of the Southern Urals are forest steppes and steppes, including extensively eroded massifs and high plains. The Southern Urals' highest point is 5,374 feet (1,638 metres), and it has a continental climate; coniferous, mixed, and broad-leaved forests are found on the slopes, with forest steppe and steppe in the foothills. The area's favourable climate and topography, valuable iron, copper, nickel, asbestos, gemstone, construction-stone, and petroleum deposits, and comparative proximity to areas of dense population have caused it to become highly industrialized. (See also URAL MOUNTAINS.)

The West Siberian Plain. The West Siberian Plain, between the Urals (west) and the Yenisey River (east), is a subdivision of the Siberian Basin, the taming and exploitation of which is forming what may be the greatest developing region in the world today. The area is a plain, marshy in the north and with marked differences encountered in proceeding from tundra to steppe. The climate is continental, with prolonged winter; January's temperatures average –18° F (–28° C) in the north and 3° F (–16° C) in the south, while July's average is 37° F (3° C) in the north and 73° F (23° C) in the south. Precipitation varies between about 18 inches (450 millimetres) in the taiga and about half that amount in the tundra and steppes.

The rivers belong to the Ob and Yenisey systems (both of which traverse the plain from the south to north and empty into the Kara Sea of the Arctic Ocean), and there

are various lakes: Chany, Ubinka, and Kulunda. Tundra and forest tundra with peat bogs cover the north, under which vast oil and natural gas deposits have been discovered. The Urengoy natural gas deposits (some 100 miles up the Pur River, which lies about halfway between the Yenisey and Ob) are considered to be the world's largest.

Taiga prevails in the central West Siberian Plain, to the north growing spruce and cedar, in the centre cedar and pine, and to the south fir, spruce, and cedar. Precipitation is, as noted above, twice that of the tundra, and the climate is kinder. Large oil and natural gas deposits have been discovered in the Ob region, and deposits of brown iron ore lie along the Yenisey River. Great expanses are covered with peat.

Western Siberia's southern stretches include the Ishim (west of Lake Chany), Baraba, and Kulunda (south of Lake Chany) steppes. This area is one of the Russian S.F.S.R.'s most important granaries. The vegetation and animal life are meagre: fir and cedar, the large-eared hedgehog, the migratory and striped hamsters, and the chestnut and red-cheeked suslik. The Kulunda Steppe has many ill-drained lakes with high mineral content.

Central Siberia. Central Siberia is a vast territory between the Yenisey River, on the west, and the mountains of northeastern Siberia, on the east. The region includes the Byrranga and Severnaya Zemlya mountains (in the far north), the North Siberian Plain, and the Central Siberian Plateau (farther south), the peaks of which reach 5,600 feet. In the east, along the Lena and Vilyuy rivers, lies the Central Yakut Lowland. The climate is harshly continental, January temperatures dropping to –47° F (–44° C), though summer, when 68° F (20° C) may be recorded in the south, is benign. Annual precipitation is eight to 20 inches (200–500 millimetres). Permafrost is virtually ubiquitous. There is a dense river network, the largest river being the Lena, with its tributary the Vilyuy, and the Yenisey, with its tributaries the Angara, Podkamennaya Tunguska, and Nizhnaya Tunguska.

Pine forests cover about 60 percent of the Central Siberian terrain; in the north there are Arctic deserts and mountain and plain tundras and in the south small strips of forest steppe and steppe, as in the areas around Achinsk, Krasnoyarsk, Irkutsk, and Kansk.

The Central Siberian Plateau is a high plain, marked by fracture zones along the edges and mountainous in places. The northern borders are covered by tundra and forest tundra, the southern by forest steppe. The remainder is taiga, with stone outcrops covered by mountain tundra sometimes rising to 2,600 feet (800 metres). In the taiga area are dark-coned forests below 1,300 feet and cold-resistant larch forests—the preponderant form of arboreal vegetation in Central Siberia—above.

The climate becomes increasingly continental eastward, while precipitation diminishes, with a long, cold, almost snowless winter and a short, mild summer.

The rivers are numerous, swift, and full of rapids, providing sources of energy complementing the rich deposits of lead and iron ores, nephelines, and coal. The Irkutsk and Bratsk hydroelectric power plants on the Angara River, which flows northwest from Lake Baikal, and the Ust-Ilimsk hydroelectric power plant, which, though not completed, began generating power in 1974, augur well for the future development of the Russian S.F.S.R.

To the north of the Central Siberian Plateau extends the Taymyr Depression. The Byrranga Mountains—an isolated, compact upland some 1,800 feet high—break into separate ridges near the Laptev Sea, in the east. In the southwestern Taymyr Depression are deposits of copper, nickel, and rare-earth metals.

Southern Siberia's mountains, which include the Altai, Salair, Kuznets Alatau, Sayan, and Stanovoy ranges, are part of the belt forming the southern border of the Soviet Union and average 1,100 feet. The climate is sharply continental, January temperatures averaging –13° F (–25° C), with mild summers. Intermontane basins receive about six inches in precipitation; the windward

Hydro-
electric
power of
Central
Siberia

western slopes gather 60–80 inches (1,500–2,000 millimetres). The region contains the sources of the Ob, Yenisey, and Lena rivers as well as Lake Baikal, the deepest lake in the world. Soil and vegetation vary greatly: a widespread mountain-taiga belt, with subalpine and alpine meadows and mountain tundras in the high mountains, steppes in the intermontane hollows and foothills, and semideserts in the south.

The greatest elevations are in the Tsentralny Alatau (Central Alatau), particularly the southern chain, formed by the Katun and Yuzhno-Chuysky (South Chuya) ranges, where Mt. Belukha, the highest point in the entire Asiatic Russian S.F.S.R., rises 14,783 feet (4,506 metres). Snow and glaciers cover the peaks—numbering more than 1,000—all year.

In the intermontane hollows are steppes: Uymon, Abay, and Kansk, the highest of which, at around 6,000 feet, are reminiscent of the deserts of neighbouring Mongolia. The soil, vegetation, and animal life differ with altitude, though mountain taiga vegetation predominates.

The Altai Mountains (*q.v.*) are crossed by rivers that, with their rapids, are large reserves of energy. Near Mt. Belukha is the source of the Katun River, which joins the Biya to form the Ob. There are more than 3,500 mountain lakes, the principal being Lake Telets.

To the east of the Altai stretch the Zapadny Sayan (West Sayan) Mountains, well broken up, and on the border with the Mongolian People's Republic are the broad Tannu-Ola Mountains. Between them is the Tuva Trough, at about 2,000 to 3,000 feet above sea level. The climate here is harshly continental—severe winters with little snow, and hot, dry summers. To the northwest of the Altai and Sayan mountains extend three nearly parallel ranges: the Salair Ridge, Vostochny Sayan (Eastern Sayan), and Kuznets Alatau. In the west of this latter chain is the Kuznetsk Basin, or Kuzbass, where high-quality coal is mined. In the east is the Minusinsk Basin, an important agricultural region. The Sayan-Shushenskoye hydropower station, one of the world's largest, is being developed there, along with a number of power-consuming industrial plants. By the end of the 1970s the region is expected to be well developed industrially and agriculturally.

The Baikal area. The Cisbaikalia area, west of Lake Baikal, and Transbaikalia, east of it, lie between Southern Siberia's mountains and the Central Siberian Plateau on the west and the Yakutsk Basin on the north. The climate is harshly continental—hot, dry summers and severe, almost snowless winters. Annual precipitation is only eight to 12 inches (200–300 millimetres), occurring chiefly in short spring cloudbursts.

Through the Yakutsk Basin, surrounded by mountains, pass the Middle Lena as well as the Lower Vilyuy and Aldan rivers. Again the climate is harshly continental, with winter temperatures reaching -76°F (-60°C) and a short, dry, hot summer. Annual precipitation is less than 16 inches (400 millimetres).

Northeastern Siberia. Northeastern Siberia is the area east of the Lena River and west of the Kolyma Mountains. Moderately high mountain ranges alternate with vast plateaus, such as the Alazeya and Yukagir, and swampy lowlands, such as those of Yana–Indigirka and Kolyma. The highest ranges—the Verkhoyansk, Chersky, Sarychev, and Suntar-Khayata—reach more than 10,000 feet (3,000 metres).

The climate of the region is, once more, harshly continental. January's temperature sometimes sinking to -94°F (-70°C). The summer is moderately warm, except in maritime and extremely mountainous parts, with an average July temperature of 63°F (17°C) in the south. The Yana, Indigirka, and Kolyma rivers belong to the Arctic Basin.

Lichen tundra, forest tundra, and thin forests predominate in the north, sparse mountain-taiga larch forests in the south.

The swampy, lake-studded East Siberian Lowland extends along the shores of the East Siberian and Laptev seas. The Anadyr Plain, extending in a broadening path to the Bering Sea, never rises above 660 feet. The extreme

eastern part is occupied by the Chukchi Highlands, covered with mountain tundra and cedar.

Northeastern Siberia has an extremely severe climate, wide expanses of mountain tundra, and extreme permafrost (up to 2,000 feet deep); possesses large deposits of gold and tin; and is still remarkably little settled. Its indigenous peoples, like those of much of the less developed regions of Siberia, retain a vigorous folk culture with roots deep in antiquity.

The Far East. The Far East, traditionally regarded as a distinctive region, extends from the Chukchi Peninsula in the north to Vladivostok in the south, including the Kamchatka Peninsula and the Commander, Kuril, and Sakhalin islands. It is of medium elevation, the highest ranges being the Dzhugdzhur, Stanovoy, Burein, and Sikhote-Alin in the southwest and the Koryak Mountains and the Sredny (Central) and Vostochny (Eastern) ranges on Kamchatka in the northeast.

The region has many active volcanoes, and severe earthquakes are common. There are more than 250 volcanoes on Kamchatka and the Kuril Islands, of which 67 are active, including Klyuchevskaya Sopka (15,584 feet [4,750 metres]). There are small lowlands—the Anadyr, Central Amur, Lower Amur, and Khanka lowlands. The climate is monsoonal, with cold, fairly snow-free winters and moderately warm, wet summers. Precipitation ranges from eight inches in the north to 30–40 inches (760–1,000 millimetres) in the Primorye (the southeasterly mainland coast) and southwest Kamchatka.

The northern Far East consists mainly of plains and mountain tundras, while in the forest zone are stony birches and Dahurian larches (*Larix gmelini*) on Kamchatka and spruce and firs around the Sea of Okhotsk. In the south grow Dahurian larch, Sayan spruce (*Picea ajanensis*), stony birch, oak, hornbeam, ash, maple, Korean cedar, Manchurian nut (*Juglans mandshurica*), and fir, with some relict vegetation, such as Amur cork and the vine *Actinidia*.

The Lower Amur Basin has a dry winter and rainy summer; 85–96 percent of the annual precipitation falls from mid-April to September, causing many floods.

The Primorye area, with its Sikhote-Alin mountain complex parallel to the coast and its intermontane and coastal plains, is economically well developed. The deeply indented coast provides many convenient inlets.

Sakhalin Island, lying between the Tatar Strait and the Sea of Okhotsk, is the largest island in the east Russian S.F.S.R. Its north is lowland, with tundra vegetation; the remainder is forest. The climate is fairly warm in the intermontane plains of the south and on the coast, the soil is fertile, and there are waterpower and timber resources. In the forests are many furbearing animals and medicinal plants. Iron, tin, molybdenum, antimony, polymetallic ores, gold, coal, and oil have been discovered there, and Siberian salmon, humpback (Pacific) salmon, carp, and bream are found in the sea and river waters.

The Kamchatka–Kuril Ridge is made up of young folded mountains, covered by Arctic tundra on the Koryak Mountains (north of the Kamchatka Peninsula) and by tundra–taiga vegetation on the Kamchatka Peninsula, where turf–podzolic soil predominates. The southern islands of the archipelago are washed by the warm Soei Current. Coal, oil, gold, copper, and sulfur have been discovered in the Kamchatka–Kuril Ridge, but only coal is mined in the Kamchatka Peninsula. It was there that Soviet engineers first harnessed the hot subterranean waters for electric power and heating.

The sealing industry is important, as is fishing for Pacific herring, cod, *Eleginus navaga*, Pacific and Siberian salmon, smelt, and crab.

Rivers and drainage. The Russian S.F.S.R. contains some of the world's largest rivers: the Ob–Irtys system (3,362 miles, or 5,410 kilometres), Amur (1,755 miles), Lena (2,650 miles), and Yenisey (2,543 miles). There are about 100,000 rivers more than six miles long. They flow into the Arctic Ocean—such as the Northern Dvina, Pechora, Ob, Yenisey, Lena, Indigirka, and Kolyma; to the Pacific Ocean—such as the Amur, Anadyr, and Kamchatka Peninsula rivers; and to the Atlantic Ocean, by

Monsoonal
climate
of the
Far East

Extreme
climate
of the
Tuva
Trough

way of the Baltic and Black seas—such as the Neva, Don, Dnepr, and Kuban. The Volga and Ural rivers flow into the Caspian Sea. Most rivers are fed by snow and rain, while ice lasts from a month in the south of the European section to nine months in Northern Siberia. There are more than 200,000 lakes, particularly in the Kola-Karelian region. Large artificial reservoirs include Rybinsk, Gorky, Kuybyshev, and Volgograd on the Volga, Kama on the Kama, Tsimlyansk on the Don, and Ob on the Ob.

Reclaimed land Russia has the largest amount of artificially drained land in the Soviet Union, mostly in the European part. Such drainage is also widespread in the Baraba Steppe beyond the Urals and along the Upper Angara, the Lower Selenga, and the Amur. Artificial irrigation occurs in the Northern Caucasus, in the Middle and Lower Volga region, in the Oka River Basin around Moscow, in the Tuva Trough, east of Lake Baikal, and near Yakutsk.

The 10th Five-Year Plan (1976–80) envisages that land improvement will be continued on a large scale. Almost 10,000,000 acres (4,000,000 hectares) of irrigated land are to be commissioned at state expense, 11,600,000 acres to be drained, and 92,800,000 acres of pastures in desert areas to be watered.

THE PEOPLE

National origins, linguistic groups, and ethnic composition. The ancient group of peoples known as the Slavs developed in eastern Europe between the 3rd and 8th centuries AD, and the first Slav state, Kievan Rus, arose in the later 9th century, laying the foundation of three related nationalities: Russian (the national backbone of the Russian S.F.S.R.), Ukrainian, and Belorussian.

The Russia that emerged from this historic nucleus has since had to ward off the Pechenegs (a Turkic people from an area north of the Black Sea) and Polovtsy (or Kipchak; a tribe from the steppe north of the Black Sea) in the 10th–12th centuries, Mongol hordes in the 13th–15th centuries, Teutonic Knights and Swedes in the 13th century, Poles and Swedes in the 17th, Napoleon's army in the 19th, the intervention of 14 governments from 1918 to 1920, and Nazi Germany from 1941 to 1945. This heritage has strongly molded the national character.

The multiplicity of peoples in the contemporary republic is reflected in 16 Autonomous Soviet Socialist republics (A.S.S.R.'s) within the Russian S.F.S.R., as well as the five autonomous regions and the 10 national districts (see Table). The rest of the republic is administratively divided into six *kraya* (territories) and 49 *oblasti* (regions).

The population of the Russian S.F.S.R. was 133,700,000 on January 1, 1975, including Russians (82.8 percent), Tatars (3.7), Ukrainians (2.6), Chuvash (1.3), Bashkirs (0.9), Mordvins (0.9), Dagestani nationalities (0.9), Belorussians (0.7), Jews (0.6), Germans (0.6), Udmurts (0.5), Chechens (0.4), Kazakhs (0.4), Cheremis (or Mari; 0.4), and many others, more than 60 in all. Most of the nationalities have deep historical roots, and communities

speaking different languages have long-established economic and cultural ties, facilitating communication among them.

Linguistically, the people of the Russian S.F.S.R. can be divided into the Indo-European group, comprising East Slavic- and Iranian-speakers; the Altaic group, including Turkic, Mongolian, and Manchu-Tungus; the Uralic group, with the Finno-Ugric and Samoyedic; and the Caucasian group, comprising Abkhazo-Adyghian and Nakho-Dagestanian.

The Slavic group. The Russian language, together with Ukrainian and Belorussian, constitutes the East Slavic group of the Indo-European languages. Despite the fact that the Russians cover an expanse from the Baltic Sea to the Pacific Ocean, the Russian language's main features are homogeneous.

The Altaic group. Another major group of languages, the Altaic, includes the Turkic-speaking people of the Altai-Sayan foothills, the Altaics, Khakass, Shors, Tuvians, and Tofalars (or Karagasy). Various groups of Siberian Tatars live in the forest steppe regions of Western Siberia and on the Upper Ob, while many Yakuts have settled in the basin of the Lena River and Dolgans in the northern Krasnoyarsk area. The Bashkirs live in the Southern Urals.

The Turkic cluster also includes the Chuvash and Tatars living along the Middle Volga, and there are Turkic peoples in the Northern Caucasus, among them the Kumyks, Nogay, Karachay, and Balkars. The Evenks and Evens speak Manchu-Tungus languages and the Buryats and Kalmyks Mongolian tongues.

The Uralic group. The Uralic-speaking group, widely disseminated along the Eurasian forest and tundra zone, has complex origins. Finnic people inhabit the European part of the Russian S.F.S.R.: Mordvins, Cheremis (or Mari), Udmurts (or Votyaks), and Komi (or Zyryans) and the closely related Komi-Permyaks are found along the Volga and in the Urals, while Estonians, Karelians, Finns, and Veps inhabit the northwest. The Mansi (or Vogul) and Ostyak (or Khant) peoples, few in number and living beyond the Urals and in the Ob Basin, belong to the Ob-Ugric group.

The Samoyedic group likewise has few members but is dispersed over a vast territory: the Selkups on the Middle Ob and on the Taz; the Nenets in the forest tundra and tundra from the Yenisey to the Yamal Peninsula and from the Urals to the Kola Peninsula; the Enets (Entsy) along the Lower Yenisey; and the Nganasans mainly on the Taymyr Peninsula.

The Caucasian group. The Caucasian-speaking aggregate, which includes people of the Abkhazo-Adyghian, Nakh, and Dagestani groups, is remarkable in its complexity. In the Northern Caucasus, the Abkhaz, Abaza, Kabardian (or Circassian), and Adyghian languages are similar to each other but differ sharply from the languages of the Nakh group (Chechen and Ingush) and of the Dagestani group (Avar, Lezgian, Dargin, Lakk, Tabasaran, Andi, Tsez, Archi, and about 20 others).

Other groups. There are in Siberia a few Paleo-Asiatic peoples, having much of their way of life and culture in common but differing in origin and also, largely, linguistically. Some of these peoples are nevertheless related by language, so that the Chukchi, Koryaks, and Kamchadals (Itelmens) belong to a group known as Luorawetan, while the Eskimos and Aleuts belong to the Eskimo-Aleut group. The languages of the Gilyaks (or Nivkhs) on the Lower Amur and Sakhalin Island and the Yukaghirs of the Kolyma area are quite isolated, while the language of the Kets, a small population living along the Middle Yenisey, is likewise unique.

(See further ALTAIC LANGUAGES; CAUCASIAN LANGUAGES; PALEOSIBERIAN LANGUAGES; SLAVIC LANGUAGES; URALIC LANGUAGES.)

Population distribution and demographic trends. The distribution of population in the republic is not uniform, depending both on the opportunities offered or denied by the environment and on the equally varied potential of various eras of history. Regions in the central band of European Russia are of long settlement

Minority peoples

and economically well developed. Here the population density varies from 135 to 200 persons per square mile (52 to 77 per square kilometre), sometimes rising to 676 (261). Elsewhere, mainly in the tundra and taiga zone, the density is well under one person per square mile.

In European Russia, the population is densest in an area between a line linking Leningrad–Cherepovets–Vologda–Kirov in the north and the Caucasus Mountains in the south. In the Urals region the people live mainly between Sverdlovsk and Chelyabinsk, the population tailing off to the east. The Trans-Siberian Railroad forms an axis along which Siberia's agricultural colonization has proceeded since the mid-19th century. The narrow population belt widens around Novosibirsk (because of the Kuznets Basin and its coalfield) and along the Yenisey to the south of Krasnoyarsk (around the Minusinsk Basin). To the east of Lake Baikal the population band narrows further, stretching along the railway to the Pacific Ocean and terminating in the Suyfun-Khanka Plain near Vladivostok.

Migration from the crowded central portion of European Russia is traditional. Immigrants traversed the Urals with the first caravans as the Russian government extended its boundaries. The Soviet period has seen rapid economic development of the eastern Russian S.F.S.R., stimulating the flow of population there. Migration has not been solely across the Urals but also to other union republics, as economic development accelerated, natural resources were exploited, and capital was invested in industry and urban construction.

Urbaniza-
tion

Rapid urbanization has been an important factor in Soviet demography. The Russian S.F.S.R.'s urban population was 14 percent of the total in 1920, 52 percent in 1959, and 67 percent in 1974. Seven of the 12 Soviet cities with more than 1,000,000 inhabitants were in the Russian S.F.S.R., as were 47 of the 74 cities with populations of more than 300,000 in 1974. There are many large, rapidly growing cities in the republic, such as Tolyatti, which from 1959 to 1974 increased 460 percent, Bratsk (328), Volzhsky (166), Cheboksary (141), and Cherepovets (140).

The population's natural growth shows a moderate birth rate, of about 15 per 1,000 annually; the death rate, around 9 per 1,000, is low. A slightly declining birth rate reflects rapid urbanization and increasing employment of women. An equally slight growth in the death rate reflects an increasing proportion of old people. The natural increase in population is slightly less than 6 per 1,000 (0.59 percent) annually.

THE ECONOMY

The Russian S.F.S.R. since World War II has been transformed into a powerful, highly developed, industrial-agrarian republic. Natural resources have undoubtedly been significant in this development. Hundreds of deposits of mineral wealth have been discovered: more than 70 percent of Soviet coal reserves are concentrated in the Russian S.F.S.R., exceptionally large deposits, estimated at 6,000,000,000,000 tons, having been discovered in Eastern Siberia and the Far East. There are also large deposits of iron ore as well as copper, zinc, lead, nickel, aluminum, tin, molybdenum, gold, platinum, and other nonferrous metals. The world's largest petroleum and natural gas reserves are located in the republic, in the northern part of Western Siberia, and the petroleum reserves have been estimated as second only to those of the Persian Gulf region.

The republic can be divided into 10 economic regions: Northwest, Central, Volga-Vyatka, Central-Chernozem, Volga, Northern Caucasus, Urals, Western Siberia, Eastern Siberia, and Far East. Industry is the principal component of the republic's economy, its structure hardly differing from that of the industry of the Soviet Union as a whole. Food and light industries account for about 12 percent of industrial production.

Heavy industry. Heavy industry plays a decisive role in the Russian S.F.S.R.'s economy, particularly the fuel and power sectors.

Fuel. More than half the fuel sector is engaged in the processing of petroleum; a third produces coal; and the remainder exploits natural gas. In 1974 the Russian Federation extracted 419,000,000 tons of petroleum, 410,000,000 tons of coal, and about 3,530,000,000,000 cubic feet of gas.

Directives of the 25th Congress of the Communist Party of the Soviet Union in 1976 called for increasing the output of natural gas to 15,400,000,000,000 cubic feet (436,000,000,000 cubic metres) and petroleum to 695,000,000 tons by 1980. Western Siberia has become the largest petroleum centre in the country. Expansion of the oil refinery at Komsomolsk-na-Amure (in the Far East) was completed during the previous Five-Year Plan (1971–75), and new factories were set up in the Far East and in the Arkhangelsk region (around the White Sea, an inlet of the Arctic Ocean).

Pipelines from the oil and gas areas in Western Siberia were extended to the Central region via the Urals and across Siberia to the Far East, and underground gas reservoirs were significantly enlarged in European Russia near the main industrial centres. A centre for gas extraction and processing was built near Orenburg.

Power. Electrical energy occupies a special place in the complex fuel and power economy of the Russian S.F.S.R. Power plants generated 605,000,000,000 kilowatt-hours in 1974, thermal power plants supplying about 80 percent of the total electric energy.

During the Five-Year Plan covering the years 1966–70, construction work on 40 large thermal power plants was undertaken: Kostroma (completed in 1973), Karmanovo (first stage completed in 1973), Reft (first stage completed in 1972, enlarged in 1975), and Novocheboksarsk (completed in 1972). The Konakovo thermal power plant was operating at a full capacity of 6,000,000 kilowatts early in the 1970s.

During 1971–75 the Russian S.F.S.R.'s electric energy capacity was expanded with the construction of thermal power plants having power units of 300,000–800,000 kilowatts' capacity. The Kirishi power plant on the Volkhov River, near Leningrad, was enlarged, and the Ryazan power plant was commissioned (1973). New power units were also installed at the Irklinsky and Reft power plants in the industrial parts of the Urals (1974), while the Surgut power plant, on the Ob River (inaugurated in 1972), and the Primorskaya, near Vladivostok, also began functioning.

Construction of hydroelectric power plants, providing generating power, with simultaneous provision of water supply and water for irrigation and development of river navigation and fishing, was also being pressed forward. The main centres of activity were on the Volga and Kama and the rivers of the Northern Caucasus. The Krasnoyarsk hydroelectric power plant, with a capacity of 6,000,000 kilowatts, was completed in 1971. Work was started or continued on the Kolyma (in Eastern Siberia), Ust-Ilimsk (first power delivered in 1974), Zeya, and Sayan plants during the mid-1970s.

Atomic power plants with unit capacity of 1,000,000 kilowatts and more were also increasing in number. Plants in operation by late 1973 included the Leningrad and Kola (near Murmansk). The Kursk and Novovoronezhsky plants were to be the next, and the construction of the Smolensk and Dūkštas (Lithuania) plants was continuing in the mid-1970s.

The total amount of electrical energy generated during the 10th Five-Year Plan (1976–80) by all types of power plants was expected to show an increase to 830,000,000,000 kilowatt-hours.

Metallurgy. About half the ferrous metallurgy plants existed before the Revolution, and they have since been fundamentally reconstructed. A large proportion of the products of ferrous metallurgy is supplied by plants built after the Revolution. The latter include the complexes at Magnitogorsk (in the Southern Urals) and Kuznetsk (in Western Siberia) and the plants at Novotulsky, Novylypetsk, Tagil, and Petrov-Transbaikalia. The Amurstal, Komsomolsk-na-Amure, and Chelyabinsk metallurgical plants and the Orsk-Khalilovo and Chere-

plants

povets complexes began production during World War II. The first unit of the large West Siberian Iron and Steel Works, near Novokuznetsk, was constructed during 1966–70. The Russian S.F.S.R. contributes 50 percent of the cast iron and 55 percent of the steel and rolled iron to the national economy.

Extension of iron mining was planned for 1971–75. In particular, the annual output of magnetite ore from the Kursk region was expected to increase to about 40,000,000 tons and that of rolled iron to 59,000,000 tons. The leading place in the production of rolled iron was to be occupied by cold-rolled sheets, curved and shaped profiles, high-precision profiles, and various types of pipes and implements.

Nonferrous metallurgy

Most of the nonferrous metallurgical plants have been installed under the Soviet administration, whether in the Northern Caucasus (at Nalchik and Ordzhonikidze) or in the subpolar region (at Monchegorsk, Kandalaksha, and Norilsk). The Urals, Western Siberia, and the Far East are the centres of nonferrous metallurgy. The industry developed rapidly in the Russian S.F.S.R.'s eastern regions during 1966–70. The production of alumina from the Belogorsk (Western Siberia) nepheline was started at Achinsk, and the output of the Bratsk, Krasnoyarsk, and Irkutsk aluminum plants has increased. The Norilsk (in Northern Siberia) copper and nickel plant and the Khrustalny (in the Far East) complex for dressing tin ores have expanded, and construction of the Gay (in the Urals) and the Solnechny (in the Far East) ore-dressing plants has been completed. The tungsten reserves in the Primorye region are also being exploited.

The base of raw materials for nonferrous metallurgy was expected to widen significantly by 1975 with the exploitation of deposits in the eastern part of the republic. Technological innovations to improve the use of raw materials were in process. The construction of a large aluminum plant and enterprises for processing nonferrous metals in the Sayan complex of Southern Siberia during the Ninth Five-Year Plan was contemplated, and the Zhireken complex for dressing molybdenum ores in the Chita *oblast* was to be constructed.

In addition, development of a northern Onega bauxite mine, the largest in the country, was under way by the mid-1970s.

Machine building. The Russian S.F.S.R.'s machine-building industry provides 96 percent of the Soviet Union's total requirements for steam boilers, 100 percent of its grain-harvesting combines, 81 percent of its automobiles, 75 percent of its main-line electric locomotives, 53 percent of its metal-cutting machine tools, and more than 60 percent of various types of instruments, means of automation, and spare parts.

Automobile manufacturing

There are important automobile factories in Moscow, notably the Likhachyov plant and the MZMA (Moscow low-powered car works), and in Gorky, Miass, Yaroslavl, Ulyanovsk, and Izhevsk (in the Udmurt A.S.S.R.). A factory at Tolyatti (near Kuybyshev) manufacturing the Zhiguli car was completed and a heavy-truck factory was being built in the same period in Naberezhnye Chelny, in the Tatar A.S.S.R. Major automobile-trailer factories were also being constructed in Stavropol and Orsk and near Krasnoyarsk.

There was a dramatic increase between 1965 and 1973 in the production of automobiles (from 160,600 to 810,000), trucks (from 334,900 to 533,800), and buses (from 27,400 to 41,500).

The Russian S.F.S.R. manufactures high-power hydraulic and steam turbines and electrical generators with unit capacity of 500,000 and 800,000 kilowatts.

By 1975 a factory manufacturing bearings at Vologda was to be built, and machine-tool factories manufacturing transfer lines were to be set up in Sukhinichi and Sasovo, while it was hoped that the Chuvash A.S.S.R. would become a tractor supplier. A railroad-car factory and electrotechnical industries were planned for Sayan. The production of instruments, means of automation, agricultural machinery, and construction and land-reclamation equipment was to be expanded as much as possible.

Chemicals. The chemical industry was developing even more rapidly by the 1970s than manufacturing, with coal, wood, and foodstuffs providing raw materials for most of its branches. Accordingly, synthetic-rubber factories had been set up at Yaroslavl, Yefremov, and Voronezh, in the potato-growing centres; sulfuric acid factories at Krasnouralsk, Kirovograd, Karabash, Mednogorsk, Chelyabinsk, and Ordzhonikidze, where nonferrous metallurgy was developed; and potassium and phosphorus fertilizer plants at Solikamsk, Berezniki, Perm, Voskresensk, Bryansk, and Krasnouralsk, near deposits of potassium salts and phosphorites.

At the end of the 1950s the chemical industry was able to make use of new natural and by-product gas and by-products of the petroleum industry and therefore no longer needed to appropriate to itself valuable raw materials that could be used for food processing instead. The result was an immediate shift in the location of newly erected chemical enterprises, which gravitated toward the Urals–Volga zone and the Northern Caucasus. Siberia, too, offers favourable conditions for chemistry involving large amounts of electrical energy. Factories manufacturing synthetic rubber, nitrogenous fertilizers, automobile parts and accessories, and various plastic goods are already in operation there.

The Russian S.F.S.R. supplies 80 percent of the Soviet Union's automobile tires, more than 70 percent of its chemical fibres and chemical insecticides, and more than 50 percent of its mineral fertilizers and sulfuric acid.

The enlargement of the Novgorod chemical complex (completed in 1975) and the starting of the second Berezniki potassium complex (first stage completed in 1973) and the Uvarovo disuperphosphate factory (completed in 1973) took place under the Eighth Five-Year Plan (1966–70), while the output of mineral fertilizers increased at the Voskresensk, Novomoskovsky, and Nevinnomyssk chemical complexes.

Output of fertilizers in the Russian S.F.S.R. by 1973 had climbed to 37,000,000 tons, and by 1980 chemical plants were expected to produce 74,000,000 tons of mineral fertilizers, almost half the national total. New construction under the Ninth Five-Year Plan (1971–75) included a fertilizer factory in the Tula region; the third Berezniki and Solikamsk potassium fertilizer plants were already under way at the beginning of the 1970s. The Primorye chemical and mining complex was expanded; construction of the Zimino electrochemical complex in the Irkutsk region had been started; a synthetic-fibre factory was being built in the Altai region; and several petrochemical complexes in the European Russian S.F.S.R. and one at Achinsk in Siberia, based on Siberian crude, were under construction. The Five-Year Plan also looked forward to the construction of petrochemical complexes around Tobolsk and Tomsk.

Fertilizer production

Forestry and wood pulp. The forest, paper, and wood industries are important, since more than 90 percent of Soviet wood resources are in the Russian S.F.S.R.; indeed, the republic has the largest forest reserves in the world. More than 43 percent of the Russian S.F.S.R. is forest, amounting to 2,773,000,000,000 cubic feet (78,500,000,000 cubic metres). Most of this is matured and over-matured trees, which are of the greatest value.

Coniferous trees, including pine, are important, and the Russian S.F.S.R. is the world's richest area in this valuable species, though other coniferous trees, such as spruce, cedar, and especially larch, are equally important.

The principal forestry enterprises are concentrated in the northwest and the Urals, supplying almost half the republic's total volume (more than 12,670,000,000 cubic feet in 1973), around 35 percent of the lumber, and about 64 percent of the paper.

Within the Soviet period the forest industry has extended even to the trans-Urals forests. Eastern Siberia has overtaken the Urals in terms of timber output, and the tempo is increasing in Western Siberia and the Far East: extensive complexes were under construction in Tavda, the Verkhaya Konda, Asino, Yeniseysk, Chuna, and Amursk in the 1970s, while Bratsk, where the first stage of a large forestry complex was completed, had

become the country's foremost chemical processor of wood. In the Far East the Komsomolsk cellulose and cardboard complex was not far behind Bratsk.

The Eighth Five-Year Plan saw the start of construction of new workshops in the Novo-Maklakov sawmill and woodworking complex. In 1973 the Russian S.F.S.R. supplied 9,994,000,000 cubic feet (283,000,000 cubic metres) of commercial wood, 4,503,000 tons of paper, almost the same amount of lumber, and 6,250,000 tons of cellulose. Further developments would be concentrated in Siberia, the Far East, and the northern regions of the European Russian S.F.S.R.

The construction of the Bratsk timber industry complex was expected to be completed by 1975, and work on the new Ust-Ilimsk complex was to have begun.

Construction materials. During the Soviet period, rapid growth in the production of structural materials has taken place. For the Ninth Five-Year Plan, the structural-materials industry was called on to produce materials and implements ready for the factory, to widen the assortment of finished materials and sanitary equipment, and to increase production of ceramic drainage and irrigation pipes.

The industry was to be helped by utilizing intermediate products from other branches of industry, such as slag and cinders.

Light and food industries. Light industry, which is concentrated in the Central region, provides 82 percent of the nation's cotton fabric, 75 percent of the linen, more than 70 percent of the silk and woollen fabrics, 51 percent of the knitted wear, and 53 percent of leather footwear.

During 1966–70, 14 textile, 13 knitting, 19 sewing, and nine leather footwear enterprises were erected in other parts of the Russian S.F.S.R. The republic was expected to produce 81,000,000,000 to 85,000,000,000 square feet (7,500,000,000 to 7,900,000,000 square metres) of textiles and 413,000,000 pairs of footwear by 1975.

The republic accounts for 70 percent of the Soviet Union's total catch of fish, whales, and seals and its utilization of other sea products. In addition, it produces 62 percent of all sausage and ham products, as well as soap, 62 percent of all whole milk, around 58 percent of the candy, 50 percent of the meat, 51 percent of all animal oil, more than 40 percent of the canned food, 34 percent of the vegetable oil, and about 28 percent of the sugar.

The Eighth Five-Year Plan (1966–70) for the food industry led to the creation of many enterprises producing cheese, whole milk, yogurt, sour milk, curds, and sour cream, while more than 700 other plants producing dairy and meat products were built or reconstructed. Six new modern sugar refineries were built, and the capacity of the canned-food industry increased by 300,000,000 containers. The construction of the largest chocolate factory in the Soviet Union was undertaken at Kuybyshev, on the Volga.

The Russian S.F.S.R.'s food output by 1975 was forecast at 5,200,000 tons of meat products, 15,400,000 tons of whole-milk products, and a wide assortment of other foods.

Agriculture. The Russian S.F.S.R. accounts for half the total agricultural production of the Soviet Union, there having been about 13,300 *kolkhozy* (collective farms) and about 10,300 *sovkhazy* (state farms) in the republic in 1974.

Agricultural land covers about 14 percent of the Russian S.F.S.R. and represents more than 36 percent of the total agricultural land of the Soviet Union. In addition, there is great potential for substantial increase through drainage and clearance. Mechanization and technological innovation are proceeding: in 1973 alone, 156,000 new tractors, 97,000 combines, 100,000 automobiles, and more than 500,000 pieces of other agricultural equipment were manufactured. Additionally, 29,000,000 tons of mineral fertilizers and more than 28,900,000,000 kilowatt-hours of electric energy were consumed in the republic.

Cereals, vegetables, and fruits. The main product of farming in the Russian S.F.S.R. has always been grain,

and 60 percent of the farmlands are devoted to wheat, rye, barley, oats, and groat (hulled) crops. Fodder crops come second, grown on 30 percent of the arable land and including about 19 percent annual and perennial grasses and almost 9 percent maize (corn). The Volga area, the Urals, the Northern Caucasus, the Central and Central-Chernozem regions, and Western Siberia are the main grain producers of the Russian S.F.S.R., supplying 87 percent of the total grain yield and about 88 percent of the wheat. In 1973 the republic harvested 142,000,000 tons of grain, including around 64,000,000 tons of wheat. In 1975, however, grain production fell to only 85,000,000 tons. European Russia has always been the leading producer of the main commercial crops, such as sunflower seeds, sugar beets, and flax fibre, which together take up more than 5 percent of the farmland; another 4.5 percent goes to potatoes, vegetables, and melons. The output of principal commercial crops in 1973 approached 34,000,000 tons of sugar beets, 189,000 tons of flax fibre, 4,100,000 tons of sunflower seeds, 68,200,000 tons of potatoes, and 13,100,000 tons of vegetables.

Livestock. Livestock breeding is the second main agricultural feature. The livestock population at the end of 1974 was 54,747,000 cattle (including 21,415,000 dairy cows), 34,981,000 pigs, and 67,304,000 sheep and goats. Animal products in the mid-1970s amounted annually to around 7,450,000 tons of meat, 47,000,000 tons of milk, 29,650,000,000 eggs, and 230,000 tons of wool.

European and Asiatic Russia differ in livestock breeding. Intensive processes such as raising of beef and dairy cattle take place in the European part; raising of distant pasture sheep takes place in Asia. About 2,300,000 reindeer graze on moss and lichens in the north.

Land reclamation projects. The Ninth Five-Year Plan anticipated that, by 1975, 3,000,000 acres (1,200,000 hectares) of irrigated lands would be available, 4,400,000 acres (1,800,000 hectares) of pasture land would be drained, and at least 1,600,000 acres (650,000 hectares) of highly productive meadows and pastures would be created.

In the Volga region and the Northern Caucasus are the main regions for irrigation, such areas having increased by 140,000 acres (57,000 hectares) in the Volga region and by about 930,000 acres (375,000 hectares) in the Northern Caucasus.

By 1975 the Bolshoy Stavropolsky Kanal (Great Stavropol Canal) was scheduled to be built in the Northern Caucasus, and the expansion of the Donskoy Magistralny Kanal (Don Main-Line Canal) was to begin. Work started in 1974 on the West Siberian Irrigation Canal. In the Volga region attention was to be concentrated on vegetable and melon cultivation, and in the Volga-Akhtuba floodlands rice was to be emphasized.

The area of irrigated lands in the Far East was to increase by almost 124,000 acres, and 800,000 acres of waterlogged lands were to be drained. Further, there were plans to increase the production of soybeans and rice in this region.

Transportation. Some 48,000 miles (77,000 kilometres) of railroad tracks form the base of the Russian S.F.S.R.'s transportation system. There are also more than 77,000 miles (124,000 kilometres) of navigable internal water routes and about 161,000 miles (260,000 kilometres) of surfaced motor roads; 81,000 miles (130,000 kilometres) of oil and natural gas pipelines; and more than 250,000 miles (400,000 kilometres) of air routes; long-distance and coastal sea routes supplement them.

Railroads. The railroads, the most widely used form of transport, are responsible for about three-quarters of the freight turnover in the republic, accounting for more than 1,420,000,000,000 ton-miles (2,070,000,000,000 metric ton-kilometres) and carrying 2,070,000,000 tons of goods. The density of the modern railroad network is by no means uniform, ranging from 39 to 49 miles of track per 1,000 square miles in the Central and Central-Chernozem regions to 2.5 to 6.5 in Western Siberia and to a mile or less in Eastern Siberia and the Far East.

Grain and subsidiary crops

Textiles and footwear

Electrification of railways

More than 30 percent of the railroads were electrified by 1971; not only individual sections around principal industrial centres but also entire trunk lines, such as the Moscow–Chita (running east of Lake Baikal), Leningrad–Yerevan, and Barnaul–Zheleznogorsk lines, are electrified.

Inland waterways. River navigation plays an important role in regions in which there are no other means of communication. Freight turnover by river transport in the Russian S.F.S.R. during 1973 amounted to 121,300,000,000 ton-miles, with a total of 396,000,000 tons of goods being transported. Thanks to the realignment of natural water routes, the creation of new types of craft, the mechanization of ports, and the improvement of navigational services, the speed of river transportation has increased substantially.

Almost 45 percent of the freight travelling by water is minerals and construction materials. Timber, wool, grain, and salt constitute one-third, though grain freight, taken by itself, has decreased to 2 percent from its 14 percent in pre-Revolution times. Oil and coal take up 15 percent. Passenger travel has increased, more than 114,500,000 passengers being transported in 1973. The river passenger fleet includes numerous high-speed hydrofoils and Hovercraft.

Roads. Motor transportation accounted for 104,460,000,000 ton-miles of freight turnover, and trucks carried 11,120,000,000 tons of goods in 1973, a contribution of more than 5 percent to the republic's annual turnover.

Pipelines. Pipelines for petroleum, petroleum products, and gas are carrying 395,000,000 tons of petroleum and products each year. The Grozny–Tuapse pipeline exceeds 380 miles and the Tuymazy–Omsk pipeline 810 miles in length. Others include the Almet'yevsk–Gorky pipeline, with branches extending to Yaroslavl and to the Ryazan–Moscow line. The Druzhba ("Friendship") is the longest pipeline—2,900 miles (4,700 kilometres)—beginning on the shores of the Volga and ending in the socialist countries of central Europe. In the early 1970s lines were built to transport gas to Italy and West Germany.

Shipping. The merchant fleet plays a great role in establishing ties within the republic, especially between regions on the Arctic seaboard, despite the seasonal nature of Arctic shipping. The port of Murmansk is open 365 days a year, partly by means of icebreakers; Arkhangelsk is open 175 days and Nizhnyekolymsk 110 days. Merchant shipping is also very important in foreign trade.

Air. Air transport is widely used for bulk goods. In 1973 more than 53,000,000 passengers and more than 1,900,000 tons of goods were carried by air. Aviation is important in the extreme north, in parts of Siberia, and in the Far East, being nonseasonal and the only means of long-distance transport to some areas.

The outlook for transportation. Under the Ninth Five-Year Plan (1971–75) the railroad networks with the heaviest freight traffic (particularly those of the Kuznets Basin–Urals and the Urals–Central region) were strengthened by second tracks. The Tyumen–Tobol–Surgut railway was completed (1974), and electrification continued, along with the construction of new routes to ensure a growing system of transportation to serve the new industrial regions.

Freight turnover by river transport was expected to increase by about 24 percent; the traffic capacity of river ports and landings was increasing, and the water-communication routes were improving, especially in the east. The construction of the Tobol and Surgut river ports was expected to be completed by 1975, and the reconstruction and widening of important seaports in the Far East was undertaken. New oil and gas pipelines were extended from Western Siberia to the oil refineries and to the areas of the Russian S.F.S.R. lacking in fuel.

Waterway-expansion plans

economic system and the socialist ownership of tools and means of production form the economic basis of the republic. Even before the Russian S.F.S.R. had been formed, the Second All-Russian Congress of Soviets had created the Soviet government and promulgated decrees on peace and on land, which ultimately took Russia out of World War I and transferred land to the peasants.

The Third All-Russian Congress of Soviets, which sat from January 23 to 31, 1918, announced the creation of the Russian S.F.S.R., and the republic's first constitution dates from the fifth congress, which assembled in July 1918. During and after the Civil War (1918–20) the Russian S.F.S.R. was organized to include Autonomous Soviet Socialist republics, the first of which was the Bashkir A.S.S.R., on March 23, 1919.

The Russian S.F.S.R. entered the Soviet Union, then being formed, in 1922.

The Soviet dictator Joseph Stalin, during the purges of the 1930s, advanced a new constitution, established by the Extraordinary 17th All-Russian Congress of Soviets on January 21, 1937.

As described above (see *The people*), the Russian S.F.S.R. is composed of A.S.S.R.'s, autonomous *oblasti*, and national *okruga* for the larger non-Russian nationalities, as well as administrative *oblasti* and *kraya* (territories), the latter incorporating such national administrative subdivisions as autonomous *oblasti*.

Autonomous republics. The autonomous republics enjoy a form of political independence; each has its own constitution, higher organs of state power, legislature, and higher judicial bodies. Each autonomous republic, being a federated part of the Russian S.F.S.R., is represented in the Presidium of the Supreme Soviet of the Russian S.F.S.R. by a vice chairman of the Presidium.

Autonomous regions and districts. Another administrative form of autonomy—the autonomous *oblast* and national *okrug*—extends only to self-government in internal affairs. While non-Russians participate extensively in the administration of both units, the needs of the Russian Communist Party to control the given nationality are always paramount.

Autonomous *oblasti* and national *okruga* send deputies directly to the Soviet of Nationalities of the Supreme Soviet of the U.S.S.R.

Legislative and executive bodies. The Soviet Union since the October Revolution of 1917 has been ruled by the Communist Party. While there are semi-autonomous administrative bodies corresponding to various geographic levels (republics, autonomous regions and *oblasti*, and so forth; see below), there is only one Communist Party. While local first secretaries of the Communist Party in non-Russian areas of the Russian Federation as well as in the other 14 republics are often non-Russians, the second secretary is almost invariably a Russian, thus assuring direct control from Moscow.

The Communist Party structure is pyramidal. At the apex is the secretary general, himself one of the 16 full members of the Politburo. The Politburo, which also has six alternate members, is the central policy-making body of the Soviet Union. Below the Politburo is the Central Committee, with 287 full members and 139 candidate (nonvoting) members. In theory, the Central Committee controls the Politburo, but in reality it serves as a forum for the preliminary testing of policies and supports the Politburo. Next is the party congress, which meets every five years to ratify the current five-year plan and to elect unanimously the Central Committee.

The highest organ of state power is the unicameral Supreme Soviet of the Russian S.F.S.R. Between sessions the Presidium of the Supreme Soviet of the Russian S.F.S.R. is the highest organ of state power, embodying all the rights accorded to the Russian S.F.S.R. by the constitution. It is elected by the Supreme Soviet of the Russian S.F.S.R. and includes a chairman, 16 vice chairmen (one for each autonomous republic), a secretary, and 13 members.

The Presidium in all its activity is subordinate to the Supreme Soviet. The latter confirms the border and

Creation of the R.S.F.S.R.

Supreme Soviet

ADMINISTRATION AND SOCIAL CONDITIONS

The constitutional background. The Russian Soviet Federated Socialist Republic is, according to its current constitution, a sovereign socialist state, the power of which derives from workers and peasants. The socialist

regional division of the autonomous republics, autonomous *oblasti*, territories (or *kraya*), and regions; confirms the economic plan and state budget of the Russian S.F.S.R.; reports on its implementation; and chooses the government of the republic—the Council of Ministers of the Russian S.F.S.R.

The Council of Ministers is the highest executive and administrative organ of state power. It coordinates and directs the work of the ministries of the republic and other bodies subordinate to it, adopts measures to carry out the economic planning and state and local budgets of the Russian S.F.S.R., ensures social order while defending the interests of the state and protecting the rights of citizens, directs and inspects the work of the councils of ministers of the autonomous republics, and supervises and inspects the work of the executive committees of the territorial and regional soviets of workers' deputies.

A unicameral Supreme Soviet with its Presidium is the highest organ of state power in each autonomous republic. The Supreme Soviet of the autonomous republic chooses the governing body of the republic—the Council of Ministers.

The local bodies of state power in the *oblasti*, autonomous *oblasti*, national *okruga*, *kraya*, *rayony*, cities, and other localities are the corresponding soviets of workers' deputies.

Electoral procedure. The Supreme Soviet of the Russian S.F.S.R. is elected, from a single list of candidates, by the citizens of the Russian S.F.S.R. for a term of four years; the Supreme Soviet of an autonomous republic is elected by the citizens of that republic only, also for a term of four years.

The Soviet of Workers' Deputies of an autonomous *oblast* is elected, also from a single slate, by its citizens for a two-year term. The regional and territorial soviets of workers' deputies, soviets of workers' deputies of national *okruga*, towns, the regions of large cities, settlements, villages, farmsteads, and *auls* (North Caucasian villages) are elected (under the same circumstances as other elections) for a term of two years. In 1975, of 904 deputies, including 317 women, elected to the Supreme Soviet of the Russian S.F.S.R., 34.8 percent were workers and 15.4 percent collective farmers.

Any citizen of the Russian S.F.S.R. over the age of 21 may be elected a deputy to the republic's Supreme Soviet or to that of an autonomous republic, regardless of racial and national affiliation, sex, religion, educational attainments, social origin, place of settlement, property holdings, or past activity. Citizens over the age of 18 may be elected to local organs of power.

Judiciary. The Supreme Court of the republic, chosen by the Supreme Soviet for a five-year term, is the highest judicial body of the Russian S.F.S.R., supervising the activities of all other judicial bodies. The main task of the supreme courts of the autonomous republics and courts of territories, provinces, autonomous *oblasti*, and national *okruga* lies in controlling the activities of the people's courts.

Judicial proceedings in the Russian S.F.S.R. are carried on either in Russian or in the language of the prevailing nationality; persons not knowing the language of the court, however, have full access to an interpreter and the right to testify in their native language.

According to the constitution enacted under Stalin, justice in the courts is based on the equality of citizens before the law and the court and in exact accordance with the law. Judges are independent and subordinate only to the law. Trials are open, and the accused is guaranteed a defense. The public procurator of the Russian S.F.S.R., who, like the procurators of the lesser jurisdictions, holds his appointment in five-year terms, has the ultimate responsibility for upholding the law.

These ideals, however, have been violated in the extreme since their promulgation. In the 1930s millions suffered from official illegality, in the 1970s thousands. The unconstitutional use of psychiatric institutions and drugs as coercive and control instruments has remained part of the Soviet judicial process since Stalin's time.

Major organizations. *The Communist Party.* The organizations of the Communist Party of the Soviet Union (CPSU) direct political life. They are guided by the Central Committee of the Communist Party and by its regional and territorial committees.

The republic's Komsomol (Young Communist League) organizations accomplish political and educational work with people between 14 and 25 years of age.

Labour organization. Trade unions in the Russian S.F.S.R., with about 62,750,900 members in 1975, were charged with looking after labour protection, industrial safety, labour legislation, and social-insurance funds. They were also prominent in business efficiency and investment and were part of an effort to enhance the popularity of socialist competition and the Communist-labour movement.

Developing production and public services require a larger labour force. The number of workers and serving personnel increased from 39,500,000 in 1960 to 58,240,000 in 1973. Women, who played an active role, accounted for 53 percent of the workers and serving personnel, 76 percent of those engaged in educational work, and 87 percent of those in health care.

The social milieu. The national income of the Russian S.F.S.R. in 1973 was more than nine times that of 1940. The average monthly wages of workers and serving personnel in the early 1970s were considerably enhanced by benefits from public-welfare funds. Wages depend on the type, chiefly the heaviness, of the work, working conditions, and importance of the branch of industry. In 1973 the average wage was 141 rubles per month. Wages higher than average are paid to labour engaged in construction work, transportation, and mining. Collective farm wages are paid after all other commitments (taxes, compulsory investments, seed reserves) have been met.

Public-welfare funds from the state budget, enterprises, and trade unions are used substantially to improve the condition of workers in the Russian S.F.S.R., both materially and socially. A major portion of public-welfare funds goes for free medical service, training, pensions, and scholarships.

Approximately 24,600,000 persons were receiving pensions in 1974, and expenditure on pensions had increased by 90 percent over the previous eight years. In addition, more than 700,000 mothers with four or more children were receiving a monthly state allowance.

Health. Health care has attained a high level. In 1974 there were almost 2,000,000 medical workers, of whom about 433,000 were doctors of all types and about 1,337,000 were subsidiary medical personnel. There were 119 hospital beds for every 10,000 inhabitants as well as 19,200 outpatient clinics, more than 11,000 maternity and pediatric consultation clinics, more than 1,200 sanatoriums, about 620 rest homes, and 875 homes for the aged and invalid. Preventive-medicine facilities are provided directly in plants, institutions, and collective and state farms.

Housing. During 1918–73, around 17,855,000,000 square feet of living space were constructed or restored and put into use, of which more than 8,012,000,000 square feet were built during 1961–73. Some 6,500,000 persons moved into newly built housing in 1973. Towns are now planned and constructed by creating self-contained residential areas, rather than mere living quarters, as before. This ensures more comfortable living conditions for residents, since day nurseries and kindergartens, schools, stores, dining halls, studios, and repair shops are located nearby.

Education. The Russian S.F.S.R.'s educational system encompasses ages from preschool onward. The main links in the educational system are the general-education schools, specialized secondary schools, and institutions of higher education, with about 43,000,000 persons involved in some form of training. Ten-year compulsory education is effective throughout the republic.

The number of general-education schools of all types was approximately 86,900, with about 24,255,000 pupils at the beginning of the academic year 1973–74. The general-education school, as in all of the union republics,

Wages

Franchise
qualifica-
tions

New
housing
construc-
tion

is officially based on principles of full secularism, respect for the individual child, humanism, and democracy. The national schools carry on instruction in their native language (there are in all 42 languages of instruction). School personnel are trained in 107 institutes, of which each autonomous republic has one for its nationals. A large amount of instructional and educational work with students is carried out through extracurricular activities; there are Young Pioneer and student palaces and houses, young-technician and young-naturalist stations, excursion and tourist centres, athletic schools, and children's parks and stadiums.

The specialized secondary schools, of which there were 2,472 in the 1973–74 academic year, prepare specialists with technical training for various branches of the economy, including industry and construction, culture, health care, and education. Highly qualified specialists are trained in 474 institutions of higher education, most of which also have evening and correspondence classes. In 1974 there were 2,700,000 students studying in institutions of higher education and 2,600,000 in the specialized secondary schools. Vocational training schools graduated about 650,000 students annually in the early 1970s. There are higher education institutions in all the territories, regions, and autonomous republics of the R.S.F.S.R.

In 1974 there were 2,952 scientific institutions, including 1,646 scientific-research institutes and their subsidiaries and divisions. The Academy of Sciences of the U.S.S.R. and its branches function in the autonomous republics and major cities. With headquarters in Moscow, the Academy of Sciences is one of the great research institutions of the world. Founded by Peter the Great in 1725, the academy and its various divisions investigate nearly every branch of knowledge and have made many valuable contributions.

The Siberian branch of the Academy of Sciences of the U.S.S.R., in Novosibirsk, is a major scientific centre focussed on Akademgorodok, where 50 academicians and associate members of the Academy of Sciences, 100 doctors of sciences, and about 2,000 candidates of sciences are employed. In the early 1970s similar centres were being established in the Urals, Western Siberia, and the Far East.

There was a total of about 760,000 scientific workers at the end of 1973, more than 207,000 with the degree of doctor or candidate of sciences.

A significant part of the public-welfare funds is spent on the very young, the system of preschool institutions having been widely developed: there were 6,100,000 children in day nurseries and kindergartens in 1974. Some 15–25 percent of the average annual expenditure on the support of children in preschool institutions is covered by contributions from parents, with the state making up the remainder.

Standard of living. With free and universal education, the rise in the workers' cultural and technological level, and mechanization and automation, distinctions between intellectual and physical labour are being reduced, and material and cultural differences between population groups are, it is hoped, disappearing.

All workers and professionals in the Russian S.F.S.R. receive paid vacations of up to one month. Advances in health care and material well-being have led to a sharp decline in mortality, especially among children, the disappearance of the more dangerous infectious diseases, and an increase in the average life-span. The mortality rate among children under the age of one year decreased from 205 per 1,000 in 1940 to 22 in 1973. By the early 1970s the average life-span in the republic exceeded 70 years, 1.6 times that of 1926–27.

CULTURE AND RECREATION

The cultural background. The Russians' modern culture differs markedly from that of the non-Slavic nations in the Russian S.F.S.R. After the October Revolution, village planning, the peasant household, dress, national cuisine, holidays, and folklore underwent substantial changes as a result of the complete reorganization of individual agriculture, cultural innovation, and the

availability of medical aid in the villages, as well as of other factors that the republic shared with the rest of the world: development of various rapid modes of transport, radio, and television. Particularly great changes came about in dress and the arts, while several holidays, although closely related to Russian traditions, took on a new colour, such as New Year's Day, End of the Russian Winter, and Harvest Festival. The centuries-old culture, with its regional variations, nonetheless still finds wide, colourful, and vigorous expression.

Innovations have also come about in the case of non-Slavic people living in the Russian S.F.S.R., though individuality is preserved and reflected in architecture, interior decoration, festivals, and folklore. The peoples of the Northern Caucasus, for example, have adopted urban attire without completely abandoning their traditional dress: Circassian coat (*cherkeska*) with cartridge belt, quilted jacket (*beshmet*), sheepskin hat (*papakha*), felt cloak (*burka*), with silver-ornamented belts, shirt (*rubakha*), and long, wide trousers (*sharovary*) for men and, for women, a dress fitting loosely at the waist, high headdress, and shawl and ornamented belt. There are also many unique features in the headdress and in the style, colours, and ornaments of clothing of the nationalities along the Volga, such as the Tatars, Chuvash, Mari (Cheremis), Kalmyks, and Mordvins.

Significant changes, too, have occurred in the customs of the Siberian people, especially in the far north. The nomadic life that prevailed before the Revolution has been replaced by a settled one; now only reindeer herders and hunters are nomadic. The log house has remained, but urban dress has replaced traditional clothing, except among the reindeer herders, who still prefer clothing made of warm reindeer skins, the most comfortable for their occupation. The ancient art of the Siberian people is preserved and encouraged, as in the case of the masterly bone carving of the Chukchi, the birch-bark carving of the Khants (Ostyaks), and the colourful fur applique work of the Nenets.

Cultural institutions. In the mid-1970s the Russian S.F.S.R. had about 62,000 libraries housing about 820,000,000 volumes; 77,000 clubs; and about 93,000 motion-picture projectors (79,100 in rural areas); while, each year, about 70,000,000 visits were made to the theatre and 2,700,000,000 to motion pictures. There are about 6,000,000 persons engaged in clubs, studios, and various other creative activities. Drama is one of Russia's leading cultural pursuits, and there are 312 theatres, including 31 national theatres, presenting plays in all 22 languages of the autonomous republics.

Theatres in Russia that are of world renown include, in Moscow, the Bolshoi Theatre, Moscow Art Theatre, Maly (Small) Theatre, Vakhtangov Theatre, and State Central Puppet Theatre; in Leningrad, the Kirov State Academic Theatre of Opera and Ballet and the Leningrad Bolshoi Dramatic Theatre; and in Novosibirsk, the Novosibirsk Theatre of Opera and Ballet. Creative artists from the theatre belong to the All-Russian Theatrical Society in Moscow.

Music has always flourished in Russia; the symphonic and chamber works, oratorios, and songs of Dmitry Shostakovich, Sergey Prokofiev, V.P. Solov'yov-Sedoy, and Georgy Sviridov are performed throughout the world, while the Pyatnitsky, Voronezh, and Northern chorus troupes, the Siberian Omsk Folk Choir, the Aleksandrov Song and Dance Troupe of the Soviet Army, and the State Academic Folk Dance Ensemble are also popular.

Authors are united in a collective, the Union of Writers of the Russian S.F.S.R. Artists and sculptors belong to the Union of Artists of the Russian S.F.S.R., architects to the Union of Architects of the Russian S.F.S.R.

Among recent sculptural and architectural monuments, the best known are the Piskarevskoye Memorial Cemetery to those who died during the siege of Leningrad in World War II, the memorial to the soldiers who perished at Stalingrad, and the Tsiolkovsky State Museum of Cosmonautical History in Kaluga.

Russian achievements in science, literature, music, and fine arts have received international recognition. Mikhail

Lomonosov, Dmitry Mendeleyev, Klement Timiryazev, Ivan Michurin, Konstantin Tsiolkovsky, Ivan Sechenov, and Ivan Pavlov are famous in Russian science; Aleksandr Pushkin, Mikhail Lermontov, Leo Tolstoy, Anton Chekhov, and Maksim Gorky in literature; Ilya Repin and Vasily Surikov in art; and Mikhail Glinka and Peter Ilich Tchaikovsky in music.

In Soviet times their successors in various fields have included Gleb Krzhizhanovsky, Igor Kurchatov, Nikolay Semyonov, Sergey Korolyov, Boris Petrovsky, Vladimir Mayakovsky, Boris Pasternak, Mikhail Sholokhov, Aleksandr Solzhenitsyn, Aleksandr Tvardovsky, Isaak Brodsky, and Tikhon Khrennikov.

There are more than 600 museums in the republic, some of them world renowned: the Central Lenin Museum, the Central Museum of the Revolution, the State Historical Museum, and the State Tretyakov Gallery in Moscow; the Hermitage and the State Museum of Russian Art in Leningrad; the museum-estate of Leo Tolstoy, Yasnaya Polyana, near Tula; and the Mikhaylovskoye A.S. Pushkin Museum in Pushkin. More than 72,000,000 visits are made to the museums annually.

The Russian S.F.S.R. leads the Soviet Union in book, newspaper, and journal publication. Almost 55,000 different books and pamphlets are published annually in the republic, amounting to some 1,369,200,000 copies, including more than 1,287,900,000 in Russian. The Sovetskaya Rossiya (Moscow), Tatarskoye Izdatelstvo (Kazan), Bashkirskoye Izdatelstvo (Ufa), and Lenizdat (Leningrad) are the leading publishing houses. The universities of Moscow, Leningrad, Voronezh, Rostov, Saratov, and Tomsk also have their own presses.

More than 5,100 journals are published in the republic. The literary journals *Novy Mir* ("New World"; Moscow), *Neva* (Leningrad), *Ural* (Sverdlovsk), and *Sibirskiy Ogn* ("Siberian Lights"; Novosibirsk) are the most widely read.

The Russian S.F.S.R. publishes more than 4,400 newspapers, *Sovetskaya Rossiya* ("Soviet Russia") being the most widely read. There are also newspapers published in the native languages of the autonomous republics, autonomous regions, and national districts. More than 2,200 newspapers are published directly by industrial enterprises, schools, and large collective and state farms.

Sports. The Russian S.F.S.R. also encourages sports. New stadiums, playing fields, and sporting camps and centres are built each year, the largest being the Lenin Central Stadium in Moscow and the Kirov Stadium in Leningrad. There are more than 1,600 stadiums, 20,000 volleyball and basketball courts, 50,000 soccer fields, 560 tourist centres and mountaineering camps, and many other sporting facilities. Large physical-fitness organizations, with 30,000,000 members in 100,000 physical-fitness collectives, have grown up in factories, plants, schools, and collective and state farms. The Russian S.F.S.R. national athletic games are held every four years.

THE OUTLOOK

Since the Russian S.F.S.R. became a union republic in 1922, it has seen the growth of thousands of major industrial enterprises, high-voltage power-transmission lines, railway and highway networks, pipelines, and agricultural technology.

The directives of the Communist Party of the Soviet Union provide for continued increase in industrial output, to be accomplished by accelerating the growth of the manufacturing, gas, petroleum, atomic energy, and chemical industries, as well as increasing labour productivity and automation.

Plans have been drawn for the further development of agriculture and for increases in the annual yield of grain crops and tonnages of meat, milk, and wool. It is expected that the continuing development of the Siberian portion of the republic will further tend to spread settlement out from the old European Russian economic and demographic base.

This process, together with added emphasis on consumer goods, social services, and science and technology, will further transform the way of life in this large political

unit. In doing so it will undoubtedly have a very significant effect upon life in the entire Soviet Union.

(S.A.V./R.He.)

BIBLIOGRAPHY. The best available sources for the Russian S.F.S.R. are usually those devoted to the entire Soviet Union. For bibliographic guides to available sources the reader may consult CHAUNCEY D. HARRIS, *Guide to Geographical Bibliographies and Reference Works in Russian or on the Soviet Union* (1975), arranged both topically and regionally and extensively annotated; or, in Russian, the annual *Bibliografiya sovyetskoy bibliografy* ("Bibliography of Soviet Bibliographies"). A comprehensive work in Russian is the 23-vol. *Sovetskii Soyuz: Geograficheskoye opisaniye*, ed. by S.V. KALESNIK et al. (1967-72), of which 7 vol. are on the Russian S.F.S.R. For general topical reference, the 3rd ed. of A.M. PROKHOROV (ed.), *Bolshaya Sovetskaya entsiklopediya* (1969-), and its English translation, *Great Soviet Encyclopedia* (1973-), are the fullest sources. Dated though still valuable is ROBERT MAXWELL, *Information U.S.S.R.* (1962), with extensive and well-indexed coverage of topics related to the Russian S.F.S.R. The best general English-language geographies are JAMES S. GREGORY, *Russian Land—Soviet People* (1968), and, for historical perspective, WILLIAM H. PARKER, *An Historical Geography of Russia* (1968); for coverage of human geography the 2-vol. study by THOMAS FITZSIMMONS (ed.), *R.S.F.S.R., Russian Soviet Federated Socialist Republic* (1957), is still valuable. Statistical data given in the 800-page annual statistical abstract for the Soviet Union, *Narodnoye khozyaystvo SSSR* ("National Economy of the U.S.S.R."; 1956 ff.), are usually broken down by republic, while annual data for the R.S.F.S.R. alone can be found in the smaller *Narodnoye khozyaystvo RSFSR* ("National Economy of the R.S.F.S.R."; 1960 ff.).

(Ed.)

Russian Steppe

The Russian steppes are vast, open, treeless expanses of predominantly grassy, drought-resistant vegetation on rich chernozem (black earth) and chestnut-brown soils. They extend across Eurasia in a vast wedge, running over the south of the Soviet Union from the southernmost part of the Moldavian S.S.R. across the southern Ukraine, the Don Basin, northern Caucasia, the Volga Basin below the Kama confluence, the lowlands north of the Caspian Sea, and northern Kazakhstan into southwestern Siberia, beyond which—east of the Altai—they break up among the mountains. Covering an area of about 1,400,000 square miles (3,500,000 square kilometres), they have been of immense importance in the historical and economic development of a huge area and have been a constant theme in Russian literature and art. (For related information see SOVIET UNION.)

General environmental characteristics. Those parts of the steppe that escaped glaciation during the early Quaternary Period of the Cenozoic Era (2,500,000 years before present [BP]) are mostly covered with loose carbonaceous rock loesses (soft porous rocks of a pale yellowish or buff colour) and loesslike loam. These deposits, together with the absence of forests and the presence of occasional torrential rain, have contributed to the formation of a water-eroded relief. Within the river valleys, which are wide and asymmetrical, some two to four terraces may often form, of which the lowest are usually of sand.

The plateaus between the rivers are also asymmetrical and are interrupted by ravines through which water flows only during the spring thaw and summer storms. In many places the steep sides of both valleys and ravines are scoured by recent gullies, the majority of which occur in the highlands rising successively west of the Dnepr, west of the Don, and west of the Volga. (In order to limit the spread of gullies, which reduce the economically exploitable potential of the steppe lands, trees have been planted and grass has been sown on them; grazing has been restricted, and surface water has been drained.)

Shallow interfluvial areas are spotted with round depressions, or "steppe saucers"; caused by subterranean collapse, they rarely exceed six feet in depth but are generally more than five times (and sometimes even 50 or more times) this measure in diameter. In the Ukrainian steppes nearest to the Black Sea, larger depressions, *pody*, are found. Between the depressions the country is

Relief

Topo-
graphic
saucers
and
mounds

drained by long, winding channels with shallowly slanting sides—the products of superficial erosion. Sometimes the uniformity of the interfluvial area's relief is broken by mounds—barrows or lookout points that reach a height of from 16 to 20 feet—or by erosion—denudation residual outcrops. Rather less conspicuous are the little mounds thrown up by burrowing marmots.

Climate. The climate is continental, with warm, sunny summers, fairly cold winters in the east, and milder winters in the west, with a stable but shallow covering of snow. Temperatures for July are about 70° F and 75° F (21° C and 24° C), while those of January are wider ranging, —22° F (—30° C) in the east, 28° F (—2° C) in the west. Most precipitation takes the form of snow. Toward the end of winter the snow cover of the Ukrainian steppe and that of northern Caucasia is from four to eight inches deep though it may reach from eight to 16 inches or even 19 inches elsewhere—and drops sharply over the trans-Baikalian steppe. Rainfall is comparatively sparse, with 18–24 inches of rain in the northwest and ten to 12 inches in the southwest. It is heaviest at the end of spring and at the beginning of summer. The degree of humidity varies. Every third year is arid, with strong dry winds blowing in spring and summer, and dust storms.

Vegetation. Among the turf grasses, of which the steppe is mainly composed, bunchgrass (*Stipa*), fescue (*Festuca*), bluegrass (*Poa*), and agropyron (*Agropyrum*) are most characteristic. Mixed perennial grasses include sage (*Salvia*), pinks (*Dianthus*), vetch (*Astragalus*), bedstraw (*Galium*), and yarrow (*Achillea*). Mosses are often found among the turf grasses, with lichens and blue-green algae also in the south. Annual and perennial plants with a short vegetational period occur—particularly in the south. Grassy plants of various species, collectively known to the Soviet people as perekati-pole, take on a spherical brushwood shape with their seasonal maturing; then, breaking off easily in the wind, they roll along the steppe to mass along the edges of the forests and ravines. Thick clumps of shrubs and bushes—including karageny, steppe cherry, blackthorn, dwarf almond, and spirea—occur in the steppes of the east European plain and in the foothills of the Urals and of the Altai.

Interrelation of forest and steppe. Though to the north of the steppe a dry climate, saline soils, and proliferation of various grasses, and the uninterrupted relief discourage forests, they do sometimes occur on interfluvial plateaus and in complicated relation to expanses of meadow and grass. Most paleo-botanists and paleo-zoologists agree that the forest was advancing over the steppe before the advent of man and cite as evidence those studies that show that in postglacial times the boundary between forest and steppe was little changed and that their natural interrelation was disturbed by man, who, with axe, fire, and grazing cattle, was responsible for the destruction of many forested areas.

Animal life. The absence of natural shelter on the steppe conditions the kind of animals that inhabit it. Typical rodents include various types of marmot and other such burrowing animals and various species of mouse. The skunk, fox, and wolf are common—as was the tarpan (or small wild horse) until the second half of the 19th century. Antelopes are found in the south. The commonest birds are bustards, steppe eagles, steppe kestrels, larks, and gray partridges. Insects are many and various.

River flow. The rivers are fed mostly by snow. They overflow their banks during the spring thaw and in summer become very shallow. A high rate of evaporation reduces river flow to insignificance. The network of rivers is not dense, and those belonging properly to the steppe (as distinct from those rising outside, such as the Volga and the Ob) are shallow; the Don, with a length of 1,160 miles and a catchment area of 163,000 square miles, has an average discharge of only 33,000 cubic feet per second at low water.

Types of steppe. The amount of moisture in the soil conditions both the composition and the structure of the steppe, so that, from north to south, marked changes in vegetation and soil occur.

Mixed-grass-and-meadow steppe. This northern region of the steppe is humid and is characterized by a thick vegetation, mainly of thick grasses, and a solid or almost solid ground cover of soil. Forty or 50 different species of plants may be found in every 10-foot square. As the alternate masses of mixed grass bloom, the steppe repeatedly changes colour. In spring and early summer it begins to shade from lilac to golden yellow, then to pale blue, and finally to white. In late summer the burned-out steppe takes on a buff-coloured hue.

Tracts of forest break up the grass—meadow steppe along the floodplains and depressions, occurring also on the sandy areas and on outcrops of close-grained bedrock between the rivers. Under the grass meadows lie granular chernozems—soils rich in humus and in ash and very fertile. Around the saucer-like depressions de-alkalized, less fertile clays (de-alkalized solonetz) have formed by draining and leaching their silty upper layers. Meadow chernozem soils occur near underground water.

Grass steppe. A drought-resistant variety in which clumps of grass or turf predominate, the grass steppe is characterized by feather grass (*stipa*), fescue, Koeleria, the perennial oat, and wheat grass. Ground cover is not continuous, and bare soil is visible between the clumps of grass. In the interfluvial areas, forests are extremely rare. (Tidal forests tend to proliferate in flood-river valleys or to spring up on the slopes and tops of gullies in times of flood.)

Sage-and-grass steppe. This most southern variety of steppe, ending in desert, abounds in drought-resistant shrubs and such herb species as *Artemisia*, Kochia, and Matricaria. Various species of bluegrass are also present, as are tulips. In general, vegetation is mainly sporadic, and various combinations of different species occur according to accidents of relief and soil (including irregular salinity). Chestnut-coloured soils, in which solonetz soils and meadow-chestnut soils are interspersed, predominate. (Their fertility is considerably lower than that of the chernozem and dark-chestnut soils.)

Regional differences. The nature of the steppe changes significantly from west to east. In the west, the East European Plain is characterized by an uninterrupted relief, a relatively mild climate, and little of the sage-and-grass vegetation common to the east. Feather grass and fescues predominate in the grass steppe, and oaks and broad-leaved species of tree dominate the forest. Soils are chernozems. Many species of animals and plants common to western Europe occur.

The steppe of eastern Kazakhstan and Western Siberia has a more complicated relief—flat lowlands typical of Western Siberia in the north, and in the south, low, rounded, isolated hills common to Kazakhstan—and a more continental climate. The vegetation, in general, resembles that of the East European Plain, but local Kazakh species of feather grass may also occur. Broad-leaved trees appear less frequently than in the east, and island birch forests predominate. The proportion of rocky and alkaline soil increases, and the chernozems, though rich in humus, are shallow and unstable.

In Central and Eastern Siberia the Russian steppe gravitates toward the steppes of Mongolia. The climate is harsh, with winters in which little snow falls but which are characterized by sharp frosts that may last for several months. Average temperatures in January are about —22° F (—30° C). *Diplachne* and *Stipa capillata* are typical grasses, and in trans-Baikalia *Stipa cupillata* and *tansey* also occur.

Steppe resources and conservation. Mixed grass-and-meadow steppe and grass steppe have long served as the country's granary, for they produce most of the wheat, sugar beets, sunflowers, corn, millet, and cucurbitaceous (cucumber family) cultures, and to the west they support both horticulture and viticulture. Agricultural products include cattle, sheep, and poultry, and there is also horse breeding. To the west some 70 or 80 percent of the steppe has been tilled, and in Kazakhstan and Siberia all suitable land has been put to the plow. On sage-and-grass steppe less soil is tilled, but cattle and sheep are raised, horses are bred, and agriculture is pursued with the help of

Steppe
coloration

The
advancing
forest

Agricultural
products

artificial irrigation. Windbreaks and strips of forest have been planted over wide areas to prevent soil erosion—particularly on the banks at the Don, Volga, and Ural rivers and on several interfluvial plateaus. Ponds and reservoirs have been built in ravines, and small river valleys and dams have been constructed across many rivers.

Few natural expanses of mixed grass-and-meadow and grass steppe remain, save in the state national forests (the most important of which is the V.V. Alekhin Central Chernozem National Forest, south of Kursk) and on the shores of the Black Sea, where certain rare species of animals are also preserved. (F.N.M.)

Rutales

The large flowering plant order **Rutales** consists of 12 families, about 324 genera, and 4,000 species. Meliaceae is the largest family in the group with about 50 genera and 1,400 species. Some families, such as Aitoniaceae and Coriariaceae, among others, consist of only a single genus. The largest genera in the order are *Trichilia* (300 species, distributed in tropical America and Africa), *Aglaia* (about 300 species in China, Indo-Malaysia, and tropical Australia), *Fagara* (250 species in the tropics generally), *Dysoxylum* (200 species in Indo-Malaysia), and *Commiphora* (185 species in North Africa). Some genera, such as *Blepharocarya* (family Anacardiaceae), *Nymania* (Aitoniaceae), *Toddalia* (Rutaceae), *Limonia* (Rutaceae), and others, are monotypic; i.e., they consist of only a single species each.

The order is possibly of greater importance as a source of hardwood timber than any other in the plant kingdom. It also includes some of the best known tropical and subtropical fruits—the cashew nut (*Anacardium occidentale*), one of the first West Indian fruit trees to be distributed throughout the tropical world by early Spanish and Portuguese adventurers, and the Indian mango (*Mangifera indica*), often called the queen of all tropical fruits; it has delightfully aromatic flesh. The mango has long been cultivated in the Indo-Malaysian regions and has recently been introduced into other parts of the world. The myrrh (*Balsamodendron*) and frankincense (*Boswellia carteri*) of biblical fame also belong to this order.

GENERAL FEATURES

Size range and diversity of structure. The order Rutales consists predominantly of woody shrubs and trees. Herbs are, as a rule, absent, although some are present in the families Rutaceae and Podoaceae. A few, such as the genera *Naregamia* and *Dictamnus*, are undershrubs. Rhizomatous (creeping) tuberous-rooted perennials are found in the family Podoaceae. The order has only few climbers, but poison ivy (*Rhus radicans*) is one well-known example. A great many beautiful forest trees, some of which are reckoned among the most elegant on earth because of their feathery foliage and magnificent fruits, belong to this order. Several trees, such as *Camposperma auriculata*, *Mangifera lagenifera*, *Buchanania lucida*, and others, attain a height of 33 metres (108 feet). Trees like *Irvingia malayana* may even reach a magnificent height of 66 metres (216 feet). Many have buttresses, which may be thin and steep as in *Irvingia*, spreading as in *Pentaspadon*, or thick and prominent as in *Gluta*, *Parishia*, *Canarium*, and others. Several growth forms occur among the trees of the order. Many, such as *Mangifera lagenifera*, have a dense and almost hemispherical crown with a tall columnar trunk. *Dracantomeilon mangiferum* has a conical crown when young, becoming dense and rounded at maturity. *Camposperma auriculata* has a flat-topped crown. There are several thorny trees in the family Rutaceae, among them the genera *Aegle*, *Citrus*, *Limonia*, and others. *Canarium* has aerial roots, especially on the side to which it leans. These roots may arise from a height above the ground of four metres (13 feet) or even more.

Distribution and abundance. The order Rutales is dominantly pantropical in distribution, with a few genera

Figure 1: Representative plants of three families of the order Rutales.

extending to temperate regions of both hemispheres. The chief centres of distribution are tropical America, South Africa, *Cneorum* in the Mediterranean region and the Some genera show restricted distribution; e.g., *Kirkia* in tropical and southern Africa, *Nymania* in southern Africa, *Naregamia* on the west coast of India and in eastern Africa, *Cneorum* in the Mediterranean region and the Canary Islands, *Melosma* in California, and *Stylobasium* in southwest Australia.

Economic importance. The group is important in several respects. It includes many fruit trees, such as the Indian mango and cashew nut. The axis under the nut in the latter swells into a pearlike body that is also edible and is used for distilling wine. This false fruit, known as cashew apple, is fragrant. In many varieties of cashew apple the juice causes a slight irritation in the throat. Other varieties are known chiefly from tropical America, where the pulpy portion is extensively consumed. The shell of the cashew nut contains an irritant skin poison that produces blisters and dermatitis. The shell liquid is salvaged and used as a lubricant in electrical insulations in airplanes. The cashew kernel is generally removed and eaten after roasting the nut.

Mango is one of the earliest fruit trees known to mankind. The representation of this tree in the Buddhist *stūpas* bears testimony to its antiquity in India. The tree is inextricably connected with Indian life and religious ceremonies. Sanskrit literature is replete with delineations of its qualities. Every part of the tree, from root to the top, is used by man in one form or another. The fruit itself, in all stages of development, is used in India and neighbouring countries. Raw fruits are used for extraction of tannin and other astringent products, for chutnies and in pickles, and for cool drinks. Squashes, syrups, marmalades, jams,

Skin
poisons

Trees of
the order

jellies, and candies are made from the ripe fruits. The kernel, rich in carbohydrates, calcium, and fat, is used as a stock feed for pigs. When dried and ground into flour, it is used as food by people in some parts of Southeast Asia.

Pistachio nuts are obtained from *Pistacia vera* of the Mediterranean countries and west Asia. Lemons (*Citrus medica* variety *limonum*), oranges (*C. aurantium*), limes (*C. medica* variety *acida*), and other citrus fruits are well-known. Originally, Citrus was a fruit of the Orient, where it has been in cultivation for thousands of years. The oldest Oriental literature includes stories about Citrus. The United States is now a principal grower of the fruit. Citrus fruits are among the best sources of vitamin C.

Kumquat (*Fortunella*), hog plum (*Spondias*), and bael (*Aegle*) are some of the other common fruits of the Rutales order. *Lansium domesticum* is cultivated for its fruit, known as langsat or lansa, in the Malayan region. The fruits of *Canarium album* are eaten like olives. The brown pulp of wood apple (*Feronia limonia*) mixed with sugar is eaten after straining through a sieve to remove the seeds. Santol (*Sandoricum koetjape*) is a favourite fruit in the Philippines.

Timber from trees of the Rutales order is often excellent. Some of the well-known timber trees are mahogany (*Swietenia mahogany*) of tropical America and the West Indies, Guiana crab tree (*Carapa guianensis*), African cedar (*Khaya senegalensis*) of West Africa, Indian redwood (*Soymida febrifuga*), Chittagong wood (*Chikrasia tabularis*) of the Indo-Burma region, toon (*Toona ciliata*) of India, satinwood (*Chloroxylon swietenia*) of the Indo-Malayan region, yellow wood (*Flindersia oxleyana*) of east Australia, and sneeze-wood, or cape mahogany (*Ptaeroxylon utile*). The important gaboon mahogany, or okoume of commerce (*Aucoumea klaineana*), is used for veneers and plywood. Sapele mahogany (*Entandrophragma*), Colorado wood (*Quebrachia lorentzii*), Spanish cedar (*Cedrela*), and African walnut (*Lovoa*), though less important, are known the world over. The best known timbers are typically reddish in colour, lustrous, easy to work, and unusually free of tendencies to warp under changing conditions of moisture and other atmospheric factors. Such characteristics make these woods eminently suited for cabinetmaking.

Tannin-yielding plants are known in the group—e.g., *Carapa* species (Indo-Malaysia), *Schinopsis* species (South America), *Coriaria myrtifolia* (Mediterranean).

Many barks are medicinal. The bark of *Guarea rusbyi*, known to pharmacologists as cocillana, has properties similar to those of *ipecacuanha* (i.e., *Cephaelis ipecacuanha*), the dried roots of which contain alkaloids such as emetine, cephaeline, and psychotrine. The tropical South American caspasia bark is obtained from *Galipea officinalis*. The extract of Surinam quassia wood (*Quassia amara*) is a tonic. Bitters are prepared from the bitter principles present in the barks of several species, such as cedron (*Simaba cedron*) of Central America, simaruba bark (*Simarouba amara*) of tropical America, and quassia wood (*Picrasma excelsa*) of the West Indies. The bitter fruits of *Brucea amarissima* are used in Malayan and Chinese medicines, particularly to treat dysentery. Among the medicinal plants are neem, or margosa (*Azadirachta indica*), and bael, both of India.

The art of lacquering had its origin in China centuries before the beginning of the Christian Era and reached its climax of development there during the time of the Ming rulers, AD 1368–1644. The lacquers used for this were obtained from the varnish tree (*Rhus vernicifera*). The exudation, a milky liquid, darkens and thickens rapidly on exposure to air. Lacquer, when applied as a varnish, affords remarkable protection, as it is unchanged by acids, alkalies, alcohol, or heat up to 160° F (70° C). *Melanorrhoea usitata* is the Burmese lacquer tree.

Members of the family Burseraceae have an abundance of fragrant balsams (aromatic substances that exude from plants spontaneously or by incision) and resins in their bark. Myrrh and frankincense, both in the family Burseraceae, contain the fragrant substances. Resins and

balsams are oxidation products of various essential oils and are very complex and varied in their chemical constitution. The resins, secreted in definite passages or cavities, exude from the bark and harden on exposure to air into lumps. Tapping usually is necessary for commercial exploitation. Other important resins are the carana gum (from *Protium carana*) of South America and balm of Gilead (from *Commiphora opobalsamum*). *Bursera gummiifera* is the turpentine tree, which furnishes the resin known as American elemi, cachibou, or gomart. From the elephant tree (*Bursera*) of Mexico is obtained a copal (a type of resin), which is used as a cement and varnish. Chian turpentine is obtained from *Pistacia terebinthus*. *Amyris elemifera* gives African elemi. *Canarium commune* furnishes the resin Manila elemi, and its nuts are edible (Java almond). *C. strictunz* of Kerala (India) is the source of black dammar. Fruits of *Canarium* are also valued for their kernels, which are processed to produce a cooking oil. Fat from the seeds of *Carapa* is used for making soap and as an illuminant. Rue (*Ruta graveolens*) is a narcotic and stimulant. Its leaves are used as savory in Mediterranean regions, and oil of rue is also distilled from it. Leaves of *Murraya koenigii* are used for flavouring curries in Indo-Malayan regions. Dyes from the fruits of *Coriaria* have been used to prepare indelible inks. *Khaya*, *Feronia*, and other genera give gums that can be used in place of gum arabic. *Anacardium humile*, *A. occidentale*, and *A. nanum* provide cashew or acajou gum, which is not only a reasonably good adhesive but also contains a small amount of cashew oil, which acts as an insect repellent. *Pistacia lentiscus* of Greece furnishes mastic. Fruits of *Semecarpus anacardium* are known as marking nuts. The young fruits yield a black resin insoluble in water and useful as a marking ink in Southeast Asia.

A few, like the tree of heaven (*Ailanthus altissima*), Persian lilac (*Melia azedarach*), cork tree (*Phellodendron*), and orange jasmine (*Murraya*), are grown in parks and gardens. Orange flowers are used widely in perfumery in France. Because of the pleasantly fragrant aroma, citrus flowers are used throughout the world as decorations in special celebrations. Various kinds of citrus oils are extracted from the rinds (peel) of fruits. These oils develop in sacs or vesicles, which are ductless and without communication with surrounding cells or the exterior.

The fruits of Persian lilac are poisonous to rabbits, poultry, pigs, sheep, and cattle. *Dysoxylum angustifolium* has a preference for riversides, and, during fruiting season, the fruits often fall into the water, where they are eaten by fishes. The flesh of such fishes becomes poisonous to men and animals. The foliage and fruits of *Coriaria* are reported to be very poisonous, and the fruits are used as a dog poison in Mexico. The poison ivy of North America, which is a pest in some of the southern states, is *Rhus radicans*.

NATURAL HISTORY

Life cycle. Members of the order are perennials. The trees in the group play a dominant role in the formation of tropical forests. Many are quick growing and evergreen, as in *Camposperma auriculata*, *Buchanania lucida*, *Melanorrhoea wallichiana*, and *Mangifera indica*, or deciduous, as in *Lannea*, *Juliania*, *Pentaspadon*, and *Rhus*.

Gluta is remarkable in having intensely violet young leaves. The young leaves of *Mangifera* may be brown, reddish brown, or violet. The leaves of *Camposperma macrophylla* wither red. The deciduous trees usually flower when leafless. Some trees, such as *Samadera indica* (Indo-Malayan), are reported to flower only once in three years. *Mangifera lagenifera* flowers only at long intervals of many years, sometimes as long as 20 years.

The flowers are mostly suited for pollination by insects. The coloured corolla (petals) and sometimes stamens (male reproductive structure) render some flowers conspicuous. Fragrance makes others attractive. The disc (a fleshy structure inside the flower) secretes an abundance of easily accessible honey. Cross-pollination appears to

Miscellaneous products from fruits, seeds, and leaves

Timber characteristics

Unusual leaf colours

be favoured by the proterandry (*i.e.*, the maturing of the stamens before the female parts of the same flower) in many flowers. In rue (*Ruta*) the stamens rise in the centre of the flower, shed pollen successively, fall back, and wither. The stigma (part of the female reproductive structure) ripens only after all the stamens have fallen back. Some of the stamens, though fallen back, may not wither, and they often retain some pollen. If by chance no insect visitor comes, the unwithered stamens may rise up again and shed the pollen grains on the stigma, effecting self-pollination. Here is a remarkable instance in which seed setting is ensured by self-pollination if necessary, but cross-pollination is sought until the last possible moment. The usual visitors are small flies and bees. Many species are also vegetatively propagated.

Ecology. Members of the family Rutaceae are adapted to various conditions. Some are xerophytes (adapted to dry habitats), frequently of heathlike habit (low dense shrubs)—*e.g.*, the South African *Diosma*. Some members have short shoots whose leaves are reduced to spines. Generally, the members of the order do not prefer open land. Many have a liking for riverside flood zones, as in the Malaysian *Aglaia salicifolia* and *Dysoxylum angustifolium*. Some species of *Aglaia* and *Amoora* grow in swamps. *Xylocarpus obovatus* and *Amoora cucullata* are found in mangrove forests. *Suriana maritima* is coastal in distribution. Plants of tidal stretches include *Gluta velutina*, but species of *Balsamodendron*, *Boswellia*, and others have a preference for dry hills. Mango does best where the climate has strongly marked seasons and rain is scarce at fruiting time. A shower at the time of flowering is inimical to the development of fruits.

FORM AND FUNCTION

Distinguishing characteristics. Members of the families Anacardiaceae, Julianiaceae, and Burseraceae have resinous bark. Leaves are generally alternately arranged along a stem and are only rarely opposite or whorled. The leaves are mostly pinnately compound (leaves with small leaflets along both sides of a central axis) and rarely simple. An interesting form of leaf is found in *Citrus*, in which the simple blade is separated from the wedge-shaped petiole (leaf stalk) by a joint. Because this type of leaf occurs in genera with compound leaves, it is believed that this is a reduced form. Reduction goes still further in *Citrus*, in which the first one or two leaves of an axillary bud (a bud located in an axil or upper angle between a stem and a branch or leaf) are reduced to spines. Leaves of *Chisocheton* (family Meliaceae) show continued growth at their tips. Members of the family Rutaceae have gland-dotted aromatic leaves. Stipules, small leaflike appendages at the base of petioles, are usually absent, and if present, obscure. In *Ailanthus* (family Simaroubaceae) abscission layers (zones of weakness) form at the base of the leaflets as well as in the petiole; the leaflets usually drop first.

The flowers may be single in the axils of leaves, as in *Naregamia*, or they may be arranged in racemes (spike-like flower dusters), cymose spikes (clusters that bloom from the top downward), or panicles (many-branched flower clusters). They may be bisexual, unisexual, or polygamous (bearing unisexual and bisexual flowers on the same plant). In *Juliania* the flowers are not only dioecious (*i.e.*, the male and female flowers are on separate plants), but the male flowers are in racemose panicles (panicles that bloom from the bottom upward), and females are crowded in an involucre (a cuplike whorl of green leaflike bracts). Generally, both calyx (sepals) and corolla (petals) are present, but in some the corolla may be lacking. In *Juliania*, which lacks petals, the male flowers have a three- to nine-lobed calyx; the females have none. The calyx in other members is generally three- to five-parted, as in the corolla. A conspicuous disc, which may be annular (ring-shaped), cushion-like, cup-like, or tubular, is present in most of the members.

Stamens are usually double the number of petals, but in some they are equal to the number of petals or sometimes indefinitely numerous. Filaments (the stalks of the stamens) are usually free, but in most of the members of

Figure 2 Representative flowers and fruits of seven families of the order Rutales.

Drawing by M. Pahl based on (Podoaceae) J. Hutchinson, *Families of Flowering Plants*, the Clarendon Press, Oxford; (Coriariaceae) G.H.M. Lawrence, *Taxonomy of Vascular Plants*, the Macmillan Company

the family Meliaceae the stamens are united into a tube at the tip of which are borne the anthers, on the inside. Some species in the family Rutaceae also have filaments united at the base. When the flowers are unisexual, staminodes (sterile stamens) are usually present in the female flowers, and pistillodes (sterile pistils—female structures) in the male flowers, but not in *Juliania*, however. Anthers, the saclike, pollen-producing parts of the stamens, are two locular (chambered) and open lengthwise. The gynoecium (female complex) may be composed of one to 20 carpels, structures of the ovary wall. It may be unilocular (*Coriaria*), multilocular at the base and unilocular above (several members of the family Meliaceae), multilocular throughout (some members of the family Rutaceae), or the carpels may be separate, as in *Ailanthus*, *Brucea*, *Samadera*, and others of the family Simaroubaceae. Styles, the upper parts of the pistil, may be three, as in the family Julianiaceae, or they may be united, as in some members of the families Rutaceae and Meliaceae. Each carpel has a single ovule (seed precursor) in some members of the families Anacardiaceae, Simaroubaceae, and others; two ovules, as in the family Burseraceae and some members of the Meliaceae; or several ovules, as in some of the Rutaceae. In the family Julianiaceae the funiculus, the stalk attaching the ovule to the ovary wall, or placenta, is unusual in being cuplike; and the nucellus, the central part of the ovule, is generally massive. An outgrowth from the base of the funiculus called the obturator is present in several genera. These obturators aid in conducting pollen tubes to the ovules. The genus *Rhus* is exceptional in that the pollen tube enters the ovule through the chalaza, the end of the ovule opposite from

where the funiculus attaches, in a process known as **chala**zogamy.

Fruit
types
and their
develop-
ment

The fruit **may** be a drupe (**stony-seeded**—e.g., *Mangifera*), a capsule (*Swietenia*), winged (*Ailanthus*), a berry (some *Burseraceae*), a berry with a woody rind (*Aegle*), or a hesperidium, a three-layered berrylike fruit derived from a multilocular ovary, as in lemons, oranges, and others of the genus *Citrus*. In *Coriaria* the petals enlarge and protect the fruits. *Juliania* has fruits enclosed in enlarged involucre. In some the fruits develop from an ovary with only partially united carpels, as in *Dictamnus*, and the carpels become isolated in fruit and dehisce (open) along the ventral suture. *Citrus* has a smooth **endocarp** (inner layer of a fruit) or encloses a fleshy part consisting of juicy emergences from the inner walls of the many-chambered fruit that fills the cavity.

Cedrela, *Swietenia*, and others have winged seeds. The seeds may be with or without endosperm, the starchy nutrient tissue for the developing embryo. The embryo in the family *Burseraceae* is sometimes rolled (**contortuplicate**). Cotyledons (seed leaves) are usually fleshy. Some genera like *Zanthoxylum*, *Citrus*, and *Mangifera* have many embryos in the seed. The embryos may come from different parts of the ovule. Apomixis, the development of unfertilized seed, is known in *Citrus*.

Physical and biochemical characteristics. It is known that the genus *Canarium* synthesizes a large series of turpenes, naturally occurring hydrocarbons of great variety, an example being turpentine, which is a mixture of turpenes. The oil obtained from various *Canarium* species contains paracymol, an aromatic hydrocarbon widely distributed in the essential oils of flowering plants. Trees with resinous sap are usually irritating and poisonous. Notable among these are some species of *Mangifera*, *Holigarna*, and the rengas trees of Malaya. Because of the irritant sap, the wood of several species, though excellent, is seldom used because no method is known to remove the annoying agent. It is known that the poison in these is a volatile and aromatic substance that gradually disappears from the sap after it has been drawn. It is doubtful whether this poison has any effect on animals such as monkeys and squirrels, which are known to eat the fruits of these trees, and insects, which feed on the sap. The irritant present in cashew nut shells has been studied in detail and has been found to contain cardol, anacardol, and anacardic acid. *Coriaria* is one of the very few non-leguminous (leguminous plants belong to the family *Leguminosae*, sometimes called *Fabaceae*) plants that fix atmospheric nitrogen in root nodules.

EVOLUTION

The order **Rutales** appears to be fairly old, as is evidenced by the available fossil records. *Anacardites amissus*, *A. antiquus*, *Rhus rnebranacea*, and others are known from Cretaceous Period (beginning about 136,000,000 years ago) rocks. Tertiary (beginning about 65,000,000 years ago) deposits are abundant in fossils of *Rhus*, *Pistacia*, *Cedrela*, *Evodia*, *Ailanthus*, and *Bursera*. Some families, such as *Simaroubaceae*, are not known from deposits older than the Tertiary.

Evolution-
ary
changes

Certain lines of specialization can be traced within the group. These include changes from spiral arrangement of leaves to opposite arrangement; reduction from two whorls of **perianth** (sepals and petals considered together) to one whorl and from two whorls of stamens to one whorl; gradual **adnation** (fusion) and cohesion of stamens to form a staminal tube; changes from bisexuality to unisexuality; changes from **apocarp**y (single, free carpels) to **syncarp**y (fused carpels); reduction in the number of carpels from several-carpelled ovaries to single-carpelled ovaries; and reduction in the number of ovules from many to one for each carpel.

As presented here, the order is derived from the order *Saxifragales*. Affinities with the orders *Sapindales* and *Dilleniales* cannot, however, be ignored.

CLASSIFICATION

Distinguishing taxonomic features. There are several characters, combinations of which are used by taxono-

mists to set the limits of the order **Rutales**, that may be used to assess the relationships among the various families included within the group and to determine connections with other groups. The characters used are, chiefly, wood; **habit**, presence or absence of oil glands in the leaves, presence or absence of resinous bark, presence of a conspicuous disc within the stamens, nature of the staminal whorl, nature of the ovary, number and attachment of the ovules in the ovary, number of styles, and features of the seed and embryo.

Annotated classification. The arrangement of the families adopted in the following section is a recent one of rather wide acceptance.

ORDER RUTALES

Mainly trees or shrubs, herbs extremely rare; bark resinous or not; leaves mostly alternate or opposite, mostly compound, sometimes simple, often gland-dotted; stipules very rare; flowers hypogynous (*i.e.*, sepals, petals, and stamens arise at the base of the ovary) to slightly perigynous (sepals, petals, and stamens partly enclose the ovary), mostly bisexual, sometimes unisexual; sepals mostly imbricate (overlapping), rarely valvate (meeting at the edges without overlapping); petals mostly present, contorted, imbricate or valvate, usually free; stamens mostly equal to or twice the number of petals, often in two whorls; disc mostly conspicuous; ovary superior (**hypogynous**), syncarpous (of fused carpels), or subapocarpous (of partly free carpels), 1- to 20-carpelled; styles free or united; ovules 1 or 2, rarely more; fruit various; seeds with thin (or without) endosperm, straight, curved, or rolled embryo, and usually fleshy cotyledons.

Family Anacardiaceae (Mango family)

Evergreen or deciduous trees with resin ducts in bark, leaves odd-pinnate (compound, with leaflets alternately arranged on either side of the central axis) or simple, without stipules or very obscurely stipulate, often polygamous flowers in panicles; sepals 3 to 7; petals 3 to 7 or absent; stamens usually twice or rarely equal to the number of petals; ovary usually **1-locular**, rarely 2- to 5-locular; ovules solitary, pendulous; fruit mostly drupes; seeds with little or no endosperm. About 73 genera and 600 species found mainly in the tropics, though some are temperate.

Family Julianiaceae

Resinous trees or shrubs; leaves deciduous, alternate, pinnate compound, without stipules; flowers dioecious, without petals, males in racemes, females crowded in involucre; calyx of male 3- to 9-lobed, absent in female; stamens equal to calyx lobes; ovary 1-locular, 1-ovuled; style 3-parted; fruits enclosed in enlarged involucre; seeds without endosperm. Two genera and 5 species distributed in Mexico and Peru.

Family Podoaceae

Shrubs or perennial rhizomatous (creeping) herbs; leaves alternate or opposite, long-petioled, without stipules; flowers unisexual, in panicles, some bracts of male spikes large, coloured and membranous with a reticulate pattern; calyx 4-toothed; petals 4, free, clawed; stamens 8; anthers extrorse (opening away from the central axis of the flower); disc only in female flowers; ovary **1-locular**, **1-ovuled**; style undivided. Two genera and 3 species distributed in eastern Asia.

Family Burseraceae (Myrrh family)

Resinous trees or shrubs; leaves alternate and compound; flowers unisexual or bisexual, solitary or in panicles; sepals and petals 3 to 5 each, imbricate or valvate; disc present; stamens twice the number of petals, free; ovary 2- to 5-locular; ovules 2 or 1 in each locule; fruit a drupe; embryo rolled or straight. Sixteen genera and 500 species distributed chiefly in tropical America with some in Africa and Asia.

Family Simaroubaceae (Tree of Heaven family)

Trees with bitter bark, no oil glands; leaves pinnate compound; flowers bisexual or polygamous, in panicles; calyx and corolla 3- to 7-parted; disc present; stamens equal to or double the number of petals, sometimes with basal scales; ovary 2- to 5-lobed or carpels free; ovule 1 for each carpel; fruit often winged. Thirty genera and 200 species distributed mainly throughout the tropics.

Family Stylobasiaceae

Small shrubs; leaves simple, alternate, coriaceous (leathery); flowers bisexual or polygamous; calyx campanulate (bell-shaped), 5-lobed; petals absent; disc absent; stamens 10, anthers extrorse; ovary 1-carpelled; ovules 2; fruit surrounded by enlarged calyx. One genus with 2 species distributed in southwest Australia.

Family Rutaceae (Orange family)

Shrubs, trees, or rarely herbs; leaves simple or compound with pellucid (clear, almost transparent) glands; sepals and petals 4 or 5, free or connate (fused) at the base; disc present;

stamens usually twice the number of petals, often in 2 whorls; ovary 4- or 5-celled, sometimes up to 20-chambered; ovules usually 2 in each cell; seeds with or without endosperm; fruit various. About 150 genera and 900 species distributed throughout temperate and subtropical regions.

Family Cneoraceae

Leaves alternate, simple, entire; leathery, exstipulate, with oil glands; flowers solitary or in corymbs, 3- or 4-merous (parts present in 3s or 4s), bisexual; disc bolster-like; stamens 3 or 4; ovary 3- or 4-lobed with 2 ovules in each; style 1; fruit a drupe; seeds with endosperm. Two genera and 3 species distributed in the Mediterranean region, the Canary Islands, and Cuba.

Family Meliaceae (Mahogany family)

Trees and shrubs without resin or oil glands; leaves mostly pinnate compound, alternate; flowers usually bisexual, in panicles or rarely solitary; sepals and petals 4- or 5-parted; stamens united into a tube or rarely free; disc conspicuous; ovary 1- to 5-celled; usually 2 ovules in each carpel; style undivided; fruit a drupe, capsule; or berry; seeds often winged. Fifty genera and 1,400 species distributed generally throughout the tropics and subtropics.

Family Aitoniaceae

Woody plants; twigs angular; leaves simple and alternate, coriaceous; flowers solitary, axillary, and bisexual; sepals and petals 4 each, imbricate; stamens twice the number of petals; disc fleshy; ovary 4-carpelled and lobed; ovules 2 in each carpel; style filiform (thin—thread-like); fruit a capsule; seeds nonendospermous. One genus (*Nymania*, formerly *Aitonia*) with a single species distributed in South Africa.

Family Kirkiaceae

Trees or shrubs; leaves pinnate compound, without stipules; flowers polygamous in axillary cymes; sepals and petals 4 to 5, imbricate; stamens equal to or double the number of petals; disc present; ovary 2- to 5-carpelled; styles free; fruit a capsule; embryo straight. One genus (*Kirkia*) and 8 species in tropical and southern Africa.

Family Coriariaceae

Shrubs; leaves opposite or whorled, parallel-veined; without stipules; flowers bisexual or unisexual in racemes, protogynous (the pistil matures before the stamens of the same flower); sepals 5, imbricate; petals 5, valvate; stamens in 2 whorls of 5 each; ovary 5- to 10-carpelled; ovules 1 in each carpel; petals become fleshy and enclose carpels in fruit. One genus and 15 species distributed from the Mediterranean to Japan, in New Zealand, and from Mexico to Chile.

Critical appraisal. There is no unanimity of opinion among taxonomists with regard to the systematic positions of the families included in the order Rutales. While most of them agree that there is close relationship among the families Rutaceae, Meliaceae, Simaroubaceae, and Burseraceae, some treat the family Meliaceae in a separate order, Meliales. The above four families are placed in the order Geraniales in the majority of earlier classification systems. These families are included in the order Rutales by several important authorities who, however, also include other families not presented here. The families Julianiaceae, Coriariaceae, Cneoraceae, and Anacardiaceae have been placed in other orders or have been elevated to ordinal status by themselves in several different classification schemes. To this list have been added Podoaceae, Stylobasiaceae, Aitoniaceae, and Kirkiaceae in the classification presented here. The affinities of Aitoniaceae, Kirkiaceae, and Coriariaceae are, however, obscure. On anatomical grounds there is strong evidence for considering the families Rutaceae, Simaroubaceae, Meliaceae, Sapindaceae, Burseraceae, and Anacardiaceae as forming a natural group, with Rutaceae standing somewhat apart, showing the closest resemblance to the family Simaroubaceae. It has been **stated** that pollen grains in the families Anacardiaceae, Burseraceae, Meliaceae, Rutaceae, and Simaroubaceae show similarities. Totality of evidence indeed suggests that these families are related. The genus *Blepharocarya* has been segregated from Anacardiaceae to an independent family Blepharocaryaceae by some authorities who feel that the female inflorescence (flower cluster) of *Blepharocarya* is apparently almost exactly homologous to the cupule (*i.e.*, the structure forming the cup in an acorn) of the family Fagaceae (oaks and beeches). The genus *Rhabdodendron* has been removed from the family Rutaceae and referred to the family Phytolaccaceae on anatomical

grounds by some authorities. *Rhabdodendron* has also been raised to family status, and this view has been endorsed by many. Sometimes the genera *Suriana*, *Irvingia*, and *Picrodendron* of the family Simaroubaceae are treated as independent families, based on anatomical characters. *Irvingia* is sometimes placed in the family Ixonanthaceae (order Geraniales; *q.v.*). It has been suggested that the tribes Melieae, Cedreleae, and Swietenaeae should be raised to the status of families. This is not supported by wood anatomy, palynology (pollen morphology), or floral anatomy. The family Podoaceae was included under the family Sapindaceae by some early workers and with Anacardiaceae by others. It has also been suggested that it could be raised to a family in its own right; this has been accepted by many authorities and is so presented here. Palynology supports such a contention. The genus *Kirkia* was formerly included in the family Simaroubaceae by early authorities. Sometimes it is referred to the family Ptaeroxylaceae, with which it has, however, fewer similarities than differences.

(N.C.N.)

Rutherford, Lord

Ernest Rutherford, nuclear physicist and Nobel prize winner, is to be ranked in fame with Sir Isaac Newton and Michael Faraday. Indeed, just as Faraday is called the "father of electricity" so a similar description might be applied to Rutherford in relation to nuclear energy. He contributed substantially to the understanding of the disintegration and transmutation of the radioactive elements; discovered and named the particles expelled from radium; identified the alpha particle as a helium atom and with its aid he evolved the nuclear theory of atomic structure, and he used that particle to produce the first artificial disintegration of elements. In the universities of McGill, Manchester, and Cambridge he led and inspired two generations of physicists who—to use his own words—"turned out the facts of Nature," and in the Cavendish Laboratory his 'boys' discovered the neutron and artificial disintegration by accelerated particles.

Rutherford was born in Spring Grove, New Zealand, on August 30, 1871, the fourth of the 12 children of James, a wheelwright at Brightwater near Nelson on South Island, and Martha Rutherford. His parents, who had emigrated from Great Britain, denied themselves many comforts so that their children might be well educated. In 1887 Ernest won a scholarship to Nelson College, a secondary school—similar to a public (private) school in England—where he was a popular boy, clever with his hands, a keen footballer, and won prizes in history, languages as well as mathematics. Another scholarship allowed him to enroll in Canterbury College, Christchurch, from where he graduated with the B.A. in 1892 and the M.A. in 1893 with first class honours in mathematics and physics. Financing himself by part-time teaching, he stayed for a fifth year to do research in physics, studying the properties of iron in high-frequency alternating magnetic fields. He found that he could detect the electromagnetic waves—wireless waves—newly discov-

ered by the German physicist Heinrich Hertz, even after they had passed through brick walls. Two substantial scientific papers on this work won for him an "1851 Exhibition" scholarship, which provided for further education in England.

Before leaving New Zealand he became unofficially engaged to Mary Newton, a daughter of his landlady in Christchurch. Mary preserved his letters from England, as did his mother, who lived to age 92. Thus, a wealth of material is available that sheds much light on the non-scientific aspects of his fascinating personality.

On his arrival in Cambridge in 1895, Rutherford began to work under J.J. Thomson, professor of experimental physics at the university's Cavendish Laboratory. Continuing his work on the detection of Hertzian waves over a distance of two miles, he gave an experimental lecture on his results before the Cambridge Physical Society and was delighted when his paper was published in the *Philosophical Transactions* of the Royal Society of London, a signal honour for so young an investigator.

Rutherford made a great impression on colleagues in the Cavendish Laboratory, but also aroused jealousies in the more conservative members of the Cavendish fraternity, as is clear from his letters to Mary; and Thomson held him in high esteem. In December 1895, when Röntgen discovered X-rays, Thomson asked Rutherford to join him in a study of the effects of passing a beam of X-rays through a gas. They discovered that the X-rays produced large quantities of electrically charged particles, or carriers of positive and negative electricity, and that these carriers, or ionized atoms, recombined to form neutral molecules. Working on his own, Rutherford then devised a technique for measuring the velocity and rate of recombination of these positive and negative ions. The published papers on this subject remain classics to the present day.

In 1896 the French physicist Henri Becquerel discovered that uranium emitted rays that could fog a photographic plate as did X-rays. Rutherford soon showed that they also ionized air but that they were different from X-rays, consisting of two distinct types of radiation. He named them alpha rays, highly powerful in producing ionization but easily absorbed, and beta rays, which produced less radiation but had more penetrating ability. He thought they must be extremely minute particles of matter.

In 1898 Rutherford was appointed to the chair of physics at McGill University in Montreal. To Mary he wrote, "the salary is only 500 pounds but enough for you and me to start on." In the summer of 1900 he travelled to New Zealand to visit his parents and get married. When his daughter Eileen, their only child, was born the next year, he wrote his mother "it is suggested that I call her 'Ione' after my respect for ions in gases."

Toward the end of the 19th century, many scientists thought that no new advances in physics remained to be made. Yet within three years Rutherford succeeded in marking out an entirely new branch of physics called radioactivity. He soon discovered that thorium or its compounds disintegrated into a gas that in turn disintegrated into an unknown 'active deposit,' likewise radioactive. Rutherford and a young chemist, Frederick Soddy, then investigated three groups of radioactive elements—radium, thorium, and actinium. They concluded in 1902 that radioactivity was a process in which atoms of one element spontaneously disintegrated into atoms of an entirely different element, which also remained radioactive. This interpretation was opposed by many chemists who held firmly to the concept of the indestructibility of matter; the suggestion that some atoms could tear themselves apart to form entirely different kinds of matter was to them a remnant of medieval alchemy.

Nevertheless, Rutherford's outstanding work won him recognition by the Royal Society, which elected him a fellow in 1903 and awarded him the Rumford medal in 1904. In his book *Radio-activity* he summarized in 1904 the results of research in that subject. The evidence he marshalled for radioactivity was that it is unaffected by external conditions, such as temperature and chemical change; that more heat is produced than in an ordinary chemical reaction; that new types of matter are produced at a rate in equilibrium with the rate of decay; and that the new products possess distinct chemical properties.

Rutherford, a prodigious worker with tremendous powers of concentration, continued to make a succession of brilliant discoveries—and with remarkably simple apparatus. For example, he showed (1903) that alpha rays can be deflected by electric and magnetic fields, the direction of the deflection proving that the rays are particles of positive charge; he determined their velocity and the ratio of their charge (E) to their mass (M). These results were obtained by passing such particles between thin metal plates stacked closely together, the size of a matchbox, each plate charged oppositely to its neighbour in one experiment; and in another experiment putting the assembly in a strong magnetic field; and in each experiment he measured the strengths of the fields which just sufficed to prevent the particles from emerging from the stack.

Rutherford wrote 80 scientific papers during his seven years at McGill, made many public appearances, among them the Silliman Memorial Lectures at Yale University in 1905, and received offers of Chairs at other universities until 1907, when he returned to England to accept a Chair at the University of Manchester, where he continued his research on the alpha particle. With the ingenious apparatus that he and his research assistant, Hans Geiger, had invented they counted the particles as they were emitted one by one from a known amount of radium; and they also measured the total charge collected from which the charge on each particle could be detected. Combining this result with the rate of production of helium from radium, determined by Rutherford and the American chemist, Bertram Borden Boltwood, Rutherford was able to deduce Avogadro's number (the constant number of molecules in the molecular weight in grams of any substance) in the most direct manner conceivable. With his student, Thomas D. Royds, he proved in 1908 that the alpha particle really is a helium atom by allowing alpha particles to escape through the thin glass wall of a containing vessel into an evacuated outer glass tube and showing that the spectrum of the collected gas was that of helium. Almost immediately, in 1908, came the Nobel Prize—but for Chemistry, for his investigations concerning the disintegration of elements.

In 1911 Rutherford made his greatest contribution to science with his nuclear theory of the atom. He had observed in Montreal that fast-moving alpha particles, on passing through thin plates of mica produced diffuse images on photographic plates, whereas a sharp image was produced when there was no obstruction to the passage of the rays. He considered that the particles

The nuclear theory of the atom

Arrival at the Cavendish Laboratory

must be deflected through small angles as they passed close to atoms of the mica, but calculation showed that to deflect such particles travelling at 20,000 kilometres per second, an electric field of 100,000,000 volts per centimetre was necessary, a most astonishing conclusion. This phenomenon of scattering was found in the counting experiments with Geiger; Rutherford suggested to Geiger and another student, Ernest Marsden, that it would be of interest to examine whether any particles were scattered backward, *i.e.*, deflected through an angle of more than 90 degrees. To their astonishment, a few particles in every 10,000 were indeed so scattered, emerging from the same side of a gold foil as that on which they had entered. After a number of calculations Rutherford came to the conclusion that the requisite intense electric field to cause such a large deflection could only occur if all the positive charge in the atom, and therefore almost all the mass, were concentrated on a very small central nucleus some 10,000 times smaller in diameter than that of the entire atom. The positive charge on the nucleus would therefore be balanced by an equal charge on all the electrons distributed somehow around the nucleus.

Although Hantaro Nagaoka, a Japanese physicist, in 1904 had proposed an atomic model with electrons rotating in rings about a central nucleus, it was not taken seriously because, according to classical electrodynamics, electrons in orbit would have a centripetal acceleration toward the centre of rotation and would thus radiate away their energy, falling into the central nucleus almost immediately. This idea is in marked contrast with the view developed by J.J. Thomson (*q.v.*) in 1910; he envisaged all the electrons distributed inside a uniformly charged positive sphere of atomic diameter, in which the negative "corpuscles" (electrons) are imbedded. It was not until 1913 that Niels Bohr, a Danish physicist, postulated that electrons, contrary to classical electrodynamics, do not radiate energy during rotation, and do indeed move in orbits about a central nucleus, thus upholding the convictions of Nagaoka and Rutherford. A knighthood conferred in 1914 further marked the public recognition of Rutherford's services to science.

During World War I he worked on the practical problem of submarine detection by underwater acoustics. He produced the first artificial disintegration of an element in 1919, when he found that on collision with an alpha particle an atom of nitrogen was converted into an atom of oxygen and an atom of hydrogen. Thus began the search that ultimately ushered in the age of nuclear energy. The same year he succeeded Thomson as Cavendish professor. Although his experimental contributions henceforth were not as numerous as in earlier years, his influence on research students was enormous. In the second Bakerian lecture he gave to the Royal Society in 1920, he speculated upon the existence of the neutron and of isotopes of hydrogen and helium; three of them were eventually discovered by workers in the Cavendish Laboratory.

His service as president of the Royal Society (1925–30), and, as chairman of the Academic Assistance Council, which helped almost 1,000 university refugees from Germany, increased the claims upon his time. But whenever possible he worked in the Cavendish Laboratory, where he encouraged and admonished students, always probed for the facts, and always sought an explanation in simple terms. When in 1934 Enrico Fermi in Rome successfully disintegrated many different elements with neutrons, Rutherford wrote to congratulate him "for escaping from theoretical physics."

Rutherford read widely, enjoyed good health, the game of golf, his home life, and hard work. He could listen to the views of others, his judgments were fair, and from his many students he earned affection and esteem. In 1931 he was made Baron Rutherford of Nelson, but this honour was marred by the death of his daughter. He died in Cambridge on October 19, 1937, following a short illness, and was buried in Westminster Abbey.

(T.E.A.)

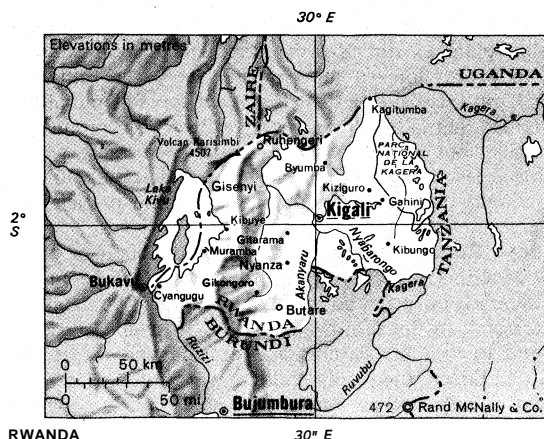

Rwanda

The Republic of Rwanda lies at an altitude of more than 5,000 feet (1,500 metres) in the mountains of east central Africa. Rwanda and Burundi, to the south, are the most densely populated countries on the African continent. Roughly rectangular in shape, Rwanda has an area of 10,169 square miles (26,338 square kilometres) and a population of about 3,736,000. Its average population density is about 386 persons per square mile. The capital is Kigali (population about 59,000).

Physically, Rwanda is bounded on the west by Lake Kivu and the Ruzizi River; on the south by the Luhwa and Akanyaru rivers; on the east by the Kagera River; and on the northwest by a chain of volcanoes, almost all extinct, whose heights range up to just under 15,000 feet. Politically its neighbours are Uganda to the north, Burundi to the south, Tanzania to the east, and Zaire (formerly Congo [Kinshasa]) located on the west and northwest.

Although Rwanda was the more important of the two, Rwanda and its southern neighbour Burundi were for centuries twin kingdoms—first as autonomous realms, then as parts of German East Africa, and then as Belgian administered territories. Rwanda became a definitive territorial unit at the end of the 19th century, as a result of the German colonial occupation, which put an end to the conquests of its ancient line of kings, dating back to the 14th century. The ruling Tutsi (Tussi, Batusi, Watusi) feudal monarchy ended, however, as a result of a social revolution on the part of the previously subject Hutu (Bahutu, Wakhutu) people, which began in 1959. The country obtained its independence on July 1, 1962. (For a detailed discussion of associated physical features, see EAST AFRICAN LAKES; EAST AFRICAN MOUNTAINS; and VIRUNGA MOUNTAINS. For a consideration of historical aspects, see EAST AFRICA, HISTORY OF.)

The natural environment. The mountain system of Rwanda is dominated in the west by a crest that separates the basin of the Nile from that of the Congo. At the western foot of this ridge lies Lake Kivu, which guards riches as yet latent. To the east, Rwanda takes the form of a high plateau, which slopes gently downward to the low marshy plains of the Kagera River. The plateau has an average altitude of about 5,600 feet (1,700 metres) in the centre, and about 4,200 feet (1,300 metres) in the plains. The extreme southeast of the country forms a great bowl-

shaped depression, in which numerous small lakes are scattered.

Drainage

The hydrographic network of Rwanda is principally situated firstly to the east of the Ruzizi, through which the waters of Lake Kivu empty into Lake Tanganyika, and secondly in the interior of the country, where numerous small rivers flow through deep, steeply embanked valleys to feed the two principal tributaries of the Kagera, the Nyabarongo in the centre, and the Akanyaru in the south. These two tributaries, together with the Ruvubu in Burundi, form the remote sources of the Nile; the Ruvubu is the more southerly, and the Nyabarongo has a more copious flow. The hydrographic network as a whole is dense; the consistent volume of its outflow is exceptional.

The subsoil of Rwanda in part belongs to an ancient geological system known as the *Rusizi*, which is composed of crystalline schist (flaky metamorphic rock, which splits into thin sheets), gneiss (a coarse-grained metamorphic rock, imperfectly foliated) and micaschist (a metamorphic rock, composed essentially of mica and quartz), and in part to the system called the Burundi, which is composed of dark schists, with or without quartzite (a granular metamorphic rock consisting of quartz in interlocking grains). Formations of secondary age, such as soft schist, or argillites (clay stone), as well as some recent volcanic lavas and sedimentary deposits, are also found. Except for areas of volcanic and of alluvial origin, the soil of Rwanda is generally poor. A multiplicity of unfavourable factors, such as erosion and the incidence of brush fires, have created and progressively aggravated the problem of soil sterility.

Climate. Rwanda has a varied rainfall regime and a generally mild climate with temperatures averaging 66° F (19° C). The region of the Congo–Nile divide has an inclement climate with frequent rain, which is often accompanied by an abrupt fall in temperature. The central plateaus, however, while experiencing abundant rainfall, enjoy a temperate climate. The region of volcanoes, to the northwest, receives much more rain. To the east, the East African type of climate, which is tropical rather than Equatorial, already makes itself felt. The mean annual rainfall is about 45 inches (1,143 millimetres) in the centre of the country and increases with altitude. Rwanda has two wet and two dry seasons per year. These are the short rainy season, which lasts from October to December; the short dry season, lasting from January to February; the long rainy season, from March to May; and the long dry season, from June through September.

Vegetation. The chain of mountains in the west is the only natural region in which the primeval forest still survives. Savannas (a grassland region), with scattered thorn trees and euphorbias (cactus-type growths containing a milky juice and having flowers with no petals), are to be found in the northeast, where the Kagera National Park is located. In the east, enormous papyrus swamps, whose topography is constantly shifting, are to be found. Grassy savanna, often broken for agriculture or left lying fallow for pasturage, occupies the centre of the country. From the altitude of 6,500 feet (2,000 metres) upward, notably in the immediate vicinity of the volcanoes, bamboo forests are found.

Animal life. Rwanda possesses an exceptionally rich and varied animal life. In the primeval-forest zone, as well as sometimes in the bushy or grassy savanna regions, are found elephants, lions, gorillas, chimpanzees, buffaloes, zebras, various antelopes, and warthogs. Kagera National Park and the adjacent Mutura Hunting Reserve contain many rare species, including the giant pangolin (a kind of anteater). Game birds include guinea fowl, partridge, ducks, and various species of geese.

The landscape under human settlement. The first impression given by the Rwandan landscape is that it resembles an immense green park dominated by banana plantations. The eye does not at first clearly distinguish the habitations standing on small hills and submerged in a sea of vegetation. Dwellings in Rwanda are not clustered together in compact villages but instead are disposed in familial groups, for which a hill serves as the basic unit.

Each place of habitation is circled by an enclosure

formed by a hedge, or palisade, of growing plants; this enclosure extends rearward in circular sections, each of which shelters—according to the social importance of the family head—one or more houses, likewise circular. Livestock are also kept in the enclosure.

The house itself, in former days, was a hut several yards in diameter, made of an interlaced frame supported inside by wooden posts and covered with straw. Its rooms were separated from each other by panels of basketwork, often ornamented with geometric designs. The entrance to the house, a low opening in the framework, faced the opening to the hedge enclosure. This type of house has now been replaced by the rectangular house built of mixed clay and straw or of baked brick, with a roof of tiles or of sheet iron.

The people. The population of Rwanda (3,735,585) is the most dense in Africa and among the most prolific in the world. The annual rate of population growth is between 3 and 3.6 percent. Assuming a rate of 3.2 percent and excluding the possibility of emigration, the population of Rwanda could reach 4,500,000 by 1976 and over 6,000,000 by 1986.

Source: Official government figures.

The inhabitants of Rwanda are divided into three distinct ethnic groups: the Hutu, classified anthropologically as Bantu, form the bulk of Rwandan society, constituting 90 percent of the total population; the Twa (Batwa), who are Pygmies, form only a tiny minority, constituting less than 1 percent; and the Tutsi of Ethiopic or Nilotic origin represent just under 10 percent. These groups are distinguished not only by physical characteristics but also by their occupations and their mode of life. Some Twa are potters, while others are hunters; the Hutu are primarily farmers; and the Tutsi are by preference raisers of long-horned cattle. Watutsi, Watousi, and Watutsi are all Swahili corruptions of the original and true name of this people, which is Abatutsi.

Language. The official languages are Kinyarwanda and French. The Swahili that is spoken in Arab or Arab-influenced town districts is only a lingua franca that diverges from the pure Swahili of the East African coast.

Kinyarwanda is a tonal Bantu language of considerable complexity. While associated with the cultural system of the interlake region, it may be classified as a dialect of a language group that also includes the languages of Burundi, as well as the Buha language of Tanzania.

The Kinyarwanda linguistic area covers all the national territory. It is spoken in nearly the same manner by all Rwandans and contributes to their cultural unity.

Religion. Traditionally, Rwandans believe in a supreme being called Imana. There is also a belief in the survival of the spirits of the dead, who are said to inhabit the lower world; as they are thought to be capable of harming the living, rites of propitiation are consecrated to them by diviners. A public initiation rite is sacred to the hero Ryangombe, king of the *imandwa* (a group of 30 powerful spirits who are joined by the spirits of humans who have been initiated before they die). The equivalent of Ryangombe in the north is Nyabingi, the spirit of a woman.

Traditional beliefs

Village dwellings

Christianity has established itself, overlaying these traditional beliefs without being able to destroy them. Nearly 45 percent of the population is Roman Catholic, 9 percent is Protestants, 1 percent is Muslim, and 45 percent is Imanists.

The national economy. As Rwanda is a landlocked country in the heart of the great lake region, having a mountainous and broken terrain, geography does not favour its economic development. As its natural resources are insufficient, the economic level of the country is low; per capita income averages only about \$70 a year. Production is based primarily upon agriculture and livestock raising. Since, however, the peasant producer owns on the average only about one hectare (about two and a half acres) of arable land and uses only rudimentary tools, such as a hoe and a cutless, the increase in food production lags behind the increase in population. Rwanda thus is confronted with the necessity of moving from a simple subsistence economy to a market economy. At present such traditional crops as beans, peas, and sweet potatoes are grown for internal consumption. Such cash crops as coffee, tea, pyrethrum, cotton, barley, and rice accounted for over 60 percent of all exports in 1970.

Although not as important as agriculture, livestock raising is also economically significant. Dairy products constitute about 7 percent of the gross domestic product, and of this about half is consumed by the producers themselves. Mining production is also significant; in 1970 it represented 30 percent of the value of all exports, although representing only 2 percent of the gross domestic product. The principal resources are cassiterite (a tin ore), tungsten, beryl, and tantalite (a mineral containing manganese and columbium). Two other resources as yet virtually unexploited are the methane gas of Lake Kivu, which is estimated to amount to 200,000,000,000 cubic feet, and peat, estimated at 10,000,000,000 cubic feet. Deposits of limestone, clay, kaolin (china clay), and glass sand are also found.

The hydroelectric energy potential is more than 2,000,000,000 kilowatt hours per year; present energy resources amount to 90,000,000 kilowatt hours a year. The small industrial economy that began to develop after the country became independent consists of the processing of coffee and tea, brewing, flour milling, butchering, cigar making, soapmaking, building, and printing.

Hunting and fishing remain the monopoly of the forest Twa and of the lakeshore inhabitants. Such crafts as basketry, coopering, and pottery are practiced by a few specialists.

To develop its export capacity, Rwanda requires certain imports that, in turn, must be paid for in either domestic or foreign currency or by a combination of the two. The national investment program amounts to an average of 1,000,000,000 Rwanda francs a year. (One Rwanda franc equals U.S. \$0.01, and 4/10 of a new penny sterling.) The share of public investment is estimated at 46 percent, that of private investment at 39 percent, and that of small savings at about 15 percent. The investment itself is directed as follows: 48 percent is invested in production, 10 percent in the economic infrastructure (roads, water supplies, etc.), and 40 percent in the social and administrative infrastructure. To accelerate the rate of investment, the domestic product would have to grow by about 5 percent a year, and exports by about 70 percent. The development of tourism, it is hoped, may constitute another source of revenue. Yet external aid, whether bilateral or multilateral, would, it seems, be required to transform the prevailing pattern.

Transport. To overcome its geographical isolation, Rwanda is faced with the necessity of improving its road system, particularly the routes linking it to neighbouring countries. At the moment, internal transport is provided by a bus service. There is an international airport at Kanombe (a suburb of Kigali), and a smaller one at Kamembe; smaller airfields link the various prefectures and also provide services to neighbouring countries.

Administration and social conditions. Three supreme institutions are empowered with the exercise of public authority. These are the presidency and the government,

which exercise executive power; the National Assembly, which, concurrently with the president, exercises legislative power; and the Supreme Court, which supervises the judiciary.

The country is divided into 10 prefectures, which are subdivided into 141 communes. Each prefecture takes the name of its chief town and is directed by a prefect who also supervises the administration of the communes. Each commune is directed by a burgomaster (a Belgian term, equivalent to mayor) and by an elected communal council.

Kigali is the principal town of the prefecture; more importantly, it is the administrative, political, and economic capital of the country. Until its independence in 1962, Rwanda was a province of Ruanda-Urundi, the capital of which was Bujumbura, now in Burundi. Hence Kigali's role as a capital is a new one.

In social affairs particular effort is being devoted to improving working conditions, as well as rural living conditions. Social centres have been opened to promote the welfare of young women and girls.

Education and health. In the early 1970s about 420,000 children were receiving primary education, and about 10,000 secondary education. The National University of Rwanda (UNR), opened in 1963, has faculties of medicine, letters, sciences, and social and economic sciences. The National Institute for Scientific Research (INRS) conducts research in the human and natural sciences, and the Rwandan Institute of Agronomic Sciences (ISAR) is concerned with the improvement of agriculture and of livestock.

Malaria is endemic in certain parts of the country, and pulmonary diseases are common. There is a shortage of doctors (1 to 60,000 inhabitants).

Cultural life and institutions. National policy encourages activities associated with art and folklore. As a result, a period of lethargy is being followed by a revival in which much spontaneity is evident. Folk songs and dances are exhibiting a new vigour, which is further stimulated by the demand for them from abroad. The museums of the country are encouraging such crafts as basketwork, coopering, ceramics, and ironwork.

There is a local press as well as a national radio broadcasting service, Kigali Radio, which broadcasts in French, Kinyarwanda, English, and Swahili and conducts a radio university.

Prospects for the future. Originally one of the more powerful of the states in the interlake region, Rwanda has a strong national tradition upon which to build. The conflicts between the Tutsi and Hutu peoples that broke out immediately before and shortly after independence was obtained in 1962 have now subsided. Geographic isolation, which has permitted the development of a marked national character, has, however, hindered economic development. External aid, whether bilateral or multilateral, is required to make available the investment needed to transform the present subsistence economy into a market economy.

BIBLIOGRAPHY. M. WALRAET, *Les sciences au Rwanda: Bibliographie (1894-1965)* (1966), is a systematic bibliography covering all fields of research. Access to the rich oral literature, including historical traditions, is provided by A. COUPEZ and T. KAMANZI, *Récits historiques Rwanda* (1962), *Littérature de cour au Rwanda* (1970); M. D'HERTEFELT and A. COUPEZ (eds.), *La royauté sacrée de l'ancien Rwanda* (1964); and A. KAGAME, *Introduction aux grands genres lyriques de l'ancien Rwanda* (1969), all of them editing the Rwandan texts with a French translation, notes, and interpretations. A. KAGAME, *L'histoire des armées-bovines dans l'ancien Rwanda* (1961), and *Les Milices du Rwanda précolonial* (1963), are minimal elaborations of the historical traditions relating to cattle herds and armies. L. DE LACGER, *Ruanda* (1961); A. KAGAME, *La notion de génération appliquée à la généalogie dynastique et à l'histoire du Rwanda des Xe-XIe siècles à nos jours* (1959); J. VANSINA, *L'évolution du royaume Rwanda des origines à 1900* (1962); and L. DE HEUSCH, *Le Rwanda et la civilisation interlacustre* (1966), provide conflicting interpretations of Rwanda history. Aspects of these are critically examined by M. D'HERTEFELT, *Les clans du Rwanda ancien: Éléments d'ethnosociologie et d'ethnohistoire* (1971). M. D'HERTEFELT, "The Rwanda," in J.L. GIBBS (ed.), *Peoples of Africa*, pp. 405-440

Mining

(1965), gives a factual account of Rwandan society and culture; J.J. MAQUET, *Le Système des relations sociales dans le Ruanda ancien* (1954; Eng. trans., *The Premise of Inequality*, 1961), is an interpretation of the traditional political system. This has been criticized by H. CODERE, "Power in Ruanda," *Anthropologica*, n.s., 4:45–85 (1962). R. LEMARCHAND, *Rwanda and Burundi* (1970), contrasts recent political developments in Rwanda and neighbouring Burundi. J.J. MAQUET, *Ruanda: Essai photographique sur une société africaine en transition* (1957), is a magnificent pre-independence collection of pictures of Rwandan life.

(T.Ka.)

Sa'adia ben Joseph

The versatile medieval Jewish exegete and philosopher Sa'adia ben Joseph (Sa'id ibn Yūsuf al-Fayyūmī) was a keen polemicist and a brilliant stylist, both in Hebrew and in Arabic, with a deep sensitivity to the spiritual needs of his time. Sa'adia ushered in a new epoch in almost every field of Jewish literary and communal activities. He is one of the foremost figures in the history of Diaspora Judaism.

He was born in 882 at Dilaz in al-Fayyūm, Egypt. Little is known of his early years. When he departed from Egypt, at the age of about 23, he left behind, besides his wife and two sons, a distinguished group of devoted students. By that time he had already composed a Hebrew–Arabic dictionary, later expanded and issued under the name *ha-Egron*. For unknown reasons he migrated to Palestine. There he found a growing community of Karaites, a heretical Jewish sect that rejected the Talmud (the authoritative rabbinic compendium of law, lore, and commentary); this group enjoyed the support of the local Muslim authorities.

Apparently disappointed with the standards of learning in Palestine, he left for Babylonia. There he was confronted with not only the Karaite schism but also a gnostic trend (derived from an ancient dualistic, theological movement), which rejected the foundations of all monotheistic religions. Books such as that of the Persian Jewish heretic Hiwi ad-Balkhi, which denied the omnipotence, omniscience, and justice of the biblical God and pointed to biblical inconsistencies, were then popular. In the face of such challenges, Sa'adia marshalled his great talents in the defense of religion in general and Jewish tradition in particular. Employing the same manner as Hiwi, Sa'adia composed his refutation of him in a somewhat complicated rhymed Hebrew. Then, too, he wrote his *Kitdb ar-radd 'alā 'Anān* ("Refutation of Anan," the founder of Karaism), a lost work that has been identified with Sa'adia's partially extant polemical poem *Essa meshali*.

In 921 Sa'adia, who by then had attained scholarly prominence, headed the Babylonian Jewish scholars in their conflict with the Palestinian scholar Aaron ben Meir, who had promulgated a far-reaching change in the Jewish calendrical computation. The conflict ended with no definite victory for either side. Yet, Sa'adia's participation in it demonstrated his indomitable courage and his importance for the Jewish community in Babylonia. Throughout this period he continued his literary polemics against the Karaites. In 928 he completed his *Kitdb at-tamyiz* ("Book of Discernment"), a defense of the traditional Rabbanite calendar.

On May 22 of the same year he was appointed by the exilarch (head of Babylonian Jewry) David ben Zakkai as the gaon (head) of the academy of Sura, which had been transferred to Baghdad. Upon assuming this office, he recognized the need to systematize Talmudic law and canonize it by subject. Toward this end he produced *Kitiib al-mawārith* ("Book on the Laws of Inheritance"); *Ahkam al-wadi'ah* ("The Laws on Deposits"); *Kitiib ash-shahddah wa al-wathā'iq* ("Book Concerning Testimony and Documents"); *Kitdb at-terefot* ("Book Concerning Forbidden Meats"); *Siddur*, a complete arrangement of the prayers and the laws pertaining to them; and some other minor works. In the *Siddur* he included his original religious poems. These works clearly show the Greco-Arabic methods of classification and composition.

His accomplishments intensified his sense of chosenness

and made him more unyielding and less compromising. As it seems, these attitudes alienated some of his friends and provoked the envy of the Exilarch. In 932, when Sa'adia refused to endorse a decision issued by the Exilarch in a litigation, an open breach ensued between the two leaders. The Exilarch excommunicated Sa'adia and the latter retaliated by excommunicating the Exilarch. After three years of embittered struggle, in which each side enjoyed the support of some rich and politically influential Jews of Baghdad, Ben Zakkai succeeded in having the Muslim ruler al-Qāhir remove Sa'adia from his office. The Gaon went into seclusion. The years that followed turned out to be the brightest in Sa'adia's literary career. During these years he composed his major philosophical work, *Kitiib al-amānāt wa al-ītiqādāt* ("The Book of Beliefs and Opinions"). The objective of this work was the harmonization of revelation and reason. In structure and content it displays a definite influence of Greek philosophy and of the theology of the Mu'tazilites, the rationalist sect of Islām. The introduction refutes skepticism and establishes the foundations of human knowledge. Chapter one seeks to establish *creatio ex nihilo* (creation out of nothing) in order to ascertain the existence of a Creator-God. Sa'adia then discusses God's uniqueness, justice, revelation, free will, and other doctrines accepted both by Judaism and by the Mu'tazilah (a great Islāmic sect of speculative theology, which emphasized the doctrines of God's uniqueness and absolute justice). The second part of the book deals with the essence of the soul and eschatological problems and presents guidelines for ethical living.

In 937 a reconciliation between the Gaon and the Exilarch occurred, and Sa'adia was reinstated as gaon. In 940 Ben Zakkai died and seven months later his son died, leaving behind a young child. Sa'adia took the orphan into his home and treated him like his own. Sa'adia himself died in September 942.

Exact chronology for many of Sa'adia's works cannot be definitely determined. The most important of these in philology are: *Kufub al-lughah* ("Books on Grammar"), fragments of which were published by Solomon Skoss, and *Tafsir as-sab' in lafzah* ("The Explanation of the Seventy Hapaxlegomina"), fragments of which were edited by N. Alony.

Sa'adia's opus magnum was on exegesis. He prepared an Arabic translation of the whole Pentateuch (published by Joseph Derenbourg) and a translation with an extensive commentary on Genesis 1–28, Exodus, and Leviticus. Only a few fragments of this extensive commentary have been published. His translation and commentaries on Isaiah, Proverbs, Job, and Psalms are extant in their entirety. Fragments of his commentaries on Daniel and Canticles, Esther, and Lamentations are preserved in the Geniza collection (fragments of medieval texts found in an old synagogue in Cairo and transferred to various libraries). In his biblical commentaries the Gaon formulated new principles of interpretation modelled on the rules of Greco-Arabic rhetoric.

His anti-Karaite works include *Kitiib ar-radd 'alā Ibn Sdkawayhi* ("Refutation of Ibn Sdkawayhi") and *Kitdb tahšil ash-shari'i' as-samā'iyah* ("Book Concerning the Sources of the Irrational Laws"). In the latter work the Gaon contends that matters pertaining to the irrational commandments of the Mosaic Law may never be decided by means of analogy but only by the regulations transmitted through oral tradition. Talmudic tradition is therefore, he argues, indispensable. Another anti-Karaite work is the *Maqālah fī sirāj as-sabt* ("Treatise on the Lights of Sabbath"). It refutes the Karaite injunction forbidding the preparation of light for the sabbath.

In philosophy he wrote a philosophical commentary on the mystical book *Sefer yetzira*. In contrast to his "Book on Beliefs and Opinions," this volume does not show any influence of *kalām* (Islāmic scholastic theology).

BIBLIOGRAPHY. NECHEMIAH ALONI, *Ha-Egron* (1969), an edition (in Hebrew) with extensive annotations; ISRAEL DAVIDSON (ed.), *Sa'adia's Polemic Against Niwi al-Balkhi* (1915), and *The Book of the Wars of the Lord* (1934), polemics against Sa'adia by Solomon ben Yeruhim (Hebrew edition with English translation)—the introductions to both editions

require revision in light of new Genizah fragments; JOSEPH DERENBOURG, *Oeuvres complètes de R. Saadia Ben Josef al-Fayyûmî*, vol. 3, *Version arabe d'Isaïe* (1896), and vol. 6, *Version arabe des Proverbes* (1894), Sa'adia's Arabic version of Isaiah and his version of the Proverbs—the Isaiah translation is accompanied by fragments of Sa'adia's lost commentary; Z. DIESENDRUCK, "Saadya's Formulation of the Argument for Creation," in *Jewish Studies in Memory of George A. Kohut, 1874-1933* (1953), a profound article; JAKOB GUTTMANN, *Die Religionsphilosophie des Saadia* (1882), traces the Greek and Arabic sources of Sa'adia's philosophy (the Arabic sources are not fully exhausted); HENRY MALTER, *Saadia Gaon: His Life and Works* (1921), the most comprehensive study on Sa'adia, although many aspects need to be revised in light of later studies; JACOB MANN, "A Fihrist of Sa'adia's Works," *Jewish Quarterly Review*, New Series, 11:423-428 (1921); MOISE VENTURA, *La Philosophie de Saadia Gaon* (1934), a doctoral dissertation with some merit; HARRY A. WOLFSON, "Saadia on the Trinity and Incarnation," *Studies and Essays in Honor of Abraham A. Neuman* (1962), a very exhaustive study; collections of articles of Sa'adia in the *Jewish Quarterly Review*, New Series, vol. 33 (1942-43); Sa'adia anniversary volume, *Proceedings of the American Academy for Jewish Research* (1943); ERWIN I.J. ROSENTHAL (ed.), *Saadya Studies* (1943); MOSES ZUCKER, *Rav Saadya Gaon's Translation of the Torah* (in Hebrew, with English summary; 1959), and *A Critique Against the Writings of R. Saadya Gaon by R. Mubashshir* (1955), an edition important for restoration of Sa'adianic material as well as for the study of the relationship of some of Sa'adia's contemporaries to his literary work.

(M.Z.)

Saarinen, Eero

A gifted American architect who died at the height of his career, Eero Saarinen largely initiated a trend toward exploration and experiment in design—a trend that departed from the doctrinaire rectangular prisms that were characteristic of the earlier phase of modern architecture. He was born in **Kirkkonummi**, Finland, on August 20, 1910, the son of a great architect, Eliel Saarinen, and Loja Gesellius, a sculptor. The Saarinen family of four, including a sister, Eva-Lisa, came to the United States in 1923. Eero attended public schools in Michigan. In 1929 he studied sculpture at the *Académie de la Grande Chaumière* in Paris but, as he recounted years later, "it never occurred to me to do anything but follow in my father's footsteps." Between 1931 and 1934 he studied architecture at Yale University, where the curriculum was untouched by modern theories. His father's architecture in Finland had focussed on a free adaptation of medieval Scandinavian forms, and in the U.S. he designed various private school buildings from 1925 to 1941, including Cranbrook Academy of Art in Bloomfield Hills, Michigan, following this loose, romantic style. At Yale, young Saarinen won a travelling fellowship that made possible a leisurely European visit in 1934-35. He stayed an additional year in Helsinki working with the architect Jarl Eklund.

Eero Saarinen's professional work in the United States began in 1936 with research on housing and city planning with the Flint Institute of Research and Planning in Flint, Michigan. He joined his father's practice in Bloomfield Hills in 1938, and their collaboration was marked by the winning of first prize in the Smithsonian Institution Gallery of Art competition (1939), a tranquil yet monumental design for the mall in Washington, D.C. Unfortunately, it was never built.

In 1939 Saarinen married Lillian Swann, a sculptor, and they had two children, Eric and Susan. This marriage ended in divorce in 1953, and Saarinen was remarried the following year to Aline Bernstein Loucheim, an art critic. A son, Eames, was born later that year.

In 1940 Eero and his father designed Crow Island School in Winnetka, Illinois, which influenced postwar school design, being a one-story structure, generously extended in plan, and suitably scaled for primary-grade children. Also in 1940 he became a naturalized citizen of the United States. In 1945 Eero joined a partnership with Eliel Saarinen and J. Robert F. Swanson that had been organized in 1939. This partnership was dissolved in 1947 and a new partnership of Saarinen, Saarinen and Asso-

Saarinen seated in one of his chair designs; photograph by Arnold Newnman, 1948.

© Arnold Newnman

ciates was then formed that lasted until the elder Saarinen's death in 1950.

In the eleven years that he survived his father, Saarinen's own work included a series of dramatically different designs that displayed a richer and more diverse vocabulary. In questioning the presuppositions of early modern architecture, he introduced sculptural forms that were rich in architectural character and visual drama unknown in earlier years. The exciting results were welcomed by many who were bored by the uniformity and austerity of the International Style of modern architecture.

Saarinen's first independent work, one that brought immediate renown, was the vast General Motors Technical Center in Warren, Michigan (1948-56). Here Saarinen arranged five major building complexes, each for a different research study, around a 22-acre (nine-hectare) reflecting pool. Strips of planted forest rimmed the 320-acre (130-hectare) site. The precision and modular rhythm of the low buildings recalls the design of the German-American architect Ludwig Mies van der Rohe, as well as the early automobile factories of the U.S. architect Albert Kahn. Saarinen's technical solution of the curtain wall (metal panels and glass set in aluminum frames) was widely copied. The scale and visual splendour of the centre suggests a 20th-century Versailles.

In 1953 Saarinen began to design the **Kresge** Auditorium and chapel of the Massachusetts Institute of Technology, choosing the basic forms of an eighth of a sphere for the auditorium and a cylinder for the chapel. The partial sphere is a "handkerchief" dome resting on three points. The auditorium is arranged entirely within this dramatically simple form. The small chapel is a stark, red-brick cylinder, lighted only from above. Both were completed in 1955. While some critics felt that the solutions were forced and arbitrary, these buildings indicated the search Saarinen had begun for significant and identifying character in public buildings.

Although Saarinen continued to use rectilinear forms on occasion, such as the United States Embassy in London (1955-60) and the Law School at the University of Chicago (1956-60), it was his freely sculptural designs that achieved greater attention. In 1956 two such works were initiated that can be considered representative: **In-galls** Hockey Rink at Yale University in New Haven, Connecticut (1958) and the Trans World Airlines ter-

First independent work

Collaboration with Eliel Saarinen

minal at John F. Kennedy International Airport, New York City (1956–62). For the Yale rink, Saarinen, avoiding the typical field house, achieved a unique and sympathetic sports building. From a lengthwise curved spine in reinforced concrete, he suspended cables to anchors on the oval periphery. This tent-like form suggests an almost Oriental shrine for the game of hockey, a blending of the structural, emotional, and aesthetic that Saarinen himself was proud of. For the design of the TWA terminal, Saarinen continued exploration of interior–exterior sculptural effects. Based on a symmetrical plan, two major cantilevered concrete shells extend dramatically outward, suggesting wings, and on the inside sculptural supports and curving stairways evoke a feeling of movement. In this distinctive and memorable building, Saarinen presented a symbol of flight. While to some it proclaimed virtuosity over logic, Saarinen believed "we must have an emotional reason as well as a logical end for everything we do." Later, Saarinen designed the Dulles International Airport at Chantilly, Virginia, outside Washington, D.C. (1958–62), with a hanging roof suspended from diagonal supports.

Saarinen's effort was primarily concerned with institutional buildings for education and industry. He built only one skyscraper, the CBS Headquarters in New York (1960–64), and one house in the midwest. His 1948 prize-winning Jefferson National Expansion Memorial design for St. Louis was completed in 1964. It is a graceful and spectacular arch of stainless steel, with a span and height of 630 feet (190 metres). It conveys a sense of ceremony and special place yet also one of delight and ease, qualities that are present in all Saarinen's works, whatever their function.

Like many contemporary architects, Saarinen was challenged by furniture design, especially the chair, which presents aesthetic and structural problems that are particularly difficult to solve. In 1941 he and the designer-architect Charles Eames won a national furniture award for a chair design in molded plywood. In 1948 Saarinen created a womblike chair using a glass fibre shell upholstered in foam rubber and fabric. His last furniture designs comprised a series of pedestal-based chairs and tables (1957) that combined a sculptural aluminum base with plastic shells for the chairs and discs of marble or plastic for the table tops. The curvilinear forms of his furniture designs paralleled his growing interest in sculptural architectural forms.

As a person, Saarinen was outwardly a stocky, calm man of informal manner and puckish humour, but underneath he was intensely serious about architecture and seemed compulsively competitive with his own most recent designs. His wish that a building make an expressive statement established new horizons for modern architecture. He was exploratory in his thinking and committed to research on every level. His buildings were created with meticulous care, from the original analysis of a client's problem to the final execution, and were sympathetically received by both the general public and his fellow architects.

Saarinen died of a brain tumour in Ann Arbor, Michigan, on September 1, 1961, leaving numerous projects to be completed by his associates. Always immersed in architecture, Saarinen had no other real interest. He never wrote a book and commented only occasionally on his buildings and architectural philosophy.

MAJOR WORKS

General Motors Technical Center, Warren, Michigan (1948–56); Jefferson National Expansion Memorial, St. Louis, Missouri (1948–64); Milwaukee County War Memorial, Milwaukee, Wisconsin (1953–57); Concordia Senior College, Fort Wayne, Indiana (1953–58); Kresge Auditorium and chapel, MIT, Cambridge, Massachusetts (1955); U.S. Embassy, Oslo, Norway (1955–59); U.S. Embassy, London (1955–60); Law School, University of Chicago, Chicago, Illinois (1956–60); Trans World Airlines terminal, John F. Kennedy Airport, New York (1956–62); Thomas J. Watson Research Centre, IBM, Yorktown, New York (1957–61); Deere & Company, Moline, Illinois (1957–63); Ingalls Hockey Rink, Yale University, New Haven, Connecticut (1958); Dulles International Airport, Chantilly, Virginia,

serving Washington, D.C. (1958–62); North Christian Church, Columbus, Indiana (1959–63); Ezra Stiles and Morse College, Yale University, New Haven, Connecticut (1962); Vivian Beaumont Theatre, Lincoln Center, New York (1962–63); CBS Headquarters, New York (completed 1964).

BIBLIOGRAPHY. There are only two books devoted entirely to Saarinen's work. *Eero Saarinen on His Work*, ed. by his wife, ALINE SAARINEN (1962), contains Saarinen's own comments but no supplementary evaluation. It includes a listing of the architect's buildings and is handsomely illustrated. ALLAN TEMKO, *Eero Saarinen* (1962), is an informative, well-illustrated, brief account with evaluation. Details on individual buildings have been reported and illustrated in professional architectural journals.

(H.F.K.)

Saarland

Its population makes the Saar one of the smallest of the ten states, or *Länder*, that make up the Federal Republic of Germany. The Saar is probably best known for its extensive deposits of coal and for its steel production, which have been sources of both wealth and political contention for over a thousand years. The state has alternated between French and German control with bewildering frequency over the centuries, and its contemporary culture contains a heritage from both nations. It is the youngest of the modern West German states, and its economy was still closely linked to that of France as late as the 1960s. By the early 1970s, however, extensive changes were taking place in the local economy, and the diversification and redirection of Saar industry in particular marked a distinct shift toward the German sphere of influence.

The *Land* is bounded by France on the south, Luxembourg on the west, and the *Land* of Rheinland-Pfalz on the north and east. It covers an area of 991 square miles (2,568 square kilometres) and supports a population that exceeded 1,100,000 at the beginning of the 1970s. The administrative capital is at Saarbrücken. (For further details see FRANCE, HISTORY OF; GERMANY, HISTORY OF; GERMANY, FEDERAL REPUBLIC OF.)

History. The Celts and Germanic Franks were the first inhabitants of the area. In AD 843 the Treaty of Verdun divided the Carolingian Empire into three realms, and the lands bordering the Saar and Mosel rivers were included in the central kingdom, which was ruled by Lothair I. In 870, however, the region was transferred to the eastern Frankish Empire, where German was spoken. The boundaries of the district (Landkreis) of Saarbrücken took shape during the 11th century at the intersection of the significant transportation routes from the upper Rhine to Flanders and from Metz to Mainz. The French Province de la Sarre was created by the Truce of Regensburg in 1684, and the area, with its centre at Saarlouis, was added to the empire of Louis XIV. In 1697, however, France was forced to return all territories except Saarlouis at the Treaty of Rijswijk. In 1792, in the aftermath of the French Revolution, French troops again occupied the Saar, along with territory on the east bank of the Rhine. With the final defeat of Napoleon in 1815, the eastern boundary of Lorraine was established, and most of the Saar was ceded to Prussia. When Alsace-Lorraine was added to the German Empire in 1871, the Saar ceased to be a boundary state and experienced rapid economic development based on the coal and iron deposits of Lorraine.

After World War I, the Saar mines were awarded to France, and Saarland was placed under the administration of the League of Nations for 15 years. In the plebiscite of 1935, however, more than 90 percent of the inhabitants of the Saar voted for its return to Germany.

In 1945, the French military forces occupied the Saar following World War II, and two years later the first state Parliament adopted a constitution that called for total independence from Germany. France and the Federal Republic of Germany agreed, in 1954, to a statute that provided for the Saar's autonomy under a European commissioner. The new status was to be approved by a referendum, but 68 percent of the voters rejected the statute and, by implication, the separation of the Saar

French
and
German
origins

Furniture
design

from Germany. The French subsequently agreed to the return of the Saar to West Germany, and, on June 7, 1959, it finally achieved its present status as the tenth *Land* of the Federal Republic.

The land and the people. Topography. The state's low, heavily forested hills are crossed by a series of brooks and three small rivers—the Saar in the west, the Prims in the north, and the Blies in the south. The highest elevation, of 2,280 feet (695 metres), is attained by the Weisskircher Heights. The climate is largely continental in character, but the maritime influence is quite evident, and the annual average temperature is 50° F (10° C). The warmest month is July, with an average temperature of 64° F (18° C), and the coldest is January, at 34° F (1° C). The annual precipitation amounts to about 31 inches (800 millimetres); winters are mild, and strong frosts seldom occur.

Vegetation and animal life. The animal and plant life of the Saar does not differ essentially from that of other similar densely settled European regions. Free-living animals—particularly mammals, birds, and fish—have lost several species and have been greatly decreased in number because of human settlements. The state program of wildlife conservation seeks to prevent the extinction of other species. Among the animals that have been hunted in the Saar are wild boars, deer, foxes, badgers, martens, hares, wild rabbits, pheasants, partridges and wild ducks.

Settlement. Most of the *Land* is settled in small, agricultural towns, and the only area with a pronounced industrial character is a nine-mile strip between Brebach, a suburb of Saarbrücken, and Volklingen, where three of the *Land's* large smelting works are located. The greatest population density is in the state's southwestern corner, in a triangle linking Saarbrücken, Dillingen, and Neunkirchen. In addition to functioning as the state capital, Saarbrücken (population 131,000) is the largest city; other urban areas include Neunkirchen (44,000), Volklingen (40,000), and Saarlouis (36,000).

Population. By the early 1970s, the Saar had a population of approximately 1,130,000, or about 2 percent of the national total, although the average density of 439 inhabitants per square mile was almost double the national average. About 70 percent of its citizens are Roman Catholic; the remainder belong to the Evangelical and Protestant churches. The official language is German, but French is also spoken. The population has quadrupled during the last century, while the mining and iron-producing industries were becoming major economic activities. During the 19th century, the Saar's mines attracted workers from Hunsrück, the Palatinate, the Harz Mountains, Thuringia, Saxony, Bohemia, and Alsace-Lorraine. In later decades, migrations were essentially internal and were detrimental to lesser developed German regions. Population concentrations vary considerably, and Saarbrücken in the early 1970s had the highest density of over 6,400 inhabitants per square mile. In the early 1970s there were 100 males for every 111 females. There are about 14 live births for every 1,000 inhabitants, and the infant-mortality rate averages about 28 per 1,000.

The economy. The Saar is dominated by its highly developed industrial activity. Over 58 percent of the gross domestic product is contributed by industry and mining, 24 percent is derived from services, 16 percent results from trade and transportation, and the remaining 2 percent is contributed by agriculture. Of the state's 157,000 industrial workers, almost 18 percent are engaged in coal mining, and 33 percent are employed by the iron, investment, and manufacturing industries.

Coal mining. The coal seams stretch for a distance of about 20 miles from Saarlouis and Volklingen in the west to Neunkirchen in the east. The reserves of 2,800,000,000 tons of workable coal are located at depths of up to 4,000 feet. In the early 1970s, about 11,100,000 tons of bituminous coal were mined annually, and the industry employed over 28,000 workers.

The iron industry. The extraction of coke from bituminous coal and the smelting of iron ore rich in phosphorus have been the bases assisting the growth of the iron industry since the 19th century. In the early 1970s iron-

producing firms employed approximately 38,000 workers. Annual production amounted to 3,900,000 tons of pig iron and 4,400,000 tons of raw steel.

The iron- and metal-processing industries include the production of steel and the construction of machinery and motors. The approximately 60,000 persons employed in the early 1970s represented 38 percent of all industrial workers.

Other industries. Other important industries include the manufacture of ceramics and textiles and food processing. Small businesses and the trades—of which construction is the most important—employ approximately 60,000 persons. Commerce, credit unions, and insurance companies serve the needs of the Saar without assuming any significance outside the region.

Agriculture. Agriculture is relatively insignificant. The major products are grains, potatoes, vegetables, fruit, dairy products, and livestock. Production is oriented toward the need of the Saar's urban population, but small quantities of dairy produce are exported to the other *Länder* and meat, cattle, and bread are sold abroad.

Foreign trade. France is the most important trading partner of the Saar, receiving approximately 70 percent of all exports. About half of the Saar's industrial products—excluding mining and electrical-engineering equipment—are sold to the other *Länder*. Primary exports to France include bar and cast iron, sheet metal, tools, wire, coal, coke, and ceramics. Among the imports from France are meat and meat products, motor vehicles, sheet metal, and iron ore.

Transportation. The Saar has a well-developed road network. A superhighway connects the Saar with the Rhine-Main area, and other roads link the state with Paris, Luxembourg, Karlsruhe, and Cologne.

The railways are equally favourable, and the main lines have been electrified. The railways cover a total distance of 250 miles; there are several multiple-railed stretches. Water transport along the canalized portion of the Saar River can accommodate ships as large as 270 tons, carrying 519,000 tons of goods annually. This is inadequate, however, and the federal government plans to equip the Saar with an efficient canal system to connect to the Rhine River through the neighbouring state of Rheinland-Pfalz. An airport at Saarbrücken-Ensheim handles both domestic and international traffic.

Administration, social services, and cultural life. The state Parliament is composed of 50 members who are elected every five years. The prime minister is assisted by a six-member Cabinet.

A well-developed educational system includes a series of technical high schools and the University of the Saarland at Saarbrücken. Public health services are adequate; in the early 1970s there were 11 hospital beds for every 1,000 inhabitants. The legal system and social welfare legislation conform to national standards.

Cultural institutions—including the City Theatre, Radio Saarland, and the Modern Gallery of Saarbrücken—draw their support from both Germany and France. In 1970 there were 12 museums and galleries, and a large number of singing, music, and theatrical groups. Of the two large daily newspapers, the *Saarbrücker Zeitung* has the greater circulation. A number of magazines are also published in the state.

The future. The future of the Saar depends both on the success of its industry and on the development of the Common Market. The federal government supports the diversification of industry and is promoting the relocation of businesses to its second least populated state. It is also possible that the Saar will be merged with another, larger state—a step that may prove necessary if current economic policy should prove unsuccessful.

Sacrament

The Latin word *sacramentum*, which etymologically is an ambiguous theological term, was used in Roman law to describe a legal sanction in which a man placed his life or property in the hands of the supernatural powers that upheld justice and honoured solemn contracts. It later became an oath of allegiance taken by soldiers to their commander when embarking on a new campaign, sworn in a sacred place and using a formula having a religious connotation.

NATURE AND SIGNIFICANCE

When *sacramentum* was adopted as an ordinance by the early Christian Church in the 3rd century, the Latin word *sacer* ("holy") was brought into conjunction with the Greek word *mystērion* ("secret rite"). *Sacramentum* was thus given a sacred mysterious significance that indicated a spiritual potency. The power was transmitted through material instruments and vehicles viewed as channels of divine grace and as benefits in ritual observances instituted by Christ. St. Augustine defined sacrament as "the visible form of an invisible grace" or "a sign of a sacred thing." Similarly, St. Thomas Aquinas wrote that anything that is called sacred may be called *sacramentum*. It is made efficacious by virtue of its divine institution by Christ in order to establish a bond of union between God and man. In the Anglican catechism it is defined as "an outward and visible sign of an inward and spiritual grace."

The term sacrament has become a convenient expression for a sign or symbol of a sacred thing, occasion, or event imparting spiritual benefits to participants; and such signs or symbols have been associated with eating, drinking, lustration (ceremonial purification), nuptial intercourse, or ritual techniques regarded as "means of grace" and pledges of a covenant relationship with the sacred order. In this way the material aspects have become the forms of the embodied spiritual reality.

TYPES AND VARIATIONS

Types. The several types of sacraments (*i.e.*, initiatory, purificatory, renewal, communion, healing, cultic elevation) are well exemplified in Christianity, though they also may be found in other Western religions, the Eastern religions, and preliterate religions. In the 12th century the several sacraments of the Western Christian Church were narrowed by Peter Lombard (12th-century theologian and bishop) to seven rites, *viz.*, Baptism, confirmation, the Eucharist (the Lord's Supper), penance, holy orders, matrimony, and extreme unction. This enumeration was accepted by St. Thomas Aquinas, the Council of Florence in 1439, and subsequently by the Council of Trent (1545–63). All these rites were thus affirmed by the Roman Catholic Church as being sacraments instituted by Christ. The number, however, has been modified by modern theologians since the precise origins of some of the seven sacraments are uncertain. Protestant Reformers of the 16th century accepted two or three sacraments as valid: Baptism, the Lord's Supper, and, in some fashion, penance. Both Roman Catholicism and Eastern Orthodoxy accept the sevenfold enumeration. In addition to these, any ceremonial actions and objects related to sacraments that endow a person or thing with a sacred character have been designated "sacramental," though they are differentiated from those of dominical (*i.e.*, Christ's) institution in conveying divine grace *ex opere operato* (it works by itself) or in conferring an indelible character on the recipient, such as Baptism, confirmation, and holy orders. Sacramentals include the use of holy water, incense, vestments, candles, exorcisms, anointing and making the sign of the cross, fasting, abstinence, and almsgiving.

The word sacrament, in its broadest sense as a sign or symbol conveying something "hidden," mysterious, and efficacious, has a wider application and cosmic signifi-

cance than that used in Christianity. For example, the evolutionary process is viewed by some as a graded series in which the lower stratum provides a basis for the one next above it. The lower, indeed, seems to be necessary to the growth of the higher. This view has introduced concepts of new powers and potentialities in organic evolution culminating in the human synthesis of mind transcending the process. The entire universe, therefore, can be said to have a sacramental significance in which the "inward" (or spiritual) and the "outward" (or material) elements meet in a higher unity that guarantees for the latter its full validity. Thus, the sacred meal has been at once a sacramental communion and a sacrificial offering (*e.g.*, wine, bread, or animal as a sign or symbol of a divine death and resurrection for the benefit of man) in which the two fundamental and complementary rites have been closely combined throughout their long and varied histories.

Variations. *Sacramental ideas and practices in preliterate societies.* In preliterate society everyday events have been given sacramental interpretations by being invested with supernatural meanings in relation to their ultimate sources in the unseen divine or sacred powers. The well-being of primitive society, in fact, demands the recognition of a hierarchy of values in which the lower is always dependent on the higher and in which the highest is regarded as the transcendental source of values outside and above mankind and the natural order. To partake of the flesh of a sacrificial victim or of the god himself or to consume the cereal image of a vegetation deity (as was done among the Aztecs in ancient Mexico), makes the eater a recipient of divine life and its qualities. Similarly, portions of the dead may be imbibed in mortuary sacramental rites to obtain the attributes of the deceased or to ensure their reincarnation. To give the dead new life beyond the grave, mourners may allow life-giving blood to fall upon the corpse sacramentally. In this cycle of sacramental ideas and practices, the giving, conservation, and promotion of life, together with the establishment of a bond of union with the sacred order, are fundamental. In Paleolithic hunting communities this sacramental idea appears to have been manifested in the sacramental rites performed to control the fortunes of the chase, to promote the propagation of the species on which the food supply depended, and to maintain right relations with the transcendental source of the means of subsistence, as exemplified in paintings—discovered in the caves at Altamira, Lascaux, Les Trois Frères, Font-de-Gaume and elsewhere in France and Spain—that show men with animal masks (illustrating a ritual or mystical communion of men and animals that were sources of food).

Sacramental ideas and practices in the ancient Near East. When agriculture and herding became the basic type of food production, sacramental concepts and techniques were centred mainly in the fertility of the soil, its products, and in the succession of the seasons. This centralization was most apparent in the ancient Near East in and after the 4th millennium BC. A death and resurrection sacred drama arose around the fertility motif, in which a perpetual dying and rebirth in nature and humanity was enacted. In this sequence birth, maturity, death, and rebirth were ritually repeated and renewed through sacramental transitional acts, such as passage rites, ceremonies ensuring passage from one status to another. In passage rites the king often was the principal actor in the promotion of the growth of the crops and the propagation of man and beast and in the promotion of the reproductive forces in nature in general at the turn of the year.

Sacramental ideas and practices in the Greco-Roman world. In the Greco-Oriental mystery cults the sacramental ritual based on the fertility motif was less prominent than in the Egyptian and Mesopotamian religions. It did, nevertheless, occur in the Eleusinia, a Greek agricultural festival celebrated in honour of the goddess Demeter and her daughter Kore. The things spoken and done in this great event have remained undisclosed, though some light has been thrown upon them by the contents of the museum at Eleusis, such as the vase paintings, and by later untrustworthy references in the writings of the early

mentals"

Church Fathers (e.g., Clement of Alexandria) and some Gnostics (early Christian heretics who held that matter was evil and the spirit good). The drinking of the *kykeōn*—a gruel of meal and water—can hardly be regarded as a sacramental beverage since it was consumed during the preparation for the initiation rather than at its climax. There is nothing to suggest that a ritual rebirth was effected by a sacramental lustration, or sacred meal, at any point in the Eleusinian ritual. What is indicated is that the neophytes (*mystae*) emerged from their profound experience with an assurance of having attained newness of life and the hope of a blessed immortality. From the character of the ritual, the mystery would seem to have been connected with the seasonal drama in which originally a sacred marriage may have been an important feature, centred in Demeter, the corn mother, and Kore (Persephone), the corn maiden.

In the 6th century BC, or perhaps very much earlier, the orgiastic religion of the god Dionysus, probably originating in Thrace and Phrygia, was established in Greece. In the Dionysiac rites the *Maenads* (female attendants) became possessed by the spirit of Dionysus by means of tumultuous music and dancing, the free use of wine, and an orgiastic meal (the tearing to pieces and devouring of animals embodying Dionysus *Zagreus* with their bare hands as the central act of the *Bacchanalia*). Though not necessarily sacramental, these rites enabled the *Maenads* to surmount the barrier that separated them from the supernatural world and to surrender themselves unconditionally to the mighty powers that transcended time and space, thus carrying them into the realm of the eternal. Ecstatic rites of this nature did not commend themselves to the Greeks of the unemotional nonsacramental Homeric tradition; such rites did appeal, however, to many, some of whom had come under the influences of the Orphic mysteries in which it was possible for them to rise to a higher level in its *thiasoi* (brotherhoods). The purpose of the Orphic ritual was to confer divine life sacramentally on its initiates so that they might attain immortality through regeneration and reincarnation, thereby freeing the soul from its fleshly bondage.

Sacramental ideas and practices in the Indo-Iranian world. To what extent, if at all, metempsychosis (the passing of the soul at death into another body) was introduced into Greece from India can be only conjectural in the absence of conclusive evidence. Though belief in rebirth and the transmigration of souls has been widespread, however, especially in preliterate religions, it was in India and Greece that the two concepts attained their highest development. In post-Vedic (the period after the formulation of the Hindu sacred scriptures, the *Veda*) India, belief in the transmigration of souls became a characteristic doctrine in Hinduism, and the priestly caste (*i.e.*, the *Brahmins*) reached their zenith as the sole immolators of the sacrificial offerings; but sacramentalism was not a feature in the *Brāhmaṇas*, the ritual texts compiled by the *Brahmins*. In the earlier Vedic conception of *soma*, the personification of the fermented juice of a plant, comparable to that of *ambros* in Greece, kava in Polynesia, and especially *haoma* in Iran, the sacramental view is most apparent (see HINDUISM).

In Zoroastrianism *haoma* (Sanskrit *soma*, from the root *su* or *bu*, "to squeeze" or "pound") is the name given to the yellow plant, from which a juice was extracted and consumed in the *Yasna* ceremony, the general sacrifice in honour of all the deities. The liturgy of the *Yasna* was a remarkable anticipation of the mass in Christianity. *Haoma* was regarded by Zoroaster as the son of the Wise Lord and Creator (Ahura Mazda) and the chief priest of the *Yasna* cult. He was believed to be incarnate in the sacred plant that was pounded to death in order to extract its life-giving juice so that those who consumed it might be given immortality. He was regarded as both victim and priest in a sacrificial-sacramental offering in worship. As the intermediary between God and man, *Haoma* acquired a place and sacramental significance in the worship of Mithra (an Indo-Iranian god of light) in his capacity as the immaculate priest of Ahura Mazda with whom he was coequal. The Mithraic sacramental banquet was derived

from the *Yasna* ceremony, wine taking the place of the *haoma* and Mithra that of Ahura Mazda. In the Mithraic initiation rites, it was not until one attained the status of the initiatory degree known as "Lion" that the neophyte could partake of the oblation of bread, wine, and water, which was the earthly counterpart of the celestial mystical sacramental banquet. The sacred wine gave vigour to the body, prosperity, wisdom, and the power to combat malignant spirits and to obtain immortality.

The early Christian leaders noticed the resemblances between the Mithraic meal, the Zoroastrian *haoma* ceremony, and the Christian Eucharist; and between Mithraism and Christianity, to some extent, there was mutual influence and borrowing of respective beliefs and practices. But Mithraism's antecedents were different, being Iranian and Mesopotamian with a Vedic background before it became part of the Hellenistic and Christian world (c. 67 BC to about AD 385).

Sacramental ideas and practices of pre-Columbian America. The recurrent and widespread practice of holding sacred meals in the sacramental system, in addition to being well documented in the Greco-Roman world, also occurred in the pre-Columbian Mexican calendrical ritual in association with human sacrifice on a grand scale. In the May Festival in honour of the war god Huitzilopochtli, an image of the deity was fashioned from a dough containing beet seed, maize, and honey; then the image was covered with a rich garment, placed on a litter; and carried in a procession to a pyramid-temple. There pieces of paste similarly compounded and in the form of large bones were transformed by rites of consecration into Huitzilopochtli's flesh and bones. A number of human victims were then offered to him, and the image was broken into small fragments and consumed sacramentally by the worshippers with tears, fears, and reverence, a strict fast being observed until the ceremonies were over and the sick had been given their communion with the particles. This ceremony was repeated at the winter solstice when the dough was fortified with the blood of children, and similar images were venerated and eaten by families in their houses. The main purpose of the sacrament was to secure a good maize harvest and a renewal of the crops, as well as human health and strength. In Peru at the Festival of the Sun, after three days of fasting, llamas, the sacred animals, were sacrificed as a burnt offering, and the flesh was eaten sacramentally at a banquet by the lord of the Incas and his nobles. It was then distributed to the rest of the community with sacred maize cakes. Dogs, regarded as divine incarnations, also were slain and parts of their flesh solemnly eaten by the worshippers.

Similar rites were celebrated in North America by Indians at the Feast of Grain among the Natchez of Mississippi and Louisiana and among the Creeks in the Mississippi Valley when the corn was ripe. Among the Plains Indians sacrificial blood was employed sacramentally to make the earth fruitful by the fructifying power of the sun.

THEOLOGY AND PRACTICE OF SACRAMENTS IN CHRISTIANITY

Though the widespread conception of the sacramental principle is an ancient heritage, in all probability going back before the dawn of civilization, it acquired in Christianity a unique significance. There it became the fundamental system and institution for the perpetuation of the union of God and man in the person of Jesus Christ through the visible organization and constitution of the church, which was viewed as the mystical body of Christ.

Baptism. Baptism, as the initial rite, took the place of circumcision in Judaism in which this ancient and primitive custom was the covenant sign and a legal injunction rather than a sacramental ordinance. Baptismal immersion in water was practiced in Judaism for some time before the fall of Jerusalem in AD 70, and it was adopted by John the Baptist (a Jewish prophet and cousin of Jesus Christ) as the principal sacrament in his messianic movement.

The purificatory lustration of John the Baptist, however, was transformed into the prototype of the Christian sacrament by the baptism of Jesus in the river Jordan and by

Mexican sacramental rites

Significance of the sacramental principle in Christianity

Rebirth

Incarnation of Haoma

the imagery of this event combined with the imagery of his death and resurrection. A distinction was made, however, between the water baptism of John and the Christian Spirit Baptism in the apostolic church. Under the influence of the missionary Apostle St. Paul, the Christian rite was given an interpretation in the terms of the mystery religions, and the catechumen (initiate instructed in the secrets of the faith) was identified with the death and Resurrection of Christ (Rom. 6:3–5; Gal. 3:12). The bestowal of the new life constituted a sacramental rebirth in the church in union with the risen Lord as its divine head.

Confirmation. With the development of infant Baptism, the regenerative initial sacrament was coupled with the charismatic apostolic laying on of hands as the seal of the Spirit in the rite of confirmation (Acts 8:14–17). By the 4th century, confirmation became a separate "unction" (rite using oil) administered by a bishop or, earlier and in the Eastern Church, by a priest to complete the sacramental baptismal grace already bestowed at birth or on some other previous occasion. At first, especially in the East, a threefold rite was performed consisting of Baptism, confirmation, and first communion; but in the West, where the consecration of the oil and the laying on of hands were confined to the episcopate, confirmation tended to become a separate event with the growth in the size of dioceses. It was not, however, until the 16th century that Baptism and confirmation were permanently separated. In England Queen Elizabeth I was confirmed when she was only three days old; and infant confirmation is still sometimes practiced in Spain. But the normal custom in Western Christendom has been for confirmation to be administered at or after the age of reason and to be the occasion for instruction in the faith, as in the case of the *mystae* in the Mysteries of Eleusis. But whether or not confirmation conveys a new gift of the Spirit or is the sealing of the same grace bestowed in Baptism, which is still debated, it has come to be regarded in some churches as conferring an indelible quality on the soul. Therefore, it cannot be repeated when it has once been validly performed as a sacrament.

The Eucharist. Together with Baptism the greatest importance has been given to the Eucharist, both of which institutions are singled out in the Gospels as dominical (instituted by Christ) in origin, with a special status and rank. Under a variety of titles (Eucharist from the Greek *eucharistia*, "thanksgiving"; the Latin mass; the Holy Communion; the Lord's Supper; and the breaking of the bread) it has been the central act of worship ever since the night of the betrayal of Christ on the Thursday preceding his crucifixion. It was then that the elements of bread and wine were identified with the body and blood of Christ in his institution of the Eucharist with his disciples and with the sacrifice he was about to offer in order to establish and seal the new covenant. This "real presence" has been variously interpreted in actual, figurative, or symbolical senses; but the sacramental sense, as the *anamnesis*, or memorial before God, of the sacrificial offering on the cross once and for all, has always been accepted.

Along these lines a eucharistic theology gradually took shape in the apostolic and early church without much controversy or formulation. In the New Testament, in addition to the three accounts of the institution of the Eucharist in the first three "books" of the New Testament known as Synoptic Gospels because they have a common viewpoint and common sources (Matt. 26:26ff.; Mark 14:22ff.; Luke 22:17–20), St. Paul's earliest record of the ordinance in I Cor. 11:17–29, written about AD 55, suggests that some abuses had arisen in conjunction with the common meal, or *agapē*, with which it was combined. Like the Iranian *haoma* ceremony, it had become an occasion of drunkenness and gluttony. To rectify this, St. Paul recalled and re-established the original institution and its purpose and interpretation as a sacrificial-sacramental rite. Fellowship meals continued in association with the postapostolic Eucharist, as is shown in the *Didachē* (a Christian document concerned with worship and church discipline written c. 100–c. 140) and in the doctrinal and liturgical development described in the writings of the Early Church Fathers little was changed. Not until

the beginning of the Middle Ages did controversial issues arise that found expression in the definition of the doctrine of transubstantiation at the fourth Lateran Council in 1215. This definition opened the way for the scholastic interpretation of the eucharistic Presence of Christ and of the sacramental principle, in Aristotelian terms. Thus, St. Thomas Aquinas maintained that a complete change occurred in the "substance" of each of the species, while the "accidents," or outward appearances, remained the same. During the Reformation, though the medieval doctrine was denied by the continental Reformers, it was reaffirmed by the Council of Trent in 1551. Holy Communion was retained as a sacrament by most of the Protestant groups, except the Society of Friends, the Salvation Army, and some of the Adventist groups, which abandoned the sacramental principle altogether.

Repentance. In its formulation, the Christian doctrine of conciliation, which, as St. Paul contended, required a change of status in the penitent, had to be made sacramentally effective in the individual and in redeemed humanity as a whole. In the Gospel According to Matthew (16:13–20, 18:18) the power to "bind and loose" was conferred on St. Peter and the other Apostles. Lapses into paganism and infidelity in the Roman world by the 3rd century had demanded penitential exercises. These included fasting, wearing sackcloth, lying in ashes and other forms of mortification, almsgiving, and the threat of temporary excommunication. Details of the sins committed were confessed in secret to a priest, who then pronounced absolution and imposed an appropriate penance. In 1215 the sacrament of penance received the authorization of the fourth Lateran Council and was made obligatory at least once a year at Easter on all mature Christians in Western Christendom. When pilgrimages to the Holy Land, to Santiago de Compostela in Spain, or going on a Crusade could be imposed as penitential exercises, commutation by means of payment of money led to abuses and traffic in indulgences and the treasury of merits, a superabundance of merits attributed to Christ and his saints that could be transferred to sinful believers. The abuses opened the way for the Lutheran revolt against the penitential system, before they were abolished by the Council of Trent. The power of absolution was retained in the Anglican ordinal and conferred upon priests at their ordination and in the Order of the Visitation of the Sick. The sacrament of penance, however, ceased to be of obligation in the Anglican Communion, though it was commended and practiced by John Whitgift, Richard Hooker, and, after the Restoration in 1660 by the Non-jurors (Anglican clergy who refused to take oaths of allegiance to William III and Mary II in 1689) and revived by the Tractarians (Anglo-Catholic advocates of High Church ideals) after 1833, who encountered some Protestant opposition notwithstanding its entrenchment in canon law and in *The Book of Common Prayer*.

Ordination. The church has claimed that the ministry of bishops, priests, and deacons derives its authority and sacramental efficacy from Christ through his Apostles. In the Roman Catholic Church it has been maintained that a special charismatic sacramental endowment conveying an indelible "character" has been conferred on those who receive valid ordination by the laying on of hands on their heads by bishops (who thus transfer to them the "power of orders"), prayer, and a right intention. In Protestant churches the ministry is interpreted as a function rather than as a status. Just as the sacramental power to ordain, confirm, absolve, bless, and consecrate the Eucharist can be given, so also it can be taken away or suspended for sufficient reason.

Marriage. In the Roman Catholic Church the institution of holy matrimony was raised to the level of a sacrament because it was assigned a divine origin and made an indissoluble union typifying the union of Christ with his church as his mystical body (Matt. 5:27–32; Mark 10:2–12; Luke 16:18; I Cor. 7:2, 10; Eph. 5:23ff.). The adherence of Jesus to a rigorist position in regard to divorce and remarriage (Matt. 19:9; *i.e.*, unchastity the only cause for divorce), similar to that adopted by the rabbinical school headed by the conservative teacher **Shammai** in

Penitential exercises

The Eucharist as the central act of Christian worship

Roman Catholic and Protestant views

Judaism, was made the basis of the nuptial union as taught by St. Paul, except in regard to the dissolution of a marriage contracted between a Christian and a pagan who refused to live with his or her partner (I Cor. 7:2ff., 15ff.).

Apart from this deviation, known as the "Pauline Privilege," which was recognized in canon law in the 13th century, a marriage validly contracted in the presence of a priest, blessed by him, and duly consummated has been regarded as a sacramental ordinance by virtue of the grace given to render the union indissoluble. In Protestant churches, marriage is regarded as a rite, not a sacrament; views about divorce, however, vary, and many traditional concepts regarding marriage and divorce are now being debated.

Healing of the sick. The anointing of the sick, an initiatory rite, conforms to the general pattern of the sacramental principle and is comparable to the other rites of passage, such as those concerned with birth and death, seed time and harvest, and with the securing of supernatural power and spiritual grace against the forces of evil that are looked upon as rampant at these critical junctures.

In Christianity anointing of the sick was widely practiced from apostolic times as a sacramental rite in association with the ceremony of the imposition of hands to convey a blessing, recovery from illness, or with the last communion to fortify the believer safely on his new career in the fuller life of the eternal world. Not until the 8th and 9th centuries, however, did extreme unction, another term for the final anointing of the sick, become one of the seven sacraments. In Eastern Christendom, it has never been confined to those *in extremis* (near death) nor has the blessing of the oil by a bishop been required; the administration of the sacrament by seven, five, or three priests was for the recovery of health rather than administered exclusively as a mortuary rite. Extreme unction is also coupled with exorcism for the restraint of the powers of evil—a practice taken over from Judaism by the early church and still retained by the Orthodox Eastern Church for mental diseases.

CONCLUSION

The ecumenical movement in the 20th century has initiated reforms in liturgical worship and in private devotions within Christianity. Such reforms, involving the celebration of sacraments (primarily the Eucharist), have done much to promote the recovery of a unity among Christians that transcends differences in beliefs and ritual practices. The second Vatican Council (1962–65) has played a significant part in the process of recovery of unity and of renewal.

BIBLIOGRAPHY

Sacramental principle: The standard pioneer work on the wider pre-Christian occurrence and interpretations is W.R. SMITH, *Lectures on the Religion of the Semites*, 3rd ed. (1927), laying stress on sacramental communion with the deity. A. GARDNER, *History of Sacrament in Relation to Thought and Progress* (1921), applied the sacramental principle to various aspects of life and belief; R.R. MARETT, *Sacraments of Simple Folk* (1933), wrote on sacraments among peoples in a primitive state of culture. In his *Dawn and Twilight of Zoroastrianism* (1961), R.C. ZAEHNER discussed the anticipation of the Christian eucharistic sacramental rite in the *Yasna* ceremony in the Avestan liturgy. The basic sacramental beliefs and cultus throughout the ages are examined and discussed anthropologically with bibliographies in E.O. JAMES, *Sacrifice and Sacrament* (1962).

Christian doctrine of sacraments: A good general study is P.T. FORSYTH, *Lectures on the Church and the Sacraments* (1917); O.C. QUICK, *The Christian Sacraments* (1927, reprinted continually to 1952), is one of the most comprehensive surveys. The positions of various religious bodies are presented in: A.J. TAIT, *Nature and Functions of the Sacraments* (1917), the evangelical viewpoint; B. LEEMING, *The Principles of Sacramental Theology*, new ed. (1960), the Roman Catholic viewpoint; D.M. BAILLIE, *The Theology of the Sacraments and Other Papers* (1957), the Protestant viewpoint; and A. SCHMERMANN, *Sacraments and Orthodoxy* (1965), the Orthodox viewpoint. J.H. SRAWLEY, *Liturgical Movement: Its Origin and Growth* (1954), gives an account of the development of

sacramental worship with special reference to the participation of the laity.

(E.O.J.)

Sacred Kingship

Sacred kingship, a religio-political concept that sees a ruler as an incarnation, manifestation, mediator, or agent of the sacred or holy (the transcendent or supernatural realm), traces its origins to prehistoric times and, at the same time, exerts a recognizable influence in the modern world. At one time, when religion was totally connected with the whole existence of the individual as well as that of the community and when kingdoms were in varying degrees connected with religious powers or religious institutions, there could be no kingdom that was not in some sense sacral.

Among the many possible kinds of sacral kingdoms, there was a special type in which the king was regarded and revered as a god—the god-kingdom, a polity of which there were three forms: preliminary, primary, and secondary.

The preliminary form exists in primitive cultures in which the chieftain is regarded as divine. The primary form was the god-kingdom of the large empires of the ancient Near and Far East, of ancient Iran, and of pre-Columbian Meso-America and South America. The secondary form occurred in the Persian, Hellenistic (Greco-Roman cultural), and European empires. Between these three forms there are many transitional types (see also SACRED OR HOLY).

The principal schools of interpretation. The phenomenon of sacred kingship was known and described in ancient times by various travellers (e.g., Aristotle, in the 4th century BC, and the 1st-century BC Greek geographers and historians Strabo and Diodorus Siculus). In more recent times, Sir James Frazer, a British anthropologist, introduced the study of sacred kingship in *The Golden Bough* (1890–1915). Taking his comprehensive material from ethnological reports and studies, Frazer concentrated on the preliminary stage. With the discovery of texts in cuneiform writing in Mesopotamia and Asia Minor, however, a new stage of research began. Called Pan-Babylonism by some scholars, the theories based on the results of these discoveries placed the god-kingdom of the ancient Near East in the foreground.

Building on the thesis of Pan-Babylonism that a homogeneous Near Eastern culture existed and on the theories of cult as a ritual drama, the so-called British and Scandinavian cult-historical schools maintained that the king, as the personified god, played the main role in the overall cultural pattern. The English branch of this school (the "Myth and Ritual School") concentrated on anthropological and folklore studies. The Scandinavian branch (the "Uppsala School") concentrated on Semitic philological, cultural, and history-of-religions studies. It is represented in the latter part of the 20th century by Swedish historians of religion who have theorized that, for the entire ancient Near East, certain cult patterns existed and that behind those cult patterns lay the sacred-king ideology.

Rejecting the cult-historical school theory of an unchanging cult pattern and an unchanging sacred-king ideology, many scholars in the latter part of the 20th century have tended to emphasize individual research of case histories. The fundamental differences between the kingdom ideology in Egypt and that in Mesopotamia have been investigated by historians and questions concerning sacred kingship in the Old Testament by Old Testament scholars. One result of such scholarly research is that the theory and practice of sacred kingship—in a history extending over thousands of years—has undergone immense changes and that, because of these widespread and extensive differences, all generalizations and categorizations are difficult to maintain. Though there may be an amazing correspondence among numerous individual phenomena, each individual sacral form of government can be explained only in its own historical, social, and religious context (see also RITUAL; MYTH AND MYTHOLOGY).

schools

The sacred status of kings, leaders, and chieftains. Basic to an understanding of sacred kingship is a recognition that the exercise of power of one person over other persons or over a community (local, regional, or imperial) in early times was general and not divided. Power could be exercised only by one person—one who simultaneously had the necessary physical (individual and corporate) and spiritual (psychic) strength and influence—over both people and objects. As ruler over a community, the king's power extended to everything pertaining to the life of the community. Only gradually did a division of these powers develop.

The sacral status of the ruler differs in form and origins. Three main forms can be distinguished: (1) the possessor of supernatural power, (2) the divine or semidivine king, or (3) the agent of the sacred.

The possessor of supernatural power. The ruler may be viewed as the possessor of supernatural power—both beneficial as well as malevolent—needed to maintain the welfare and order of the community and to avert danger and damage. In primitive, or preliterate, societies, he represents the life-force of the tribe, in which worldly and spiritual or political and religious spheres are not distinguished. Concentrated in the chief is the common inheritance of the magical power of the community, and his authority is based solely on the possession and exercise of this supernatural power. The impact and comprehensiveness of such power wielded by a chief, for example, reaches into all areas of life of the tribe: provision of food, fertility, weather, all forms of communal life, and protection against enemies and misfortune. Because the supernatural (magical) power of the chief is identical with his own life-force, the chief (or king) of such a society is not allowed to have any physical defects. With the dwindling of his own physical powers (illness, graying of hair, and loss of teeth), his own power to maintain and secure the common welfare and his own ability to rule are believed to be correspondingly diminished.

This form of sacral status is found mainly among rulers over one tribe (or several) in primitive cultures—he may be a chief, medicine man, shaman (a religious personage who has healing and psychic transformation powers), or king (as, for example, a rainmaker-king in Africa)—in which a fixed definition or limitation of such functions is not possible.

The divine or semidivine king. In some societies, especially in ancient kingdoms or empires, the king was regarded as a god or identified with some god. In early Egypt he was identified with the sky-god (Horus) and with the sun-god (Re, Amon, or Aton). Similar identifications were made in early China and early Erech in Mesopotamia. In the Turin Papyrus (a list of kings written c. 13th–12th centuries BC), the sun-god Ra is viewed as the first king of Egypt and the prototype of the pharaoh (the god-king). The symbol of the sun circle, one of the most prevalent artistic representations of the sacred king, and the practice of addressing the king as "my sun" are well depicted in rock reliefs and inscriptions in areas ruled by the Hittite kings. The Persian king was regarded as the incarnation of the sun-god or of the moon-god. In addition to sky or sun deities, the sacred king has also been identified with other gods: the town-god (Mesopotamia), the gods of the country, the god of the storm, and the weather-god. Generally, however, the king was not identified with a specific god but rather was regarded as himself a god. As the incarnation of all that is divine, the Egyptian pharaoh was addressed simultaneously in inscriptions as Aton, Horus, and Re (sun deities). Significant for Egyptian royal theology was the doctrine of the god-kingdom spanning two generations; each king ruled as King Horus and became Osiris (the father of Horus, a fertility god and later god of the dead) after his death.

A broader foundation for the divinity of the king is the view of the king as the son of a god, which can take on different forms. The first king has been regarded as a god and his successors as sons of the god in a number of societies—in Africa, Polynesia, Japan (where the emper-

or, until the end of World War II, was revered as a descendant of the sun goddess), Peru (where the inca, or ruler, was believed to be a descendant of the sun-god), Egypt, Mesopotamia, and Canaan. Because he personifies the divine national hero (as among the Shilluk in Africa), the king can demand divine status, a practice that was taken up in the Greco-Roman world by Alexander III the Great and by the Roman emperors. When a king who has been sired by a god or when a god who takes on the external form of the living king approaches his queen, he begets the future king—the queen is thus called the mother of God. An essentially different foundation is the king's divine sonship through adoption, as, for example, in the legend of King Sargon of Akkad in ancient Mesopotamia. The adoption of the crown prince by a god is often part of the coronation ritual, especially in Mesopotamia: the god declares the king as his son when he ascends the throne.

An especially frequent expression of the relationship of the king to divinity, in Egypt and Mesopotamia, was that of the king as a god's image. In Egypt, the king—addressed by the god as "my living image on earth"—is shown in the likeness of Re, Aton, Amon, or Horus. In Mesopotamia, this kind of description was rare.

The myth of divine birth, such as that of Romulus, the legendary founder of Rome, in many places served to legitimize the claims of the king. Unusual natural phenomena, such as an especially bright star, are sometimes connected with the birth of a divine king.

The conception and practice of making a king divine after his death are very old and widespread. Probably connected with ancestor worship, deification is practiced most often when the living king, although connected with gods, is not regarded as a god in the fullest sense. Only after his death does he become god. Among the Hittites, for example, the expression "the king becomes a god" means that the king has died.

The king as the principal agent of the sacred. In addition to the conception of a king as the incarnation of supernatural power and the possible equality of the king with the divinity, there is also a widespread belief that the king is the executive agent of a god. As the servant of a god, he carries out the work of the god on Earth. The divine character of this form of sacred kingship is connected not so much with the individual king as with the institution of kingship. In this emphasis on the institution of kingship lies the difference between kingship in Mesopotamia and Egypt and in India and China. The institution was emphasized in Mesopotamia and China. Sharp distinctions cannot be drawn between the different conceptions of the relationship of a god to kingship. Despite all the different expressions of kingship in the history of Mesopotamia (especially among the empires of Sumer, Babylon, and Assyria), there nevertheless was a continuous theme: the real lord of the city, the country, or the state remains the god, and the king remains in a subservient relationship to him. Even when the king possessed or disposed divine power and had sacral character and sacral duties, he remained subordinate to the god who selected him and put him into his regal position. The king had a mediating position between the gods and man, especially in his significance for the cult (thus, Sargon of Akkad is first described in inscriptions as deputy of Ish-tar). The king also had a similar status as agent in Mongolia, where it was believed that the king came from heaven and was enthroned by God to carry out his will.

Functions of the sacred king: the king as the source of cosmic power, order, and control. *The king as bringer of blessed power.* The usual function of a sacred king is to bring blessings to his people and area of control. Because he has a supernatural power over the life and welfare of the tribe, the chief or king is believed to influence the fertility of the soil, cattle, and man but mostly the coming of rain. He has power over the forces of nature.

Where rain is vitally necessary for the welfare and continuity of a people, the king can be described primarily in terms of this special function. Protection against evil of all sorts also is important for the welfare of the country. If the tribe or the country is beset by misfortune, epidemic-

The king as a god's image

The king's influence over men and nature

The basis of authority in tribal communities

ic, starvation, bad harvests, or floods, the king can be held responsible. Sometimes the king is believed to have the power to heal sickness by means of touch or contact with his garment.

The function of the king as bringer of good fortune is prevalent in primitive cultures. Especially prevalent in Africa, it also has been observed in Polynesia, Scandinavia, and in ancient Greece. This power to bring good fortune is also an aspect of sacral kingship in advanced cultures, such as in India, Iran, China, Japan, pre-Columbian Meso-America, Egypt, Mesopotamia, and Canaan. The difference between Egypt and Mesopotamia is significant; in Egypt the pharaoh is the direct dispenser of all good fortune in the country, whereas in Mesopotamia the king mediates for good fortune through cultic speeches and actions.

The function of the king as dispenser of good fortune has had an amazingly long influence: the English king was believed to have had healing power over a special disease (the king's evil) until the time of the Stuarts in the 17th century, and until the 20th century a folklore belief persisted in Germany that the ruler has influence over the weather ("emperor weather"). Words sometimes used to symbolize the king as the wielder of beneficial influence are gardener, fisherman, and shepherd.

The king as shepherd. An Egyptian pharaoh once said of himself: "He made me the shepherd of this country." In Mesopotamia the description of the king as a shepherd was quite frequent; in the 3rd millennium BC, the term was applied to Sumerian city princes (e.g., Lugalbanda in the 1st Dynasty of Uruk [Erech]). The function of the king as shepherd also has been noted in India. The image of the shepherd expresses the most important functions of the king—he provides his people with food; he leads them and protects them from dangers and, at the same time, shows his superiority over them. Christ's description of himself in the New Testament as the "good shepherd" is, in a sense, a description of his official position in the Christian Church, which also describes him as king, prince of peace, and Lord.

The king as judge. From earliest times, in addition to other functions, the chief was the judge of his tribe; he personified the protection that the community provided for the individual. Providing for a balance of power in the community, mediating quarrels, and protecting individual rights, the chief or king was the lawgiver and the highest administrator for all community affairs. The *ensi*, the lawgiver and the highest judicial authority in the Sumerian city-state, was responsible for order. In Egypt the king was the highest judge, the guarantor of all public order, the lord over life and death. Early Egypt and India developed a high degree of justice that described the activities of the king as *ma'at* in Egypt and *dharma* in India. Both conceptions may be expressed as "justice" or "order" but actually are more comprehensive. Because the king preserves the god-given world order, the task to be just has been viewed as one of his fundamental functions. The pharaoh of Egypt and the emperor of China were believed to be responsible for the maintenance of cosmic as well as social order.

The king as warlord. Belief in the supernatural power of the ruler caused him to be viewed as the protector of his tribe or his people from enemies. On the one hand, he was the chief warlord and decided on questions of war and peace (as in ancient Sumer). The Egyptian pharaoh was represented, in his divine capacity as warrior, in larger-than-life dimensions. He alone was regarded as the one who triumphed over the enemy. On the other hand, there was the concept that the king, because of his sacral character, should not personally take part in war. These concepts existed, for example, among the Persian kings.

The king as priest and seer. Religious duties quite often are connected with the office of chieftain, who is also priest or seer and rainmaker—all in one. Correspondingly, in nontribal societies, cultic functions belong to the office of the king. In the 3rd Dynasty of Uruk, Lugalzagesi is described as king of the country, priest of the god Anu (the god of the heavens), and prophet of Nisaba (goddess of grasses and writing).

When a division of functions evolved, the intrinsically royal priestly and other cultic functions were transferred to priests, seers, and other servants of the cult; the old concept of the king as priest, however, survived in some fashion for thousands of years. The Egyptian king was the chief priest of the land and the superior of all priests and other cult functionaries. In many images he is portrayed as presiding over the great festivals and bringing offerings to the gods. Later, priests carried out their functions as his representative. In Mesopotamia, the king was viewed as the cultic mediator between god and man. As head of all of the priests of the country, he had important cultic functions at the New Years' festival. In critical situations, the king might issue an oracle of blessing; through him the land would be promised salvation, which was often accompanied by the words, "Fear not!" The Persian king performed the sacrifice at the horse offering and was also the "guardian of the fire." In all questions of religion he was the highest authority; he was also the most cultivated of the magicians. The king in Ugarit (in Canaan) also carried out priestly functions and as prophet was the receiver of revelations. Like other ancient Near Eastern monarchs, the Hittite king was the chief priest.

The relationship between sacred kingship and priestly cultic functions has extended over widespread geographical areas and historical eras: East Asia, China, Japan, India, Europe (among the Germanic and Scandinavian kings), Africa (in the great empires), and Madagascar. Sometimes, the division of functions brought about a transfer of the royal title to those who carried out cultic functions. In Africa, from the earliest times, there was a type of king who was called lord of the earth; he originally combined political and cultic functions but, with changing times, retained only the cultic ones. The strict separation of the priestly office from that of the king, as in India, where king and priest belong to different castes—Kṣatriya and Brāhman, respectively—is an unusual exception, however.

The king may be the recipient of a direct revelation of the will of a god. Thus, in Egypt the pharaoh received a divine oracle through dreams in the temple (a practice known as incubation). In Mesopotamia, the duty of the king to ascertain the will of the gods was more strongly emphasized; a directive of the gods could result from omens, dreams, or reading the entrails of offerings. All major undertakings of the king were dependent on directives of the god, who was to be consulted in advance. A direct divine revelation to a king is related in the Old Testament I Kings, chapter 3, which tells of a dream of the 10th-century-BC Israelite Solomon in which he received the promise of the gift of wisdom. Likewise, in the Old Testament (in Genesis, chapter 41), Yahweh, god of the Hebrews, gives the pharaoh a directive in a dream (see also PRIESTHOOD; DIVINATION).

The king as the centre of ruler cults. Although a pharaonic cult occasionally existed in Egypt, the ruler cult differs entirely from sacred kingship, because it came into being from political impulses. The ruler cult, generally developed in a country or empire with many peoples and many religions, was one of the ruler's means of power. Syncretism, the fusing of various beliefs and practices, often succeeded in bringing together completely different religious and nonreligious motives. Alexander the Great (who established an empire of many peoples and religions), for example, revealed a conscious effort at continuity with the Egyptian kingdom, inasmuch as the oracle of the Egyptian god Amon at Siwah designated him as the son of Amon and thus the successor of the pharaohs. Among the *diadochoi* (successors to Alexander) of the first generation, the ruler cult remained limited, but, under Ptolemy II Philadelphus of Egypt (reigned 285–246 BC), it became an established institution that was connected with the deified Alexander. When the ruler cult was carried over to Rome, the emperor Augustus (reigned 27 BC–AD 14) allowed it to be practiced only in the east in connection with the worship of the goddess Roma—though he allowed it to be pursued with fewer restrictions in the newly conquered western provinces; the adaptation of honouring the divine Caesar (or **emper-**

or of Rome) soon became, however, an important expression of the unity of the empire. Serious resistance to the imperial cult was encountered only among the two radical monotheistic religions: Judaism (*e.g.*, against Antiochus IV Epiphanes of Syria in the mid-2nd century BC) and Christianity. The Hellenistic and Roman ruler cults never generated a strong religious movement. The sacrifices brought to the king (emperor) go back to the custom of bringing tribute to the king (or chief) of primitive cultures. From this practice, the custom of bringing offerings to the deceased king developed.

Regal ceremonies. Modes of selection and succession. Succession to rulership was not in the beginning necessarily connected with the sacral kingship; the sacral king could also be elected or, through a power struggle, could also receive a divine, magical, or supernatural anointment. If the first-born son of the king was not stipulated to succeed him or if the king left no children, severe struggles for the succession often occurred, generally resulting in a change of dynasty. The death of a king often was kept secret until the succession was assured, because of potential danger to the people and country. To counteract problems of succession, there were rituals to secure the continuity of the sacral power. In primitive cultures the successor of the dead chief was brought into physical connection with his predecessor, his utensils, or clothing—he had to stay, for example, in the home of the dead chief and use his utensils. The funeral of the dead king took place after the new king was established in his office or just before his coronation (as in Egypt). Efforts to secure the succession show high regulatory standards; in Egypt a complicated succession theology linked the new and old king as Osiris and Horus. During the lifetime of his father, the crown prince could be designated as co-regent. The designation of the successor often came through an oracle, a sign, or some other manifestation of the word of the god; Thutmose III of Egypt (reigned 1504–1450 BC), for example, reported how he was designated to the succession through the oracle of the god Amon. In ancient Iran, after an interregnum, the election of the king took place through an omen. The king was chosen by the god; sometimes he was described as divinely predestined in the womb of his mother as the ruler.

Forms and types of sacred legitimization of kings. The coronation or ascent to the throne by a king is an official act that most clearly shows the sacral character of the kingdom. Until the 20th century two characteristics in the coronations of kings and emperors remained: through ascent to the throne, the king is placed higher than other men, and the act of accession is connected with supernatural powers. With this action a new era begins. This was expressed in Egypt and Mesopotamia in two acts that marked the beginning of the government of the new ruler. First, with the death of the old ruler, the crown prince took control of the government and soon thereafter established his accession in a festive celebration. The coronation, however, generally had to coincide with a new beginning in nature, such as the New Years' festival. The coronation also was viewed as a cosmic new beginning. The most important initial actions of sacred kingship—the ascent to the throne and coronation with proper insignia and king's robes—have remained the same in primitive cultures in ancient and modern times, as well as in the high cultures of the present. The throne, crown, head-dress, garment (as sign of dignity), and sceptre (the staff through which the rule is carried out) were originally believed to contain the power through which the king ruled. The star garment of the Persian king symbolized his world rulership, similar to the feather mantle of the kings of Hawaii. In many higher cultures the throne, the crown, and the sceptre are viewed as divine and identified with gods and goddesses. This view was especially expressed in the Egyptian royal theology: in the hymnal prayer during coronations, the crowns of Upper and Lower Egypt were addressed as goddesses of the red and white crown by the king. In India the throne personified the kingdom. Sometimes, the throne that a new king ascends is viewed as the throne of the god. For example, Hatshepsut, an Egyptian queen (reigned 1503–1482 BC),

was announced by Horus: "You have appeared on the throne of Horus." On many Egyptian images the king sits on the throne, and the god is at his side holding a hand over the king. In becoming someone else (a god), the king receives a new name, a throne name. Throne names are known in Africa, Mesopotamia, and Egypt (where the five throne names comprise the whole king theology: birth name, royal name, hawk name, serpent name, and a name that designates the king as heir of the power of the gods of the stars). In Iran, for example, the king is proclaimed by his royal name as world ruler. Immediately upon the proclamation of the new status of the king and his royal name, the subject people generally evoke a jubilant shout, such as "Long live the king." An African variety of a response to the proclamation is "He is our corn and our shield," which shows the importance of the king for his people. Another response to the proclamation is a prayer for the king: African and Polynesian prayers; Egyptian, Mesopotamian, and Israelite psalms; and hymns, such as the British hymn "God Save the King."

The act of adoration of a king is based on the throne rite, which is known only in areas having national kings. Though ascent to the throne and coronation with investiture are worldwide, there are many other rituals connected with sacred kingship. Among these are the anointment of the kings in Israel, India, and Iran, which originally was a ritual that gave strength to the recipient—as noted in primitive cultures (*e.g.*, rubbing with the fat of a lion); pseudo-fights (sham battles), from which the king emerges as victor; ritual cleansing; and ritual meals. The survival of elements of the sacred kingship in the Christian West is especially depicted in coronation rites. In early Christian art, Christ is shown as kingly ruler on his throne with a royal court; he is emperor and universal ruler. Sacred kingship also survived in the papacy, as well as in the Holy Roman Empire (until the words Holy Roman were dropped in 1806). In the papacy, for example, the court ceremonies employ forms of address that go back to the imperial language of ancient sacred kingdoms: "Holy Father" or "Holiness."

Ritual roles prescribed for kings in public or state functions. Many and various rituals express the concept that in the chief or king is concentrated the well-being of the country. At the order of a god, a Mesopotamian king might become involved in war; thus, his loot was placed before the god in the temple. If the king made a decision as judge, it was because of his unique wisdom as king. If he mediated a quarrel, the parties recognized his supreme power. The king acted to protect his land against the enemy; after his accession, in some areas, the king shot four arrows to the cardinal directions of the compass. In Africa and Egypt, for example, he then said: "I am shooting down the nations, to overcome them." He acted to insure fertility and to distribute growth power when he started sowing corn, the seed of the tribe. He also was regarded as the guardian of the hearth fire (*e.g.*, Africa and Rome).

The king exercised an important function through his participation in the great festivals, which were of utmost importance to the life of his people. In such festivals, various functions were differentiated: (1) priestly, as when the king presided over the sacrifices, said prayers, and gave the benediction; and (2) cultic participation, as when the king took part in the cult drama. The origin of the cult drama as a spontaneous event is known in primitive cultures (*e.g.*, the Ashanti in Africa), but it had its fullest expression in Mesopotamia and Egypt. In the Sed festival (in Egypt), the king, as ruler, renewed his rulership over the whole world. In the New Years' festival his ascent to the throne was renewed; and at the festival of Min, the god of life-force and reproduction, the king played a significant role.

In Mesopotamia, festivals, originating in cultic drama had great importance, especially the Babylonian New Years' festival. The events of the epic Enuma elish, which describes the sun god Marduk's victory over the powers of chaos and the resulting creation of the universe, were re-created in the cultic drama of the New Years' festival,

in which the king represented Marduk, the victor and creator. Another cult drama represented the death and resurrection of the god of vegetation, in which the participants in mourning processions searched for the vanished god (represented by the king) and rejoiced at this triumphant return. Another Mesopotamian cult drama was the sacred marriage that the god Dumuzi celebrated with the goddess Innana. In the "holy wedding" the king and a priestess represented the god and the goddess and through this sexual union the forces of growth and fertility in nature were renewed. These cult dramas originated in early prehistory, when gods were identified with the forces of nature and the cultic actions were understood as exerting direct influences on nature. At the Persian New Years' festival the king appeared as a killer of the dragon, whose rule was identified with the dry season.

The theory of the kingship in which the king occupied the position of mediator between people and gods also implies that the king may have to atone and suffer for the people of the cult. Under such a theory the absolution and reinstatement of the king meant the renewal of land and people. Perhaps behind this theory was a ritual similar to that found among African coronations of prehistory (as, for example, among the Ashanti) in which the king was beaten by priests before his installation.

Private ritual forms peculiar to kings and their families. The special status of the sacral king necessarily also influences his private life. In order to keep the supernatural force dwelling within him, the king had to observe a number of regulations and taboos in the details of his daily life. To this belongs temporary separation—in some cases, the king lived completely separated (e.g., in Africa). The king often appeared only for audiences, on great festivals, or special occasions—sometimes veiled (as in Iran) or with a mask. There also have been special food taboos: he was not allowed to eat certain foods or may have had to drink only from a certain well. The custom of the king taking his meals alone is widespread. The isolation—separation theme in sacred kingship also appears in court ceremonials: the king must be addressed only from a certain measured distance; a person is only allowed to approach the king kneeling; if the king is encountered the head of the subject must be covered with the hands (as in Iran); he must not be touched; and the king must not touch the ground. Inasmuch as the king is filled with supernatural power, everything he touches can take on some of that power (as in Tahiti). Such proscriptions and taboos for the private life of the king are especially evident in Africa but also occur in Polynesia and Micronesia, East Asia, and the ancient Near East. The divine or superhuman character pertained not only to the king but also, in lesser measure, to his family. The king's consecration could involve ritual incest. The participation of the family in the sacral status of the king was evidenced in several places (e.g., Egypt), where, upon the death of the king or queen, members of the royal family and the court were killed or buried with them. Brother-sister marriages in some areas give evidence to this kind of royal ideology.

When a king began to grow old, it was said in Africa: "The grass is fading." To preserve the growth and well-being of the land, the aging king had to be killed and his power transferred to his successor. The compulsory killing of the king was widespread among the Hamitic and Nilotic peoples in northern Africa; and among some peoples the killing of the king occurred after a specified period of time and was integrated into the cosmic ritualistic rhythm. The real meaning of the killing of the king showed itself in rituals in which the blood of the murdered king is mixed with the seed corn, which then became especially fertile.

Conclusion. With the increasing secularization of all areas of life, sacred kingship will of necessity disappear everywhere. Where monarchies are still retained, the sacred features will most likely diminish or vanish altogether. Only in the great regal ceremonies—especially coronations—are traces of sacred kingship still retained in the 20th century.

Certain elements of sacred kingship, however, are still

encountered in modern life: in state ceremonies (e.g., the red carpet at formal receptions), in governmental and ecclesiastical titles, and in the honour and respect given to particular personalities in different walks of life, such as in politics, art, and sports, in which the title king is often used to designate the secular veneration of an individual in the modern cult of personalities.

(C.W.)

Sacred or Holy

The sacred (or holy) is the power, being, or realm understood by religious persons to be at the core of existence and to have a transformative effect on their lives and destinies. Other terms, such as divine, transcendent, ultimate being (or reality), mystery, and perfection (or purity) have been used for this domain. "Sacred is also an important technical term in the scholarly study and interpretation of religions.

THE EMERGENCE OF THE CONCEPT OF THE SACRED IN THE STUDY OF RELIGION

It was during the first quarter of the 20th century that the concept of the sacred (or holy) became dominant in the comparative study of religions. Nathan Soderblom, an eminent Swedish churchman and historian of religions, asserted in 1913 that the central notion of religion was "holiness" and that the distinction between sacred and profane was basic to all "real" religious life. In 1917 Rudolf Otto's *Heilige* (Eng. trans., *The Idea of the Holy*, 1923) appeared and exercised a great influence on the study of religion through its description of religious man's experience of the "numinous" (a mysterious, majestic presence inspiring dread and fascination), which Otto, a German theologian and historian of religions, claimed, could not be derived from anything other than an a

Otto's
Idea
of the
Holy

Personal
regula-
tions for
a king's
daily life

priori sacred reality. Other scholars who used the notion of sacred as an important interpretive term during this period included the sociologist Émile Durkheim in France, and the psychologist-philosopher Max Scheler in Germany. For Durkheim, sacredness referred to those things in society that were forbidden or set apart; and since these sacred things were set apart by society, the sacred force, he concluded, was society itself. In contrast to this understanding of the nature of the sacred, Scheler argued that the sacred (or infinite) was not limited to the experience of a finite object. While Scheler did not agree with Otto's claim that the holy is experienced through a radically different kind of awareness, he did agree with Otto that the awareness of the sacred is not simply the result of conditioning social and psychological forces. Though he criticized Friedrich Schleiermacher, an early 19th-century Protestant theologian, for being too subjective in his definition of religion as "the consciousness of being absolutely dependent on God," Otto was indebted to him in working out the idea of the holy. Soderblom recorded his dependence on the scholarship of the history of religions (*Religionswissenschaft*), which had been a growing discipline, in European universities for about half a century; Durkheim had access to two decades of scholarship on nonliterate peoples, some of which was an account of actual fieldwork. Scheler combined the interests of an empirical scientist with a philosophical effort that followed in the tradition of 19th-century attempts to relate human experiences to the concept of a reality (essence) that underlies human thoughts and activities.

Since the first quarter of the 20th century many historians of religions have accepted the notion of the sacred and of sacred events, places, people, and acts as being central in religious life if not indeed the essential reality in religious life. For example, Dutch phenomenologists of religion (students of the basic patterns and meanings of religious phenomena) such as Gerardus van der Leeuw and W. Brede Kristensen have considered the sacred (holy) as central and have organized the material in their systematic works around the (transcendent) object and (human) subject of sacred (cultic) activity, together with a consideration of the forms and symbols of the sacred. Such German historians of religions as Friedrich Heiler and Gustav Mensching organized their material according to the nature of the sacred, its forms and structural types. Significant contributions to the analysis and elaboration of the sacred have been made by Roger Caillois, a French sociologist, and by Mircea Eliade, an eminent Romanian-American historian of religions.

BASIC CHARACTERISTICS OF THE SACRED

Sacred–profane and other dichotomies. The term sacred has been used from a wide variety of perspectives and given varying descriptive and evaluative connotations by scholars seeking to interpret the materials provided by anthropology and the history of religions. In these different interpretations, however, common characteristics were recognized in the sacred, as it is understood by participant individuals and groups: it is separated from the common (profane) world; it expresses the ultimate total value and meaning of life; and it is the eternal reality, which is recognized to have been before it was known and to be known in a way different from that through which common things are known.

The term sacred comes from Latin *sacer* ("set off, restricted"). A person or thing was designated as sacred when it was unique or extraordinary. Closely related to *sacer* is *numen* ("mysterious power, god"). The term numinous is used at present as a description of the sacred to indicate its power, before which man trembles. Various terms from different traditions have been recognized as correlates of *sacer*: Greek *hagios*, Hebrew *qadosh*, Polynesian *tapu*, Arabic *haram*; correlates of *numen* include the Melanesian *mana*, the Sioux *wakanda*, the old German *haminja* (luck), and Sanskrit *Brahman*.

Besides the dichotomy of sacred–profane the sacred includes basic dichotomies of pure–impure and pollutant–“free.” In ancient Rome the word *sacer* could mean that which would pollute someone or something that came

into contact with it, as well as that which was restricted for divine use. Similarly, the Polynesian *tapu* ("tabu") designated something as not "free" for common use. It might be someone or something specially blessed because it was full of power, or it might be something accursed, as a corpse. Whatever was *tapu* had special restrictions around it, for it was full of extraordinary energy that could destroy anyone unprotected with special power himself. In this case the sacred is whatever is uncommon and may include both generating and polluting forces. On the other hand there is the pure–impure dichotomy, in which the sacred is identified with the pure and the profane is identified with the impure. The pure state is that which produces health, vigour, luck, fortune, and long life. The impure state is that characterized by weakness, illness, misfortune, and death. To acquire purity means to enter the sacred realm, which could be done through purification rituals or through the fasting, continence, and meditation of ascetic life. When a person became pure he entered the realm of the divine and left the profane, impure, decaying world. Such a transition was often marked by a ritual act of rebirth.

Ambivalence in man's response to the sacred. Because the sacred contains notions both of a positive, creative power and a danger that requires stringent prohibitions, the common human reaction is both fear and fascination. Otto elaborated his understanding of the holy from this basic ambiguity. Only the sacred can fulfill man's deepest needs and hopes; thus, the reverence that man shows to the sacred is composed both of trust and terror. On the one hand, the sacred is the limit of human effort both in the sense of that which meets human frailty and that which prohibits human activity; on the other hand, it is the unlimited possibility that draws mankind beyond the limiting temporal–spatial structures that are constituents of human existence.

Not only is there an ambivalence in the individual's reaction to the numinous quality of the sacred but the restrictions, the tabus, can be expressive of the creative power of the sacred. Caillois has described at length the social mechanism of nonliterate societies, in which the group is divided into two complementary subgroups (moieties), and has interpreted the tabus and the necessary interrelationship of the moieties as expressions of sacredness. Whatever is sacred and restricted for one group is "free" for the other group. In a number of respects, e.g., in supplying certain goods, food, and wives, each group is dependent on the other for elemental needs. Here the sacred is seen to be manifested in the order of the social-physical universe, in which these tribal members live. To disrupt this order, this natural harmony, would be sacrilege, and the culprit would be severely punished. In this understanding of the sacred, a person is, by nature, one of a pair; he is never complete as a single unit. Reality is experienced as one of prescribed relationships, some of these being vertical, hierarchical relationships and others being horizontal, corresponding relationships.

Another significant ambiguity is that the sacred manifests itself in concrete forms that are also profane. The transcendent mystery is recognized in a specific concrete symbol, act, idea, image, person, or community. The unconditioned reality is manifested in conditioned form. Eliade has elucidated this "dialectic of the sacred," in which the sacred may be seen in virtually any sort of form in religious history: a stone, an animal, or the sea. The ambiguity of the sacred taking on profane forms also means that even though every system of sacred thought and action differentiates between those things it regards as sacred or as profane, not all people find the sacred manifested in the same form; and what is profane for some is sacred for others.

Manifestations of the sacred. The sacred appears in myths, sounds, ritual activity, people, and natural objects. Through retelling the myth the divine action that was done "in the beginning" is repeated. The repetition of the sacred action symbolically duplicates the structure and power that established the world originally. Thus, it is important to know and preserve the eternal structure

The elements of fear and fascination

Sacer
and
numen

Sacred
sounds

through which man has life, for it is the model and source of power in the present.

The recognition of sacred power in the myth is related to the notion that sound itself has creative power—in particular special, sacred sounds. Sometimes these sounds are words, such as the name of god, divine myth, a prayer, or hymn; but sometimes the most sacred sounds are those that do not have a common meaning, for example, the Hindu *om*, the Buddhist *om mani padme ham*, or the Jewish and Christian "Hallelujah."

Closely connected with verbal expressions of sacred power are activities done in worship, in sacraments, sacrifices, and festivals. Part of the importance of religious ritual is that in the realm of the sacred all things have their place. In order for human existence to prosper (or even continue) it must correspond as closely as possible to the divine pattern (destiny, or will). Different religious traditions have different theological and philosophical formulations of the meaning of sacraments. In Roman Catholic Christianity, a sacrament is "an outward and visible sign of an inward and invisible grace." In Brahmanic Hinduism a *samskāra* (sacrament) is a sacred act that perfects a person and that culminates at the end of a series of *samskāras* in a spiritual rebirth, a symbolic "second birth." In both of these cases, the sacred action establishes the relation between the divine and human worlds.

Initiation,
sacrifice,
and
festival

Other sacred activity includes initiation, sacrifice, and festival. Initiation rites among **nonliterate** societies both expose and establish the world view of the participants. The initiate learns the eternal order of life as proclaimed in the myth. Life is viewed essentially as the work of supernatural beings, and the initiate in this ritual is taught this secret of life and how to gain access to divine benefits. The initiate learns the tabus and is often given a sacred mark, *e.g.*, circumcision, tattoo, or incisions, to express physically that he is part of the sacred (original) community. In other religions, such as Christianity, Buddhism, and Hinduism, an initiate to a special holy (often monastic) community within the larger religious community is designated by a change in name and wearing apparel, denoting his special relation to the sacred.

In festivals and sacrifices two religious functions are often combined: (1) to provide new power (energy, life) for the world, and (2) to purify the corrupted, defiled existence. Religious festivals are a return to sacred time, that time prior to the structured existence that most people commonly experience (profane time). Sacred calendars provide the opportunity for the profane time to be rejuvenated periodically in the festivals. These occasions symbolically repeat the primordial chaos before the beginning of the world; and just as the world was created "in the beginning," so in the repetition of that time the present world is regenerated (see also *Dimensions of the sacred*, below). The use of masks and the suspension of normal tabus express the unstructured, unconditioned nature of the sacred. Dancing, running, singing, and processions are all techniques for re-creation, for stimulating the original power of life. Ritual activity moves power in two directions: (1) it concentrates it in one place, time, and occasion, and (2) it releases power into the everyday stream of events through its self-abundance—the primal vibration reverberates throughout existence. The new energy dispels the old, depleted, polluted energy; it cleanses the constricted, clogged, hardened channels of life.

One of the most important forms in which man has access to the sacred is in the sacrifice. The central procedure in all sacrifices is the use of a victim or substitute to serve as a mediator between the sacred and profane worlds. The sacrifice (Latin *sacri-ficium*, "making sacred") is a consecration of an offering through which the profane world has access to the sacred without being destroyed by the sacred. Instead, the sacrificial object (victim) is destroyed in serving as a unique, extraordinary channel between these two realms. In sacrificial rites it is important to duplicate the original (divine) act; and because creation is variously conceived in different religious traditions, different forms are preserved: the burning or crushing of the "corn mother," the crushing of

the soma stalks, the slaughter of the lamb without blemish, the blood spilling of a sacred person, such as the firstborn.

Sacredness is manifested in sacred officials, such as priests and kings; in specially designated sacred places, such as temples and images; and in natural objects, such as rivers, the sun, mountains, or trees. The priest is a special agent in the religious cult, his ritual actions represent the divine action. Similarly, the king or emperor is a special mediator between heaven and earth and has been called by such names as the "son of heaven," or an "arm of god."

Just as certain persons are consecrated, so specific places are designated as the "gate of heaven." Temples and shrines are recognized by devotees as places where special attitudes and restrictions prevail because they are the abode of the sacred. Likewise, certain images of God (and sacred books) are held to be uniquely powerful and true (pure) expressions of divine reality. The image and the temple are, in traditional societies, not simply productions by individual artists and architects; they are reflections of the sacred essence of life, and their measurements and forms are specified through sacred communication from the divine sphere. In this same context, natural objects can be imbued with sacred power. The sun, for example, is the embodiment of the power of life, the source of all human consciousness, the central pivot for the eternal rhythm and order of existence. Or, a river, such as the Nile for the ancient Egyptians and the Ganges for the Hindu, gave witness to the power of life incarnated in geography. Sacred mountains (*e.g.*, Sinai for Jews, Kailāsa for Hindus, Fujiyama for Japanese) were particular loci of divine power, law, and truth.

Dimensions of the sacred. The sacred, by definition, pervades all dimensions of life. Within the kind of religious apprehension that is expressed in sacred myth and ritual, however, there is a special focus on time, place (cosmos), and active agents (heroes, ancestors, divinities). When existence is seen in terms of the dichotomy of sacred and profane—which assumes that the sacred is wholly other than, yet necessary for, everyday existence—it is very important to know and to get in contact with the sacred. In periodic festivals men celebrate sacred time; a sacred calendar marks off the intervals of man's life, and these sacred festivals provide the pattern for productive and joyous living.

Seasonal sacred calendars are especially important in predominantly agricultural societies. In the very order of nature, people see that different seasons have their distinct values. These differences are celebrated with spring festivals (when the world is re-created through ritual expressions of generation) and harvest festivals (of thanksgiving and of protecting the life force in seeds for the next spring). Here time is regarded as cyclical, and one's life is marked by those rituals in which one continually returns to the divine source.

Similarly, the myths and rituals mark off the world (cosmos) into places that have special sacred significance. The territory in which one lives is real insofar as it is in contact with the divine reality. Within this territory is life; outside it is chaos, danger, and demons. Throughout most of history the "sacred world" was coextensive with a certain territory, and one could speak literally of Christian lands, the Jewish homeland, the Muslim world, the place of the noble people (*Āryāvarta*, Hindu), or the central kingdom (China). Consecrating one's possession of land with certain rituals was equal to establishing an order with divine sanction. In Vedic ritual, for example, the erection of a fire altar (in which the god Agni—fire—was present) was the establishment of a cosmos on a microcosmic scale. Once a cosmos is established, there are certain places that are especially sacred. Certain rivers, mountains, groves of trees, caves, or human constructions such as temples, shrines, or cities provide the "gate," "ladder," "navel," or "pole" between heaven and earth. This sacred place is that which both allows the sacred power to flow into existence and gives order and stability to life.

Another dimension of the sacred is divine or heroic

Sacred
time and
place

Divine
or
heroic
activity
and social
relations

activity: the decisive action done by creative or protective agents. One's spiritual ancestors need not be biologically defined ancestors; they may not even be human. They are the essential forces on which survival depends and can be embodied in animal skills (longevity, rebirth, magical skills), in the "ways of the ancients," or through a special hero who has provided present existence with material and spiritual benefits. If the notion of sacred manifestation is extended to include the social relationships (especially tabus) in a community, then communal relations can be viewed as a dimension through which the sacred is manifested. Here human values are sacralized by social restraints that prescribe, *e.g.*, with whom one can eat or whom one can marry or kill. The establishment of a community requires forming certain relationships; and these relationships are sacred when they bear the power of ultimate, eternal, cosmic force. For example, the consecration of a king or emperor in traditional agricultural societies was the establishment of a system of allegiance and order for society.

By extending the notion of "sacralization" to include human reorganization of experience within the context of any absolute norm, the sacred can be seen in such dimensions of life as history, self-consciousness, aesthetics, and philosophical reflection (conceptualization). Each of these modes of human experience can become the creative force whereby some people have "become real" and gained the most profound understanding of themselves.

CRITICAL PROBLEMS

Phenomenologists of religion who use the concept "sacred" as a universal term for the basis of religion differ in their estimation of the nature of the sacred manifestation. Otto and van der Leeuw hold (in different formulations) that the sacred is a reality that transcends the apprehension of the sacred in symbols or rituals. The forms (ideograms) through which the sacred is expressed are secondary and are simply reactions to the "wholly other." Kristensen and Eliade, on the other hand, regard the sacred reality to be available through the particular symbols or ways of apprehending the sacred. Thus, Kristensen places emphasis on how the sacred is apprehended, and Eliade describes different modalities of the sacred, while Otto looks beyond the forms toward a meta-empirical source.

A second problem is the continuing question of whether or not the sacred is a universal category. There are religious expressions from various parts of the world that clearly manifest the kind of structure of religious awareness characterized above. It is especially apropos of some aspects in the religion of nonliterate societies, the ancient Near East, and some popular devotional aspects of Hinduism. There is, however, a serious question regarding the usefulness of this structure in interpreting a large part of Chinese religion, the social relationships (*dharma*) in Hinduism, the effort to achieve superconscious awareness in Hinduism (Yoga), Jainism, Buddhism (Zen), some forms of Taoism, and some contemporary (modern) options of total commitment that, nevertheless, reject the notion of an absolute source and goal essentially different from human existence. If one takes the notion of sacred as something above (beyond, different from) the religious structure dominated by divine or transcendent activity (described above), then this suggests that the notion of sacredness should not be limited to that structure. Thus, some scholars have found it confusing to use the notion of sacred as a universal religious quality, for it has been accepted by many religious people and by scholars of religion as referring to only one (though important) type of religious consciousness.

The 20th-century discussion of the nature and manifestation of the sacred includes other approaches than those of scholars in the comparative study of religions. For example, Sri Aurobindo, a Hindu mystic-philosopher, speaks of the supreme reality as the "Consciousness-Force"; and Nishida Kitaro, a Japanese philosopher, expresses his apprehension of universal reality as that of "absolute Nothingness." Martin Heidegger, a German philosopher, speaks of "the holy" as that dimension of

existence through which there is the illumination of the things that are, though it is no absolute Being prior to existence; rather it is a creative act at the point of engaging the Nothing (*Nichts*). In contrast, the Protestant theologian Karl Barth rejects philosophical reflection or mystical insight for apprehending the sacred, and insists that personal acceptance of God's self-revelation in a particular historical form, Jesus Christ, is the place to begin any awareness of what philosophers call "ultimate."

Sociologists who study religion have, since Durkheim, usually identified the sacred with social values that claim a supernatural basis. Nevertheless, the sacred has been identified predominantly as found in the social occasions (festivals) that disrupt the common social order (by Caillois), or as the reinforcing of social activities that secure a given social structure (by Howard Becker). During the 1960s, however, the usual definition of religion as those sacred activities which claimed a transcendent source was questioned by some empirical scholars. For example, Thomas Luckmann, a German-American sociologist, described the sacred in modern society as that "strata of significance to which everyday life is ultimately referred"; and this definition includes such themes as "the autonomous individual" and "the mobility ethos."

THE SACRED TODAY

The problems of defining and investigating religion mentioned above are already expressive of the shifts in modern consciousness regarding the sacred. Both the physical and social sciences have given modern man a new image of himself and techniques for improving his present life. The acceptance of rational and critical perspectives for judging the claims of religious authorities in Europe since the 18th century, plus the development of historical criticism and a sense of historical relativism, has contributed to the affirmation of man as basically a secular person. The once absolute authorities in the West (the Bible, priest, rabbi) are no longer the prime sources for one's self-identity. To a growing extent the cultures in the East are also experiencing a loss of their traditional authorities. Some attempts have been made to resacralize contemporary cosmology, history, and personal experience by (1) extending the scope of religious concerns to "secular" areas such as politics, economics, personality development, and art; and (2) modifying theological positions, ethical norms, and liturgical forms to incorporate new modes of expression and to experiment with new styles of living.

An important 20th-century development in religious life has been the easy flow of information between religious communities on different continents. This has provided an opportunity for experimenting with religious forms from outside the traditionally acceptable forms in a culture. During the 1950s and 1960s, for example, Yoga and Zen meditation were serious religious options for some Westerners and a form of experimentation for large numbers. The concern to experiment with personal experience and with styles of living during the 1960s in the West has itself been considered an important religious expression by some commentators. These years saw considerable exploration in exotic experience with psychedelic drugs, many attempts to set up new communities for group living (communes)—though few lasted more than a year—and a shift in the values of middle class youth from a concern for personal economic security to social and experiential concerns. These recent activities may be viewed as attempts to recapture the experience of the sacred.

Throughout the past hundred years a number of philosophers and social scientists have asserted the disappearance of the sacred and predicted the demise of religion. A study of the history of religions shows that religious forms change and that there has never been unanimity on the nature and expression of religion. Whether or not man is now in a new situation for developing structures of ultimate values radically different from those provided in the traditionally affirmed awareness of the sacred is a vital question. The suggestion that a radically different

Assertions
of the
end of
the sacred

Nonuni-
versalist
views of
the sacred

kind of reality is possible is, of course, nonsense for those to whom the sacred already has been manifested once and for all in a particular form.

BIBLIOGRAPHY. The socio-anthropological analyses written near the beginning of the 20th century that are still useful for their interpretations of the sacred in preliterate societies include HENRI HUBERT and MARCEL MAUSS, *Essai sur la nature et le fonction du sacrifice* (1899; Eng. trans., *Sacrifice: Its Nature and Function*, 1964); and EMILE DURKHEIM, *Les Formes élémentaires de la vie religieuse, le système totémique en Australie* (1912; Eng. trans., *The Elementary Forms of the Religious Life*, 1954; paperback 1961). More recently, in the same vein, are E.O. JAMES, *Sacrifice and Sacrament* (1962), a comparative analysis of sacred ritual from many different religious traditions; and ROGER CAILLOIS, *L'Homme et le sacré* (1939; Eng. trans., *Man and the Sacred*, 1960), a general reflective interpretation of various social expressions of the sacred. From a position combining philosophical and theological concerns are the following: RUDOLF OTTO, *Das Heilige*, 9th ed. (1922; Eng. trans., *The Idea of the Holy*, 2nd ed. 1950, reprinted 1966), originally published in 1917, appealed to an a priori preconceptual knowledge of the holy; MAX F. SCHERER, *Vom Ewigen im Menschen*, 2nd ed. (1923; Eng. trans., *On the Eternal in Man*, 1960), an expression of an intuitive philosopher who insisted on the eternal reality of the sacred prior to man's awareness or social expression of it; NATHAN SODERBLOM'S long article "Holiness," in the *Encyclopedia of Religion and Ethics*, vol. 6, which stressed the quality of holiness in all religion four years prior to Otto's more famous statement, and his *Living God: Basal Forms of Personal Religion* (1933), which is a comparative study of religion organized according to various ways, through which man encounters God; and JOACHIM WACH, *The Comparative Study of Religions*, ed. by J.M. KITAGAWA (1958), a systematic analysis of the modes (thought, action, fellowship) used to express the religious experience. Two Dutch phenomenologists of religion who have made notable contributions to the interpretation of forms that express man's relation to the sacred are GERARDUS VAN DER LEEUW, *Phänomenologie der Religion* (1933; Eng. trans., *Religion in Essence and Manifestation*, 1963), which organizes a wide spectrum of data into three foci: the object of religion, the subject of religion, and their reciprocal relation; and W. BREDE KRISTENSEN, *The Meaning of Religion* (1960), a series of lectures given during the 1930s that elucidates the sacredness of man's cosmological, anthropological, and cultic awareness as expressed in the preliterate cultures and those of the ancient Mediterranean area. The most extensive analysis of the forms and modes in which the sacred is recognized is found at present in the writings of MIRCEA ELIADE. Four of his works that deal with the nature and meaning of the sacred in different types of expression are: *Le Mythe de l'éternel retour* (1949; Eng. trans., *The Myth of the Eternal Return*, 1954; rev. ed., 1965); *Myth and Reality* (1963); *Traité d'histoire des religions* (Eng. trans., *Patterns in Comparative Religion*, 1958); and *The Sacred and the Profane: The Nature of Religion* (1959). For Eliade, the apprehension of the sacred is a unique kind of experience in which the creative power(s) of life appear(s) in particular symbols, myths, and rites.

(F.J.S.)

Sacred Scriptures

Sacred scriptures, the revered texts, or Holy Writ, of the world's religions, comprise a large part of the literature of the world. They vary greatly in form, volume, age, and degree of sacredness; but their common attribute is that their words are regarded by the devout as sacred.

Nature and significance. Sacred words differ from ordinary words in that they are believed either to possess and convey spiritual and magical powers, or to be the means through which a divine being or other sacred reality is revealed to men in phrases and sentences full of power and truth.

Religious rituals and myths provide both ancient and modern instances of the way in which sacred words are believed to possess and convey power; examples of such instances are when, with the aid of sacred words, one experiences a sacred reality in everyday life (the function of ritual), or when one, with the use of the traditional and correct words, establishes beyond question the fact of such a reality (the function of myth). When men first began to use words, they most likely tended to regard the names for persons and things as possessing a subtle, even organic, tie with the objects that these words design-

nated, and therefore believed that an inherent power imparted a magical potency to phrases and sentences containing them. (There is still a tendency to find hidden power in swear words, curses, and holy names.) But with the fuller development of language, men in all parts of the world attributed sacred power not to words used in ordinary senses but rather to words that had proved to be magically or religiously effectual in securing certain desired relations with the sacred realities in the world around them—realities that seemed to wield power and appeared to exist in a superior and changeless condition, in contrast to mankind's changeful and relatively powerless condition. Such words and sentences were principally the province of revered old men, leaders of the community, magicians, and priests; and they were spoken not only to impart sacred truths or to establish the existence of transcendent, eternal realities but also to bring dynamic, eternal realities to bear on human existence. From very early times, myths and rituals throughout the world arose from such origins and were orally transmitted until they were eventually written down and became sacred scripture.

A later, and very important, source of sacred scripture has been the experience of revelation. Revelation is believed to occur when a divine being or sacred reality is revealed in a crucial event, a supernatural manifestation, or, more immediately, in an auditory experience of a group or an individual receiving an oral communication from a divine being (see also REVELATION).

Oral tradition and sacred texts. Most sacred scriptures were originally oral, and were passed down through memorization from generation to generation until they were finally committed to writing. A few are still preserved orally, such as the hymns of the American Indians (only now being recorded by anthropologists). Many bear the unmistakable marks of their oral origin and can best be understood when recited aloud; in fact, it is still held by many Hindus and Buddhists that their scriptures lack, when read silently, the meaning and significance they have when recited aloud, for the human voice is believed to add to the recited texts dimensions of truth and power not readily grasped by the solitary reader. A further instance of Hindu and Buddhist recognition of the oral nature of their scriptures is their use of certain portions (stanzas, syllables) as mantras—formulas having a magical and spiritual efficacy, when recited with the correct gestures (*mudrās*) or used in connection with the correct magical symbol (*yantra*). By pronouncing a *mantra* in the correct manner it is believed that one may induce or even coerce the gods to bestow upon the devotee magical and spiritual powers not available to him otherwise (see also BUDDHISM).

Most oral compositions that were effectual in securing the flow of magical and spiritual powers were everywhere considered as possessed of a sacred authority of their own and in no need of the sanction or authorization of rulers and priests.

Types of sacred and semisacred writings. Not all scriptures, however, were originally oral, nor were they in all parts directly effectual in rituals that sought the granting of magical and spiritual powers. The greater part of recorded scripture has either a narrative or expository character. The types of sacred and semisacred texts are, in fact, many and varied. Besides magical runes (ancient Germanic alphabet characters) and spells from primitive and ancient sources, they include hymns, prayers, chants, myths, stories about gods and heroes, epics, fables, sacred laws, directions for the conduct of rituals, the original teachings of major religious figures, expositions of these teachings, moral anecdotes, dialogues of seers and sages, and philosophical discussions; in fact, they include every form of literature capable of expressing religious feeling or conviction.

Canonical texts of superior authority. Types of sacred literature vary in authority and degree of sacredness. The centrally important and most holy of the sacred texts have in many instances been gathered into canons (standard works of the faith), which, after being determined either by general agreement or by official religious bodies, be-

Significance of oral recitation

Importance of the sacred word

Distinction
between
canonical
and
semi-
canonical
scriptures

come fixed—*i.e.*, limited to certain works that are alone viewed as fully authoritative and truly beyond all further change or alteration. The works not admitted to the canons (those of a semisacred or semicanonical character) may still be quite valuable as supplementary texts.

A striking instance of making a distinction between canonical and semicanonical scriptures occurs in Hinduism. The Hindu sacred literature is voluminous and varied; it contains ancient elements and every type of religious literature that has been listed, except historical details on the lives of the seers and sages who produced it. Its earliest portions, namely, the four ancient Vedas (hymns) seem to have been provided by Indo-Aryan families in northwest India in the 2nd millennium BC. These and the supplements to them composed after 1000 BC, the *Brāhmaṇas* (commentaries and instruction in ritual), the *Āraṇyakas* (forest books of ascetics), and the *Upaniṣads* (philosophical treatises), are considered more sacred than any later writings. They are collectively referred to as *Śruti* ("heard"; *i.e.*, communicated by revelation); whereas the later writings are labelled *Smṛti* ("remembered"; *i.e.*, recollected and reinterpreted at some distance in time from the original revelations). The former are canonical and completed, not to be added to nor altered, but the latter are semicanonical and semisacred. Sects like the Vaiṣṇavites (followers of the god Viṣṇu) and Śaivites (followers of the god Śiva) prefer texts in the *Smṛti* category (*e.g.*, their own Tantras, or treatises on esoteric practices) even to the *Śruti* (see also HINDU SACRED LITERATURE).

Where a literature clusters about a single founding figure, as in the cases of Christianity and Buddhism, it bases itself on recollections and interpretations of the founder's life and original teaching. Buddhist sacred literature recollects Gautama Buddha's life and teaching in the 6th century BC, and first appeared in the dialect called Pāli, allied to the Māgadhī that he spoke. As time passed, and his movement spread beyond India, Buddhism adopted as its medium Sanskrit, the Indian classical language that was widely used in the ancient Orient. A distinction arose between the Theravāda (or "Way of the Elders"), preserved in Pāli and regarded as canonical, and the vast number of works written in Sanskrit within the more widely dispersed Buddhism called by its adherents Mahāyāna (the "Greater Vehicle"). The Mahāyāna works were later translated and further expanded in Tibetan, Chinese, and Japanese. Depending on the school (or sect) of Mahāyāna Buddhism making the judgment, selected works—in effect a canon in relation to the whole body of scriptures—are preferred as more inspired—*i.e.*, believed to be closer to the ultimate truth, and thus to the centres of spiritual power (see also BUDDHIST SACRED LITERATURE).

Whether the basic texts of indigenous Chinese religion should be called sacred, in the sense of Holy Writ, is open to question. Neither classical Taoism nor Confucianism can be said to have been based on revelation; the texts of these faiths were originally viewed as human wisdom, books written by men for men. They acquired authority, actually a canonical status, however, that caused them to be regarded with profound reverence and thus, in effect, as sacred. This certainly was true of the Taoist revered book, the Tao-te Ching ("Classic of the Way of Power"), and of the Wu Ching ("Five Classics") and the Ssu Shu (Four Books) of Confucianism. The present government of China, however, seeks to deprive these books of whatever sacredness they once possessed (see also TAOIST LITERATURE; CONFUCIAN TEXTS, CLASSICAL).

The most precisely fixed canons are those that have been defined by official religious bodies. The Jewish canon, known to Christians as the Old Testament, was fixed by a synod of rabbis (religious leaders and teachers) held at Yavneh, Palestine, about AD 90. The semisacred books that were excluded were labelled by Christians the Apocrypha (which means in Greek "hidden away"). Roman Catholicism later included them in its canon. Jesus, the founder of Christianity, left nothing in writing, but he so inspired his followers that they preserved his sayings and

biographical details about him in oral form until they were written down in the four Gospels. To these were added the letters of St. Paul and others, and the Book of Revelation to John, the whole forming a sacred canon called the New Testament, which was ecclesiastically sanctioned by the end of the 4th century AD. There was also a New Testament Apocrypha, but it did not achieve canonical status because of numerous spurious details (see also BIBLICAL LITERATURE).

Where no religious body has provided sanction or authorization, scriptures have had to stand on their own authority. Muslims believe that the Qur'ān does this easily. The Qur'ān, their only sacred canon or standard of faith, authenticates itself, they believe, by its internal self-evidencing power, for it is composed of the very words of God communicated to Muḥammad and recited by him without addition or subtraction. This faith of Muslims in the Qur'ān is similar to that of Fundamentalist Christians who believe that the Bible, as God's word, is verbally inspired from beginning to end.

Secondary sacred literature with semicanonical authority. There exists a large body of literature that possesses less of the aura of true scripture than the works just noted. They are interpretations about divine truth and divine commands, or stories that illustrate how persons, exalted or lowly, have acted (with or without awareness) in response to a divine stimulus. They are, in effect, supportive of true scripture.

An outstanding instance is the Talmud, a compendium of law, lore, and commentary that to many Jews has very nearly the authority of the Mosaic Torah (the Law, or the Pentateuch). Indeed, in the postbiblical rabbinical writings it was generally considered a second Torah, complementing the Written Law of Moses (see also TALMUD AND MIDRASH). Another instance is provided by the Christian Church. Its major creeds have, at one time or another, been regarded as infallible statements, to depart from which would be heresy. This is particularly true of the Apostles' Creed and the three "ecumenical creeds" of Nicaea (325), Constantinople (381), and Chalcedon (451). Roman Catholics add to these the papal decrees summarizing in credal form the conclusions of the councils of the Roman Catholic Church concerning the sacraments, transubstantiation (the changing of the substance of the bread and wine in the mass into the body and blood of Christ), confession, the immaculate conception of the Virgin Mary, papal infallibility, and the assumption of the body and soul of the Virgin Mary to heaven. More or less binding for Protestants are their distinctive statements of faith: the Augsburg Confession of 1530 (Lutheran), the Heidelberg Catechism of 1563 (Reformed), the Westminster Confession of 1646 and Shorter Westminster Catechism of 1647 (Presbyterian), and others.

An exceedingly large body of literature, accorded a more or less sacred character by millions of people, especially in the Orient, comprises the epics, myths, legends, folk tales, and allegories of mankind. This type of literature has proliferated in every part of the world and has amazing staying power, being composed of unforgettable stories of the origin of the world and man's exciting life in it. In ancient Europe, such literature determined the structure of Greek and Roman religious and civic rituals (see also GREEK RELIGION; GREEK MYTHOLOGY; ROMAN RELIGION). The lives of Egyptians and Mesopotamians were deeply affected by their mythologies and books dealing with death (see also EGYPTIAN RELIGION; MESOPOTAMIAN RELIGIONS). Of equal significance were the myths, epics, and sagas of the ancient Germans, the Slavs, the Scandinavians, and the Celts (see also GERMANIC RELIGION AND MYTHOLOGY; SLAVIC RELIGION; CELTIC RELIGION: FINNO-UGRIC RELIGION).

India and the Far East have their corresponding semisacred traditions. The great religious and cultural epics of India (the *Mahābhārata* and the *Rāmāyaṇa*), the 18 *Purāṇas* (ancient legendary histories) so important to the followers of Śiva and Viṣṇu, and the esoteric *Tantras* central to Śāktism (a system of Hindu cults and philosophical schools devoted to the supreme energy personi-

Epics,
myths, and
other
writings

The
Jewish
and
Christian
canons

fied in the mother-goddess), all attest to the power of religion in India. The many Chinese myths are difficult to locate in the remaining literature, but the Shintō myths are very significant in Japanese literature and were given the status of true scripture during the nationalistic period in Japan prior to World War II (see HINDU MYTHOLOGY; CHINESE MYTHOLOGY; JAPANESE MYTHOLOGY; SHINTO).

During the last seven centuries in the West, some religious writings have attained a semisacred, if not a fully sacred, status: *Imitatio Christi* of Thomas à Kempis (1379/80–1471); John Bunyan's (1628–88) *Pilgrim's Progress*; Mary Baker Eddy's (1821–1910) *Science and Health with a Key to the Scriptures*; and the reputed discovery of Joseph Smith (1805–44), the *Book of Mormon*.

The cultural role of sacred writings. That sacred writings perform the public function of shaping an emerging culture or stabilizing an established one is demonstrable in nearly every national history. In this process the private reading and study of scripture is less important than their public recitation and their ritualization and use in public ceremonies; but their effect on private life and domestic ceremony is cumulatively important.

Sacred scriptures are a rich source for symbols and themes in the arts. They provide images and imagery for sculpture, painting, architectural ornamentation, stories that are acted out in drama and dancing, and the inspiration for and thematic content of much music, poetry, and secular literature.

The impact of sacred scriptures on education, oratory, nationalism, wars, religious sects and denominations, international missionary efforts, ecumenical movements, peace crusades, and other aspects of culture is very noticeable throughout human history.

Sacrifice

Sacrifice is a religious rite in which an object is offered to a divinity in order to establish, maintain, or restore a

right relationship of man to the sacred order. It is a complex phenomenon that has been found in the earliest known forms of worship and in all parts of the world. The present article will treat the nature of sacrifice and will survey the theories about its origin. It will then analyze sacrifice in terms of its constituent elements, such as the material of the offering, the time and place of the sacrifice, and the motive or intention of the rite. Finally, it will briefly consider sacrifice in the religions of the world.

NATURE AND ORIGINS

Nature of sacrifice. The term sacrifice derives from the Latin *sacrificium*, which is a combination of the words *sacer*, meaning something set apart from the secular or profane for the use of supernatural powers, and *facere*, meaning “to make.” The term has acquired a popular and frequently secular use to describe some sort of renunciation or giving up of something valuable in order that something more valuable might be obtained; e.g., parents make sacrifices for their children, one sacrifices a limb for one's country. But the original use of the term was peculiarly religious, referring to a cultic act in which objects were set apart or consecrated and offered to a god or some other supernatural power; thus, sacrifice should be understood within a religious, cultic context.

Religion is man's relation to that which he regards as sacred or holy. This relationship may be conceived in a variety of forms. Although moral conduct, right belief, and participation in religious institutions are commonly constituent elements of the religious life, cult or worship is generally accepted as the most basic and universal element. Worship is man's reaction to his experience of the sacred power; it is a response in action, a giving of self, especially by devotion and service, to the transcendent reality upon which man feels himself dependent. Sacrifice and prayer—man's personal attempt to communicate with the transcendent reality in word or in thought—are the fundamental acts of worship.

In a sense, what is always offered in sacrifice is, in one form or another, life itself. Sacrifice is a celebration of life, a recognition of its divine and imperishable nature. In the sacrifice the consecrated life of an offering is liberated as a sacred potency that establishes a bond between the sacrificer and the sacred power. Through sacrifice, life is returned to its divine source, regenerating the power or life of that source; life is fed by life. Thus, the word of the Roman sacrificer to his god: “Be thou increased (*macte*) by this offering.” It is, however, an increase of sacred power that is ultimately beneficial to the sacrificer. In a sense, sacrifice is the impetus and guarantee of the reciprocal flow of the divine life-force between its source and its manifestations.

Often the act of sacrifice involves the destruction of the offering, but this destruction—whether by burning, slaughter, or whatever means—is not in itself the sacrifice. The killing of an animal is the means by which its consecrated life is “liberated” and thus made available to the deity, and the destruction of a food offering in an altar's fire is the means by which the deity receives the offering. Sacrifice as such, however, is the total act of offering and not merely the method in which it is performed.

Although the fundamental meaning of sacrificial rites is that of effecting a necessary and efficacious relationship with the sacred power and of establishing man and his world in the sacred order, the rites have assumed a multitude of forms and intentions. The basic forms of sacrifice, however, seem to be some type of either sacrificial gift or sacramental meal. Sacrifice as a gift may refer either to a gift that should be followed by a return gift (because of the intimate relationship that gift giving establishes) or to a gift that is offered in homage to a god without expectation of a return. Sacrifice as a sacramental communal meal may involve the idea of the god as a participant in the meal or as identical with the food consumed; it may also involve the idea of a ritual meal at which either some primordial event such as creation is repeated or the sanctification of the world is symbolically renewed.

Theories of the origin of sacrifice. Since the rise of the comparative or historical study of religions in the latter part of the 19th century, attempts have been made to discover the origins of sacrifice. These attempts, though helpful for a greater understanding of sacrifice, have not been conclusive.

In 1871 Sir Edward Burnett Tylor, a British anthropologist, proposed his theory that sacrifice was originally a gift to the gods to secure their favour or to minimize their hostility. In the course of time the primary motive for offerings sacrificial gifts developed into homage, in which the sacrificer no longer expressed any hope for a return, and from homage into abnegation and renunciation, in which the sacrificer more fully offered himself. Even though Tylor's gift theory entered into later interpretations of sacrifice, it left unexplained such phenomena as sacrificial offerings wholly or partly eaten by worshippers.

William Robertson Smith, a Scottish Semitic scholar and encyclopaedist, marked a new departure with his theory that the original motive of sacrifice was an effort toward communion among the members of a group, on the one hand, and between them and their god, on the other. Communion was brought about through a sacrificial meal. Smith began with totemism, according to which an animal or plant is intimately associated in a "blood relationship" with a social group or clan as its sacred ally. In general, the totem animal is taboo for the members of its clan, but on certain sacred occasions the animal is eaten in a sacramental meal that ensures the unity of the clan and totem and thus the well-being of the clan. For Smith an animal sacrifice was essentially a communion through the flesh and blood of the sacred animal, which he called the "theanthropic animal"—an intermediary in which the sacred and the profane realms were joined. The later forms of sacrifice retained some sacramental character: people commune with the god through sacrifice, and this communion occurs because the people share food and drink in which the god is immanent. From the communion sacrifice Smith derived the expiatory or propitiatory forms of sacrifice, which he termed *piaculum*, and the gift sacrifice. There were great difficulties with this theory: it made the totem a sacrificial victim rather than a supernatural ally; it postulated the universality of totemism; and, further, it did not adequately account for holocaust sacrifices in which the offering is consumed by fire and there is no communal eating. Nevertheless, many of Smith's ideas concerning sacrifice as sacramental communion have exerted tremendous influence.

Sir James George Frazer, a British anthropologist and folklorist, author of *The Golden Bough*, saw sacrifice as originating from magical practices in which the ritual slaying of a god was performed as a means of rejuvenating the god. The king or chief of a tribe was held to be sacred because he possessed mana, or sacred power, which assured the tribe's well-being. When he became old and weak, his mana weakened, and the tribe was in danger of decline. The king was thus slain and replaced with a vigorous successor. In this way the god was slain to save him from decay and to facilitate his rejuvenation. The old god appeared to carry away with him various weaknesses and fulfilled the role of an expiatory victim and scapegoat.

Henri Hubert and Marcel Mauss, French sociologists, concentrated their investigations on Hindu and Hebrew sacrifice, arriving at the conclusion that "sacrifice is a religious act which, through the consecration of a victim, modifies the condition of the moral person who accomplishes it or that of certain objects with which he is concerned." Like Smith, they believed that a sacrifice establishes a relationship between the realms of the sacred and the profane. This occurs through the mediation of the ritually slain victim, which acts as a buffer between the two realms, eliminating the need for direct contact, and through participation in a sacred meal. The rituals chosen by Hubert and Mauss for analysis, however, are not those of preliterate societies.

Another study by Mauss helped to broaden the notion of sacrifice as gift. It was an old idea that man makes a

gift to the god but expects a gift in return. The Latin formula *do ut des* ("I give that you may give") was formulated in classical times. In the Vedic religion, the oldest stratum of religion known to have existed in India, one of the Brāhmaṇas (commentaries on the Vedas, or sacred hymns, that were used in ritual sacrifices) expressed the same principle: "Here is the butter; where are your gifts?" But, according to Mauss, in giving it is not merely an object that is passed on but a part of the giver, so that a firm bond is forged. The owner's mana is conveyed to the object, and, when the object is given away, the new owner shares in this mana and is in the power of the giver. The gift thus creates a bond. Even more, however, it makes power flow both ways to connect the giver and the receiver; it invites a gift in return.

Gerardus van der Leeuw, a Dutch historian of religion, developed this notion of gift in the context of sacrifice. In sacrifice a gift is given to the god, and thus man releases a flow between himself and the god. For him sacrifice as gift is "no longer a mere matter of bartering with gods corresponding to that carried on with men, and no longer homage to the god such as is offered to princes: it is an opening of a blessed source of gifts." His interpretation thus melded the gift and communion theories, but it also involved a magical flavour, for he asserted that the central power of the sacrificial act is neither god nor giver but is always the gift itself.

German anthropologists have emphasized the idea of culture history, in which the entire history of mankind is seen as a system of coherent and articulated phases and strata, with certain cultural phenomena appearing at specific levels of culture. Leo Frobenius, the originator of the theory that later became known as the *Kulturkreis-lehre*, distinguished the creative or expressive phase of a culture, in which a new insight assumes its specific form, and the phase of application, in which the original significance of the new insight degenerates. Working within this context, Adolf E. Jensen attempted to explain why men have resorted to the incomprehensible act of killing other men or animals and eating them for the glorification of a god or many gods. Blood sacrifice is linked not with the cultures of the hunter-gatherers but with those of the cultivators; its origin is in the ritual killing of the archaic cultivator cultures, which, in turn, is grounded in myth. For Jensen the early cultivators all knew the idea of a mythic primal past in which not men but Dema lived on the Earth and prominent among them were the Dema-deities. The central element of the myth is the slaying of a Dema-deity, an event that inaugurated human history and gave shape to the human lot. The Dema became men, subject to birth and death, whose self-preservation depends upon the destruction of life. The deity became in some way associated with the realm of the dead; and, from the body of the slain deity, crop plants originated, so that the eating of the plants is an eating of the deity. Ritual killing, whether of animals or men, is a cultic re-enactment of the mythological event. Strictly speaking, the action is not a sacrifice because there is no offering to a god; rather, it is a way to keep alive the memory of primeval events. Blood sacrifice as found in the later higher cultures is a persistence of the ritual killing in a degenerated form. Because the victim is identified with the deity, later expiatory sacrifices also become intelligible: sin is an offense against the moral order established at the beginning of human history; the killing of the victim is an intensified act restoring that order.

Another interpretation of some historical interest is that of Sigmund Freud in his work *Totem und Tabu* (1913; Eng. trans., *Totem and Taboo*, 1918). Freud's theory was based on the assumption that the Oedipus complex is innate and universal. It is normal for a child to wish to have a sexual relationship with its mother and to will the death of its father; this is often achieved symbolically. In the primal horde, although the sons did slay their father, they never consummated a sexual union with their mother; in fact, they set up specific taboos against such sexual relations. According to Freud, the ritual slaughter of an animal was instituted to re-enact the primeval act of parricide. The rite, however, reflected an ambivalent atti-

Mid-20th-century theories

tude. After the primal father had been slain, the sons felt some remorse for their act, and, thus, the sacrificial ritual expressed the desire not only for the death of the father but also for reconciliation and communion with him through the substitute victim. Freud claimed that his reconstruction of the rise of sacrifice was historical, but this hardly seems probable.

In 1963 Raymond Firth, a New Zealand-born anthropologist, addressed himself to the question of the influence that a people's ideas about the control of their economic resources have on their ideology of sacrifice. He noted that the time and frequency of sacrifice and the type and quality of victim are affected by economic considerations; that the procedure of collective sacrifice involves not only the symbol of group unity but also a lightening of the economic burden on any one participant; that the use of surrogate victims and the reservation of the sacrificial food for consumption are possibly ways of meeting the problem of resources. Firth concluded that sacrifice is ultimately a personal act in which the self is symbolically given, but it is an act that is often conditioned by economic rationality and prudent calculation.

Most social anthropologists and historians of religion in the mid-20th century, however, concentrated less on worldwide typologies or evolutionary sequences and more on investigations of specific historically related societies. Consequently, since World War II there have been few formulations of general theories about the origin of sacrifice, but there have been important studies of sacrifice within particular cultures. For example, E.E. Evans-Pritchard, a social anthropologist at Oxford University, concluded after his study of the religion of the Nuer, a people in the southern Sudan, that for them sacrifice is a gift intended "to get rid of some danger of misfortune, usually sickness." They establish communication with the god not to create a fellowship with him but only to keep him away. Evans-Pritchard acknowledged, however, that the Nuer have many kinds of sacrifice and that no single formula adequately explains all types. Furthermore, he did not maintain that his interpretations of his materials were of universal applicability. Many scholars would agree that, though it is easy to make a long list of many kinds of sacrifice, it is difficult, if not impossible, to find a satisfactory system in which all forms of sacrifice may be assigned a suitable place.

ANALYSIS OF THE RITE OF SACRIFICE

It is possible to analyze the rite of sacrifice in terms of six different elements: the sacrificer, the material of the offering, the time and place of the rite, the method of sacrificing, the recipient of the sacrifice, and the motive or intention of the rite. These categories are not of equal importance and often overlap.

Sacrificer. In general, it may be said that the one who makes sacrifices is man, either an individual or a collective group—a family, a clan, a tribe, a nation, a secret society. Frequently, special acts must be performed by the sacrificer before and sometimes also after the sacrifice. In the Vedic cult, the sacrificer and his wife were required to undergo an initiation (*dīkṣā*) involving ritual bathing, seclusion, fasting, and prayer, the purpose of which was to remove them from the profane world and to purify them for contact with the sacred world. At the termination of the sacrifice came a rite of "desacralization" (*avabhṛta*) in which they bathed in order to remove any sacred potencies that might have attached themselves during the sacrifice.

There are sacrifices in which there are no participants other than the individual or collective sacrificer. Usually, however, one does not venture to approach sacred things directly and alone; they are too lofty and serious a matter. An intermediary—certain persons or groups who fulfill particular requirements or qualifications—is necessary. In many cases, sacrificing by unauthorized persons is expressly forbidden and may be severely punished; e.g., in the book of Leviticus, Korah and his followers, who revolted against Moses and his brother Aaron and arrogated the priestly office of offering incense, were con-

sumed by fire. The qualified person—whether the head of a household, the old man of a tribe, the king, or the priest—acts as the appointed representative on behalf of a community.

The head of the household as sacrificer is a familiar figure in the Old Testament, particularly in the stories of the patriarchs; e.g., Abraham and Jacob. Generally, in cattle-keeping tribes with patriarchal organization, the *paterfamilias* long remained the person who carried out sacrifices, and it was only at a late date that a separate caste of priests developed among these peoples. In ancient China, too, sacrifices were not presided over by a professional priesthood but by the head of the family or, in the case of state sacrifices, by the ruler.

The old man or the elders of the tribe are in charge of sacrifices among several African peoples. Among the Ila, a people of Zambia, for instance, when hunters have no success, the oldest member of the band leads the others in praying for the god's aid; when the hunters are successful in killing, the old man leads them in offering portions of the meat to the god. Similarly, among peoples in Australia the leading role in all sacrificial acts is filled by the old men as bearers of tradition and authority. In cases in which there is a matriarchal organization, as in some parts of West Africa, the oldest woman of the family acts as priestess.

The king has played an important role as the person active in sacrificing, particularly in those cultures in which he not only has temporal authority but also fulfills a religious function. The fact that the king is the primary sacrificer may stem from two roots. It may be that the most important gods of the state were originally family gods of the rulers, and, thus, the king is simply continuing the task of *paterfamilias*, only now on behalf of the whole community. The second root lies in the notion of sacred kingship, according to which the royal office is sacred and the king set apart from ordinary people is the intercessor with the supernatural world. These two concepts often go together. Thus, in ancient Egypt the pharaoh was divine because he descended from the sun god Re. The pharaoh stood for Horus, the son of Re. The concepts of the god as family ancestor and of sacred kingship were combined. Although worship in ancient Egypt was controlled by a powerful priesthood, officially all sacrifices were made by the pharaoh.

Most frequently, the intermediary between the community and the god, between the profane and the sacred realms, is the priest. As a rule, not everyone can become a priest; there are requirements of different kinds to be satisfied. Usually, the priest must follow some training, which may be long and severe. There is always some form of consecration he has to undergo. For communities in which a priest functions, he is the obvious person to make sacrifices.

The sacrificer is not always man, however; at times gods also make sacrifices. Examples of this are found chiefly in India and are set down particularly in the *Bṛihmana* texts; e.g., it is said in the *Taittiriya Bṛihmana*: "By sacrifice the gods obtained heaven." The idea of gods making sacrifice, however, is found in the older *Rgveda-Saṃhitā*, a collection of sacred Vedic hymns: "With offerings the gods offered up sacrifice." In this conception man makes sacrifices in imitation of a divine model inaugurated by the gods themselves. Another instance is the Iranian primordial god *Zurvān* (Time), who offered sacrifice for 1,000 years in order to obtain a son to create the world.

Material of the oblation. Any form under which life manifests itself in the world or in which life can be symbolized may be a sacrificial oblation. In fact, there are few things that have not, at some time or in some place, served as an offering. Any attempt to categorize the material of sacrifice will group together heterogeneous phenomena; thus, the category human sacrifice includes several fundamentally different sacrificial rites. Nevertheless, for convenience sake, the variety of sacrificial offerings will be treated as (1) blood offerings (animal and human), (2) bloodless offerings (libations and vegetation), and (3) a special category, divine offerings.

Gods as sacrificers

The role of the intermediary

Blood offerings. Basic to both animal and human sacrifice is the recognition of blood as the sacred life-force in man and beast. Through the sacrifice—through the return of the sacred life revealed in the victim—the god lives, and, therefore, man and nature live. The great potency of blood has been utilized through sacrifice for a number of purposes; *e.g.*, earth fertility, purification, and expiation. The letting of blood, however, was neither the only end nor the only mode of human and animal sacrifice.

A wide variety of animals have served as sacrificial offerings. In ancient Greece and India, for example, oblations included a number of important domestic animals, such as the goat, ram, bull, ox, and horse. Moreover, in Greek religion all edible birds, wild animals of the hunt, and fish were used. In ancient Judaism the kind and number of animals for the various sacrifices was carefully stipulated so that the offering might be acceptable and thus fully effective. This sort of regulation is generally found in sacrificial cults; the offering must be appropriate either to the deity to whom or to the intention for which it is to be presented. Very often the sacrificial species (animal or vegetable) was closely associated with the deity to whom it was offered as the deity's symbolic representation or even its incarnation. Thus, in the Vedic ritual the goddesses of night and morning received the milk of a black cow having a white calf; the "bull of heaven," Indra, was offered a bull, and Sūrya, the sun god, a white, male goat. Similarly, the ancient Greeks sacrificed black animals to the deities of the dark underworld; swift horses to the sun god Helios; pregnant sows to the Earth mother Demeter; and the dog, guardian of the dead, to Hecate, goddess of darkness. The Syrians sacrificed fish, regarded as the lord of the sea and guardian of the realm of the dead, to the goddess Atargatis and ate the consecrated offering in a communion meal with the deity, sharing in the divine power. An especially prominent sacrificial animal was the bull (or its counterparts, the boar and the ram), which, as the representation and embodiment of the cosmic powers of fertility, was sacrificed to numerous fertility gods (*e.g.*, the Norse god Freyr; the Greek "bull of the Earth," Zeus Chthonios; and the Indian "bull of heaven," Indra).

The occurrence of human sacrifice appears to have been widespread and its intentions various, ranging from communion with a god and participation in his divine life to expiation and the promotion of the Earth's fertility. It seems to have been adopted by agricultural rather than by hunting or pastoral peoples. Of all the worldly manifestations of the life-force, the human undoubtedly impressed men as the most valuable and thus the most potent and efficacious as an oblation. Thus, in Mexico the belief that the sun needed human nourishment led to sacrifices in which as many as 20,000 victims perished annually in the Aztec and Nahua calendrical maize ritual in the 14th century AD. Bloodless human sacrifices also developed and assumed greatly different forms: *e.g.*, a Celtic ritual

with him, and such internments continued intermittently until the 17th century.

In many societies human victims gave place to animal substitutes or to effigies made of dough, wood, or other materials. Thus, in India, with the advent of British rule, human sacrifices to the Dravidian village goddesses (*grāma-devīs*) were replaced by animal sacrifices. In Tibet, under the influence of Buddhism, which prohibits all blood sacrifice, human sacrifice to the pre-Buddhist Bon deities was replaced by the offering of dough images or reduced to pantomime. Moreover, in some cults both human and animal oblations could be "ransomed"—*i.e.*, replaced by offerings or money or other inanimate valuables.

Bloodless offerings. Among the many life-giving substances that have been used as libations are milk, honey, vegetable and animal oils, beer, wine, and water. Of these, the last two have been especially prominent. Wine is the "blood of the grape" and thus the "blood of the earth," a spiritual beverage that invigorates gods and men. Water is always the sacred "water of life," the primordial source of existence and the bearer of the life of plants, animals, human beings, and even the gods. Because of its great potency, water, like blood, has been widely used in purificatory and expiatory rites to wash away defilements and restore spiritual life. It has also, along with wine, been an important offering to the dead as a revivifying force.

Vegetable offerings have included not only the edible herbaceous plants but also grains, fruits, and flowers. In both Hinduism and Jainism, flowers, fruits, and grains (cooked and uncooked) are included in the daily temple offerings. In some agricultural societies (*e.g.*, those of West Africa) yams and other tuber plants have been important in planting and harvest sacrifices and in other rites concerned with the fertility and fecundity of the soil. These plants have been regarded as especially embodying the life-force of the deified earth and are frequently buried or plowed into the soil to replenish and reactivate its energies.

Divine offerings. One further conception must be briefly mentioned: a god himself may be sacrificed. This notion was elaborated in many mythologies; it is fundamental in some sacrificial rituals. In early sacrifice the victim has something of the god in itself, but in the sacrifice of a god the victim is identified with the god. At the festival of the ancient Mexican sun god Huitzilopochtli, the statue of the god, which was made from beetroot paste and kneaded in human blood and which was identified with the god, was divided into pieces, shared out among the devotees, and eaten. In the Hindu soma ritual (related to the *haoma* ritual of ancient Persia), the soma plant, which is identified with the god Soma, is pressed for its intoxicating juice, which is then ritually consumed. The Eucharist, as understood in many of the Christian churches, contains similar elements. In short, Jesus is really present in the bread and wine that are ritually offered and then consumed. According to the traditional eucharistic doctrine of Roman Catholicism, the elements of bread and wine are "transubstantiated" into the body and blood of Christ: *i.e.*, their whole substance is converted into the whole substance of the body and blood, although the outward appearances of the elements, their "accidents," remain.

Time and place of sacrifice. In many cults, sacrifices are distinguished by frequency of performance into two types, regular and special. Regular sacrifices may be daily, weekly, monthly, or seasonal (as at planting, harvest, and New Year). Also often included are sacrifices made at specific times in each man's life—birth, puberty, marriage, and death. Offerings made on special occasions and for special intentions have included, for example, sacrifices in times of danger, sickness, or crop failure and those performed at the construction of a building, for success in battle, or in thanksgiving for a divine favour.

In the Vedic cult the regular sacrifices were daily, monthly, and seasonal. The daily rites included fire offerings to the gods and libations and food offerings to the ancestors and the Earth divinities and spirits. The month-

involved the sacrifice of a woman by immersion, and among the Maya in Mexico young maidens were drowned in sacred wells; in Peru women were strangled; in ancient China the king's retinue was commonly buried

ly sacrifices, conducted at the time of New and Full Moons, were of cakes or cooked oblations to sundry deities, especially the storm god Indra. Some daily and monthly sacrifices could be celebrated in the home by a householder, but only the official priesthood could perform the complex seasonal sacrifices, offered three times a year—at the beginning of spring, of the rainy season, and of the cool weather—for the purpose of expiation and of abundance. Of the occasional sacrifices, which could be celebrated at any time, especially important were those associated with kingship, such as the royal consecration and the great "horse sacrifice" performed for the increase of the king's power and domain.

In ancient Judaism the regular or periodic sacrifices included the twice daily burnt offerings, the weekly sabbath sacrifices, the monthly offering at the New Moon, and annual celebrations such as *Pesah* (Passover), Yom Kippur (Day of Atonement), and Sukkot (Feast of Tabernacles). Special sacrifices were usually of a personal nature, such as thank and votive offerings and "guilt offerings."

The common place of sacrifice in most cults is an altar. The table type of altar is uncommon; more often it is only a pillar, a mound of earth, a stone, or a pile of stones. Among the Hebrews in early times and other Semitic peoples the altar of the god was frequently an upright stone (*matzzeva*) established at a place in which the deity had manifested itself. It was *bet el*, the "house of God."

Frequently, the altar is regarded as the centre or the image of the universe. For the ancient Greeks the grave marker (a mound of earth or a stone) was the earth altar upon which sacrifices to the dead were made and, like other earth altars, it was called the *omphalos*, "the navel" of the Earth—*i.e.*, the central point from which terrestrial life originated. In Vedic India the altar was regarded as a microcosm, its parts representing the various parts of the universe and its construction being interpreted as a repetition of the creation of the cosmos.

Method of sacrifice. Along with libation and the sacrificial effusion of blood, one of the commonest means of making an oblation available to sacred beings is to burn it. In both ancient Judaism and Greek religion the major offering was the burnt or fire offering. Through the medium of the fire, the oblation was conveyed to the divine recipient. In ancient Greece the generic term for sacrifice (*thysia*) was derived from a root meaning to burn or to smoke. In Judaism the important sacrifices (*'ola* and *zevah*) involved the ritual burning, either entirely or in part, of the oblation, be it animal or vegetation. For the Babylonians, also, fire was essential to sacrifice, and all oblations were conveyed to the gods by the fire god *Girru-Nusku*, whose presence as intermediary between the gods and men was indispensable. In the Vedic cult the god of fire, *Agni*, received the offerings of men and brought them into the presence of the gods.

As burning is often the appropriate mode for sacrifice to celestial deities, so burial is often the appropriate mode for sacrifice of Earth deities. In Greece, for example, sacrifices to the chthonic or underworld powers were frequently buried rather than burned or, if burned, burned near the ground or even in a trench. In Vedic India the blood and entrails of animals sacrificed on the fire altar to the sky gods were put upon the ground for the Earth deities, including the ghosts and malevolent spirits. In West Africa yams and fowls sacrificed to promote the fertility of the Earth are planted in the soil.

In sacrifice by burning and by burial, as also in the effusion of blood, the prior death of the human or animal victim, even if ritually performed, is in a sense incidental to the sacrificial action. There are, however, sacrifices (including live burial and burning) in which the ritual killing is itself the means by which the offering is effected. Illustrative of this method was the practice in ancient Greek and Indian cults of making sacrifices to water gods by drowning the oblations in sacred lakes or rivers. Similarly, the Norse cast human and animal victims over cliffs and into wells and waterfalls as offerings to the divinities dwelling therein. In the Aztec sacrifice of human beings

to the creator god *Xipe Totec*, the victim was lashed to a scaffold and shot to death with bow and arrow.

There are also sacrifices that do not involve the death or destruction of the oblation. Such were the sacrifices in ancient Greece of fruits and vegetables at the "pure" (*katharos*) altar of Apollo at Delos, at the shrine of Athena at Lindus, and at the altar of Zeus in Athens. These "fireless oblations" (*apura hiera*) were especially appropriate for the deities of vegetation and fertility; *e.g.*, Demeter and Dionysus. In Egypt bloodless offerings of food and drink were simply laid before the god on mats or a table in a daily ceremony called "performing the presentation of the divine oblations." In both Greek and Egyptian cults such offerings were never to be eaten by the worshippers, but they were probably surreptitiously consumed by the priests or temple attendants. In ancient Israel, on the other hand, the food offerings of the "table of the shewbread" (the "bread of the presence" of God) were regarded as available to the priests and could be given by them to the laity. In Hinduism the daily offering of cooked rice and vegetable, after its consecration, is distributed by the priests to the worshippers as the deity's "grace" (*prasāda*). In some cases the sacrificial gifts are put out to be eaten by an animal representative of the deity. In Dahomey wandering dogs consume, on behalf of the trickster deity *Eshu* (*Elegba*), the consecrated food oblations presented to the god each morning at his shrines.

Recipient of the sacrifice. Sacrifices may be offered to beings who can be the object of religious veneration or worship. They will not be made to human beings unless they have first been deified in some way. In some cases sacrifice is made only to the god or gods; in others it is made to the deity, the spirits, and the departed; in others it is made only to the spirits and the departed, who are considered intermediaries between the deity and men. The Nkole people of Uganda, for example, are said to make no sacrifices to God, thinking he does not expect any. But, on the third day following the New Moon, they make offerings to the guardian spirits (*emandwa*), and they also make offerings at the shrines of ancestors (*emizimu*) of up to three generations back. Worship of spirits and of ancestors, often including the offering of sacrifices, occurs in widely distributed cultures; in fact, according to some scholars, probably the major recipients of sacrifice in non-Western traditions are the ancestors (see ANCESTOR WORSHIP).

Intentions. Sacrifices have been offered for a multiplicity of intentions, and it is possible to list only some of the most prominent. In any one sacrificial rite a number of intentions may be expressed, and the ultimate goal of all sacrifice is to establish a beneficial relationship with the sacred order, to make the sacred power present and efficacious.

Propitiation and expiation. Serious illness, drought, pestilence, epidemic, famine, and other misfortune and calamity have universally been regarded as the workings of supernatural forces. Often they have been understood as the effects of offenses against the sacred order committed by individuals or communities, deliberately or unintentionally. Such offenses break the relationship with the sacred order or impede the flow of divine life. Thus, it has been considered necessary in times of crisis, individual or communal, to offer sacrifices to propitiate sacred powers and to wipe out offenses (or at least neutralize their effects) and restore the relationship.

Among the Yoruba of West Africa, blood sacrifice must be made to the gods, especially the Earth deities, who, as elsewhere in Africa, are regarded as the divine punishers of sin. For the individual the oblation may be a fowl or a goat; for an entire community it may be hundreds of animals (in former days, the principal oblation was human). Once consecrated and ritually slain, the oblations are buried, burnt, or left exposed but never shared by the sacrificer.

In ancient Judaism the *ḥaṭṭat*, or "sin offering," was an important ritual for the expiation of certain, especially unwittingly committed, defilements. The guilty laid their hands upon the head of the sacrificial animal (an *unblem-*

"Fireless oblations"

Burning, burying, and ritual killing

Atonement
in Judaism
and
Chris-
tianity

ished bullock or goat), thereby identifying themselves with the victim, making it their representative (but not their substitute, for their sins were not transferred to the victim). After the priest killed the beast, blood was sprinkled upon the altar and elsewhere in the sacred precincts. The point of the ritual was to purify the guilty and to re-establish the holy bond with God through the blood of the consecrated victim. It was as such an expiatory sacrifice that early Christianity regarded the life and death of Christ. By the shedding of his blood, the sin of mankind was wiped out and a new relationship of life—eternal life—was effected between God and man. Like the innocent and "spotless" victim of the *ḥaṭṭa't*, Christ died for men—i.e., on behalf of but not in place of them. Also, like the *ḥaṭṭa't*, the point of his death was not the appeasement of divine wrath but the shedding of his blood for the wiping out of sin. The major differences between the sacrifice of Christ and that of the *ḥaṭṭa't* animal are that (1) Christ's was regarded as a voluntary and effective sacrifice for all men and (2) his was considered the perfect sacrifice, made once in time and space but perpetuated in eternity by the risen Lord.

There are sacrifices, however, in which the victim does serve as a substitute for the guilty. In some West African cults a person believed to be under death penalty by the gods offers an animal substitute to which he transfers his sins. The animal, which is then ritually killed, is buried with complete funeral rites as though it were the human person. Thus the guilty person is dead, and it is an innocent man who is free to begin a new life.

Finally, some propitiatory sacrifices are clearly prophylactic, intended to avert possible misfortune and calamity, and as such they are really bribes offered to the gods. Thus, in Dahomey libations and animal and food offerings are frequently made to a variety of Earth spirits to ensure their good favour in preventing any adversity from befalling the one making the offering.

Gift sacrifices. Although all sacrifice involves the giving of something, there are some sacrificial rites in which the oblation is regarded as a gift made to a deity either in expectation of a return gift or as the result of a promise upon the fulfillment of a requested divine favour. Gift sacrifices have been treated above. Here, it can be briefly noted that numerous instances of the votive offering are recorded. In ancient Greece sacrifices were vowed to Athena, Zeus, Artemis, and other gods in return for victory in battle. The solemnity and irrevocability of the votive offering is seen in the Old Testament account of the judge Jephthah's sacrifice of his only child in fulfillment of a vow to Yahweh.

Thank offerings. One form of thank offering is the offering of the first fruits in agricultural societies. Until the first fruits of the harvest have been presented with homage and thanks (and often with animal sacrifices) to the deity of the harvest (sometimes regarded as embodied in the crop), the whole crop is considered sacred and thus taboo and may not be used as food. The first-fruits sacrifice has the effect of "desacralizing" the crops and making them available for profane consumption. It is a recognition of the divine source and ownership of the harvest and the means by which man is reconciled with the vegetational, chthonic powers from whom he takes it.

Fertility. Another distinctive feature of the first-fruits offering is that it serves to replenish the sacred potencies of the earth depleted by the harvest and to ensure thereby the continued regeneration of the crop. Thus, it is one of many sacrificial rites that have as their intention the seasonal renewal and reactivation of the fertility of the earth. Fertility rites usually involve some form of blood sacrifice—in former days especially human sacrifice. In some human sacrifices the victim represented a deity who "in the beginning" allowed himself to be killed so that from his body edible vegetation might grow. The ritual slaying of the human victim amounted to a repetition of the primordial act of creation and thus a renewal of vegetational life (see above *Theories of Jensen and Freud*). In other human sacrifices the victim was regarded as representing a vegetation spirit that annually died at harvest time so that it might be reborn in a new crop. In still other

sacrifices at planting time or in time of famine, the blood of the victim—animal or human—was let upon the ground and its flesh buried in the soil to fertilize the earth and recharge its potencies.

Building sacrifices. Numerous instances are known of animal and human sacrifices made in the course of the construction of houses, shrines, and other buildings, and in the laying out of villages and towns. Their purpose has been to consecrate the ground by establishing the beneficent presence of the sacred order and by repelling or rendering harmless the demonical powers of the place. In some West African cults, for example, before the central pole of a shrine or a house is installed, an animal is ritually slain, its blood being poured around the foundations and its body being put into the posthole. On the one hand, this sacrifice is made to the Earth deities and the supernatural powers of the place—the real owners—so that the human owner may take possession and be ensured against malevolent interferences with the construction of the building and its later occupation and use. On the other hand, the sacrifice is offered to the cult deity to establish its benevolent presence in the building.

Mortuary sacrifice. Throughout the history of man's religions, the dead have been the recipients of offerings from the living. In ancient Greece an entire group of offerings (*enagismata*) was consecrated to the dead; these were libations of milk, honey, water, wine, and oil poured onto the grave. In India water and balls of cooked rice were sacrificed to the spirits of the departed. In West Africa, offerings of cooked grain, yams, and animals are made to the ancestors residing in the Earth. The point of such offerings is not that the dead get hungry and thirsty, nor are they merely propitiatory offerings. Their fundamental intention seems to be that of increasing the power of life of the departed. The dead partake of the life of the gods (usually the chthonic deities), and sacrifices to the dead are in effect sacrifices to the gods who bestow never-ending life. In Hittite funeral rites, for example, sacrifices were made to the sun god and other celestial deities—transcendent sources of life—as well as to the divinities of Earth.

Communion sacrifices. Communion in the sense of a bond between the worshipper and the sacred power is fundamental to all sacrifice. Certain sacrifices, however, promote this communion by means of a sacramental meal. The meal may be one in which the sacrificial oblation is simply shared by the deity and the worshippers. Of this sort were the Greek *thysia* and the Jewish *zevak* sacrifices in which one portion of the oblation was burned upon the altar and the remainder eaten by the worshippers. Among the African Yoruba special meals are offered to the deity; if the deity accepts the oblation (as divination will disclose), a portion of the food is placed before his shrine while the remainder is joyfully eaten as a sacred communion by the worshippers. The communion sacrifice may be one in which the deity somehow indwells the oblation so that the worshippers actually consume the divine; e.g., the Hindu *soma* ritual. The Aztecs twice yearly made dough images of the sun god Huitzilopochtli that were consecrated to the god and thereby transubstantiated into his flesh to be eaten with fear and reverence by the worshippers.

meal

SACRIFICE IN THE RELIGIONS OF THE WORLD

The constituent elements of sacrifice have been incorporated into the particular religions and cultures of the world in various and often complex ways. A few brief observations that may illustrate this variety and complexity are given here.

Religions of India. Speculations regarding sacrifice and prescribed rituals seem to have been worked out more fully in the Vedic and later Hindu religion in India than anywhere else. These rites, laid down in a complicated system known mainly from the *Brāhmaṇa* texts, included obligatory sacrifices following the course of the year or the important moments in the life of an individual and optional sacrifices occasioned by the special wishes of a sacrificer. Yet cultic sacrifice has not developed in Buddhism, another religion that arose in India. Ritual sacri-

fice was judged to be ineffective and in some of its forms to involve cruelty and to run counter to the law of *ahimsā*, or non-injury. There are, however, in the *Jātaka* stories of the Buddha's previous births accounts of his self-sacrifices. Furthermore, Buddhism emphasizes the notion of ethical sacrifices, acts of self-discipline; and there are instances of devotional offerings, such as burnt incense, to the Buddha.

Religions of China. In China sacrifice, like other aspects of religion, has existed at a number of different levels. The essential feature of Imperial worship in ancient China was the elaborate sacrifices offered by the emperor himself to Heaven and Earth. There are also records of sacrifice, including human sacrifice, associated with the death of a ruler because it was thought proper for him to be accompanied in death with those who served him during life. But, because the common people were excluded from participation in Imperial sacrifices, they had lesser gods—some universal, some local—to whom sacrifices were made. Furthermore, ancestor worship has been the most universal form of religion throughout China's long history; it was the responsibility of the head of a household to see to it that sacrificial offerings to the dead were renewed constantly. The blending of these elements with such established religions as Buddhism and Taoism influenced the great diversification of sacrificial rites in China.

Religions of Japan. In ancient Japan offering occupied a particularly important place in religion because the relationship of the people to their gods seems frequently to have had the character of a bargain rather than of adoration. It is probable that the offerings were originally individual, but they gradually became collective, especially as all powers, including religious, were concentrated in the hands of the emperor, who officiated in the name of all his people. Human sacrifice to natural deities and at burials was once common but seems generally to have been abandoned in the early Middle Ages. Besides human sacrifices and their more modern substitutes, the Japanese offered to the gods all the things that man regards as necessary (e.g., food, clothing, shelter) or merely useful and pleasing (e.g., means of transportation, tools, weapons, objects of entertainment) for life. These practices, which were found in the traditional religion known as *Shintō*, were modified when Confucianism and Buddhism were introduced into Japan during the 5th and 6th centuries AD.

Ancient Greece. The Homeric poems contain the most complete descriptions of sacrificial rites in ancient Greece. These rites, which were maintained almost without change for more than 10 centuries, were of two types: rites (*thysia*) addressed to the Olympian deities, which

included burning part of a victim and then participating in a joyful meal offered to the gods during the daytime primarily to serve and establish communion with the gods; and rites (*sphagia*) addressed to the infernal or chthonic deities, which involved the total burning or burying of a victim in a sombre nocturnal ceremony to placate or avert the malevolent chthonic powers. Besides the official or quasi-official rites, the popular religion, already in Homer, comprised sacrifices of all kinds of animals and of vegetables, fruits, cheese, and honey offered as expiation, supplication, or thanksgiving by worshippers belonging to all classes of society. Furthermore, the secret worship of what are known as the mysteries—cults normally promising immortality or some form of personal relationship with a god—became widespread. This practice became especially prominent during the Hellenistic period.

Judaism. The destruction of the Second Temple in AD 70 marked a profound change in the worship of the Jewish people. Before that event, sacrifice was the central act of Israelite worship; and there were many categories of sacrificial rites that had evolved through the history of the Jews into a minutely detailed system found in that part of the Torah (Law; the first five books of the Hebrew Bible) that is ascribed by biblical scholars to the Priestly Code, which became established following the Babylonian Exile (586–538). The sacrificial system ceased, however, with the destruction of the Temple, and prayer took the place of sacrifices. In modern Judaism the Orthodox prayer books still contain prayers for the re-institution of the sacrificial cult in the rebuilt Temple. Reform Judaism, however, has abolished or modified these prayers in keeping with the conception of sacrifice as a once adequate but now outmoded form of worship, and some Conservative congregations have also rephrased references to sacrifices so that they indicate solely past events without implying any hope for the future restoration of the rite.

Christianity. The notion of sacrifice emerged in the early Christian communities in several different contexts. The death of Christ upon the cross preceded by the Last Supper was narrated in the Gospels in sacrificial terms; the life of Christ, culminating in his Passion and death, was seen as the perfect sacrifice, and his Resurrection and glorification were seen as God the Father's seal of approval on that life. The notion that members of the church are vitally linked to Christ and that their lives must be sacrificial was also elaborated, especially in the letters of St. Paul. Moreover, from the first decades of the church's existence, the celebration of the eucharistic meal was connected with the sacrifice of Jesus; it was a "memorial" (*anamnēsis*)—a term denoting some sort of identity

The
Eucharist
as
sacrifice

between the thing so described and that to which it referred—of that sacrifice.

The interpretation of sacrifice and particularly of the Eucharist as sacrifice has varied greatly within the different Christian traditions, partly because the sacrificial terminology in which the Eucharist was originally described became foreign to Christian thinkers. In short, during the Middle Ages, the Eastern Church viewed the Eucharist principally as a life-giving encounter with Christ the Resurrected; the Roman Church, however, saw it primarily as a bloodless repetition of the bloody sacrifice of Christ on the cross. For the Protestant Reformers in the 16th century, the sacrifice of Christ was unique and all sufficing, so that the idea of repeating it in cult became unnecessary. Sacrifice was separated from liturgy and was associated, especially in Calvinist Protestantism, with the personal ethical acts that should be made by a Christian believer. The ecumenical movement of the 20th century, bolstered by modern biblical scholarship, has led some of the Christian churches—e.g., the Roman Catholic and Lutheran churches—to realize that they are not so far apart in their understanding of the Eucharist as sacrifice as was formerly thought and that they hold many elements of belief in common.

Islām. Sacrifice has little place in orthodox Islām. Faint shadows of sacrifice as it was practiced by the pre-Islāmic Arabs have influenced Muslims, so that they consider every slaughter of an animal an act of religion. They also celebrate feasts in fulfillment of a vow or in thanksgiving for good fortune, but there is no sacrificial ritual connected with these festive meals. On the last day of the annual pilgrimage to Mecca, animals are sacrificed; nevertheless, it is not the sacrificial rite that is important to the Muslims, but rather their visit to the sacred city.

Conclusion. The organization of sacrificial rites in the different cultures and religions has undoubtedly been influenced by a number of factors. Economic considerations, for example, certainly have had some impact upon primitive peoples in the selection of the victim and the time of sacrifice and in the determination of whether the victim is consumed or totally destroyed and whether the sacrificer is an individual or a collective group. The importance of such factors is an aspect of sacrifice that deserves increased investigation. Nevertheless, sacrifice is not a phenomenon that can be reduced to rational terms; it is fundamentally a religious act that has been of profound significance to individuals and social groups throughout history, a symbolic act that establishes a relationship between man and the sacred order. For many peoples of the world, throughout time, sacrifice has been the very heart of their religious life.

BIBLIOGRAPHY

General treatments of sacrifice: Classic formulations of theories of the origin and nature of sacrifice are found in: EDWARD B. TYLOR, *Primitive Culture*, 2 vol. (1871, reprinted 1958), a presentation of the gift theory of sacrifice; W. ROBERTSON SMITH, *Lectures on the Religion of the Semites*, 3rd ed. (1927), the clearest formulation of the author's theory of communion through a sacrificial meal; JAMES G. FRAZER, *The Golden Bough*, 3rd ed., 12 vol. (1907–15; abridged ed., *The New Golden Bough*, 1964), a famous and influential treatise on ancient religion that advanced the notion of sacrifice as a means for rejuvenating a god; HENRI HUBERT and MARCEL MAUSS, "Essai sur la nature et la fonction du sacrifice," *L'Année sociologique* (1898; Eng. trans., *Sacrifice: Its Nature and Function*, 1964), a sociological approach that explained the sacrificial victim as a buffer between man and the god. More recent formulations include: GERARDUS VAN DER LEEUW, *Phänomenologie der Religion* (1933; Eng. trans., *Religion in Essence and Manifestation*, 1938), an expansion of the notion of the sacrificial gift by a phenomenologist of religion; ADOLF E. JENSEN, *Mythos und Kult bei Naturvölkern*, rev. ed. (1960; Eng. trans., *Myth and Cult Among Primitive Peoples*, 1963), which correlates types of cultures and their sacrifice; RAYMOND FIRTH, "Offering and Sacrifice: Problems of Organization," in W.A. LESSA and E.Z. VOGT, (eds.), *Reader in Comparative Religion*, 3rd ed., pp. 185–194 (1971), an economic interpretation of sacrifice; and E.O. JAMES, *Sacrifice and Sacrament* (1962), a good survey.

Treatments of sacrifice in particular religions and civilizations: Brief articles on several religions are found in "Sacrifice," in JAMES HASTINGS (ed.), *Encyclopaedia of Religion and Ethics*, vol. 11, pp. 1–39 (1928, reprinted 1955). On Vedic religion, A.B. KEITH, *The Religion and Philosophy of the Veda and Upanishads*, 2 vol. (1925), is still a standard work; LOUIS RENOU, *Religions of Ancient India* (1953), offers a brief survey. On Chinese sacrificial rites, see C.K. YANG, *Religion in Chinese Society* (1961); on ancient Egypt, J.H. BREASTED, *The Elder Development of Religion and Thought in Ancient Egypt* (1912); and on ancient Greek and Roman religions, R.K. YERKES, *Sacrifice in Greek and Roman Religions and Early Judaism* (1952), a clearly written, well-documented work; M.P. NILSSON, *Geschichte der griechischen Religion*, 2nd ed., 2 vol. (1941–50; Eng. trans., *A History of Greek Religion*, 2nd ed., 1963), the best handbook on the whole subject of Greek religion. On sacrificial rites in Judaism there is extensive literature, including the article "Sacrifice" in the *Encyclopedia Judaica*, vol. 14, pp. 599–615 (1971), which offers a good survey with a bibliography; ROLAND DE VAUX, *Les Sacrifices de l'Ancien Testament* (1964; Eng. trans., *Studies in Old Testament Sacrifice*, 1964); and YERKES (above). On ancient Scandinavian rites, see E.O.G. TURVILLE-PETRIE, *Myth and Religion of the North* (1964); on the rites of the ancient civilizations of the American continents, WALTER KRICKBERG et al., *Die Religionen des Alten Amerika* (1961; Eng. trans., *Pre-Columbian American Religions*, 1968). On the religions of the peoples of Africa, JOHN S. MBITI, *Concepts of God in Africa* (1970), is an introduction with extensive bibliography. Important specific studies include: MELVILLE HERSKOVITS, *Dahomey*, 2 vol. (1938); E.E. EVANS-PRITCHARD, *Nuer Religion* (1956); E.B. IDOWU, *Olódūmarè: God in Yoruba Belief* (1962); and GEOFFREY PARRIND-ER, *West African Religion*, 2nd ed. rev. (1961).

(R.F.)

Sade, Marquis de

Count Donatien-Alphonse-François de Sade, better known as the Marquis de Sade, was the author of erotic and licentious writings from which developed the concept of "sadism," meaning a sexual compulsion to achieve gratification by inflicting pain on others. In the course of a life that scandalized his contemporaries, he lived out many examples of his compulsion. His writings are still officially banned by the French courts. As an author, Sade is to some an incarnation of absolute evil who advocates the unleashing of instincts even to the point of crime. Others have looked upon him as a champion of man's total liberation through the satisfaction of his desires in all forms. Sade's works were widely read (mostly "underground") in the 19th century, especially by writers and artists. At the outset of the 20th century the French poet Guillaume Apollinaire helped to establish Sade's status in the domain of culture. Today Sade's writings belong to the history of ideas and mark an important moment in the history of literature—with Sade figuring as the first of the modern *écrivains maudits* (the "damned writers").

Related to the royal house of Condb, the Sade family numbered among its ancestors Laure de Noves, whom the 14th-century Italian poet Petrarch immortalized in verse. When the Marquis was born on June 2, 1740, at the Condé mansion, his father was on a diplomatic mission at the court of the Elector of Cologne; his mother, Marie Elénore Maillé de Carman, was lady-in-waiting to the Princess de Condé. He inherited estates in France from the seigneurie of Saumane, La Coste, and from the co-seigneurie of Mazan, as well as domains in the provinces of Bugey, Valromey, and Gex.

After early schooling with his uncle, Abbb de Sade of Ébreuil, he continued his studies at the Lycée Louis-le-Grand in Paris. His aristocratic background entitled him to various ranks in the king's regiments, and in 1754 he began a military career, which he abandoned in 1763 at the end of the Seven Years' War. In that year he married the daughter of a high-ranking bourgeois family *de robe* (of the magistracy), the Montreuil. His wife's father was president of the Parisian Parlement, a judicial and legislative body under the monarch. By her he had two sons, Louis-Marie and Donatien-Claude-Armand, and one daughter, Madeleine-Laure.

In the very first months of his marriage he began an

Heritage
and youth

affair with an actress, La Beauvoisin, who had had numerous previous protectors. He invited prostitutes to his "little house" at Arcueil and subjected them to various sexual abuses. For this he was imprisoned, on orders of the King, in the fortress of Vincennes. Freed several

First
public
scandal

weeks later, he resumed his life of debauchery and went deeply into debt. In 1768 the first public scandal erupted: the Rose Keller affair.

Rose Keller was a young prostitute he had met on Easter Sunday in Paris. He took her to his house in Arcueil, where he locked her up and abused her sexually. She escaped and related the unnatural acts and brutality to persons in the neighbourhood, as well as showing them her wounds. Sade was sentenced to the fortress of Pierre-Encise, near Lyons.

After his release he retired to his château of La Coste. In June 1772 he went to Marseilles to get some much-needed money. There he engaged his male servant Latour to find him some prostitutes, upon whom the Marquis committed his usual sexual excesses. (Meanwhile, at his bidding, Latour engaged in sodomy with him.) The young women helped themselves liberally to the Marquis' pill-box filled with candies that contained the aphrodisiac Spanish fly. When soon thereafter they suffered upset stomachs, they feared they had been poisoned. Sade and Latour fled to the estates of the King of Sardinia, who had them arrested. The Parlement at Aix sentenced them to death by default and, on September 12, 1772, executed them "in effigy." After escaping from the fortress of Miolans, Sade took refuge in his château at La Coste, rejoining his wife. She became his accomplice and shared his pleasures, until the parents of the neighbourhood boys and girls he had abducted complained to the crown prosecutor. Sade fled to Italy accompanied by his sister-in-law, the Canoness of Launay, who had become his mistress. He returned to La Coste on November 4, 1776. One incident followed another in an atmosphere of continual scandal, and, on his return to Paris, the Marquis was arrested and sent to the dungeon of Vincennes on February 13, 1777.

Detention
at
Vincennes

Conditions in this prison were harsh. During his detention Sade quarrelled with his jailer, with the prison director, and with a fellow prisoner, Victor Riqueti, the Marquis de Mirabeau, whom he had insulted. He tried to incite the other prisoners to revolt. Visits from his wife, who was eventually allowed to see him, were banned after an episode in which he fell into a fit of jealous rage precipitated by his suspicion that she was about to leave him and was plotting against him. The Marquis retired to a convent.

Sade overcame his boredom and anger in prison by writing sexually graphic novels and plays. In July 1782 he

finished his *Dialogue entre un prêtre et un moribond* (*Dialogue Between a Priest and a Dying Man*), in which he declared himself an atheist. His letters to his lawyer as well as to his wife combine incisive wit with an implacable spirit of revolt. On February 27, 1784, he was transferred to the Bastille in Paris. On a roll of paper some 12 metres (39 feet) long, he wrote *Les 120 Journées de Sodome* (*One Hundred and Twenty Days of Sodom*), in which he graphically describes numerous varieties of sexual perversion. In 1787 he wrote his most famous work, *Les Infortunes de la vertu* ("The Adversities of Virtue"), and, in 1788, the novellas, tales, and short stories later published in the volume entitled *Les Crimes de l'amour* (*Crimes of Passion*).

A few days before the French Revolutionaries stormed the Bastille on July 14, 1789, Sade had shouted through a window, "They are massacring the prisoners; you must come and free them." He was transferred to the insane asylum at Charenton, where he remained until April 2, 1790.

On his release, Sade offered several plays to the Comédie-Française as well as to other theatres. Though five of them were accepted, not all of them were performed. Separated from his wife, he lived now with a young actress, the Widow Quesnet, and wrote his novels *Justine, ou les malheurs de la vertu* (*Justine; or, the Misfortunes of Virtue*) and *Juliette*. In 1792 he became secretary of the Revolutionary Section of Les Piques in Paris, was one of the delegates appointed to visit hospitals in Paris, and wrote several patriotic addresses. During the Reign of Terror he saved the life of his father-in-law, Montreuil, and that of the latter's wife, even though they had been responsible for his various imprisonments. He gave speeches on behalf of the Revolution, but was nevertheless accused of *modérantisme* ("moderatism") and mistakenly inscribed on the list of *émigrés*. He escaped the guillotine by chance, the day before the Revolutionary leader Robespierre was overthrown. At the time he was living with the Widow Quesnet in conditions of abject poverty.

On March 6, 1801, he was arrested at his publisher's where copies of *Justine* and *Juliette* were found with notes in his hand and several handwritten manuscripts. Again he was sent to Charenton, where he caused new scandals. His repeated protests had no effect on Napoleon, who saw to it personally that Sade was deprived of all freedom of movement. Nevertheless he succeeded in having his plays put on at Charenton, with the inmates themselves as the actors. He began work on an ambitious ten-volume novel, at least two volumes of which were written: *Les Journées de Florbelle ou la nature dévoilée* ("The Days of Florbelle or Nature Unveiled"). After his death on December 2, 1814, his elder son burned these writings, together with other manuscripts.

His remains were scattered. There is no portrait of him. In his will, drawn up in 1806, he asked that "the traces of my grave disappear from the face of the earth, as I flatter myself that my memory will be effaced from the mind of men."

MAJOR WORKS

Justine, ou les malheurs de la vertu (1791; *Justine; or, The Misfortunes of Virtue*, new trans. by Helen Weaver, 1966); *Les Infortunes de la vertu*, another version of *Justine* (1930 and 1946); *La Nouvelle Justine . . . suivie de l'histoire de Juliette sa soeur* (1797; *The Complete Justine, Philosophy in the Bedroom, and Other Writings*, comp. and trans. by Richard Seaver and Austryn Wainhouse, 1966); *Juliette, ou la suite de Justine* (published in the last 6 vol. of the 1797 *Nouvelle Justine* edition; Eng. trans. by Austryn Wainhouse, 1 vol., 1968); *Aline et Valcour, ou le roman philosophique. Écrit à la Bastille, un an avant la Révolution de France* (1793); *La Philosophie dans le boudoir* (1795; see Seaver-Wainhouse trans. above); *Les Crimes de l'amour, nouvelles héroïques et tragiques, précédées d'une idée sur les romans* (Year VIII, 1800; *Crimes of Passion*, ed. and trans. by Wade Baskin, 1965); *Historiettes, contes et fabliaux* (1926-27); *Les 120 Journées de Sodome, ou l'école du libertinage*, 3 vol. (1931-35; *The 120 Days of Sodom, and Other Writings*, comp. and trans. by Austryn Wainhouse and Richard Seaver, 1966); *Dialogue entre un prêtre et un moribond* (1926; *Dialogue Between a Priest and a Dying Man*, 1927); *Oxtiern*,

Composi-
tion of
Justine and
Juliette

ou les malheurs du libertinage (Year VIII, 1800); *Correspondance in'edite du marquis de Sade*, ed. by Paul Bourdin (1929); *Lettres choisies*, ed. by Gilbert Lty (1963); *Selected Letters*, trans. by W.J. Strachan, ed. by Margaret Crosland, (1966).

BIBLIOGRAPHY. The *Oeuvres complètes* of the Marquis de Sade have been in the course of publication since 1962. Numerous recent editions of the major works of the Marquis exist, certain of which are tolerated by censorship, others whose publication always falls within the provisions of law. One man, above all, had linked his name to these publications — MAURICE HEINE, who died in 1940. He published the first version of *Justine*, under the title *Les Infortunes de la vertu* (1930); collected the stories which make up the volume *Historiettes, contes et fabliaux* (1926–27); published the manuscript of *Les 120 Journées de Sodome, ou l'école du libertinage*, 3 vol. (1931–35); revealed the existence of the *Dialogue entre un prêtre et un moribond* (1926); put together an anthology under the title *Oeuvres choisies et pages magistrales du Marquis de Sade* (1933); and undertook a biography that remained unfinished, and was published in 1950 under the title *Le Marquis de Sade*. Other biographical studies are GILBERT LELY, *La Vie du Marquis de Sade*, 2 vol. (1952–57; Eng. trans., 1961; paperback edition, 1970); and GEOFFREY GORER, *The Life and Ideas of the Marquis de Sade* (1963).

The works of Sade have provoked studies and commentaries by several contemporary French writers. The most remarkable of these studies come as prefaces to the publication of the works: that of GEORGES BATAILLE for *Justine, ou les malheurs de la vertu* (1930); that of JEAN PAULHAN for *Les Infortunes de la vertu* (1946); and that of MAURICE NADEAU for the most complete anthology to date: *Marquis de Sade, Oeuvres* (1948). The philosophical exegesis of Sade's work was undertaken by PIERRE KLOSSOWSKI in a fundamental, though debatable, work — *Sade, mon prochain* (1947); while MAURICE BLANCHOT expressed the most pertinent views in *Lautréamont et Sade* (1949). See also SIMONE DE BEAUVOIR, *The Marquis de Sade* (Eng. trans. 1962), with selections from his writings. ROLAND BARTHES has studied Sade from a point of view that owes a great deal to structuralism and to the science of language: *Sade, Fourier, Loyola* (1972).

(M.Na.)

Safety Engineering

Safety engineering is that profession concerned with the scientific analysis of the causes of accidental deaths and injuries in a given environment and their elimination or reduction. In the industrialized areas of the world, accidents now cause more deaths than all infectious diseases and more than any single illness, except those related to cancer and heart disease. In 1967, some 459,000 accidental deaths occurred in 50 countries reporting to the World Health Organization. Of this number, 175,000 or 38 percent occurred in motor vehicle accidents. On a worldwide basis, motor vehicle accidents tend to be the primary cause of accidental deaths, followed by those in industry and in the home. Nonfatal injuries are far more frequent than deaths, but the pattern of frequency changes. In the United States, for example, each year about six times as many persons receive nonfatal injuries in accidents at home as in motor vehicle accidents, and about twice as many at home as in industrial accidents.

The most striking advances in safety during the last 40 or 50 years have been made in industry. Safety engineering has played an important role in this development. Between 1926 and 1961, the frequency rate for disabling injuries dropped from approximately 32 to 6 in the United States. After that year, however, there was no significant improvement. During the same period, both the number of accidental deaths and total disabilities in relation to the man-hours worked declined by almost 80 percent. The reduction in accident rates was the result of the cooperation of management and trained specialists in the fields of safety engineering, industrial hygiene, and industrial medicine in (1) reducing the hazards inherent in the equipment and working methods and (2) in educating employees in the basic principles of accident prevention. In many companies, the time lost from injuries that occur off the job constitutes a greater problem than that lost from accidents while at work.

An especially productive area for safety engineering has been that involving relatively stable industrial situations,

repetitive in nature, in which there are common accident factors that can be identified and controlled. The great majority of highway and nonoccupational accidents, on the other hand, are not homogeneous in regard to common variables. In addition, most such accidents have multiple causes, making it more difficult to introduce preventive measures. Consequently, in these areas the impact of safety engineering has not yet been so great.

DEVELOPMENT OF THE INDUSTRIAL SAFETY MOVEMENT

The initial stimulus for the industrial safety movement came from the largest industries, in which severe injuries and loss of life were common occurrences. Public opinion based on humanitarian motives was aroused in both Europe and the U.S., but the most significant advances did not occur until management became fully aware that accidents interrupted production, raised operating costs, and formed the basis for future injuries and loss of equipment.

In the 19th century, the safety of an employee was generally considered to be his own responsibility. The liability of the employer for accidental injuries depended on certain common-law doctrines that operated against the employee. The "fellow-servant" doctrine, for example, held that the employer was not responsible for employee injuries resulting from the action of a fellow worker. The "assumption of risk" doctrine stated that by accepting employment, the worker assumed any risks connected with it. Finally, the doctrine of "contributory negligence" absolved the employer from responsibility for injuries resulting from accidents if the employee had contributed to the cause in any degree.

Early
common-
law
liability
doctrines

An important segment of progressive industrial management saw the fallacies in these concepts and felt that management should do more for the safety of the workers. The social progress of the times was reflected in the development of the safety movement which was given impetus by workmen's compensation laws enacted in most of the industrial countries in the late 19th and early 20th centuries. A new concept was inherent in these laws, namely that the employer should accept primary responsibility for injuries incurred at work, even though they could not be attributed to any one person or cause. Industry became legally liable for injuries to its workers and became obligated to provide benefits during time lost from work, medical and surgical care, and death benefits to dependents.

Once it was recognized that disablement represented a part of the cost of industrial production and had to be incorporated in the price of the product, management had a strong economic incentive for preventing accidents. At the same time, workmen's compensation laws led to the rapid growth of casualty insurance as a means of furnishing protection to the employer. The insurance companies collaborated with industry in playing a major role in accident-prevention programs, developing methods of evaluating risks, and aiding employers in taking preventive action.

The three specialized skills—safety engineering, industrial hygiene, and industrial medicine—were developed as methods of preventing injury to the worker and of reducing costs. The first two aim at reducing the number of work injuries and disabilities in the occupational setting by removing their causes, and the third is concerned with minimizing the consequences of injury and disease and with restoring disabled workers to useful employment. The initial emphasis in safety engineering was on the installation of guards and protective devices; this led to a sudden, sharp decline in machine accidents, and today the rates for accidents involving machine hazards are only about half those of about 40 years ago. Industrial hygiene has concentrated on controlling environmental hazards: *i.e.*, the inhalation of toxic gases, fumes, and other harmful exposures. More recently there has been a growing emphasis on personal factors, including recognition of the role mental and emotional adjustment on the part of a worker may play in accidents.

From an emphasis on mechanical guarding and education of workers in safety, experience tended to shift the focus to an application of basic safety engineering principles in the design of machinery, plant layout, and working methods. More emphasis was placed on the role of supervisory personnel, and safety was recognized as an integral part of normal operating procedure. The role of personal errors and accident proneness has been dealt with by analysis of jobs and of the functional capacities of workers. Variables relating to the health of the worker have been stressed, and working methods have been modified to ensure an optimum working environment as far as employee health is concerned.

These developments were paralleled by a growing participation of various states in setting up supervisory and enforcement agencies. In addition, organizations such as the United States Bureau of Mines, the United States Department of Labor, the National Safety Council (NSC), the American National Standards Institute, the Underwriters' Laboratories, and various professional societies were formed in the United States and elsewhere. The Bureau of Mines, which was organized in 1912, has led in research and education pertaining to hazardous agents and their control; it sets the pattern for the mining industry. The NSC is the organization around which the general industrial safety movement evolves; it is a focal point of leadership in the safety movement. The other organizations have performed specialized and important functions. Safety principles have been incorporated into engineering courses, and departments of safety engineering have been established in various graduate and technical schools. The most important directing force for accident prevention, however, remains within industry itself. Although many outside agencies may contribute, the direct and immediate responsibility for the application of safety engineering principles, employee education, and on-the-job enforcement rests upon the individual employer. In most instances, laws represent only minimal requirements and are below the goal of ultimate objectives.

Accident frequency and severity rates. Most statistical analyses of accidents are based on either frequency or severity. Of the many systems devised, one—used by the American National Standards Institute—provides a substantial degree of standardization for comparative purposes. In this system, the standard frequency rate represents the number of disabling injuries per 1,000,000 man-hours of exposure. The standard severity rate is the total time charged as a result of lost-time injuries per 1,000,000 man-hours of exposure. The time charges include both actual days lost and certain standardized charges for permanent disabilities and deaths. The greatest penalties are imposed for death or permanent total disability, for each of which the time charges are arbitrarily set at 6,000 days per case. Various permanent partial-disability charges range from 35 to 4,500 days, in accordance with a prescribed schedule.

The frequency rate indicates how many injuries are occurring in relation to the number of man-hours worked, and the severity rate indicates how serious those injuries are in terms of days lost in relation to hours of exposure. The former has been most widely used and can be most quickly and easily computed. It does not, however, indicate the seriousness of an accident, since it merely gives the rate at which accidents are occurring. The severity rate was developed to meet this need and to give an expression of the total time lost per million man-hours of exposure. Other composite indexes usually involve weighted averages of some type, obtained by multiplying the severity rate by ten and adding the frequency rate.

The safety engineer is concerned with reducing both the frequency with which accidents occur and the frequency with which they threaten. He wants to know why a man fell off a ladder even if no serious injury resulted. The severity rate, which takes into account the extent and seriousness of the injuries, is also closely associated with the efficiency of the safety program. If an employee receives lacerations and abrasions in falling from a ladder,

prompt and adequate medical care will limit this to a first-aid case, whereas inadequate care may permit infection to occur.

Frequency and severity rates vary widely from one industry to another. Certain industries, such as communications, have low-frequency and low-severity rates; mining and lumbering are at the opposite extreme. These differences reflect not only the inherent dangers in an industry but also many other factors, including the efficiency of the safety program. In the electrical-equipment industry, hazards are limited and most injuries minor. In the steel industry, the frequency rates have been kept down by extensive accident-control programs, but the hazards are such that most of the accidents that do occur result in serious disabling injuries. In mining and lumbering, the men work more or less independently over a large area and direct supervision is quite difficult. Permanent safeguards are not widely applicable because the work location is constantly changing. The worker is very frequently his own protector from a mining machine, explosives, or axes.

Methods of evaluating safety programs. Various attempts have been made to obtain more useful and accurate indexes of the effectiveness of safety programs than the frequency and severity rates. One method is to obtain an estimate of the total direct and indirect costs of accidents. Another method is to find the "loss ratio," an index based on the amount paid for insurance compensation in terms of what might be expected on the basis of averages in a similar industry. A third method is to apply the techniques of statistical quality control to the accident record. This procedure gives an accurate index of whether the frequency of accidents is becoming excessive, or improving, in relation to past experience. Although none of these indexes give information as to what is wrong in the work situation, they alert management and safety directors. All are sufficiently quantitative to indicate the extent to which accidents can be reduced if effective efforts are applied.

The currently recommended approach is to define the total costs of work injuries and accidents as the sum of "insured" and "uninsured" costs. The former are simply the amount paid for compensation and medical insurance premiums. For the ascertainment of "uninsured" costs, methods and recording procedures have been developed to provide more reliable quantitative data. This involves the calculation of specific categories of uninsured costs for each of four classes of accidents: lost-time cases; injuries requiring the attention of a physician, but not loss of a day's work; first-aid cases; and accidents involving property damage and disruption of work.

Statistical control shows when increases or decreases in rates should be considered excessive and indicates other than chance variations in the work situation. The changes may reflect the introduction of new machines in which adequate safety features are not incorporated; the influx of new personnel without adequate training in safety practices; an increasing laxity in the supervision of employees by the foreman; or many other sources of trouble.

In summary, if the criteria of direct and indirect costs, loss ratio, or quality control are applied in evaluating the accident-injury rates of a plant, they will indicate to the safety engineer, medical officer, or management whether their accident rates are acceptable. An evaluation should include items relating to plant layout, housekeeping, maintenance, protective equipment, safety organization, medical facilities, and employee training. The degree of cooperation achieved between the safety engineer, the shop foremen, and medical officers is critical. Employee safety education is of paramount importance, especially if a relatively high proportion of the injuries are occurring in new and untrained workers. Finally, the effectiveness achieved will reflect the active participation of management at the higher executive levels.

Safety engineering as a profession. The field of safety engineering has not developed as a unified, specific discipline, and its practitioners have operated under a wide variety of position titles, job descriptions, responsibilities, and reporting levels in industry and the loss-prevention

Cost of
accidents

Standard
frequency
rate

activities of insurance companies. There has also been little uniformity in the development of educational programs in engineering schools and universities for the specialized training needed for this field.

The most recent trends include increased emphasis on prevention by the anticipation of hazard potentials; changing legal concepts concerning product liability and negligent design or manufacture, and the developing emphasis on consumer protection; and the development of national and international legislation and controls, not only in the areas of transportation safety, product safety, and consumer protection, but also in occupational health and environmental control.

Safety
engineer's
functions

Four general areas that have been identified as the major functions carried out by the professional safety engineer or safety professional are: (1) identification and appraisal of accident-producing conditions and practices and evaluation of the severity of the accident problem; (2) development of accident and loss-control methods, procedures, and programs; (3) communication of accident and loss-control information to those directly involved; and (4) measurement and evaluation of the accident and loss-control systems, and the modifications needed to obtain optimum results. Some of the more specific techniques developed and utilized in these functional areas will be subsequently outlined.

The basis for specific safety procedures. The safety engineer contributes to the prevention of accidents by using his specialized knowledge of accident causation and control by (1) seeking to eliminate hazards and causation factors, (2) designing machines and procedures to reduce the hazards, and (3) minimizing their effects by prescribing specialized equipment to prevent injury or reduce the severity.

The control of abnormal exchanges of energy. In studies of accidents, the "agent" of injury has often been identified as the environmental object; *e.g.*, loose floor board, or motor vehicle. A more comprehensive and more useful approach appears to be the understanding that all injuries (and damage to inanimate objects) result from abnormal exchanges of energy between persons and the environment (or objects and the environment). Thus, accidental injuries are considered to result from (1) the application of various forms of energy to the human body in amounts exceeding the tolerance thresholds of its various parts, or (2) interference with the normal exchanges of energy between the body and the environment (as in drowning). The forms of energy producing accidental injuries of all types would logically include thermal, electrical, radiant, mechanical, and chemical.

The concept of energy as the cause of injury presents a close analogy to the agent in the causation of disease. Each form of energy produces specific kinds of injury. Thermal energy impinging on the body, for example, may produce inflammation, coagulation, charring, and incineration at all body levels; *i.e.*, first-, second-, and third-degree burns. The specific result will depend on the location and manner in which the energy is dissipated. The energy that impinges on the body is delivered by various means, usually inanimate objects. Wires carry electricity, moving objects carry mechanical or kinetic energy, poisonous plants carry toxins. The modification of the carriers of injurious energy thus affords an important means of preventing injury.

Resistance
to injury

Another parallel to disease is the variation in natural or acquired resistance to injury, corresponding to resistance to infection. Increased susceptibility to mechanical injuries characterizes such conditions as hemophilia. Shifts in resistance with age and sex also occur. Thus, postmenopausal women, compared with men of comparable ages, more frequently suffer fractures in falls. One study has shown a positive correlation between the incidence of fractures and osteoporosis (wasting away of bone tissue). Thus, postmenopausal women suffer more fractures and osteoporosis than men of comparable age. Lower death rates from falls have been found in areas with naturally high fluorides in the water. Physical conditioning and training for contact sports increases the resistance to injury. Repeated or continuous exposure to moderately high

altitudes produces some tolerance to oxygen deficiency.

The prevention of abnormal exchanges of energy between the body and the environment can be achieved through interference in the early stages leading to the transfer event, or by directly blocking or attenuating the exchange. Four initial levels of prevention are: (1) elimination of the source of hazardous energy (*e.g.*, by prohibiting the manufacture of fireworks or of flammable blankets and clothing); (2) prevention or modification of its release (*e.g.*, by grounding of electrical appliances); (3) separation of the energy and the persons in time or space (*e.g.*, by unplugging the power cord of the television set before replacing a part); and (4) interposition of a barrier that blocks or attenuates the energy transfer between the energy source and the person (*e.g.*, providing a guard on a power saw, crash padding on dashboards, helmets for motorcyclists, and insulation on electrical appliances).

Engineering and medical collaboration. Two considerations are essential in devising barrier measures to prevent or attenuate injurious energy exchanges that result: the identification of the carriers or "vectors" of energy, which then may be modified; and a knowledge of injury thresholds of the human body in relation to the magnitude of the forces encountered in accident situations. These are of particular importance for the prevention of injury in motor-vehicle crashes, but little precise information has been available until recently. Information is being obtained from on-the-site medical-engineering analyses of accidents, experimental crashes of instrumented cars, and laboratory studies on injury thresholds using cadavers or animals.

Sources
of data

Classification of injuries and accidents. One of the most important functions of the safety engineer is to identify hazards in the working area and to evaluate the loss-producing aspects of a given method or operational system. In the past, a great deal of attention has been devoted to analyzing the existing hazards and products, while the newer methods involve not only learning from accidents that have occurred but also emphasizing the advance analysis of accident potentials and the prevention of accidents prior to their occurrence.

One widely used analysis of the circumstances of accidents includes the following: (1) identification and location of the materials, machines, and tools most frequently involved in accidents and the jobs most likely to produce injuries; (2) location of the departments and occupations involved; (3) disclosure of the unsafe practices, which may necessitate retraining or shifting of employees; (4) study of the role of supervisors, and provision of information about the principal hazards.

Significant factors include the type of physical injury incurred; the source of the injury in relation to the object, substance, or motion that inflicted it; the specific part of the material or agency that was hazardous; and finally, the unsafe act that took place, presumably in violation of commonly accepted safety practices. Other aspects include age, sex, occupation, and type of work being performed.

Advance analysis and critical incident technique. All possible faults in equipment and in the work areas in industry or in transport vehicles, as well as the capacities

Table 1: Advance Analysis of Equipment

Mock-up stage:	task performance physical size of operators age of operators skill levels accessory equipment interfering structures or motions physiological changes errors "near accidents"

of the operator, should be subjected to an advance analysis designed to prevent accidents. If defects are present, it is only a matter of time before some operator "fails" and has an accident.

Advance analysis assumes the following: (1) an operational job analysis that should include a survey of the nature of the task, the work surroundings, the location of controls and instruments, and the way the operator performs his duties (Table 1); (2) a "functional concept of accidents" (that is, anticipation of the errors that may occur while the operator is working at the machine). The repetition or recurrence of near or real accidents clearly indicates a need for redesign (Table 2); (3) an assumption of human limitations.

Table 2: Typical Human Errors in Equipment Operation

type of error	possible causal factors
Failure to detect signal	input overload: too many significant signals input underload: too little variety of signals too few signals adverse noise conditions: poor contrast high intensity of distraction stimuli
Incorrect identification of signal	code form or typology unclear lack of differential cues conflicting cues
Error of commission	correct tool or control not available action-control relationship not understood action feedback unavailable or delayed

A wide margin of safety should be provided to eliminate any possible situation that places the operator near his maximum ability with regard to aptitude or effort, especially when adverse factors, such as fatigue, are present.

Operational job analysis. One of the first steps in insuring safety on the job is an analysis of what is required of the individual worker, focussing on the hazardous features. Techniques involving "near accidents" are often revealing. Studies have been made of near accidents during routine bus operations at night and during the day to discover the number of variables involved in emergencies; how drivers reacted; the variety and frequency of critical situations; and the relations between near and real accidents.

The study revealed that as a rule critical situations develop rapidly and are of short duration. Of the 66 near accidents observed, 53 or 80 percent were closely related to the three most common types of accidents that actually occur on the highway, namely, sideswipe, rear-end, and head-on collisions.

The most important variables contributing to the critical situations were as follows: (1) following too closely; (2) following too closely while approaching to pass (cornering); (3) operator inattention—i.e., dozing at the wheel; (4) vehicle running off the road; (5) errors at intersection; (6) errors in passing; (7) operating in wrong lane of traffic; (8) leaving and entering the roadway; and (9) pedestrian errors.

It is possible that some of the near accidents are related to the personality and aptitude of the drivers or that certain drivers have a tendency to become involved in the same type of situation repeatedly. Observations thus far indicate a characteristic failure of most drivers to take defensive action at an early stage of a developing hazardous situation. This is found to have occurred in 95 percent of the 66 incidents observed. The implications are clear that studies of near accidents offer an unusual opportunity for training the driver to anticipate hazardous situations and to avoid them.

The critical-incident technique. One method of identifying unsafe conditions involves selecting a random sample of workers from various portions of the plant or population, exposed to various hazards. An interviewer questions the workers, asking them to describe near-miss safety errors they have made in the past, or unsafe conditions they have observed. The data are classified into hazard categories to illuminate factors which have contributed to an actual or potential loss-producing event. In

one large manufacturing plant 187 different unsafe acts or conditions were identified by an analysis of "near-misses." It was also found that 52 percent more unsafe acts and conditions were revealed by the critical-incident technique than had been identified from accident records compiled during the previous two-year period.

Systems safety engineering. In recent years, a great deal of attention has been devoted to "systems safety engineering." In brief, the primary objective of systems safety engineering is the reduction or elimination of all hazardous consequences of equipment operation in an industrial plant or similar large man-machine complex. It characteristically involves a systematic application of special analytical techniques, derived criteria, evaluation methodology, and management skills. Since it emphasizes prevention rather than correction of problems, particular attention is placed upon early engineering design and procedural analysis. It is broadly conceived to take into consideration all aspects of the planning, design, development, fabrication, test, installation, maintenance, operation, and overall evaluation of man-machine systems.

Until recently, when a new aircraft was developed, it first was designed, then an experimental model was constructed and test flown to determine its capabilities and faults. From this came information to make necessary design changes, and the process was repeated until the performance specifications were achieved. Present aircraft and missiles are too complex and costly for this procedure. Now the defects must be located and corrected as far as possible in the design stage, using the analytic techniques of systems analysis and the systems approach to safety. These procedures are applicable for all complex equipment and man-machine combinations.

Accidents result from deficiencies in human operation, defects in tools and mechanical equipment, and a variety of environmental influences. Usually failures are compound. An accident may include mechanical or electrical failure, defective materials, and such environmental conditions as extreme heat or noise levels inhibiting intercommunication. Human failure may derive from such factors as distraction, fatigue, worry, improper attitude, lack of skill, and taking chances.

One of the principal methods of analyzing potential failure of equipment is to trace through the system and detect the ultimate effect on the task being performed, such as a switch being jammed in the "on" position. The "failure mode and effect analysis" is straightforward, providing that the analyst is well informed. It has the drawback, however, of analyzing only one failure in the system at a time, and, thus, other possibilities may be overlooked.

In recent years, especially in the aircraft industry, the "fault-tree" method has been developed. In this plan, an undesired event is selected, and all of the possible happenings that can contribute to the event are diagrammed in the form of a tree. The branches of the tree are continued until independent events are reached. Mathematical probabilities for the independent events are determined and both the probability of the undesired event and the most likely chain of events leading to it can be computed.

One of the most difficult problems in analyzing the effectiveness of systems is to evaluate quantitatively the role of human errors in the degradation of the quality or effectiveness of a product. One of the newer methods of predicting errors in quantitative terms depends upon the calculation of rates at which errors occur in various operations.

The value of the systems-analysis approach for the safety engineer is to widen or enlarge his point of view. In visualizing the interrelationships of the various components that enter into accidents, it helps to change safety engineering from an art to a science by codifying much of the knowledge that has been derived, especially before or in advance of the occurrence of damaging events.

Design failures and human limitations. The concept of design failure appears to be promising. In many instances failures in the designing of equipment are so subtle that those responsible for analyzing and reporting accidents are not aware of them. Often because the designers of

Table 3: Limits for Variables Influencing Comfort and Safety

variable	desirable	maximum or minimum value for comfort
Ventilation	sufficient additional fresh or recirculated odour-free air to remove all odours	20 cubic feet (0.6 cubic metres) per minute of fresh air
Air temperature	ambient temperature adjusted to give effective temperature of 63–71° F (20–22° C) (winter) or 66–75° F (21–24° C) (summer)	70–72° F or 22° C
Air velocity	adjusted to ambient temperature to give appropriate cooling power without drafts	40–60 feet (12–18 metres) per minute
Humidity	adjusted to air temperature and velocity to maintain comfort	25–50 percent relative humidity
Carbon dioxide	not a requirement as long as ventilating requirements for removal of odours are met	0.5–1.0 percent
Carbon monoxide	none	0.003 percent
Noise	reduced to permit conversation at least 3 feet (900 millimetres) with no extra effort	80–85 decibels overall and 50–60 decibels in 1200–2400 hertz band
Vibration	reduced to below threshold of perception	0.002 inches (0.05 millimetres) at 20 hertz or more

equipment are unaware of human limitations no attempts are made to build the apparatus or working areas in relation to the wide range of human capabilities, differences, and limitations. This applies particularly to such problems as variations in body size of the working population, design and arrangement of controls and displays, and the influence of environmental factors on safety. Some of the basic principles in each of these areas are outlined below (see also HUMAN-FACTORS ENGINEERING).

Layout of working areas and human-sizing problems. In order to improve the ease, efficiency, and safety of operating all types of equipment in shops and hangars, consideration has to be given to the application of physical anthropometric data to design and to its use in a dynamic setting. In many instances, an engineer is given instructions to design the equipment and the operator's area in such a way as to "prevent reaching beyond range of vision," to "avoid off-balance positions," and to "provide adequate head room and clearance." He is rarely supplied with quantitative descriptions to meet these requirements. On the other hand, if quantitative measurements are provided, the "average value" fallacy is often committed. Although such values can be applied to special cases in the design of equipment, arrangements based on averages would be unsuitable for 50 percent of the operators in a normally distributed group. Provision should be made for 90 or 95 percent or any other predetermined percentage of the potential operators. If this is not done for such a requirement as arm reach required to operate manual controls, many of those who exceed or are below the average values are handicapped. Mannequins are often used in mock-ups of proposed machines to see if the controls are within reach and if sufficient clearance is provided. Standard sources of anthropometric data relating to body measurements are available.

Many other illustrations can be given for the use of standard body measurements in an industrial setting. Requirements for standing and sitting heights should be such that controls that must be used often and smoothly are not placed at shoulder height or below the waistline. Splash guards and machine aprons should be so designed that work is within easy reach of the operator. Control pressures relating to arm, hand, and leg strength should be within the limits of the weakest persons who are expected to run the machines. Unless all these conditions are fulfilled, unnecessary fatigue, irregular operation, and injuries will occur.

Dynamic body measurements of the worker while operating his machine are also valuable. Among desirable criteria are a stable standing or sitting posture with an adequate base support, an unobstructed view of all operations, and readily accessible controls designed for operating at an advantage with respect to muscular activity. In regard to moving equipment, such as trucks, boats, and other vehicles, either adequate distances for deceleration or restraining or protective devices are needed.

Design of controls and displays. In the design of controls, safety is enhanced by the shape and colour-coding of knobs, the radius of knobs and winding handles, the gear ratio, and the amount of friction and inertia.

Among important factors relating to the operation of controls are convenient location, efficient direction of movement, and appropriate speed in relation both to rotary and wrist movements and to movement from point to point. Unless controls are designed carefully, placed properly, and identified easily, they may be operated inadvertently. Design criteria for many of these variables have been determined experimentally for aircraft, and similar techniques are now being used in studying automotive and industrial equipment.

A fundamental principle is to make the various switches and dials of different sizes and shapes to eliminate errors of identification. Accidents may occur if an operator does not clearly perceive the location or movement of indicators, meters, or dials. Clear and unambiguous information is especially important if several tasks must be performed successively or simultaneously for long periods.

The following factors have a significant effect on ease of seeing: size and spacing of critical detail, especially in instrument markings and figures; contrast between object and background; amount of illumination, including the use of colour; and contrast between the objects to be seen and their surroundings.

Auditory signals should be recognizable against the background of the sound pattern, and attempts should be made to use a range in which the ear is most sensitive with respect to frequency, intensity, and duration.

Environmental factors influencing safety. Additional factors influencing the efficiency and safety of workers relate to the physical variables in the environment. These may be broken down into temperature, humidity, ventilation, noise, and vibration. Extremes of any of the factors result in discomfort, lowered efficiency, and increased accident risk.

A summary of the various stimuli influencing worker comfort and safety in terms of desirable and maximum values is presented in Table 3. The highest degree of comfort would be achieved by conforming to the comments listed in the "desirable" column. Discomfort might be expected to arise if the maximum values given in the last column are exceeded.

The values indicated in the table cannot always be considered as rigid standards because of the interdependence of one variable with others.

HAZARDS AND THEIR PREVENTION

Safeguarding machinery and working areas. The automation of devices to move and handle materials for machine operations has greatly reduced exposure to mechanical and handling hazards. The basic principles of safeguarding continue to be of great importance, however, in many industrial operations. The primary purpose of machine guarding is to prevent injury from direct contact with moving parts, from features of the work in progress (e.g., chips from metal, splashing of chemicals, kickback from a saw), from mechanical or electrical failures in the equipment, and from predictable human errors or failures.

In general, machine guards relate to hazards in the transmission of power to the working areas such as belts, gears, rotating shafts, and sliding parts, and to the area in

Mannequins in mock-ups

Machine guards

which the operator performs his functions. Injuries result when loose clothing or hair is caught by rotating mechanisms; when fingers and hands are caught in pinch points such as rollers, meshing gear teeth, belts, and chain drives; and when moving parts supply cutting, shearing, or crushing forces. In the modern machine lathe, for example, external shafts, pulleys, and belts are eliminated, and the motor and gear train are completely enclosed. When fixed guards cannot be used, automatic interlocking guards can be designed to prevent operation of a machine unless a guard is in position at the danger point. Another type of guard that automatically comes into position while the machine is in operation prevents the operator from coming in contact with the dangerous part through a barrier, through devices which push his hands away, or by using sensor devices to stop the machine when hands are put into danger zones.

The principles of guarding are also important in relation to plant layout and the movement of men and materials. Railings and toe boards around floor openings or on elevated platforms, for example, prevent workers and rolling objects from falling. Guards may be needed on forklifts and motorized dollies to protect the operators. Piping conveying hot or hazardous substances may be identified by appropriate colour-coding.

Safety principles in materials handling. In the industrial countries a steady trend toward mechanization of materials handling has long been discernible. Yet in the 1970s a vast amount of manual lifting and carrying remained indispensable in industry and agriculture, especially in the underdeveloped regions of the world. Prevention of unsafe work practices, such as improper lifting, carrying too heavy a load, incorrect gripping or failing to observe proper foot or hand clearances, is still an important safety function. Many injuries can be avoided by proper design of the work station or of the physical activities involved. One of the most commonly reported injuries is to the back and spinal column. Manual handling of materials is the cause of a large percent of all fatal injuries and of permanent and temporary disabilities.

Factors
in lifting

In lifting, the most important determinant of the force exertable is the distance of the feet from the point at which the object is grasped. Lifting force is greatest when the weight lifted is in the same vertical plane as the body, and decreases sharply as the weight moves away from the body plane. The best height for lifting, as in vertical pull, is at or slightly above the level of the middle fingertip of a person standing erect with arms hanging at his sides. Above this height, lifting power decreases very rapidly; below it, more slowly. With a load near the floor, lifting force is about $\frac{3}{4}$ to $\frac{4}{5}$ that at the best height.

In general, "leg lift," with back vertical and legs bent, affords a slightly stronger vertical pull than "back lift," with legs straight and back bent, and entails much less risk of back injury.

Women, when measured by their ability to lift a weight, demonstrate about 55 to 65 percent as much strength as do men.

Relatively little research has been done on carrying, though it is established that a "normal" man can move about 200 metric tons (220 tons) a day through a horizontal distance of one metre (3.3 feet), or 50 metric tons (55 tons) through a vertical distance of one metre. For loads of 20 to 60 pounds (nine to 27 kilograms) a yoke has been found to be most efficient (though this may sometimes be impractical), with the hand carry, one load in each hand, the next best. For heavy weights, it is less physically tiring to carry one load a given distance than to carry two loads, each weighing half as much, the same distance in two trips.

In general, the more compact the container the more easily it can be carried. For bulky equipment the centre of gravity should be not more than 20 inches (51 centimetres) from the carrier's body, and when such articles are as big as 30 inches (76 centimetres) to a side, their weight should not exceed 20 pounds (nine kilograms).

While the above statements on lifting and carrying are by no means as definitive and comprehensive as could be wished, they represent a synthesis of the currently avail-

able data, and they illustrate the kind of potential contribution that the study of human-body mechanics can make to industrial safety.

Electrical hazards. It is now generally recognized that electricity is less hazardous in many ways than steam or other sources of energy. The fire and explosion hazards of steam boilers and other systems involving vapours under pressure have led to many specific standards for performance and safety features required to prevent accidents, as well as strict inspection programs in most countries. Yet in spite of the advances in the control of electrical hazards, many injuries and fatalities result from causes that are preventable. The severity of electric shock is a function of the rate of current flow through the body. In general, a 60-cycle commercial-voltage, alternating current of 100 milliamperes (0.1 ampere) may result in fatal injury if it passes through the vital organs. The average values of current at which a person can still free himself from an object held by the hand ranges from about eight milliamperes to 16, depending on a number of factors.

The body's resistance to electric current is chiefly supplied by the skin, and is greatest when the skin is dry. The resistance of moist or wet skin is 100 to 600 times less than that of dry skin. The longer the current continues to flow through the body, the more serious the result is likely to be, and with high-voltage sources, only very short exposures can be survived. The effects of electric currents on the body may involve interference with breathing through contraction of chest muscles or paralysis of the respiratory nerve centres; interference with or blocking of the rhythm and muscular action of the heart; or destruction of tissues, nerves, and muscles from the heat due to heavy current. Burns from electrical flashes and arcs are deep and slow to heal.

In many respects, the general principle of machine guarding can be applied to electrical equipment (e.g., barriers and enclosures) with consideration also given to the conductivity of materials used and the necessity for proper insulation and grounding of all electrical fixtures and equipment. Many accidents are caused by use of switches and items improperly selected for the specific purpose, or without interlock or fail-safe features. Modern circuit breakers and ground-fault circuits interrupters (devices that cut off electrical current if the machine is improperly grounded) are important protective devices; and the significance of control of such factors as dirt, stray oil, and moisture for the safe operation of electric motors is well recognized. Air-tight and explosion-proof switching equipment (that will not release sparks into the atmosphere) has been developed for locations in which flammable gases, vapours, and ducts are present. Sparks and arcs in electrical equipment are frequently the cause of fires and explosions, and explosion-proof equipment has been developed for use against specific hazards of different types. In most countries, independent testing laboratories test and approve electrical equipment for use in industry and in the home. Such laboratories test for shock and fire hazards and may also evaluate radiation and heat hazards.

Protection against chemicals. Many common industrial chemicals involve toxic and fire hazards. New chemicals are constantly being introduced, and safety experts generally consult the most up-to-date references for each chemical substance.

Modern chemical plants are designed and constructed to provide protection from specific hazards and for control of the effects of all possible mishaps. Personnel are protected by a high degree of safeguarding and by automatic control of processes at all stages in the flow from entry of the raw materials through packaging of the final product. This degree of automation and control is less prevalent, however, in many manufacturing processes in which chemicals in solid, gaseous, or liquid form are used for a variety of purposes. These substances may be poisonous or harmful, corrosive, or combustible and explosive.

Chemical hazards, in general, are described in terms of their biological effects (*i.e.*, their toxicity and such physical characteristics as ignition temperatures, corrosive ac-

Protection
against
electrical
injuries

tions, chemical reactions with other agents, and decomposition under heat). The safety engineer is concerned with the identification of exposures to chemical agents and how exposure can be prevented; and the industrial toxicologist the application of information on the biological and potential toxicity of substances. In industry, toxic materials are most commonly absorbed either through the respiratory system, from breathing dusts and atmospheric contaminants, or through the skin, or through the gastro-intestinal tract. Effects may be local, as in the case of burns and tissue damage from splashes of caustic liquids or acids or transient dermatitis (inflammation of the skin) from irritants. Systemic reactions result when poisons are carried to organs of the body where they exert their effects, such as the liver, kidneys, and bones. All organic solvents, with sufficient exposure, involve a paralysis of the central nervous system; *e.g.*, inhaling cleaning fluids has resulted in many accidental deaths. Asphyxiation may result from excessive carbon monoxide exposure.

Recommended practices have been developed for the storage, transport, and handling of hazardous and flammable materials. Exhaust hoods; air-filtering and air-monitoring systems to protect against gases, vapours, and air-borne hazards; individual respiratory devices; protective clothing to guard against splashes and spillage; and safety showers and eye-wash stands illustrate some of the devices used to prevent or minimize injuries.

Control of radiation hazards. Both very subtle and extreme effects derive from overexposure to radiation. Radiation is emitted from either the atom's unstable nucleus or its unstable orbital area and is divided into two general types, particulate and electromagnetic. Particulate (also called corpuscular) radiation is the motion of small particles that have mass and usually electric charge and that transfer energy from one part to another. Electromagnetic radiation (radio waves, light waves, X-rays) has both particulate and wavelike aspects. In its particulate phase, electromagnetic radiation is described as small bundles of energy called photons or quanta. The energy of a photon depends on the frequency or wavelength of the electromagnetic radiation associated with it. Measurement of radiation is indirect, by the ionization (production of electrically charged atoms) produced in the passage of the radiation through a medium. Cosmic radiation may be a hazard to humans during space flights, but few of these particles reach the earth's surface because the earth's atmosphere acts as a protective shield.

The problem of greatest concern to the safety specialist concerns alterations in the cells of the body induced by radioactive exposure. The serious aspects of these effects is that they can occur in any of the cells of the body, since all of the body tissue may be vulnerable. Extensive research work has been concerned with determining the lowest dose at which injurious effects can occur. The safest biological assumption is that at any level of exposure, no matter how small, it can be assumed that when a large number of people suffer the exposure, at least a few individuals will suffer damage.

While keeping as closely as possible to the principle that all ionizing radiation may be harmful, protection programs include detection and measurement, shielding, and monitoring of personnel to limit exposure to the accepted minimum level.

Radioactive sources increasingly are being used in production processes. Potential applications in industry are almost limitless. Irradiated tools, for example, can measure the wear of cutting tools, pistons, and dies; gauges can measure and control the thickness of steel, paint, or other processed products; tracers can follow fluid flow in process lines; and radiation as low-intensity light sources may power exit signs or traffic-lane markers.

A number of instruments have been developed to make surveys of radiation. The devices most widely employed are designed to determine contamination, dosage, and dosage rate. These operate variously on the basis of the capacity of certain materials to absorb radiation at a known rate, the measurement of ionization (*e.g.*, by the

Geiger counter), and on the rates at which certain materials emit flashes of light when struck by radiation. Monitoring systems measure the radiation exposure of personnel and of work areas. The film badge, which indicates degree of exposure by means of photographic film worn by the person; hand and foot counters; and pocket dosimeters for continuously monitoring the total radiation, or "dose," received by the wearer, all devised for determining exposure to specific radiation such as X-rays and gamma rays, are examples of devices worn by personnel. Preplacement physical examinations are important in safeguarding the health of employees. Attempts are made in the medical examinations to learn whether or not a new worker has a family history of cataracts, deformity, anemia, retarded blood clotting, or leukemia, because these data may offer clues relating to the individual's sensitivity to radiation.

The safety specialist in cooperation with the company medical department is also concerned with protection in the handling and storage of radioactive materials, the disposal of residue and wastes, and the proper shielding of new installations. Comprehensive regulations covering such activities have been developed in each country.

Personal protective equipment. Protection through engineering and equipment design is generally more reliable than through methods dependent on human behaviour. The use of personal protective equipment becomes imperative, however, when hazards, revealed by advance analysis or from analyses of injuries by type or part of the body involved, are impossible to control through engineering revision. In construction work, for example, it would be extremely difficult to design the job processes to eliminate the possibility of a dropped hand tool, bolt, or a wind-blown piece of debris or building material from falling from an elevated level. Thus, protective headgear for construction workers is essential in minimizing injuries from falling objects.

If many injuries involve the eyes, safety goggles may be required, or if they are already provided, their use may be enforced when working at such jobs as grinding, chipping, or hammering. Flying particles or chips frequently occur when such work is being done. It must be emphasized, however, that the development of protective devices does not represent a basic solution of an accident hazard. More satisfactory corrective measures are those that are incorporated in the design of the equipment or the plant layout, preferably in the original planning.

The nature of injuries and parts of the body involved in first-aid cases often furnishes additional information on the type of accident hazards to which workers are being subjected. For example, the daily records of first-aid treatments in an air-transport maintenance unit for a two-year period were analyzed at half-year intervals in terms of nature of injury and area of the body involved. Lacerations and abrasions and foreign bodies in the eye were the most frequent type of injury. Most of the lacerations and abrasions occurred to hands and fingers. An inspection of the records indicated that most of the injuries resulted from misuse of hand tools—*e.g.*, the slipping of a poorly fitting screwdriver or wrench resulting in cut fingers or scraped knuckles. In addition, an important factor was the necessity for working in close quarters or around very compact assemblies. The puncture wounds were attributed almost entirely to the use of safety wire, cotter pins, screwdrivers, and steel wool. Flying particles associated with the machining or grinding of parts, the slipstream of a propeller, or the use of compressed air for dislodging dirt also constituted hazards for which protective goggles were either not available or their use not enforced.

A wide variety of devices have been developed for protection of relevant parts of the body against many specific hazards. Performance standards have been formulated for some categories, such as safety belts, devices to protect the eyes from impact and harmful radiations, rubber insulating gloves, and safety shoes. Factors determining the selection—or development—of a particular protective device include both the amount of protection provided under the various conditions of use, its ease of use,

Importance
of physical
examina-
tions

Protection
against
radiation

Metal
helmets

and acceptability by workers. A few examples of other devices follow.

The familiar "hard hat" helmet worn by construction workers is designed to absorb the energy of falling objects and spread it over a wider surface through its inner suspension. In addition to impact resistance, helmets may also, for certain purposes, be constructed of material that protects against electric shocks and be fire resistant; for example, for electric linemen and fire fighters. Lightweight plastic "bump caps" are frequently used in industrial situations involving working in close quarters and with low overhead clearances. Special caps have been developed for use in general factory work to reduce the hazard of hair being caught by moving machine parts or lifted into them by static electricity. The welder's helmet with face shield is an example of protection against a combination of hazards—infra-red heating from the process, impact from flying molten metal particles, electric shock, and injury to the eye from the ultraviolet rays of the electric arcs. Other types of face shields have also been developed to protect the face and neck from flying particles, chemical mists and sprays, and splashes from hot liquids or molten metals. For some operations, such as in the handling of acids or where there are high concentrations of acid fumes, it has been necessary to design combined face shields and hoods to envelop the head and shoulders, which may also be equipped with devices to provide the worker with breathing air and ventilation.

The need for eye protection in many industrial operations has long been recognized, and many types of safety glasses or goggles have been devised. These range from nonbreakable lenses for general use by those normally wearing glasses, through special designs for the specific hazards of particular jobs. For example, flying dust and small particles occur in woodworking, stone dressing, and metallurgical and other grinding operations. Some goggles are especially designed to protect against chemical splashes and fumes, and others are essentially optical filters to screen out intense light or harmful rays. One of the most recent applications is in relation to the increasing use of laser devices. Lenses in these spectacles or goggles are designed to attenuate (cut down) the intensity of light at the specific wavelength of the laser beam involved by factors of **10, 100, or 1,000**.

Injuries to the fingers, hands, and arms comprise about a third of the disabling injuries in work accidents and are responsible for about a quarter of the compensation paid for injuries. The most frequently used protective device is some adaptation of the glove, but sometimes extending from fingertips to shoulder. For handling rough or abrasive materials or using edged tools, gloves of leather, or leather reinforced with metal stitching, are often used. Asbestos and wool protect against heat. Rubber gloves extending above the wrist are common in handling chemicals, but synthetic rubbers are necessary in gloves if petroleum products are involved. Specially designed rubber gloves are required by linemen and others working on high-voltage electrical equipment, and these are usually worn with an outer leather glove to protect the integrity of the insulation from cuts and abrasions. For gloves, headgear, and other items of personal equipment, proper fitting is important, and the wide ranges of individual differences in size must be considered. Also, for the operation of recessed knobs, or the grasp of lifting handles, it is necessary to take into account the increase in clearances necessitated by the thickness of protective clothing.

Safety shoes have been developed for protection in a wide variety of situations. A common form is one in which the toes and front part of the foot are covered by a steel cap, guarding against objects dropped or bumped into. Insulated soles are provided for electrical workers, and demolition workers wear shoes with additional metal shields over the instep and steel innersoles to prevent penetration by nails and sharp objects.

Some of the most complex personal protective equipment is illustrated by the items developed for firefighting and emergency rescue workers, where extremes of heat, flame, atmospheric contamination, and other forms of destructive energy may be encountered. The space-walks

and lunar excursions of the cosmonauts and astronauts have involved very advanced equipment to protect against the hostile environmental factors of space, and to provide a personal atmosphere adequate for sustaining human life and performance (see also LIFE-SUPPORT SYSTEMS).

SAFETY ENGINEERING IN NONINDUSTRIAL AREAS

Impact injuries from abrupt decelerative forces. One of the most important functions of the safety engineer is to prevent injuries resulting from the exchanges of energy beyond human limitations. As indicated previously, helmets are recommended for construction workers and athletes, and susceptible humans have been protected from many different sources of energy to prevent damage. In the field of medicine, once immunization procedures are developed and applied, the need for active participation on the part of human subjects is eliminated. If it becomes necessary to rely on voluntary participation, it is well known that safety measures are often not applied. Thus it is necessary for the safety engineer to identify the sources of energy and to reduce injury through designs that control the forces that are encountered in accident situations. This principle is of particular importance for the prevention of injury in motor-vehicle crashes.

It would be desirable, of course, to prevent crashes from occurring, and the engineer aids in this respect by providing good handling and operating qualities, fail-safe braking systems, good vehicular stability, adequate vision both day and night, controls that are easily identified and operated, and designs for highways that eliminate collision hazards. The record thus far, however, does not lead to anticipation of substantial reductions in the frequency of crashes and protection of vehicle occupants against the very high decelerative forces involved has become of great importance.

In automobile crashes these forces are dissipated in two phases, the first—the initial collision—producing vehicle damage; and the second, the collision of the occupants with the interior of the vehicle or, if ejected, with the environment. The effects of the high-impact forces on the body can be greatly minimized by restraining devices and, also, if certain well-established principles of crashworthiness are carried out. These principles have been proved to be very effective in aviation. The rigidity of the structures determines the abruptness and seriousness of the forces for both the car and the occupants. Bumper heights, protective characteristics of roofs, and strength of door locks are important, as is the padding of interior surfaces—such as dashboards, visors, and door handles. The role of the steering wheel and column in inflicting head and chest injuries is well documented, and this control has now been redesigned to absorb some of the energy on impact. Penetration-resistant windshields significantly reduce injuries to the head and face. Numerous studies have shown that multiple injuries result in most automobile crashes, but the head appears to be most vulnerable and may be seriously affected in **70–80** percent of the severe crashes.

Insofar as protective devices are concerned, the combined lap belt and shoulder strap gives the greatest amount of protection if properly adjusted and worn. According to a recent Swedish study, fatalities were reduced by approximately **85–90** percent when a three-point belt was used, in comparison to crashes in which protective equipment was not worn. In fact, no belted occupant was killed in any accident at speeds below **60** miles (**97** kilometres) per hour, whereas fatalities occurred among unbelted occupants at speeds as low as **12** miles (**19** kilometres) per hour. In spite of the convincing evidence for the proper use of restraining devices, it has been found that only a fraction of persons in automobiles use them when they are available. Current efforts are being directed toward developing devices or systems that do not depend on voluntary use, such as the automatically inflating **airbag**.

Product safety engineering. In recent years an increasing amount of attention has been given to the safe design of all types of products.

Safety
shoesPenetration-
resistant wind-
shields

While legal responsibilities fixed by laws and courts vary, a trend was apparent in the early 1960s toward increasing the liability of the manufacturer for all the hazards associated with his product and its use or reasonably foreseeable misuse.

Defects in products may involve faulty materials, manufacturing, and packaging, and may be aggravated or brought into play by human errors in product use. Thus, the design engineer must avoid features that enhance the probability of errors or misuse. It is only logical to believe that the future will see considerably greater attention paid by the safety engineer to product safety at the stage of original design.

Educational programs in safety engineering. In the past many safety engineers have had their academic training in courses of industrial or management engineering. Graduate courses are also offered in some universities in such areas as industrial safety and accident prevention, safety engineering, safety management and administration, fire protection, driver and traffic safety, and in more general areas of safety and accident prevention. Only a small proportion of colleges and universities (about one in five in the U.S. and Canada) offer courses in safety and related subjects. The 1970s and '80s are certain to see a substantial increase in such courses and in the licensing of safety engineers.

The development of a uniform curriculum for the safety-engineering profession has been subject to considerable disagreement and debate. In part this is the result of the variety of scientific disciplines applied in safety procedures and the varied importance of different sciences and specialties in different industries, work situations, and work processes.

BIBLIOGRAPHY. Sources for statistical information regarding accidents include the *Annual Statistical Reports* of the International Labour Office of the United Nations; *Annual Global Data on Mortality*, published each year by the World Health Organization of the United Nations; and reports published by various national governments. R.H. SIMONDS and J.V. GRIMALDI, *Safety Management: Accident Cost and Control*, rev. ed. (1963), is one of the more detailed textbooks giving comprehensive coverage of safety management and basic principles governing the prevention and control of work accidents in both large and small industrial organizations. The NATIONAL SAFETY COUNCIL in Chicago publishes the *Accident Prevention Manual for Industrial Operations*, 6th ed. (1969), which is the most comprehensive manual for accident prevention in industrial organizations. Specific details are clearly presented for the safety engineering of a wide variety of hazards, such as mechanical, chemical, electrical, principles of guarding, and fire protection, with extensive bibliographies at the end of each chapter. A. DAMON *et al.*, *The Human Body in Equipment Design* (1966), contains extensive data on anthropometric measurements of the working population, and includes a discussion of working activities from the point of view of human body mechanics. The *International Labour Office Bibliography on Safety Engineering* (1970) contains extensive listings of international sources of information on safety engineering.

(R.A.McF.)

Saga

In medieval Iceland the literary term *saga* denoted any kind of story or history in prose, irrespective of the kind or nature of the narrative or the purposes for which it was written. Used in this general sense, the term applies to a wide range of literary works, including those of hagiography (biography of saints), historiography, and secular fiction in a variety of modes. Lives of the saints and other stories for edification are entitled *sagas*, as are the Norse versions of French romances and the Icelandic adaptations of various Latin histories. Chronicles and other factual records of the history of Scandinavia and Iceland down to the 14th century are also included under the blanket term *saga* literature. In a stricter sense, however, the term *saga* is confined to legendary and historical fictions, in which the author has attempted an imaginative reconstruction of the past and organized the subject matter according to certain aesthetic principles. Using the distinctive features of the hero as principal guideline, medieval Icelandic narrative fiction can be classified as:

(1) kings' sagas, (2) legendary sagas, and (3) sagas of Icelanders.

The origin and evolution of *saga* writing in Iceland are largely matters for speculation. A common pastime on Icelandic farms, from the 12th century down to modern times, was the reading aloud of stories to entertain the household, known as *sagnaskemmtun* ("saga entertainment"). It seems to have replaced the traditional art of storytelling. All kinds of written narratives were used in *sagnaskemmtun*: secular, sacred, historical, and legendary. The Icelandic church took a sympathetic view of the writing and reading of sagas, and many of the authors whose identity is still known were monks or priests.

NONFICTIONAL SAGA LITERATURE

Translations. A good many European narratives were known in Iceland in the 12th and 13th centuries, and these undoubtedly served as models for Icelandic writers when they set out to form a coherent picture of early Scandinavian history. Translations of lives of the saints and the apostles and accounts of the Holy Virgin testify to the skill of Icelandic prose writers in handling the vernacular for narrative purposes from the 12th century onward. Histories were also adapted and translated from Latin, based on those of the 7th- and 8th-century Anglo-Saxon writer Bede, the 7th-century Spanish historian Isidore of Seville, and other authorities; on fictitious accounts of the Trojan wars, notably, one of the 5th century attributed to Dares Phrygius and one of the 4th century attributed to Dictys Cretensis; on the 12th-century British chronicler Geoffrey of Monmouth; and on the 1st-century Roman historians Sallust and Lucan. In the 13th century, Abbot Brandr Jónsson wrote a history of the Jews based on the Vulgate, on the 10th-century biblical scholar Peter Comestor, and on other sources.

In the 13th century, *saga* literature was also enriched by a number of Norwegian prose translations of French romance literature. These soon found their way into Iceland, where they became immensely popular and were quite a strong influence on native storywriting. Probably the earliest, *Tristrams saga* (the story of Tristan and Iseult), was translated in 1226. Most of the themes of French romance appear in Icelandic versions; e.g., *Karlsmagnús saga* was based on Charlemagne legends.

Native historical accounts. Icelandic historians seem to have started writing about their country's past toward the end of the 11th century. Saemundur Sigfþsson, trained as a priest in France, wrote a Latin history of the kings of Norway, now lost but referred to by later authors. The first Icelandic to use the vernacular for historical accounts was Ari Thorgilsson, whose *Íslendingabók* (or *Libellus Islandorum* [*The Book of the Icelanders*]) survives. It is a concise description of the course of Icelandic history from the beginning of the settlement (c. 870) to 1118. Ari seems to have written this book about 1125, but before that date he may already have compiled (in collaboration with Kolskeggr Ásbjarnarson) the so-called *Landnámabók* ("Book of Settlements"), which lists the names and land claims of about 400 settlers. Because this work survives only in 13th- and 14th-century versions, it is impossible to tell how much of it is Ari's. Both books gave the Icelanders a clear picture of the beginning of their society; both works served to stimulate public interest in the period during which events recounted in the sagas of Icelanders (see below) are supposed to have taken place. Other factual accounts of the history of Iceland followed later: *Kristni saga* describes Iceland's conversion to Christianity about the end of the 10th century and the emergence of a national church. *Hungrvaka* ("The Appetizer") contains accounts of the lives of the first five bishops of Skálholt, from the mid-11th to the third quarter of the 12th century; the biographies of other prominent bishops are in the *Biskupa sogur*. Though some of these have a strong hagiographical flavour, others are soberly written and of great historical value. The period c. 1100–1264 is also dealt with in several secular histories, known collectively as *Sturlunga saga*, the most important of which is the *Íslendinga saga* ("The Icelanders' Saga") of Sturla Thórdarson, who describes

Themes of French romance literature

in memorable detail the bitter personal and political feuds that marked the final episode in the history of the Icelandic commonwealth (c. 1200–64).

LEGENDARY AND HISTORICAL FICTION

Contemporary writings of remoter periods

Kings' sagas. After Saemundur Sigfússon, Icelandic and Norwegian authors continued to explore the history of Scandinavia in terms of rulers and royal families, some of them writing in Latin and others in the vernacular. Broadly speaking, the kings' sagas fall into two distinct groups: contemporary (or near contemporary) biographies and histories of remoter periods. To the first group belonged a now-lost work, written in about 1170 by an Icelander called Eiríkr Oddsson, dealing with several 12th-century kings of Norway. *Sverris saga* describes the life of King Sverrir (reigned 1184–1202). The first part was written by Abbot Karl Jónsson under the supervision of the King himself, but it was completed (probably by the Abbot) in Iceland after Sverrir's death. Sturla Thórðarson wrote two royal biographies: *Hðkonar saga* on King Haakon Haakonsson (c. 1204–63) and *Magnús saga* on his son and successor, Magnus VI Lawmender (Lagabøter; reigned 1263–80); of the latter only fragments survive. In writing these sagas Sturla used written documents as source material and, like Abbot Karl before him, he also relied on the accounts of eyewitnesses. Works on the history of the earlier kings of Norway include two Latin chronicles of Norwegian provenance, one of which was compiled c. 1180, and two vernacular histories, also written in Norway, the so-called *Agrip* (c. 1190) and *Fagrskinna* (c. 1230). The Icelandic *Morkinskinna* (c. 1220) deals with the kings of Norway from 1047–1177; an outstanding feature of it is that it tells some brilliant stories of Icelandic poets and adventurers who visited the royal courts of Scandinavia.

The kings' sagas reached their zenith in the *Heimskringla*, or *Noregs konunga sögur* ("History of the Kings of Norway"), of Snorri Sturluson, which describes the history of the royal house of Norway from legendary times down to 1177. Snorri was a leading 13th-century Icelandic poet, who used as sources all the court poetry from the 9th century onward that was available to him. He also used many earlier histories of the kings of Norway and other written sources. *Heimskringla* is a supreme literary achievement that ranks Snorri Sturluson with the great writers of medieval Europe. He interpreted history in terms of personalities rather than politics, and many of his character portrayals are superbly drawn. Two of the early kings of Norway, Olaf Tryggvason (reigned 995–1000) and Olaf Haraldsson (Olaf the Saint; reigned 1015–30), received special attention from Icelandic antiquarians and authors. Only fragments of a 12th-century *Olafs saga helga* ("St. Olaf's Saga") survive; a 13th-century biography of the same king by Styrmir Káráson is also largely lost. (Snorri Sturluson wrote a brilliant saga of St. Olaf, rejecting some of the grosser hagiographical elements in his sources; this work forms the central part of his *Heimskringla*.) About 1190 a Benedictine monk, Oddr Snorrason, wrote a Latin life of Olaf Tryggvason, of which an Icelandic version still survives. A brother in the same monastery, Gunnlaugr Leifsson, expanded this biography, and his work was incorporated into later versions of *Olafs saga Tryggvasonar*. Closely related to the lives of the kings of Norway are *Færeyinga saga*, describing the resistance of Faeroese leaders to Norwegian interference during the first part of the 11th century, and *Orkneyinga saga*, dealing with the rulers of the earldom of Orkney from about 900 to the end of the 12th century. These two works were probably written about 1200. The history of the kings of Denmark from c. 940 to 1187 is told in *Knýtlinga saga*.

Legendary sagas. The learned men of medieval Iceland took great pride in their pagan past and copied traditional poems on mythological and legendary themes. In due course some of these narrative poems served as the basis for sagas in prose. In his *Edda* (probably written c. 1225), Snorri Sturluson tells several memorable stories, based on ancient mythological poems, about the old gods of the North, including such masterpieces as the tragic

death of Balder and the comic tale of Thor's journey to giantland. Snorri's book also contains a summary of the legendary Nibelungen cycle. (A much fuller treatment of the same theme is to be found in *Volsunga saga* and *Thidriks saga*, the latter composed in Norway and based on German sources.) Other Icelandic stories based on early poetic tradition include *Heidreks saga*; *Hrólfs saga kraka*, which has a certain affinity with the Old English poem *Beowulf*; *Hálfs saga ok Hálfsrekka*; *Gautreks saga*; and *Ásmundar saga kappabana*, which tells the same story as the Old High German *Hildebrandslied*. The term legendary sagas also covers a number of stories the antecedents and models of which are not exclusively native. These sagas are set in what might be called the legendary heroic age at one level and also vaguely in the more recent Viking age at the other, the action taking place in Scandinavia and other parts of the Viking world, from Russia to Ireland, but occasionally also in the world of myth and fantasy. It is mostly through valour and heroic exploits that the typical hero's personality is realized. He is, however, often a composite character, for some of his features are borrowed from a later and more refined ethos than that of early Scandinavia. He is in fact the synthesis of Viking ideals on the one hand and of codes of courtly chivalry on the other. Of individual stories the following are notable: *Egils saga ok Ásmundar*, which skillfully employs the flashback device; *Bdsa saga ok Herrauds*, exceptional for its erotic elements; *Fridthjofs saga*, a romantic love story; *Hrólfs saga Gautrekssonar*; *Göngu-Hrólfs saga*; and *Halldanar saga Eysteinnssonar*. There are many more. The legendary sagas are essentially romantic literature, offering an idealized picture of the remote past, and many of them are strongly influenced by French romance literature. In these sagas the main emphasis is on a lively narrative, entertainment being their primary aim and function. Some of the themes in the legendary sagas are also treated in the *Gesta Danorum* of the 12th-century Danish historian Saxo Grammaticus, who states that some of his informants for the legendary history of Denmark were Icelanders.

Sagas of Icelanders. In the late 12th century, Icelandic authors began to fictionalize the early part of their history (c. 900–1050), and a new literary genre was born: the sagas of Icelanders. Whereas the ethos of the kings' sagas and of the legendary sagas is aristocratic and their principal heroes warlike leaders, the sagas of Icelanders describe characters who are essentially farmers or farmers' sons or at least people who were socially not far above the author's public, and their conduct and motivation are measurable in terms of the author's own ethos. These authors constantly aimed at geographic, social, and cultural verisimilitude; they made it their business to depict life in Iceland as they had experienced it or as they imagined it had actually been in the past. Though a good deal of the subject matter was evidently derived from oral tradition and thus of historical value for the period described, some of the best sagas are largely fictional; their relevance to the authors' own times mattered perhaps no less than their incidental information about the past. An important aim of this literature was to encourage people to attain a better understanding of their social environment and a truer knowledge of themselves through studying the real and imagined fates of their forbears. A spirit of humanism, sometimes coloured by a fatalistic heroic outlook, pervades the narrative. The edificatory role, however, was never allowed to get out of hand or dominate the literary art; giving aesthetic pleasure remained the saga writer's primary aim and duty.

Nothing is known of the authorship of the sagas of Icelanders, and it has proved impossible to assign a definite date to many of them. It seems improbable that in their present form any of them could have been written before c. 1200. The period c. 1230–90 has been described as the golden age of saga writing because such masterpieces as *Egils saga*, *Víga-Glúms saga*, *Gísla saga*, *Eyrbyggja saga*, *Hrafnkels saga Freysgoda*, *Bandamanna saga*, *Haensa-thóris saga*, and *Njáls saga* appear to have been written during that time. Although a number of

Aim of the sagas of Icelanders

Sagas in prose

sagas date from the 14th century, only one, *Grettis saga*, can stand with the classical ones.

The sagas of Icelanders can be subdivided into several categories according to the social and ethical status of the principal heroes. In some, the hero is a poet who sets out from the rural society of his native land in search of fame and adventure to become the retainer of the king of Norway or some other foreign ruler. Another feature of these stories is that the hero is also a lover. To this group belong some of the early-13th-century sagas, including *Kormuks saga*, *Hallfredar saga*, and *Bjarnar saga Híttdælakappa*. In *Gunnlaugs saga ormsstungu*, which may have been written after the middle of the 13th century, the love theme is treated more romantically than in the others. *Fostbraeda saga* ("The Blood-Brothers' Saga") describes two contrasting heroes: one a poet and lover, the other a ruthless killer. *Egils saga* offers a brilliant study of a complex personality—a ruthless Viking who is also a sensitive poet, a rebel against authority from early childhood who ends his life as a defenseless, blind old man. In several sagas the hero becomes an outlaw fighting a hopeless battle against the social forces that have rejected him. To this group belong *Hardar saga ok Hólmverja* and *Droplaugarsona saga*; but the greatest of the outlaw sagas are *Gísla saga*, describing a man who murders his own brother-in-law and whose sister reveals his dark secret; and *Grettis saga*, which deals with a hero of great talents and courage who is constantly fighting against heavy odds and is treacherously slain by an unscrupulous enemy.

Most of the sagas of Icelanders, however, are concerned with people who are fully integrated members of society, either as ordinary farmers or as farmers who also act as chieftains. *Hrafnkels saga* describes a chieftain who murders his shepherd, is then tortured and humiliated for his crime, and finally takes cruel revenge on one of his tormentors. The hero who gives his name to *Hænsa-thoris saga* is a man of humble background who makes money as a peddler and becomes a wealthy but unpopular landowner. His egotism creates trouble in the neighbourhood, and after he has set fire to one of the farmsteads, killing the farmer and the entire household, he is prosecuted and later put to death. *Ölkofra tháttir* (the term *tháttir* is often used for a short story) and *Bandamanna saga* ("The Confederates' Saga") satirize chieftains who fail in their duty to guard the integrity of the law and try to turn other people's mistakes into profit for themselves. The central plot in *Laxdæla saga* is a love triangle, in which the jealous heroine forces her husband to kill his best friend. *Eyrbyggja saga* describes a complex series of feuds between several interrelated families; *Hávarðar saga* is about an old farmer who takes revenge on his son's killer, the local chieftain; *Víga-Glúms saga* tells of a ruthless chieftain who commits several killings and swears an ambiguous oath in order to cover his guilt; while *Vatnsdæla saga* is the story of a noble chieftain whose last act is to help his killer escape.

In the sagas of Icelanders justice, rather than courage, is often the primary virtue, as might be expected in a literature that places the success of an individual below the welfare of society at large. This theme is an underlying one in *Njáls saga*, the greatest of all the sagas. It is a story of great complexity and richness, with a host of brilliantly executed character portrayals and a profound understanding of human strengths and weaknesses. Its structure is highly complex, but at its core is the tragedy of an influential farmer and sage who devotes his life to a hopeless struggle against the destructive forces of society but ends it inexorably when his enemies set fire to his house, killing his wife and sons with him.

BIBLIOGRAPHY. The best guide to current research is the annual *Bibliography of Old Norse-Icelandic Studies* (1964–); for earlier works on the sagas, see *Islandica* (1908–), Standard editions of important texts include *Íslenzk fornrit* (1933–); *Altnordische Saga-Bibliothek*, ed. by G. CEDER-SCHOLD *et al.*, 18 vol. (1892–1929); *Editiones Arnarnag-naeanae* (1958–); *Fornaldar Sögur Nordurlanda*, 4 vol. (1950); *Sturlunga saga*, 2 vol. (1946); and *Nelson's Icelandic Texts* (1957–), with English translations. Useful general surveys of the sagas are PETER HALLBERG, *Den Isländska Sa-*

gan (1956; Eng. trans., *The Icelandic Saga*, 1962); S. NORDAL, *Sagalitteraturen* (1953); and KURT SCHIER, *Sagaliteratur* (1969). Conflicting theories of the origin of this literature are discussed by WALTER BAETKE, *Über die Entstehung der Isländersagas* (1956); THEODORE M. ANDERSSON, *The Problem of Icelandic Saga Origins* (1964); and GABRIEL TURVILLE-PETRE, *Origins of Icelandic Literature* (1953). For literary interpretations of the sagas of the Icelanders, see THEODORE M. ANDERSSON, *The Icelandic Family Saga: An Analytic Reading* (1967); HERMANN PALSSON, *Art and Ethics in Hrafnkel's Saga* (1971); and EINAR O. SVEINSSON, *A Njálsbúð, bok um mikid listaverk* (1943; Eng. trans., *Njáls Saga: A Literary Masterpiece*, 1971). For the background of the legendary sagas, see GABRIEL TURVILLE-PETRE, *The Heroic Age of Scandinavia* (1951) and *Myth and Religion of the North* (1964). Their literary qualities are discussed in HERMANN PALSSON and PAUL EDWARDS, *Legendary Fiction in Medieval Iceland* (1970). The outstanding works on the Romances are MARGARET SCHLAUCH, *Romance in Iceland* (1934); and E.F. HALVORSEN, *The Norse Version of the Chanson de Roland* (1959).

Of translations into English, the following may be mentioned: L.M. HOLLANDER (ed. and trans.), *Heimskringla: History of the Kings of Norway* (1964) and *The Sagas of Kormák and the Sworn Brothers* (1949); GWYN JONES (ed. and trans.), *The Vatnsdalers' Saga* (1944), *Egil's Saga* (1960), and *Eirik the Red, and Other Icelandic Sagas* (1961); GEORGE JOHNSTON (ed. and trans.), *The Saga of Gísli* (1963); HERMANN PALSSON (ed. and trans.), *Hrafnkel's Saga and Other Icelandic Stories* (1971); PAUL EDWARDS and HERMANN PALSSON (eds. and trans.), *Arrow-Odd: A Medieval Novel* (1970), *Gautrelle's Saga, and Other Medieval Tales* (1968), *Hrólfr Gautreksson: A Viking Romance* (1972), and *Eyrbyggja Saga* (1973); MAGNUS MAGNUSSON and HERMANN PALSSON (eds. and trans.), *Njáls Saga* (1960), *The Vinland Sagas* (1965), *King Harald's Saga* (1966), and *Laxdæla Saga* (1969); M.H. SCARGILL and MARGARET SCHLAUCH (eds. and trans.), *Three Icelandic Sagas* (1950); J.I. YOUNG (ed. and trans.), *The Prose Edda of Snorri Sturluson: Tales from Norse Mythology* (1964); J.H. MCGREW (ed. and trans.), *Sturlunga Saga*, vol. 1 (1970); DENTON FOX and HERMANN PALSSON (eds. and trans.), *Grettir's Saga* (1973).

(He.P.)

Sahara (Desert)

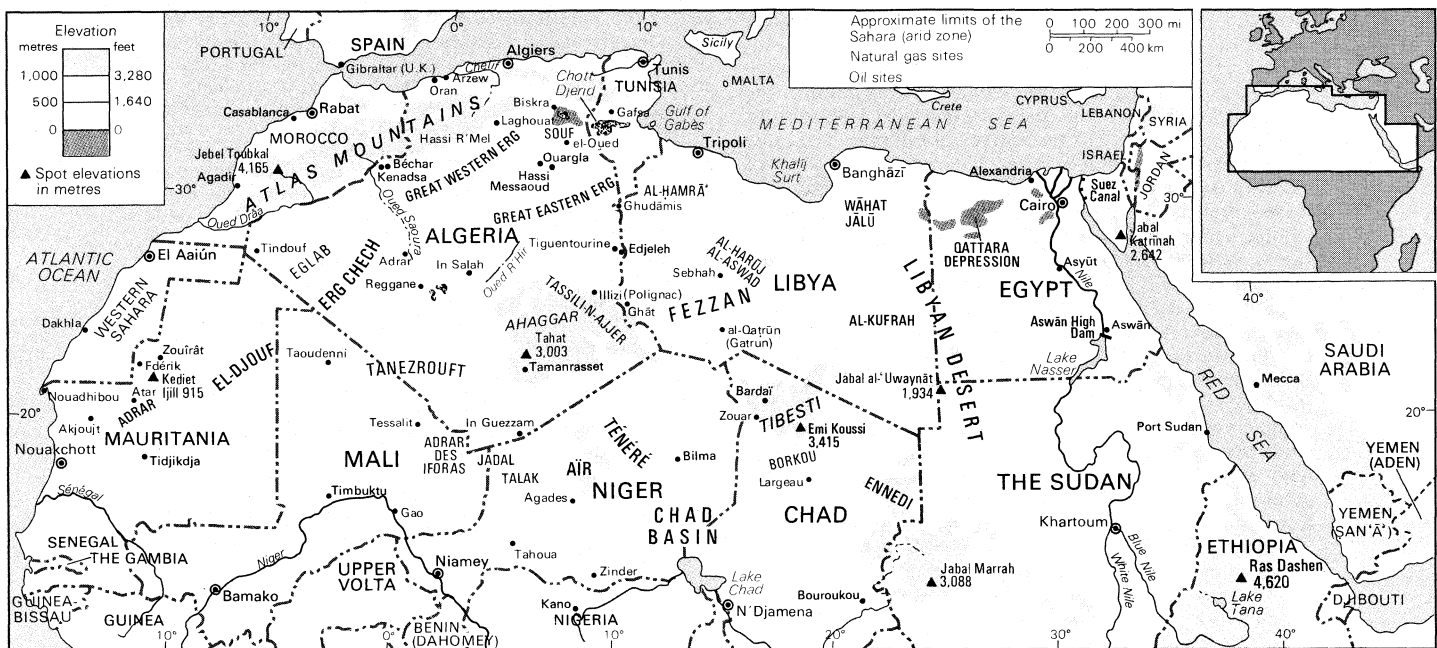

The Sahara is the largest tropical and climatic desert in the world. With an area of 3,320,000 square miles (8,600,000 square kilometres), it fills almost all of the east–west oriented northern part of the African continent and constitutes the western end of the Afro-Asian desert zone. It is bordered by the Mediterranean Sea and the Atlas Mountains to the north, the Atlantic Ocean to the west, and the Red Sea (an arm of the Indian Ocean) to the east; in all, the Sahara has a 3,200-mile coastline. Its main topographical features include plains lying at from 600 to 1,200 feet (180 to 360 metres) above sea level, lowlands and depressions (the largest of these being the Qattara Depression, with its deepest point 436 feet [133 metres] below sea level), and two mountain chains—the Ahaggar (Hoggar) mountains, which rise to a height of 9,852 feet (3,003 metres), and the Tibesti mountains, which rise to 11,204 feet (3,415 metres) in Emi Koussi, the highest point in the Sahara. Only about 20 percent of the desert is sand; the remainder of the region is covered by rubble or smooth rock.

Sharp borderlines in the north and south cannot be drawn. Rather, the concept of a 60-mile border zone, in each instance, is useful. The northern zone is defined (to the east and west) by a band of salt savanna receiving seven inches of precipitation annually and stretching from the Atlantic Ocean to the Atlas Mountains, the southern slope of the Atlas Saharien (Saharan Atlas), and the Mediterranean coast. The southern border (the *sahel* in Arabic) is composed of a belt of vegetation covering "dead" (fossil) sand dunes and receiving an annual rainfall of six inches. This region contains "critical zones," where the desert is slowly encroaching.

The name Sahara derives from the Arabic noun *ṣaḥrāʾ*, meaning desert, and its plural, *ṣaḥārāʾ*. It is also related to the adjective *aṣḥar*, meaning desert-like, and carrying a strong connotation of the reddish colour of the vegetationless plains. There are also indigenous names for particular areas—such as Tanezrouft (a region of southwestern Algeria) and Ténéré, or Land of Fear (central Niger),

The Sahara

in the eastern Sahara—which are often of Berber origin.

The desert is divided up within the boundaries of Western Sahara (former Spanish Sahara), Morocco, Algeria, Tunisia, Libya, and Egypt (which contain its northern reaches) and Mauritania, Mali, Niger, Chad, and The Sudan (which make up the southern section). According to their proportion of arid area, Libya (which is 99 percent arid) and Egypt (98 percent) are strictly Saharan states. (For associated physical features, see ATLAS MOUNTAINS; CHAD. LAKE; NIGER RIVER; and NILE RIVER.)

LANDSCAPE AND ENVIRONMENT

General description and relief. The Sahara's topography is dominated by the monotony of its plains. The lack of any plant cover, the uniform covering of gravel or sand, the slight undulation, and the empty horizons evoke—even more than the dune regions—the notion of the boundless "ocean of the sands." Even the escarpments, stretching for long distances, provide only slight variety. Wide areas, regardless of variations in the type of surface stone, are uniformly covered with a brown to black "stone skin"—the fatty, glossy "desert varnish" resulting from physiochemical processes.

The most prominent feature of the desert is the Mid-Sahara Rise, a series of peneplains (erosion surfaces of considerable extent and slight relief) and plateaus. These form a vast semicircle, extending from west to north to east—from the Adrar des Iforas, to the Ahaggar, Tibesti, and Ennedi mountains. The rise encloses a depression, separated by the Air massif into two expanses of unequal size—the Jadal and Talak regions in the west, and the larger Ténéré region in the east.

Drainage and soils. Networks of valleys, originating in past wet periods, extend over the mountains and plains. An individual valley is called a *wādī* (*oued*), *kori*, *enneri*, or *karkur*. Many of them are so narrow as to be canyon-like, being plugged with boulder detritus in their pitch-dark depths, while those with high groundwater tables may hide thick acacia forests. The valley sands retain water that can be obtained from springs, ephemeral lakes, and water holes.

Except for absolutely smooth rock surfaces (sometimes called billiard-table deserts), the plains are covered with angular stone fragments of boulders (*hamada*; found in al-Hamrā' in Libya), gravel (known as *reg* in the west and as *serir* in the east), and sand (*erg*, *edeyin*, or *ramlah*). Dust and gypsum deserts also occur north of the Tibesti, their powder-fine earth being known as *fesch-fesch*. Salt soils (*sabkha*) and salt lakes (*chotts* or *shatt's*), are very common, while salt-free depressions (*dayas*) are located

in the northwest. Structured soils of reticular pattern, similar to those of the Arctic tundras, also occur.

Although they cover only about 20 percent of the Saharan surface, the ergs (areas of continuous sands) were long considered to be a typical feature of the desert. The dunes are mainly oriented in a southwesterly direction but also acquire a southerly direction in the east and a varying orientation in the south. Their rotating movement in the north and west and their long "tails" in the lee of mountains reflect the formative influence of ground-surface configuration and of air movements near the ground. Long, narrow dunes are called *sif* and half-moon-shaped dunes, *barchan*. Many reach heights of from 325 to 750 feet. Within the ergs, pyramid-shaped dunes are formed. The ergs store water, therefore sometimes having grassy surfaces. In the wind, the sand "smokes" and a drumming is heard, called the Spirit of Raoul, the drummer of death.

Erosional forces have produced fantastic rock formations. In the sandstone regions, "ghost castles," grotesque "mountains," and forests of stone pillars seem tossed about in confusion. On the plains, petrified trees are found, half buried in the sand.

The movement of the ergs and the formation of transverse dunes have not yet been adequately studied. It is known, however, that wandering sand masses threaten settlements and that sandstorms and dust clouds hinder travel. Almost all ergs are rich in relics of the Stone Age, containing fishhooks on old lake bottoms, artifacts, pottery, and tombs.

Climate. Recent studies of the Sahara's climatic history reveal a series of pluvial and arid periods. In a wet stage of the Tertiary Period (from 65,000,000 to 2,500,000 years ago), also characterized by a strongly marked annual dry season, the monsoon front lay more than 750 miles farther north of its modern line, as is revealed by the fossil soils of tropical red earth in the Ahaggar mountains. An arid period in the early part of the Pleistocene Epoch (from 2,500,000 to 10,000 years ago) was followed in the middle Pleistocene by a cool, wet stage characterized by brown loam soils. Another arid period at the end of the Pleistocene was followed by the short wet stage that occurred within the past 10,000 years, producing a growth of trees including the Atlas cedar, sycamore, ash, linden, and willow.

The transition to the present arid period took place about 3000 bc, and—except for temporary minor fluctuations—the Saharan climate has since remained uniform. Desiccation effects are cumulative and are hastened by overgrazing and wood-gathering—activities that prevent a

The ergs

The Mid-Sahara Rise

natural regeneration of plant cover originating from the desert's edge.

The Sahara exhibits climatic extremes. It has the highest evaporation rates in the world—more than 304 inches (7,720 millimetres) per year at Bouroukou, in Chad—and contains the largest areas (about 770,000 square miles [2,000,000 square kilometres]) receiving no precipitation for years at a time. During the summer months, in the north where there are high wind velocities or elsewhere on mountain heights, the relative humidity (with a mean value of 30 percent) can fall to the life-endangering value of 2.5 percent, the world's lowest. Also, the highest degree of aridity—that of the hyperarid "extreme" desert—was found at Sebhah, Libya, where isolation (the amount of solar radiation received at ground level) is measured at 3,285 hours per year.

The temperatures may also reach extremes: the highest value of the annual amplitude of the ground temperature at Tamanrasset, Algeria, at an altitude of 4,513 feet (1,376 metres) was 183° F (84° C). The warmest months are July and August in the north and May and June in the south. The latter is generally hotter, while frost and ice formation can occur in the north and at high altitudes. In the Tibesti mountains, at 8,200 feet, temperatures fall as low as 5° F (−15° C). Areas covered with hushes as well as ravines register lower temperatures than the bare surface, and oases, usually located in low areas close to the groundwater level, constitute microclimatic areas.

The Saharan climate is controlled by the north–south shifting of the trade-wind belt. The dry northeast wind (called the *alizés*) is directed toward the Equator, in opposition to the flow of the southwest wind (the monsoon). During the summer months, their common front stretches in a line west to east through Taoudenni, Mali, around the southern end of the Ahaggar mountains, and on through Bilma, Niger. This front shifts southward in the winter, from the bend of the Niger River to the northern margins of Lake Chad.

The winds blow continuously during the day, often laden with sand and dust. The town of Salah, Algeria, experiences 55 sand-wind days, while Bouroukou, Chad, receives a maximum of 70. The dry, desiccating south winds, moving walls of dust that darken everything, are known by various Arabic names, such as *ghibli*, simoom or *samūn*, khamsin, haboob, and *irifi*.

Atmospheric pressure changes with the winds. During the summer months, low pressure over the desert attracts the moist wind from the southwest, and rain falls on the central mountains, in a decreasing degree to the north. In the winter, high pressure over the Ahaggar mountains attracts the eastward-moving polar front from near the Mediterranean coast, bringing rain and snow to the Atlas Mountains and the northern oases. In the southern Sahara during October, the dry, easterly wind called the harmattan reaches upper Senegal.

The climate is only slightly affected by the surrounding oceans. In the west, the cool ocean current moves southward and parallel to the coast, bringing little moisture inland. In the north, however, cloud banks, fog, and dew have some effect as far as 155 miles into the semi-savanna region.

Climatic data is incomplete because the few research stations are situated in unfavourable locations, as much as 600 miles apart; moreover, most of them, in the early 1970s, had been in operation for less than 25 years. Little is known about the climatic effects of the high-altitude winds (the jetstream) or of the infrared heat rays given off by the dust particles in the dry fog of the southern interior.

Rainfall patterns occur in three distinct zones—a northern zone with rain in the winter; the tropic region, where, except in the mountains, a succession of years without rain is possible; and a southern area, with fairly regular precipitation in the summer. Thunderstorms have sharp regional boundaries and last for several hours. They cause shock waves as well as tremendous flash floods that rush into areas where no precipitation has fallen. Continuous rain also occurs and may last for several weeks, with the raindrops evaporating over the hot-air strata lying

next to the ground. Dew is not infrequent, while cloud formation decreases toward the east.

Vegetation and animal life. The Sahara's natural vegetation may be divided into two groupings—that of the northern and central regions, which belongs to the Holarctic region (the biogeographic realm of the world that includes the northern parts of both the Old and New Worlds), and that of the southern region, which belongs to the Palearctic realm (which includes the Oriental and Ethiopian regions). About 25 percent of the plant species occurring in the north are still of Mediterranean origin. Over large areas, great poverty of species prevails; in some areas there are as few as 150 to 230 species every 4,000 square miles (10,000 square kilometres), as compared to 1,500 species in Europe. The drier eastern half of the Sahara is particularly poor in species. Among the endemic species found in the higher parts of the mountains is *Pentzia monodiana* (a member of the sunflower family). Evidence of earlier wet periods is furnished by the presence of figs, olives, myrtles, and cypresses.

The most frequently found plants include grasses, Fabaceae (members of the pea family), and species belonging to the goosefoot and sunflower families; the briefly flourishing rain vegetation of the *acheb* (a group of plants that flower for a few days) is composed of these. Adaptive plant characteristics occurring in the desert climate include expanded root systems and salt tolerance. The most frequently occurring trees are date palms in the north, doum palms in the centre, and various species of tamarisk and acacia. Huge pistachio trees grow in the depressions, and Mediterranean types of vegetation are found in the mountains between about 4,000 and 5,000 feet.

Near the high humidity of the west coast, the trees are covered with lichens, and there are also succulents. On the east coast, where very high temperatures occur, accompanied by high humidity, there is only a narrow strip of vegetation with salt marshes; mangroves are also found. In the southern part there are fog oases (where the vegetation derives sustenance from the fog) in the mountains. Deep in the interior, in valleys with high groundwater tables, one may be startled to find forests with thousands of acacias.

Most of the Saharan animals belong to the Palearctic region, and the desert offers them few means of existence. Their characteristic traits are dull colours, moderate water requirements, and a subterranean mode of life. Insects and mouselike rodents are the most common, and some reptilian species inhabit the interior. The characteristic animal of the plateaus is the gazelle, while in the mountain regions the waddan (*Ammotragus lervia*) is the most typical animal. Other animals occur only sporadically, or in specialized locations. The Mendes antelope, the maned sheep, and the coney (a rabbit) are found in the north and east, while monkeys and guinea fowl occur in the Tibesti region, crocodiles and one species of parrot in the Ennedi area, and bustards in the south. Foxes and fennec (small African foxes) inhabit the islands of vegetation, and fish, toads, and frogs are found in the water holes. Gnmbusia (the mosquito fish) have been introduced to oasis ponds to combat mosquitoes. Domestic animals include camels, sheep, goats, donkeys, and chickens. The interior regions are traversed by migrating species of locusts, butterflies, and birds.

(H.Sc.)

THE HUMAN FACTOR

The inhabitants. Although as large as the United States, the Sahara is estimated to contain barely 2,000,000 inhabitants. Huge areas are wholly empty; but wherever meagre vegetation can support grazing animals or reliable water sources occur, scattered clusters of inhabitants have survived in fragile ecological balance with one of the harshest environments on earth.

Long before recorded history, the Sahara was evidently more widely occupied. Stone artifacts and rock pictures, widely scattered through regions now far too dry for occupation, reveal the former presence of man, together with big game animals including buffalo, giraffe, ele-

winds

Early
human
occupation

phant, and even hippopotamus. Hunters of the early Paleolithic Period (the second period of the Stone Age, characterized by the use of rough or chipped stone implements) of perhaps 50,000 to 100,000 years ago ultimately gave way to cattle herders of the Neolithic Period (the latest period of the Stone Age, characterized by polished stone implements, the domestication of animals, some agriculture, and the invention of the wheel) during the last 10,000 years, while horsemen appear in the petroglyphs (rock inscriptions) before the camel and the present aridity—the camel appearing in the last few centuries BC. Although discovered skeletal remains are few, indications suggest these early peoples had Negroid affinities; but by the 1st millennium BC, with aridity well-established, racial migrations (presumably from the east and north) had established the Hamitic-to-Semitic-speaking Eurasian ancestors of the present populations—the dominant Berber element. The historic invasions of the Arabs introduced Islam and Arabic speech but probably did not significantly alter the racial composition. Southward, increasing elements of darker peoples occur and are found in pockets in the Fezzan and in Mauritania—and in the Ḥarāṭīn a depressed class found in most oases (possibly an element of an earlier population or descendants of slaves); and, in the south, the Teda group.

The modern peoples of the Sahara are usually divided into four main groups: the Arabo-Berber peoples in the north; the less Arabized Moors of the west; the distinctive Tuareg of the south central mountains; and the Teda (also Toubou) of Tibesti and areas south. Ethnically, all are predominantly Berber, although the Teda show a Negroid intermixture.

Despite much diversity in culture, speech, and linkage, primary differences among Saharan peoples stem from the dominant modes of subsistence—whether characterized by pastoralism or by sedentary cultivation. Pastoralism, always nomadic in some degree, occurs where sufficient scanty pasturage exists, as in the marginal areas, on the mountain borders, and in the slightly moister west. Cattle appear along the southern borders with the *sahel*, but sheep, goats, and camels are the mainstays in the desert. Major pastoral groups include the Regeibat of Mauritania and the Chaamba of the northern Algerian Sahara. Hierarchical in structure, the larger pastoral groups formerly dominated the desert, owning the oases (which supplied dates and grain) and controlling the caravan trade and all movement. Warfare and raiding (*razzias*) were endemic, and in drought periods wide migrations in search of pasture took place, with heavy loss of animals. The Tuareg were renowned for their warlike qualities and fierce independence, their men wearing the blue litham—a strip of cloth worn around the head, covering all but the eyes—hence their name: "People of the Veil." Although Islāmic, they retain a matriarchal organization and an unusual degree of female freedom. The Moorish groups to the west formerly possessed powerful tribal confederations and warred with both Moroccans and with black-skinned peoples to the south. The Teda, isolated and less advanced, are mainly camel herders, renowned for their endurance.

In the desert proper, sedentary occupation is confined to the oases, where irrigation permits limited cultivation of the date palm (the mainstay), millet, barley and wheat, fruits (apricot and others), and vegetables. Cultivation is in small "gardens," maintained by a great expenditure of hand labour. Irrigation utilizes ephemeral streams in mountain areas, *gueltas* (permanent pools), *foggaras* (inclined underground tunnels dug to tap dispersed groundwater in the beds of oueds), springs ('ayn), and wells (*bi'r*). Some shallow groundwaters are artesian, but generally water has to be lifted from wells by devices such as the shadoof (a pivoted pole and bucket), worked by hand or animal. To a limited extent diesel pumps are now replacing these ancient means in more accessible oases. Water availability strictly limits oasis expansion, and in some, overuse of water has produced a serious fall in the water level, as in the Oued R'Hir (Algeria). Salinization of the soil by the fierce evaporation as well as

burial by encroaching sand are further dangers; the latter, as in the Souf oases (Algeria), necessitates constant hand labour in clearing. Overcrowding, moisture, and elementary sanitation tend to produce much ill health.

History and exploration. Classical accounts describe the Sahara much as it is today—a vast and formidable barrier. The Egyptians controlled only their neighbouring oases and, occasionally, lands to the south; the Carthaginians confined their settlements to the coast. Although attempting a few recorded desert penetrations and one possible crossing, the Romans also confined the limits of their occupation to the desert margins. The Arab invasions (dating from AD 642 to that of the Banū Hilāl in the mid-11th century) swept along the northern coastlands but met powerful Berber confederations inland; the Almoravids of northwest Africa, who ruled in the 11th and 12th centuries, drove them back and conquered Morocco. Islam steadily spread, and Arab traders penetrated to the Sudan (the area stretching east to west across Africa between the Sahara and the rainy tropics). European penetration of the Sahara did not begin until the end of the 18th century.

Attempts to solve the mystery of the course of the Niger River took J. Ritchie and G.F. Lyon to the Fezzan area in 1819, and in 1822 the British explorers Dixon Denham, Hugh Clapperton, and Walter Oudney succeeded in crossing the desert and discovering Lake Chad. The Scottish explorer Maj. Alexander Gordon Laing crossed the Sahara and reached the fabled city of Timbuktu in 1825, but he was killed there. The French explorer Rent Caillet, disguised as an Arab, returned from his visit to Timbuktu by crossing the Sahara from south to north in 1828.

The French military conquest of North Africa had begun in 1830, and by 1850 the French stood on the edge of the desert. Their advance south was slow and was preceded by the penetrations of a series of European explorers, of which the most notable were those by the German geographer Heinrich Barth from 1849 to 1855, the French explorer Henri Duveyrier in the 1850s, and the German explorers Gustav Nachtigal (1869 to 1874) and Gerhard Rohlfs (1862 to 1878). The discoveries of these men and those of others revealed the main features of the western and central Sahara. After a period marked by "pacification" and military occupation by the various European colonial powers in the desert—in which Gen. François Henry Laperrine was pre-eminent—more detailed exploration took place. Radio, the motorcar, and light aircraft facilitated further investigation of the desert. While by the early 1970s prospecting and scientific exploration had greatly increased knowledge of the Sahara, vast tracts remained remote, little known, and difficult of access.

ECONOMIC DEVELOPMENT

Mineral resources. The century of colonial dominion over the Sahara, which lasted from the mid-19th to the mid-20th century, witnessed little fundamental change, except for military pacification; colonial powers were little interested in the economic development of this unpromising region. After World War II, however, France began a major program of Saharan assessment; the discovery of oil, in particular, attracted international interest and investment. Within a few years major discoveries had been made, particularly in mineral resources.

In metallic minerals, major iron-ore reserves have been found, particularly at Gara-Djebilet, Algeria, southeast of Tindouf, Algeria, where reserves are estimated to approach 1,500,000,000 metric tons, and at Kediet Ijill in western Mauritania, where reserves are also substantial. Smaller iron-ore reserves have been found elsewhere. Near Akjoujt, in southwest Mauritania, lie an estimated 27,000,000 tons of copper ore; extensive manganese deposits occur at Djebel Guettara, south of Béchar, in Algeria; and in the older crystalline rocks of the Ahaggar, Air, Tibesti, and Eglab regions have been found a long list of metals, including tin, nickel, chromium, zinc, lead, cobalt, silver, gold, platinum, molybde-

European
explorers

Oil and
gas
reserves

num (a metallic element used in strengthening steel), wolfram (used as a source of tungsten), thorium (a radioactive metallic element), and uranium. Inaccessibility, however, delays exploitation.

In fuels, no significant coal reserves have been found to supplement the small and poor-quality field at Kenadsa, near B  char, but the discovery of major oil and gas resources followed the first strikes in 1954 near In Salah, Algeria; estimated reserves amount to some 1,000,000,000 tons. Algerian resources so far discovered are mainly near the Tunisian border (at Tiguentourine, Zarzaitine, Edjeleh, and other places) and around Hassi Messaoud, east of Ouargla. There is also a major natural-gas field at Hassi R'Mel, with estimated reserves of 1,000,000,000,000 cubic yards (800,000,000,000 cubic metres). In Libya, minor oil strikes in the extreme west led to major oil discoveries in the region south of the Khalij Surt; estimated Libyan reserves amount to about 4,000,000,000 tons. Some smaller fields have been found in the Tunisian and Egyptian (el-Alamein) sectors of the Sahara.

As a result of geological and oil prospecting, vast underground reserves of water have also been found in at least seven sedimentary basins, mainly within sandstone formations. Some recoverable water is also present in surface sand formations.

Resource exploitation. While the iron-ore deposits at Gara-Djebilet await exploitation, those at Kediet Ijill have been linked by rail to Nouadhibou on the Atlantic coast of Mauritania since 1962; in 1971 alone, some 6,000,000 tons of high-grade hematite (red-coloured) iron ore was exported. Pipelines collect oil from the Algerian fields and convey it to outlets on the coast. In 1971, Algerian oil production totalled some 38,000,000 tons. A pipeline from the Hassi R'Mel field delivers gas to Arzew, near Oran, where it is used both for export and for local industry. In Libya, in 1971, some 30 oil centres were in production, which were connected by pipeline to coastal outlets. Total Libyan production in 1971 was some 150,000,000 tons.

Economic development of the desert, however, offers enormous difficulties and has not yet changed the traditional Sahara. Oil and ore extraction bring modern technology and improved communications to scattered locations but provide limited opportunities for local employment. While the oil revenues offer the means for desert development, the more immediate and attractive returns possible in inhabited coastal regions tend to take priority. The underground water offers possibilities for major developments in both agriculture and industry, but exploitation on a large scale would be expensive; some aquifers are heavily mineralized. Heavy exploitation would also result in progressive depletion, and hydrological changes might also increase the threat of locust plagues, such as those that have occurred in Niger.

Currently, the desert peoples have benefited little from mineral exploitation—perhaps indeed the reverse. The decline in pastoralism, started by pacification, has been accelerated by changing economic conditions and official settlement policies (for nomads are administratively inconvenient). Archaic methods and excessive animal numbers have produced ecological deterioration, increasing the drift of people to oases and towns, with resultant overcrowding and poverty. High wages in the oil fields attract labour but disrupt traditional life, and the jobs are relatively few and impermanent. Of the traditional desert products—animal skins and wool, surplus fruits, salt—only dates (particularly the *daglet nour* of the northern oases) retain much commercial importance. Salt, although still extracted and sent south to The Sudan, now competes with cheap imported salt. Industrial occupations to relieve growing unemployment have as yet made little progress. In the long-term future, as pressures build up in the advanced and overcrowded Western countries, the high costs of Saharan development may become more acceptable. Nuclear energy and more efficient solar energy convertors could be utilized to raise deep-seated water (and, if necessary, to remove the salt) for new settlements and to provide power for industries needing space and a dry sunny climate. Tourism, already begin-

ning to grow, also has potentialities if handled with imagination. But the high costs of transport, of provision of acceptable artificial living conditions, and of technology seem likely to prevent any rapid changes.

Travel and transport. Traditionally, travel in the Sahara was by camel caravan and was slow, arduous, and dangerous. To the hazards of losing the way, excessive heat, stifling sandstorms, and death by starvation—or more probably thirst—were added those of attack by raiders. Despite all this, trans-Saharan trade along caravan routes linking oases has persisted from very early times. The principal routes were (in sequence from west to east): the "Mauritanian Way" (Senegal–Atar–Ijill–Agadir); Gao–Tessalit–Reggane–Adrar–B  char; Gao–Tessalit–In Salah–Laghout–Algiers; (or In Salah–Ouargla–Biskra); Zinder (or Tahoua)–Agades–In Guezzam–Tamanrasset–In Salah; Agades (or Chad)–Bilma–Gatrun–Fezzan–Tripoli; and Faya–Zouar–Gatrun–Tripoli. East of Tibesti, oases are too few, but the *darb al-arba'in* ("road of the forty" [days]), west of the Nile, was a former slave route. Gold, ivory, slaves, and salt were major items of trade in the old days, but today camel caravans have almost ceased, except for a residual trade in salt (from Bilma, Niger, and Taoudenni, Mali). The main routes remain in use, however, by especially equipped motor trucks, often travelling in convoys. Year by year newly made roads extend along them and their feeders; by 1971 good modern roads extended south to Tindouf, Adrar (Saoura), In Salah, Ouargla, the Polignac oil fields, and the Fezzan oases. Beyond these limits, two main routes continue across the desert that are usable by ordinary cars. The French initiated a trans-Saharan bus service, but it has been terminated. Off the main routes a network of recognized tracks are motorable; with care; but in the open desert four-wheel drive is virtually essential, with at least two vehicles, ample spares, and large emergency supplies of fuel, food, and water—particularly in summer, when special regulations apply to all travellers. In large areas maps are inadequate, and navigational methods may be necessary.

To supplement ground travel, numerous international air services cross the Sahara on scheduled flights, while local services link the main inhabited centres. Railways, with the abandonment of the "Trans-Saharan" at Abadla (near B  char, Algeria), have been little developed except for the new mineral line in Mauritania. Future mineral developments may, however, justify extensions.

Prospects for the future. The Sahara, the Earth's largest desert, remains a challenge. Traditional solutions to the problems of living in it are becoming obsolete, but, although technology now offers technically possible alternatives, high costs for limited returns seem likely to delay their serious adoption for a long time. Proposals to alter natural conditions on a large scale have often been made, as by cutting canals to admit the sea to the below-sea-level Tunisian *chotts* and the Qattara Depression, but the resultant climatic benefits are at best doubtful. Greater benefit might result from a suggested scheme (were it feasible) of diverting central African rivers north into the lower areas, but the engineering problems and costs would be colossal. Suggestions for progressive reclamation by planting trees seem to have very limited application (apart from the vast scale required), for, although overgrazing and reckless cutting of trees and shrubs for firewood have undoubtedly extended the desert margins through history, the basic causes of Saharan aridity are climatic and far beyond man's power to alter. Significantly increased and varied uses of this and other major deserts seem likely to await extreme pressure on areas elsewhere, which will render the economic returns greater and more certain. (R.F.Pe.)

(H.Sc./R.F.Pe.)

Sa'id ibn Sulṭān

Sa'id ibn Sulṭān, ʿĀl Bii Sa'id, sayyid (ruler) of Muscat and Oman and of Zanzibar, was one of the most remarkable of 19th-century Arab rulers. He made Oman stable and organized a prosperous East African commercial empire, stretching from Mogadishu to the Ruwuma River and inland to the great lakes.

Born in 1791, he succeeded his father jointly with his brother Salim in 1804, but their cousin Badr immediately usurped the throne. In 1806 Sa'id assassinated Badr and became virtual sole ruler, though Salim, a non-entity, had titular status until his death in 1821. Although Europeans frequently called him *imām* and *sulṭān*, Sa'id himself used the style sayyid. He was never elected to the purely religious office of *imām* that all his predecessors held.

His earlier years were complicated by family and tribal quarrels, by Anglo-French rivalry in the Indian Ocean, by the expansion of the Wahhābī Muslim puritan move-

ment in Arabia, and by the incessant depredations of the Qawāsīm pirates. He developed a small army and a fleet that also served mercantile purposes. His pilgrimage to Mecca in 1824 was in the nature of a triumph: it demonstrated that he had overcome both internal and external enemies and could risk absence from his own land.

At this time the eastern African coast was divided into numerous small states owing allegiance to Oman because Oman had expelled the Portuguese from them in 1698. At Sa'id's accession Omani weakness made this allegiance little more than nominal, for at Mombasa the Mazar'i family had set up a virtually independent dynasty. In 1822 Sa'id sent an expedition that drove them from Pemba Island. A British naval force occupied Mombasa irregularly from 1824 to 1826, when the action was repudiated by the British government. In 1827 Sa'id went to assert his authority in person: one effect was greatly to increase the revenues remitted. There ensued a struggle between Sa'id and the Mazar'i for Mombasa that ended only in 1837 when, by a ruse, he took some 30 of the enemy captive. All were deported and some were killed. If he preferred peaceable settlements, Sa'id could show himself as ruthless as any Mamlūk.

Sa'id first visited Zanzibar in 1828: he shortly acquired the only two properties on which cloves were then grown. He lived to make the islands of Zanzibar and Pemba the largest clove producers in the world. By 1834 it was believed that he intended to transfer his capital from Muscat to Zanzibar, but, until the 1840s, he divided his time more or less equally between them. His interest in East Africa was not simply to gain increased tax revenue: it was primarily commercial. From the 1820s caravans from Zanzibar reversed the immemorial system of trade by which African products had been brought to the coast by African caravans. Now the Zanzibar caravans, Sa'id's among them at latest by 1839, actively sought ivory, slaves, and other products, and a wholly new commercial system was created reaching beyond Lake Tanganyika and into modern Uganda. At a formal level the transfer of his court and other changes are marked by the establishment in Zanzibar of foreign consulates: United States (1837), Britain (1841), France (1844). These countries, with Germany, became the principal buyers, but Sa'id also exported goods in his own ships to Arabia and India and, occasionally, to Europe and to the United States. By the 1840s he had made Zanzibar the principal power in eastern Africa and the commercial capital of the western Indian Ocean. There was no mock modesty in his remark, "I am nothing but a merchant." Trade was his predominant interest.

Throughout his reign he was under British pressure to end the slave trade. He told a captain of the Royal Navy that "to put down the slave trade with the Muslims, that is a stone too heavy for me to lift without some strong hand to help me." By a treaty of collaboration with Britain concluded in 1822, he agreed to forbid his subjects to sell slaves to the subjects of Christian powers. By 1842 the average annual import of slaves was reported as some 15,000, some doubtless necessitated by the development of the clove plantations. In 1845 he signed a further treaty with Britain, prohibiting both the export and import of slaves from or into his African dominions. His domestic slaves may have numbered over 1,000. On his death, his will freed them but not his plantation slaves.

His commercial empire had no developed system of administration. His government was essentially personal and patriarchal. He sat daily in public to settle cases and complaints. He depended heavily in his commercial ventures on Indian merchants, whose immigration he encouraged. His naval force was commanded by officers who also traded on his behalf. He belonged to the *Ibādī* sect of Islām, which, if puritanical, is notably tolerant of others. A majority of his subjects were Sunni (orthodox), and for them he appointed a special judge. His daughter Salamah's *Memoirs of an Arabian Princess* (1886) gives an intimate portrait of his private life. He left no children by his legal wives. He maintained some 70 *surias*, or concubines, chiefly Circassians or Ethiopians, by whom he had 25 sons and an unknown number of daughters.

Assess-
ment

Early
years

Strict in his habits, lavish in his generosity, he was an affectionate father, taking great pleasure in elaborate family gatherings. He had a patriarchal relationship with his many slaves, whose weddings he sometimes attended. He was a keen horseman and practical seaman. He died at sea in 1856 and was greatly mourned by his subjects. His will divided his dominions between his sons Mājid, who became ruler of Zanzibar, and Thuwayn, who received Muscat and Oman. Sa'id, wrote the British consul, was "most truly every man's friend: he wishes to do good to all."

BIBLIOGRAPHY. J.M. GRAY, *History of Zanzibar, from the Middle Ages to 1856* (1962), a detailed account of Sa'id's reign in Zanzibar; for the earlier part of his reign it is superseded by J.B. KELLY, *Britain and the Persian Gulf, 1795-1880* (1968), based on a most exhaustive study of the available archives. E. SAID-RUETE (the married name of Sa'id's daughter Salamah), *Memoirs of an Arabian Princess* (Eng. trans. 1888), gives an intimate portrait of his court, and is one of the very few descriptions of a *harem* written by a woman.

Saigon (Ho Chi Minh City)

Saigon, renamed Ho Chi Minh City in 1976, is the largest city in the Socialist Republic of Vietnam. The former capital and chief port of the French colony of Cochinchina (1862-1954) and of the Republic of Vietnam (1954-75), the city lies on the Saigon River (Song Sai Gon) immediately north of the Mekong River delta and about 50 miles (80 kilometres) west of the meandering seacoast of the South China Sea. It has long been a dominant centre of economic and cultural life in the southern third of Vietnam.

The city proper is a municipality (thi-xa) that, since 1942, has included the adjoining town of Cholon. In the early 1970s, it had an area of about 27 square miles (70 square kilometres) and a population of about 1,845,000. The municipality itself is the centre of a larger urban area that includes the northern suburb of Gia Dinh and that had a reported population of about 3,150,000 in the early 1970s, although its actual population may have been more than 3,800,000. The population of the urban area in the early 1980s was unknown, but it had almost certainly been reduced. Large numbers of former Saigon residents fled the country after the takeover of Saigon by North Vietnamese troops in 1975 and the establishment of the new Communist government, which initiated programs to relocate people from urban areas to the countryside.

History. Early Vietnamese rule. The area now occupied by Ho Chi Minh City was long part of the Kingdom of Cambodia. The Vietnamese first gained entry to the region when the marriage of a Vietnamese princess to the king of Cambodia, Chey Chetta II (reigned 1618-28), led to the establishment of a Vietnamese customhouse in the small town that was to become Saigon. Although the border between Vietnam and Cambodia was still some 200 miles to the north near Tuy Hoa, an enclave of Vietnamese settlers at the same time put down roots in the Mo Xoai region (which became Phuoc Tuy province), only 40 miles from the town near the South China Sea. In 1658 a Vietnamese expeditionary force occupied the Mo Xoai area and ensured the continued settlement of Vietnamese there, despite serious misgivings on the part of the Cambodians; a Vietnamese community was growing in the future Saigon area by the 1670s.

During the 1660s, in southeastern China, the newly victorious Ch'ing (Manchu) dynasty adopted a scorched-earth policy to suppress supporters of the deposed Ming dynasty. In 1679 several thousand of these exiles began moving into sparsely settled areas to the north of the site of Saigon (around Bien Hoa) and to the south (around My Tho). Fighting among the Cambodians, the Chinese, and the Vietnamese in 1689 led many of the Chinese exiles to abandon their scattered settlements and gravitate toward the Saigon area. A Chinese trading centre, known as the Cholon (Big Market), began to flourish just a few miles from the Vietnamese village that came to be called Saigon.

In 1698, the Saigon-Cholon area was officially incor-

porated into Vietnamese territory, and Vietnamese moved into the vicinity as part of an organized resettlement program in which pioneers were recruited from the more densely populated central coastal plain. Both Vietnamese and Chinese continued to migrate into the frontier area between Bien Hoa and My Tho during the 18th century. Throughout this period, Vietnam was divided under the de facto rule of two rival houses that intermittently waged war against each other. The house of Nguyen ruled in the south, the house of Trinh ruled in the north, and the emperors of Vietnam sat in impotent glory as virtual prisoners upon the throne.

The decades of the 1770s and '80s saw the eruption of a massive peasant rebellion led by the so-called Tay Son brothers. Initially a revolt against the Nguyen, who were defeated by 1783, it spread north to topple the Trinh (1786) and defeat a Chinese expeditionary force (1788). Chinese merchants fled to the Saigon-Cholon area seeking greater security, and Cholon emerged as a major centre of regional trade, although the flourishing Chinese market in Cholon was attacked and burned in 1782, and as many as 10,000 members of that community were slaughtered.

In 1788, the surviving head of the house of Nguyen, young Prince Nguyen Anh, returned to Vietnam with French assistance and regained control of the southern third of the country. Over the next 14 years Nguyen Anh's forces defeated the Tay Son and gained control of the entire country. In 1802 the Nguyen dynasty was established over all of Vietnam and Nguyen Anh was proclaimed Emperor Gia Long. In return for the considerable aid accorded him by the French, Gia Long permitted French traders and Roman Catholic missionaries—who had long been in the area—to continue, and even to expand, their activities during his rule (1802-20). French experts assisted in the construction of an imposing citadel in Saigon, and the city began to assume its modern form in and around this stronghold.

The society of the Saigon-Cholon area was conspicuously more wealthy, open, heterodox, and ethnically diverse than that of the traditional and densely populated Red River delta and central coastal plain to the north. By the mid-19th century, Saigon and Cholon were rapidly growing twin cities at the heart of what was an important trade centre with a population that probably reached 100,000. By Vietnamese standards of the time, this was an exceptionally large urban area and a remarkable hub of commercial activity.

The French colonial period (1859-1954). The spread of French influence and of Roman Catholicism—which was perceived as a threat to the cultural foundations of Vietnamese society—was interrupted by the suppression of French missionary activity under some of Gia Long's successors. The French responded with military intervention; their first important victory was the capture of the Saigon citadel in 1859. Within two years French military control of the area was well established, and their right to administer the upper Mekong Delta was conceded by the Vietnamese court in a treaty signed in 1862.

Saigon then underwent a spectacular period of growth and development as the administrative headquarters of an expanding French colonial organization that gained control over all of Vietnam, Cambodia, and Laos during the next 20 years. Business activity in Cholon also expanded steadily. French capital and technology transformed Saigon into a major port city and a metropolitan centre of spacious and graceful villas, imposing public buildings, and well-paved, tree-lined boulevards. Railroad lines were constructed linking Saigon with My Tho to the south and to Hanoi and beyond in the north. Highways, bridges, ferries, and telephone and telegraph lines brought all of French Indochina into contact with Saigon.

After World War I, all of French Indochina experienced economic growth, and a large proportion of the profits flowed to Saigon. In 1921, the estimated population of Saigon was 83,000, that of Cholon, 94,000. By the end of the decade, the twin cities formed a single metropolitan area of about 250,000 inhabitants. It was by far the largest and most prosperous city in all of Indochina, with an ethnically diverse and cosmopolitan population. It was

The Tay
Son
revolt

Growth

Beginnings
of
Vietnamese
control

in this period that the city acquired its reputation as the "Pearl of the Orient" and the "Paris of the East."

Downtown Saigon was dominated by a few fashionable streets along which the more influential segments of society met for business and amusement. The renowned Rue Catinet extended inland for about three-quarters of a mile from the right bank of the Saigon River to the heart of the city. It ended in a vast open square, in the very centre of which an impressive red-brick cathedral of Romanesque architecture stood alone, its front doors facing directly down the middle of the street toward the river. Near the middle of the Rue Catinet was another large square with an ornate opera house standing off to one side in isolated dignity. Surrounded by a thin cluster of elegant shops, charming outdoor cafes, and picturesque hotels, the cathedral and the opera house were eloquent symbols of a European civilization untouched by the agrarian Asian society that surrounded it. The other prominent buildings of downtown Saigon were equally assertive in their essentially Western character.

Although France fell to the Axis Powers in June 1940 and the Japanese assumed control of Indochina that September, French colonial authorities continued to administer Vietnam, and Saigon itself was largely untouched by World War II. There were some shortages of goods and political tensions, but many businesses flourished as never before. The Vietnamese acquired more opportunities to participate in the economic and political life of the colony, were given greater educational opportunities, and were permitted to hold higher administrative positions previously reserved for Frenchmen. As usual, Saigon received a goodly share of these new benefits.

On March 9, 1945, the Japanese overpowered their French "allies" and interned them. While creating a Vietnamese government to rule northern and central Vietnam, the Japanese assumed direct rule in Saigon and the southern third of the country, the former French colony of Cochinchina. Following the surrender of Japan to the Allies, control of Saigon was briefly assumed by a weak coalition called the United Nationalist Front. This group was quickly and peacefully replaced by a Provisional Executive Committee headed by Tran Van Giau, the man who led the southern branch of both the Indochinese Communist Party and its fighting arm, the Viet Minh.

On September 2, 1945, when Vietnamese independence was declared by Ho Chi Minh in Hanoi, celebration in Saigon turned into a riot in which several Frenchmen were killed. The British general who arrived shortly thereafter to disarm the Japanese on behalf of the Allies announced his intention to return full civil and military control of the area to French authorities. Under pressure from the frightened French community in Saigon, the French troops that had been confined to their barracks under humiliating conditions for six months were released to help restore the crumbling public order.

Before daybreak on September 24, 1945, the French seized all public buildings in Saigon and expelled the Provisional Executive Committee from its offices. Mobs of Frenchmen and Vietnamese battled each other in Saigon's streets, the central market was set afire, and the small, temporary British force was unable to maintain order. By the end of October, the French had announced themselves ready to assert their full authority by force of arms and Tran Van Giau had left Saigon, calling for a complete state of insurgency. Saigon was soon a French-controlled city surrounded by a generally hostile countryside.

Throughout the ensuing years of the First Indochina War, daily life in Saigon went on much as usual for most people, although gambling, opium, and prostitution flourished as never before. Despite war and corruption, Saigon offered a pleasant life to anyone who was not poor. There were Vietnamese, Chinese, and European operas; theatres showing a wide variety of motion pictures; outdoor cafes; street stands; and soup vendors. For all nationalities and all pocketbooks, Saigon provided the amenities of both convenience and indulgence.

The Republic of Vietnam (1954-75). The First Indochina War ended in June 1954 with the Geneva Convention, which divided Vietnam into northern and southern zones

at the 17th parallel of latitude. The cultural and political life of Saigon, which became the capital of the Republic of Vietnam (South Vietnam), was enriched and complicated by an influx of refugees from the Democratic Republic of Vietnam (North Vietnam). The old French opera house became the National Assembly Building, and the Rue Catinet was renamed Duong To Do (Freedom Street). The more conspicuous dens of vice were quickly closed down and, by 1962, public morality had become so strict that dancing and even sentimental songs were banned. Through all of this, Saigon continued to grow and prosper. When Pres. Ngo Dinh Diem was overthrown in November 1963, Saigon once again assumed a gay and lively appearance, despite the growing level of insurgency. Terrorists occasionally blew up a bar or a restaurant, but in the evening streets remained crowded and a remarkable air of normality prevailed.

By 1965, the population of the Saigon metropolitan area had grown to nearly 1,500,000, swollen by refugees who had fled from North Vietnam in 1954 and from the increasingly insecure countryside. As the fighting of the Second Indochina War grew more fierce and the urban economy was stimulated by the spending of U.S. troops, the number of people in Saigon and its expanding suburbs quickly soared to 3,000,000 and continued to grow. Parts of Saigon were severely damaged by fighting in 1968, but the process of urban growth continued at a dizzying pace.

While the U.S. involvement in Vietnam was at its peak between 1965 and 1972, Saigon underwent considerable alteration. The graceful French colonial heritage of tree-lined boulevards, squares, and ornate public buildings was overshadowed by hastily constructed buildings that extended as many as 15 stories into the air in simple functional lines. Trees were chopped down so that streets could be widened, but rush-hour traffic nevertheless was snarled with tens of thousands of small motor bicycles introduced by the U.S. Public transportation remained grossly inadequate for the swollen population, although public buses and three-wheeled jitneys holding 10 or 12 crowded passengers shuttled constantly between downtown and the suburbs. Small taxis swarmed throughout the city for those able to afford them.

Southwest of the National Assembly Building down Tran Hung Dao Boulevard toward the Cholon area, the character of the city changed abruptly. The streets became narrow and haphazard and the buildings a mixture of small shops, private homes, and small factories. Shantytowns grew up in previously uninhabited areas along the various drainage and navigation canals that crisscrossed the city, flowing eastward into the Saigon River. Wooden shacks extended over the edges of the murky, sewage-contaminated canals in which children swam and women washed clothes. Fresh running water and electricity were unknown in many of these areas, which provided minimal shelter for displaced peasants who sought to achieve a foothold among the entrepreneurs.

The streets of downtown Saigon always bustled with activity. Thousands of people earned a precarious living from street vending, selling everything from soap and film and sunglasses to delicacies such as rice cakes; hard-boiled, half-hatched duck eggs; several different kinds of local soups and sandwiches; meat rolls; and luxury goods purchased or stolen from the Americans. In 1966, television antennas began to appear over elegant townhouses and shanties alike.

The city since 1975. On the morning of April 30, 1975, North Vietnamese troops swept into Saigon, and a new phase in the city's life began. Under Communist control, Ho Chi Minh City lost its administrative functions, and strenuous efforts were made to reduce its population and dependence upon foreign imports and to nationalize its commercial enterprises. More than 700,000 ethnic Vietnamese residents of Ho Chi Minh City were reportedly transferred by the government to "new economic zones" designed to exploit marginal land areas in the plateau transition zone and foothills to the north and west. But many of these people were poorly prepared for the difficult life of such settlements, and later reports suggested that some returned to urban areas.

Saigon as the capital of South Vietnam

Japanese rule

Growth of shantytowns

Reduction
of the
Chinese
population

The ethnic Chinese population was drastically reduced after 1975. Not only did the Chinese appear to have accounted for a disproportionate number of the hundreds of thousands who fled the Communist takeover in 1975 but efforts by the new government in 1978 to nationalize business and convert small private firms into state-operated cooperatives provoked fear and resentment among some segments of the large Chinese business community. In that year an estimated 160,000 ethnic Chinese fled Vietnam for the People's Republic of China, which claimed about 250,000 immigrants, some of them ethnic Vietnamese, by 1979. Many Chinese also fled to other Asian countries.

While many business firms closed or suffered disruption after 1975, new ventures began, with emphasis placed on self-sufficiency. A film studio now produces local motion pictures to replace those formerly imported, and a state-run handicraft enterprise exports a wide range of products—including furniture, carpets, lacquer paintings, and other works of art—made largely from local materials. There are many more bicycles and far fewer motor scooters, taxis, and private cars in the streets of Ho Chi Minh City than there were in those of Saigon.

Most of the bars and restaurants that thrived in Saigon have closed their doors. The elegant Cercle Sportif, a focal point of social life for Westerners after it was founded in 1912, has become a people's museum. The old opera house, for 20 years the National Assembly Building, has been converted to a national theatre. The University of Saigon and Buddhist University of Van Hanh have been merged to form the new national Ho Chi Minh University. The once busy Tan Son Nhat Airport was virtually shut down in 1975; it now has regularly scheduled flights by Air Vietnam to other domestic urban centres and by Air France to Paris.

The population of Ho Chi Minh City in the early 1980s could not be estimated with accuracy, although it was certainly well below 3,000,000. Although the city was still in a state of transition, it was greatly changed from the days when an artificially inflated economy and insecurity in the countryside combined to make Saigon one of the most densely populated cities in the world.

(Q.-T.-T./N.L.J.)

Saigō Takamori

Saigō Takamori, a Japanese soldier-hero, was one of the leaders of the movement that overthrew the Tokugawa shogunate, which had ruled Japan from 1603, and restored power to the emperor. Although his participation in the Restoration made him a legendary hero, it also, to his mortification, relegated his samurai class to impotence. As the final act of his life, he rose in rebellion against the Imperial government.

Saigō was born on December 7, 1827, in Kagoshima, then the main centre of Satsuma *han* (fief, or feudal domain), Kyushu. His family were samurai of a low but honourable rank whose traditional responsibility was that of serving in the feudal lord's bodyguard.

From boyhood, Saigō was distinguished by his unusual size and physique; as an adult he was almost six feet tall, weighing some 200 pounds. A giant among his contemporaries, he appeared frightening at first glance with his

Saigō Takamori, crayon on paper by Edoardo Chiossone, 1883. In a private collection, Tokyo

for Educational Information Tokyo, Inc

large piercing eyes and bushy eyebrows, but he was friendly and unassuming in manner. With all the samurai virtues—bravery, generosity, and excellent swordsmanship—he attracted friends and followers in great numbers. He was impatient with details, making decisions quickly and preferring action over argument; his natural disposition was probably reinforced by his education, which included training in Zen Buddhism and the Neo-Confucianism of the Chinese philosopher Wang Yang-ming, who espoused sincere convictions and forthright action. Saigō's personal motto was *Kei-ten; ai-jin* ("Revere Heaven; love man").

Role in Meiji Restoration. Before reaching the age of 40, Saigō had achieved prominence as commander of the forces of Satsuma *han* stationed in Kyōto, the Imperial capital. One of the inner group of decision makers in his *han*, he also had wide contacts among the Imperial loyalist element throughout the country that was soon to overthrow the shogunate government. He was experienced in the complicated internal diplomacy of the time, having arranged the surrender of the fief of Chōshū to the authority of the shogunate in 1864-65, and was one of the small group who negotiated the secret alliance of Satsuma and Chōshū in 1866. He also worked secretly to force the Shōgun's resignation, which occurred November 8, 1867.

The events that made Saigō a national hero began immediately after this, when the loyalists, dissatisfied with the administrative stalemate resulting from the Shōgun's resignation, plotted the coup d'état that was to become known as the Meiji Restoration. Before dawn on January 3, 1868, troops under Saigō's command seized control of the palace gates. A council of notables was summoned to which the young emperor read the Imperial rescript that was to inaugurate a new era for Japan.

A brief war ensued between the shogunate and troops, now called the Imperial army, supplied mainly by the fiefs of Satsuma and Chōshū. Saigō as chief of staff successfully arranged for the surrender of Edo (the shōgun's administrative centre; modern Tokyo) in May; he then directed a campaign against supporters of the shogunate in the north that lasted until November 1868.

Saigō had completed the task as he saw it: that of ensuring the supremacy of the Imperial court over the nation. Then, instead of participating in the difficult problems of organizing a new administration or even merely basking in the adoration of his countrymen, Saigō entered into retirement in Satsuma. In 1869, when the Emperor awarded honours to those who had brought about the Restoration, Saigō's were the highest granted; but he still refused to take part in the new government.

In 1871 Saigō was at last persuaded to join the government and was given command of the newly created Imperial Guard, consisting of some 10,000 troops. With a reliable military force under their control for the first time, the leaders of the Restoration were able to take a vital step, which they considered the most daring taken

Com-
mander
of the
Imperial
Guard

so far: the abolition of the *han* (see above) and their replacement by prefectures. To further strengthen the government at this juncture, Saigō was appointed to the Council of State (*Dajōkan*) and assumed joint responsibility (with Kido Takayoshi) for carrying out the new program. The change went smoothly and was followed by the disbandment of all *han* troops. Thus, by the end of 1871, the government had eliminated all potential military opposition, and, in the summer of 1872, Saigō was promoted to the new rank of full general.

During this period, however, serious differences were developing over the question of introducing conscription. Some members of the government, influenced by a study of European army organization, insisted that universal military training was a necessity. Others felt that it was unwise to deprive the samurai class of their ancient monopoly on warfare. While the debate raged, Saigo, the leading military figure in the nation, declined to commit himself publicly. It is known that he privately supported the plan, and there is general agreement that without his encouragement, conscription probably would not have been adopted by the government. The question remains, however, as to why he could not bring himself to support it openly. Saigō's inability to take a stand on conscription was perhaps an indication of a deeper malaise: fearful that Japan was losing the samurai spirit, he was beginning to regret his part in having started an apparently irreversible process. During the summer 1873, these emotions boiled over in connection with the problem of Korea.

This "Hermit Kingdom" had refused to recognize the Meiji government, and it rebuffed three successive missions from Japan. Like many others, Saigō felt Korea's attitude was insulting and that Korea deserved chastisement. From his particular viewpoint, a war would also have the advantage of reinvestigating the samurai, many of whom were sulking or rebellious over the trend toward modernization that had set in with the Restoration, but who felt especially aggrieved by the conscription act.

In order to realize these objectives, Saigō argued in the Council of State for a unique plan: he would go to Korea as a special envoy, ostensibly to settle outstanding issues. While there he would contrive to behave in such a way as to provoke his own murder, thus affording Japan unquestionable justification for a declaration of war. Saigō replied to all objections that offering up his life for his country was his dearest desire. After continued entreaties, he succeeded in having his proposal approved by the Emperor on August 18, shortly before government leaders returned from a lengthy foreign trip. Appalled at the decision, these men argued the priority of internal development over foreign adventure and were eventually able to have the plan cancelled.

Furious at this reversal, Saigō resigned as state councillor and commander of the Imperial Guard and returned once more to his old home; several other high-ranking officials tendered their resignations also, while at a lower level, over 100 officers of the Imperial Guard shared Saigō's retirement. Thus, his intransigence had irreparably split the leadership of the nation. That Saigō felt impelled to take such a drastic step indicates the depth of his feeling.

A few months after returning to Kagoshima, Saigō opened his own private school, with emphasis on military science and physical training. Disaffected former samurai from all parts of Japan flocked to study under him. It was estimated that by 1877 the students numbered about 20,000. To Saigō, this was a simple private school that trained young men for public service. To the government in Tokyo, however, it was a cause for concern: the administration of the prefecture from the governor down was in the hands of Saigō's supporters, and graduates of his school were being preferred for new appointments. With samurai rebellions occurring in other parts of the country during 1876, there was real fear that Kagoshima might become the centre of a serious insurrection. In an attempt to assert authority, the government took some ill-advised steps that only inflamed the already tense atmosphere, and on January 29, 1877, a group of Saigō's disciples attacked the Kagoshima arsenal and navy yard.

Rebellion against Imperial government. Saigō, who was in the mountains on a hunting trip, hastily returned. By the time he reached Kagoshima his supporters were operating the arsenal themselves to provide supplies for further military action, and Saigō reluctantly agreed to become the leader of their rebellion.

Plans were made to march on Tokyo with the vague idea of presenting grievances to the government, and on February 15, Saigō's army started out. Government forces blocked his advance at Kumamoto, and full-scale war ensued for the next six months. Saigō's old friend Yamagata Aritomo (1838–1922), now minister of war, became the field commander against him. By May, Saigō was on the defensive; during the summer he suffered a series of disastrous defeats, and by September the situation was hopeless. With a few hundred men, he returned to Kagoshima to make his last stand on a hill overlooking the city. On September 24, 1877, the government troops launched the final attack; Saigō was critically wounded and as previously had been arranged one of his faithful lieutenants took his life by beheading him. Of the 40,000 troops he had captained in February, only some 200 remained to surrender to the government. Losses on both sides were estimated at about 12,000 dead and 20,000 wounded.

In the narrow sense, the failure of Saigō's rebellion meant the end of what he had lived for. The conscript army had defeated the samurai; never again would the government fear local uprisings or samurai threats. If the great Saigo could not win, no one else would be foolhardy enough to try. But in a broader sense, Saigō probably emerged the victor. To the Japanese people, he became the apotheosis of the national character, one more exemplification of the *giri-ninjō* conflict ("duty" versus "sentiment," or "compassion") that is such a well-loved theme of Japanese tale and drama. He became a legend: as late as the 1890s, some still believed that he had not really died but was in retirement waiting to emerge once more at the proper time.

Assessment. Such a complex character must necessarily have had detractors as well as admirers. His critics have called him changeable, because he joined a government he did not believe in and then left it; insincere, because he proposed offering negotiation to Korea although he was hoping for war; undignified, in seriously proposing to have himself murdered by the Koreans. Possibly the most serious criticism is that if Saigō had truly regarded the rebellion as unwise, he could certainly have prevented it. Yet there are few who would call him a rebel: the government itself gave him a posthumous pardon and raised his son, Toratarō, to the nobility. His contemporary Fukuzawa Yukichi, Japan's great modernizer and one of its most independent thinkers, in a detailed analysis of the rebellion pointed out that Saigō could not be called a rebel against the Emperor, since there was never the slightest doubt of his loyalty, and that the government with its increasing authoritarianism, suppression of criticism, and lack of interest in consulting public opinion, was as much at fault as Saigo.

In attempting to summarize this argument objectively, it is probably fair to say that Saigō's real weakness lay in his inability to think things through logically to their conclusion; that he was ruled more by intuition than by reason. To say this is to say that he was a tragic figure, possessed of undeniable talent, who, although he had had much to do with bringing a new age to birth, could not make a complete adjustment to it in his own mind, and finally sought escape in the only way that seemed honourable to him: self-destruction.

BIBLIOGRAPHY. Of the many Japanese-language biographies of Saigo, MUSHAKOJI SANEATSU, *Great Saigō* (1942), is the only one translated and published in English. Not completely satisfactory in every way, it is nevertheless distinguished by its interpretation of Saigō's attitudes and motivations. Also useful are: FURUKAWA TESSHI, "Saigō Takamori," *Philosophical Studies of Japan*, 8:1–17 (1967); W.G. BEASLEY, *Modern History of Japan* (1963); and JOHN K. FAIRBANK, EDWIN O. REISCHAUER, and ALBERT M. CRAIG, *East Asia: The Modern Transformation* (1965).

The fight over conscription

Saigō's Korean plan

Last stand at Kagoshima

Sails and Sailing Ships

One of man's earliest inventions, the sail, which utilizes the power of the wind, was the most important means of propelling boats and ships for most of maritime history. Not until the second half of the 19th century was the sail seriously challenged by steam, and, as it faded out in the competition for commercial cargo, it found a growing role in recreation. The following article treats both the history of the sailing ship, from the earliest known beginnings up to the present day, as well as the sport-sailboat industry. For the history of the sport and the classes of boats, racing competition, and the techniques of sailing, see BOATING AND YACHTING.

HISTORY

Developments to the 14th century. *Early sails and sailboats.* The boat, either as a single log or a raft, may be nearly as old as man, and sailing craft can be traced back almost to the beginning of recorded history. Boats with sails appear in predynastic (c. 3300 BC) Egyptian rock carvings in Wadi Hammamat in the Nile Valley, on a scrap of Egyptian linen now in a Turin museum, and on Egyptian vases currently housed in the British Museum. Egyptian vessels altered little in basic character during the next thousand years, except for their increasing size and seaworthiness. In the earliest craft, which were made of reeds, the mast was a bipod, composed of two spars joined together at the top to form a triangle. The mast, supported by lines from the masthead to various parts of the vessel, carried a square sail, of papyrus or cotton, laced at the head to a long, heavy horizontal spar called a yard. The halyards (lines for hoisting and lowering sails) were led aft from the masthead toward the stern of the ship to act as additional support for the mast. A crew of strong rowers served as an alternative motive force, and the vessel was steered by a large oar or with two or three oars in parallel, slung over each quarter (the side of the boat near the stern).

By about 2000 BC a pole mast had replaced the bipod, and the foot of the sail, like the head, was spread on a horizontal spar. The multiple steering oars gave way to two ponderous oars hinged behind the helmsman and pivoted on the quarter. Each steering oar was worked by a tiller that projected downward from the high top of the oar. A curious feature was the hogging truss, a stout rope stretching from bow to stern above the heads of the crew, strained taut to prevent the high ends of the narrow craft from sagging and causing it to arch up, or hog, in the middle.

Egyptian seamen had habitually traded with Crete during the time Cretans dominated the eastern Mediterranean (about 1500 BC). Though the Cretans also sailed cargoes to Egypt, only cryptic scratches on stone remain to tell of their ships. The later, far-ranging Phoenicians, master seafarers of antiquity, left more explicit records in bas-reliefs, cylinder seals, on coins, and even through a crude ship model of terra-cotta, made sometime between 1580 and 1200 BC at Byblos, on the coast of Lebanon. The Phoenicians may even have sailed through the Strait of Gibraltar on trading voyages to Britain, and it is possible that they sailed around the coasts of Africa. They were able to stand clear of the coast and to sail by night, using tables of distances and navigating by the stars.

As ships developed in size from small fishing or trading craft, used perhaps in sporadic raids, they diverged into two distinct types: merchantmen and warships. This divergence was true of the vessels of Assyria, which closely resembled the Phoenician ships.

Those of the Etruscans, of pre-Roman Italy, are represented by a unique wall painting of a merchant vessel, discovered in an Etruscan tomb in 1968 and now exhibited in the Tarquinia museum, north of Rome. This vessel, which dates from about 475–450 BC, has a short mast, carrying a sail of some size, stepped forward of her mainmast. In common with later ships, her bulwarks (sides above the upper deck) are latticed and her hull deep, appearing to disprove theories that no Mediterranean craft had more than one mast until well into the 2nd century BC.

The Greeks succeeded the Phoenicians as the leading sea power and built a war galley very similar to that of the Phoenicians, with a fierce ram, a wide sail, and two tiers of oars of different lengths, rowed by men on two different levels. Roman shipbuilders took over this long, low warship, changing its general design little.

The Greco-Roman merchantman, however, was essentially a sailing vessel, not a galley, even though it could be rowed when the wind failed. The mainmast stood in the centre of the ship and carried two small triangular topsails in addition to the mainsail; a strong spar, the artemon, was canted upward at a steep angle in the bow to carry a small square sail, which made the ship easier to steer. Also typical of the merchantman was the way her curving sternpost was brought up through the deck, its end becoming a large carving of a swan facing aft. Both warship and merchant ship had two features in common adopted from Egypt: the sail halyards served as extra backstays for the masts, and precautions were taken against hogging. In these ships, however, there was a thick belt of planking along the ships' sides instead of the hogging truss. From these times until the Middle Ages, the galley, fast and manoeuvrable independent of wind, was used primarily for war; the larger, rounder sailing and oar ship carried cargo. A ship raised from the bottom of the Thames River in 1962, believed to have been built by native craftsmen in the 2nd century AD and the oldest vessel yet discovered in northwest Europe, was a Romano-British sailing barge designed for river navigation. A coin from the reign of the emperor Domitian still lay in the mast step, placed there as part of the age-old rite of ensuring good fortune to a ship.

The Viking ships. By at least the 7th century AD a new phase of ship design was opening in northern Europe, a phase that can be traced by the remains of large, open rowboats, such as the Nydam boat found near Flensburg in Schleswig (1863) and others like it discovered elsewhere in Scandinavia. These boats had only a rudimentary keel and resembled the 7th-century Saxon vessel, found buried with a hoard of treasure in a mound at Sutton Hoo in England. In the 8th century, as a series of carvings on the Swedish island of Gotland attest, the sail grew from a scrap of cloth into the full square sail that, striped red and blue or plain bloodred, became a flamboyant warning on many a coast. This sail was loose-footed; that is, it was not attached to a spar at the foot.

The true Viking ship, which was raiding the coast of Europe by the end of the 8th century, was of similar shape and construction to the Nydam boat but immensely improved. Evidence for this comes from two ships found in Norway, one at Gokstad in 1880 and the other at Oseberg in 1903, after being buried for 1,000 years. The 70-foot- (21-metre-) long Oseberg galley with shallow draft and intricate carving may well have been a pleasure craft for sheltered waters. The 78-foot (24-metre) Gokstad ship, however, was a typical war vessel and may have taken part in raids on the British coast in the 9th century.

The Gokstad ship was clinker-built—that is, with overlapping 16-inch- (41-centimetre-) wide oak planks (strakes). Because the lower eight strakes were lashed in place, rather than bolted to the ribs, they had elasticity and give in a seaway. The mast was stepped, nearly in the centre, in a solid block shaped like a fish. Like all Viking craft it was double ended with bow and stern rearing up in a graceful sweep to a high stem or sternpost and probably to a figurehead of a fierce snake or dragon, which could be removed when necessary to avoid risk of damage. The ship was rather flat bottomed for easy landing on a beach, even though the Norsemen had by now evolved a definite keel. A long, massive rudder had its pivot on the starboard or "steer-board" quarter (right-hand side) and was swung by a short tiller, placed at a right angle to the oar. The holes for 16 oars, cut below the gunwale (upper edge of the ship's side) along each side, were ingeniously shaped like keyholes and could be closed by shutters when under sail. Outboard of the gunwale was a rack in which the crew's round shields were

placed for a harbour display of overlapping black and yellow. In time the Vikings devised the bowline, a line leading forward to pull the weather edge of the sail around to enable the ship to sail off the wind.

The discovery, at the entrance to Roskilde Fjord, north of Copenhagen, of five double-ended ships has greatly increased our knowledge of these craft. The five ships had been filled with stones and skillfully sunk to block the narrow channel against some invader, probably in the 10th century. Although all were built roughly in the same pattern, no two of the five vessels were exactly alike in size, type, or age. The largest of the five, built more for sailing than rowing, is thought to have been a 10th-century troop transport. Smaller vessels probably sailed with marauding fleets up the Thames and the Seine to plunder London and Paris or up the Tagus to Lisbon or even into the Mediterranean. One stout ship was deep, with high sides and an open hold. Had she been manned from Norway instead of Denmark, she might have made the ocean voyages to the Faeroe Islands, Iceland, Greenland, and perhaps to the mainland of North America.

Medieval developments. The ships that carried William the Conqueror's army to England in 1066, as shown in the more or less contemporary Bayeux tapestry, are hardly distinguishable from Viking vessels of two centuries earlier. In northern European waters, ships continued to be clinker-built and double ended, with a single, central mast, for another 300 years. Some improvements were introduced, however, in the form of "castles," or fighting towers, at either end, at first temporary (for war only) and later permanent. Also a "fighting top," a square box from which men could fire or drop missiles on an enemy craft, was added to the mast. Its weight, together with the pull of the large square sail, made it necessary to add extra stays and shrouds to the standing rigging. At the start of the 13th century, or perhaps earlier, northern ships received a bowsprit, a large spar projecting over the stem (the timber to which the ship's sides are joined at the bow) to hold the bowline farther out and give the sail greater effect. Even so, the outsize oars, known as sweeps, were retained by every vessel as a standby precaution.

In the Mediterranean, where commerce was far ahead of that in northern regions, ships were better built and much larger in size. Instead of the overlapping clinker construction, Mediterranean ships, both Arab and European, had their planks fitted together edge to edge (carvel construction), nailed to the ribs, and caulked with pitch. By the mid-12th century, Genoese ships had two decks, three-deckers appearing in the late 13th century. Two masts were used, the forward, taller and slightly heavier and carrying three lateen-rigged, triangular fore-and-aft sails to two for the aftermast. The best sails, made of strong cotton or linen canvas, were of Genoese or Marseilles manufacture. Often, instead of a single castle at the stern, Italian ships had two castles, one atop the other. A combination galley and sailing ship, the *tarida*, was widely used throughout the high Middle Ages. One reason for the continued survival of the galley, in the face of competition from the sail, was that the large crew of a galley made it formidable in the event of attack by pirates.

Yet a significant advance in ship design, the stern rudder, first appeared not in the Mediterranean but in the north. The earliest picture of a stern rudder with the gudgeons (metal eyes or sockets attached to the sternpost to receive the rudder pintles, or pins) to form a hinge appears on an English civic seal dated 1200. At first the new rudder had to be curved to conform to the curving sternpost; later, ships were built with straight sterns. Despite the spread of the innovation in the north (a German seal shows a stern rudder in 1242), it did not appear in the Mediterranean until the 14th century. Possibly the larger Mediterranean ships, some of which were over 100 feet long in the mid-13th century, could be handled better with the existing technique of a pair of lateral rudders, one on either side, near the stern. In all other respects the Mediterranean shipbuilders remained in the vanguard of the world, their only serious competition being the Chinese junks, which Marco Polo admired.

Sailboat development (15th–17th century). At the start of the 15th century, three-masted ships were common in the Mediterranean, while in northern European waters the single mast remained the rule. But during the course of this century, the three-master became universal, with a short foremast forward of the tall mainmast and a mizzenmast aft. The foremast at first carried a single lateen sail; later, a square spritsail was rigged under a pole extending from the ship's bow, which made it practicable to move the foremast farther aft and increase its height. The additional shrouds (lines fixed to the sides of the ship to brace the mast) that were necessary found a secondary use: ratlines (short horizontal lines secured between shrouds) provided rope ladders, which replaced the wooden ladders used to climb the mast.

At this time a new fashion was being set by the carracks, the deep, broad vessels of Venice, Genoa, and Spain. These carracks had a high poop (stern) and a still higher forecastle thrusting out over the bow. Competing with the Italian and Spanish carracks, as the century progressed, were the simpler and lighter Portuguese caravels. Originally a fishing vessel, the caravel was not so deep and broad as a carrack. Named for the carvel method of construction, the caravel helped to popularize the fore-and-aft, lateen-rigged sail, which permitted a ship to take advantage of a beam wind. The two types of sails were often used in combination in an effort to allow for changing winds, but opinions varied on how the two sails should be mixed. One favoured rig had square sails on foremast and mainmast, possibly with a square topsail above the mainsail and the high, pointed lateen on the mizzen. Another class of caravels, however, kept to a complete lateen rig.

A few of the larger ships could carry three sails on the mainmast: from bottom to top, the course, the topsail, and the topgallant. Four-masters were also built, with square sails on the foremast and lateens on the other three masts.

There was now a standard method of shortening sail. A square sail was no longer reduced in area by reefing (folding and tying). Instead, a length of sailcloth called a bonnet, which had been added to its foot, could be unlaced and taken off. For increasing the sail area in light winds, there was a narrower strip called the drabblor, which could be laced to the bonnet. Both bonnet and drabblor remained in use until the 18th century.

Along with revolutions in the design, size, and rigging of ships came improvements in navigational equipment, notably the cross-staff, a 16th-century device that virtually replaced the astrolabe as a means of finding the altitude of a star or the sun and therefore the latitude of the ship. The mariner's compass had long been known in various forms. As early as AD 868 Norsemen are reputed to have used a lodestone (magnetic iron ore) compass during a voyage to Iceland. In the 13th century a lodestone that floated on a circular piece of wood in a bronze bowl was used in Scandinavian waters. Meantime, the instrument had arrived in the Mediterranean in the 12th century. In the latter part of the 15th century, the Portuguese sailed their caravels southward down the African coast and around the Cape of Good Hope, while Columbus sailed similar Spanish ships across the Atlantic.

Guns, galleons, and galleasses. The 16th century ushered in the era of the large carrack, which was followed by the galleon. In the early part of the century, there was an outburst of rivalry among six countries in the building of big carrack-type ships, with their triangular, overhanging forecastles. The "Santa Anna" of the Knights of Malta, the "São João" of Portugal, the "Great Michael" of Scotland, the French "Grand François," the Swedish "Stora Karfvel," and the English "Henri Grâce à Dieu" were all launched within a few years of one another.

The "Great Michael," built by James IV and launched in 1511, was 200 feet (61 metres) in length and 36 feet (11 metres) in beam. Its building exhausted the timber of Fifeshire, and extra lumber was brought from Denmark. Its canvas and cables came from France and its anchors from Spain. Its sides were protected along the waterline by a stout belt of timber five feet (1.5 metres) in thick-

ness, an odd predecessor of the blisters that were added to the sides of British warships in World War I. Its crew is said to have included 300 mariners, 120 gunners, and 1,000 men-at-arms. After brief service at sea, when the king was killed in 1513, it was sold to the French.

Iron guns, sometimes lethal to their crews when they exploded, had been carried on board ships as early as the 14th century and were later placed in the forecastle and sterncastle. In the early 1500s an abrupt and universal change occurred. The clumsy iron guns gave way to heavy brass or bronze cannons, and these were mounted along the side to fire through holes cut in the ship's sides. The development of gunports is traditionally ascribed to a French shipbuilder in about 1501, and the idea was adopted in the "Great Michael," the builders of which lined its gunports with leather as precaution against fire.

Henry VIII laid down his "Henri Grâce à Dieu," known as the "Great Harry," in 1512. The first four-masted ship to be launched in England, it set square sails on the foremast and mainmast and lateen sails on the mizzen and bonaventure (the two masts aft of the mainmast). It had topsails on all of its masts and topgallants on the first three masts. After a major refit in 1540, it took gun mounting a step further by arranging some of its guns in two tiers, firing through ports in the side.

In the Mediterranean, oared galleys, with lateen sails as auxiliaries, continued to be used; but these were never a success in the rough, northern waters, although the English navy retained a few into the 16th century. The Spanish Armada (1588) included no galleys, but there were four galleasses, a hybrid type. More seaworthy than the galley, the galleasse supplemented a crew of rowers with two or three high-peaked lateen sails.

The galleon, which seems to have originated in Spain, was slimmer than the carrack that it was built to replace. Decked in a series of steps at each end and mounting high at the stern, it had a long, projecting beakhead, which was largely composed of open gratings instead of the carrack's overhanging forecastle. It may have looked top-heavy with the towering stern; and, though its weaknesses became apparent to the Spaniards after the defeat of the Armada, it did much ocean voyaging. In the 16th and early 17th centuries the Spaniards, identifiable from afar by the large pictures of saints on their sails, as were the Portuguese by their huge crosses, brought gold and silver from the New World in "plate fleets" composed of such vessels. The whipstaff, a vertical lever that was pivoted through the poop deck, was invented to control the tiller. Though a clumsy contrivance by later standards, it greatly facilitated steering and lasted until early in the 18th century.

Another idea, originated by the English captain John Hawkins, was more effective. He had the topmast made separate from its lower mast, secured with a cap and supported by trestletrees (two horizontal timber cross-pieces fixed fore and aft of the mast to support the cross-trees, which spread the shrouds at the upper section of a mast and the top, a platform at the lower cross-trees). Now topmasts could be struck and sent down on deck in threatening weather, making taller masts and more sails feasible. A Swedish warship of this era, the "Wasa" of 1627, which sank on first hoisting sail, was salvaged in astonishingly good state from the mud of Stockholm Harbour in 1962. It is now on view as a unique example of a 17th-century ship.

By the 17th century all English warships were rigged with square topsails on the mizzen. In addition to the regular spritsail under the bowsprit, a spritsail topsail was rigged on a small mast at the end of the bowsprit. A different kind of spritsail, one supported by a diagonal spar called a sprit and rigged as a fore-and-aft sail on the mainmast—in addition to the regular square sail—appeared on some coastal vessels. At the opposite extreme was the rigging of the huge "Sovereign of the Seas" of Charles I of England in 1637. Some idea of its size can be gathered from the fact that six men could stand upright inside the great lantern at its stern. The "Sovereign of the Seas" had three masts instead of the usual four. In order to spread something like the same amount of canvas on

one less mast, she was rigged for a new sail above her topgallants on foremast and mainmast. This new sail was called a royal, possibly because it was set where the flag-staff for the royal standard had previously been placed. But royals were not seen again until they reappeared as fair-weather sails in men-of-war at the end of the century.

Sailing ships of the East. The Chinese junk, unwieldy and strange as it appears to Western eyes, is one of the most efficient vessels under sail; it has been said that it represents the ultimate in aerodynamic efficiency. Nobody knows how long junks have sailed the Far Eastern seas, but they were making prosperous voyages to India in the 9th century and for a time controlled the Indian Ocean. Through the Middle Ages Chinese merchantmen sailed regularly to Indonesia, Ceylon, India, the east coast of Africa, and even to Aden (Yemen). A good demonstration of the junk's seaworthiness was an 1848 voyage from China all the way to Boston, New York, and London.

There are, or were, upward of 70 different types of junks, oceangoing and riverine, varying in hull form and other respects. The number of masts vary from one to five (five-masters are uncommon, however); all share the same general characteristics. Usually, junks are high-sterned, with outthrust bows. There is no keel, but the massive rudder, often mounted in a slot so that it can be raised and lowered, is deep enough to act as a centre-board to reduce drifting to leeward. The unique feature of the junk was the watertight compartment. The junks of the Huang Ho were built with four of these compartments, but the idea was not adopted in the West for centuries. A curiosity is the square lugsail. It is composed of a series of panels, of matting or linen, each panel stiffened and kept flat by a bamboo batten, which extends all the way across the sail. Each panel has its own parrel, or collar, around the mast and its own sheet leading to the mainsheet. Thus, all parts of the sail, from foot to head, can be close-hauled, enabling the junk to sail very close to the wind. These bamboo battens also act on the principle of a Venetian blind. When the halyard is let go, the panels fold up on top of one another, so that shortening sail is a matter of minutes for a practiced hand. Between one-third and one-sixth of each sail is forward of its mast. The mast itself is unsupported, having no stays or shrouds.

The Chinese invented the lodestone compass long before the 11th century, but by 1085 they were using the floating needle. This was described by the author Shen Kua in his book of that year on the magnetic compass. The dry compass (with pivoting needle) was also devised in China, during the 13th century, but was not in general use until it was reintroduced in the 16th century by the Portuguese and the Dutch.

The Japanese junk, now rapidly passing from the sea, is different from the Chinese in nearly every respect. There is only one type, squat and heavy. The sails, made of matting or cloth, have no bamboo panels but are loose-footed and square. The rudder, while it can also be raised or lowered, is not enclosed but works in a well, open to the sea. Strangely enough, the Japanese junk has more than a hint of the old Roman artemon in the short foremast canted up in the bows to take the square sail.

To the south and southwest of Japan, in the Pacific and Indian oceans, there were and are myriad types of craft, each built to suit local conditions, and a host of varied rigs. There are mixtures of lateen and square sails, sails in parallelograms, sails like lobster's claws or leaves, and sails in inverted triangles. Outstanding among these craft for their ocean sailing were the big canoes of the Polynesians, who made voyages of several days' duration to other islands 200 to 300 miles (300 to 500 kilometres) distant. They are credited with having a corps of pilots trained in weather lore and the courses of the heavenly bodies for their own mysterious kind of navigation. Remarkable as these craft were, all that the West has borrowed from them—and that only recently—has been the modern catamaran and trimaran.

finest merchantmen of six European countries—Portugal, France, the Netherlands, England, Denmark, and Sweden—traded in rivalry in India and the East Indies. Ships of the Dutch and British East India companies, similar in appearance, were built like men-of-war, apart from the fuller lines for their cargo carrying, which made them the "fat East Indiamen." They were well armed; English ships, for example, had more than 20 guns. These were used to cope with the normal hazards of Algerian and Malabar corsairs as well as rival European ships. The Dutch Indiaman "Amsterdam" (1749), found in the sand on an English south coast beach in 1970, was 150 feet (46 metres) in length and carried 56 guns.

Though the East Indiamen gave good service, they were not very speedy; the swiftest sailer of the era was a new class of warship, the frigate, designed for scouting, escort duty against privateers, and commerce raiding. Smaller, lighter, speedier than the massive ships of the line, frigates originated with the Spanish Navy; they were copied and redesigned by the French, and these French frigates were in turn copied by the British and U.S. navies. The first U.S. frigates were built during the Revolutionary War. A later class, which included the renowned "Constitution," still in existence at Boston, came into service in 1797. They were intended for the protection of American merchant ships in the Mediterranean against the piratical xebecs (or chebeks) of the Bey of Algiers and later of Tunis. The xebecs were very swift craft of shallow draft with high, triple lateen sails.

Refinements of hull and rigging. From 1765 to 1812, within the span of the active life of Nelson's flagship, "Victory," large British men-of-war underwent a number of changes, which were copied in other navies. Forecastle and quarter deck had been linked by temporary gangways above the main deck guns; these gangways were gradually widened into a permanent decking, all but covering the waist of the ship. Bulwarks were added, low at first but heightened later. Instead of the old, beaklike prow, ships were given round bows, which allowed more guns to be brought forward and also helped to reduce the amount of water coming on board in a heavy sea. The square shape of the stern was altered to a curve, which allowed guns to be fired from each quarter, and, later, the curve became an ellipse. The stern gallery (balconies

across the stern and around the quarters) returned after vanishing in Elizabethan times. The elaborate decorations of the 17th century nearly disappeared; only some gilding around the figurehead and fancy scrollwork at the stern remained. A method was found, at last, to protect the ship's bottom from the teredo worm by sheathing it below the waterline with copper, fastened by copper nails. The sheathing also had the effect of reducing marine growths on the bottom and so gave the ship more speed. This practice proved so successful that it was speedily adopted by merchant ships in the tropics.

Sails were undergoing a transformation that had begun in the 16th century, when the jib, a triangular headsail, was first used in some light craft. The staysail, also triangular and set on a stay (a line led forward and down from the upper part of a mast—to pull against the backstay to help support the mast—and set between masts) appeared in Dutch and then in British vessels late in the next century. Jibs began to be rigged on a jibboom (a spar extending from the bowsprit to which the foot of the jib was secured), at first on smaller ships, later by the big three-deckers. The jib's advantage over the old spritsail was that it was much easier to handle in heavy weather, and also it is a fore-and-aft sail. The pull of jib and fore-staysail on the bowsprit was countered by a line or chain, the bobstay, leading from the tip of the bowsprit down to the ship's stem at the waterline. Another step was an overdue alteration to the lateen mizzen. Because the part of the sail forward of the mast had little effect, it was cut off. Eventually the cumbersome lateen yard was replaced with a gaff, and the sail, increased in length over the stern, was set on a boom to become the spanker or, as it was named in men-of-war, the driver.

For more than a century, ships had reefed or shortened sail by the use of reef points. These short, light lines, hanging down across both sides of the head of the sail (or across the foot, if a fore-and-aft sail), reefed it to smaller size by tying it up to its yard (or down to its boom, if fore-and-aft). In time, in place of the bonnet, reef points were added to the courses, the lowest sails. In 1805, however, a British naval captain maintained that if sails were reefed at the foot instead of, or as well as, at the head, it would save time and labour and would lessen risks to men's lives. Sails made to his specifications and

New
kinds
of sail

tested in a dozen naval and merchant ships brought enthusiastic reports but failed to convince the Admiralty. Later, however, reef points were lowered among Western shipping.

In the 19th century the square-rigged ship had reached maturity. The mizzen had been lengthened, by addition of a mast, to take a topgallant sail; and in light winds royals were set above the topgallants. A pair of the light, additional studding sails (stuns'ls), extending wide of the mainsails on either side could be set on foremast and mainmast in a man-of-war. Merchant captains were even more ambitious. The mass of canvas they might spread when the wind served could verge on insanity. The most extravagant ever was probably the East Indiaman "Essex," with its capability of setting 63 sails. Taking only the mainmast and starting with the lowest sail, it could set eight sails: the course or mainsail, topsail, topgallant, royal, skysail, cloudscraper, moonraker, and stargazer; in addition, each of these, up to the skysail, could be extended on each side with studding sails. By 1880, however, stuns'ls had gone out of fashion, along with several of the topmost sails.

Schooners, clippers, and Cape Horners. Though the forerunners of the schooner were probably Dutch craft of the 17th century, the type was developed by American shipbuilders into a vessel designed for speed. The fame of these slim, fast schooners, called Baltimore clippers because the Baltimore yards specialized in them, spread quickly. As freighters down the American east coast, as light naval cruisers, as privateers, as fishing vessels on the Grand Banks, or as smugglers or slavers, they soon came into their own. Most of these Baltimore clippers had two masts and were rigged as topsail schooners, having two jibs, gaff-rigged foresails and mainsails, a square fore-topsail, and a gaff main-topsail. Others were rigged as brigs, brigantines, and hermaphrodite brigs—all of which are square-rigged on the foremast, with varying combinations of square or fore-and-aft sails, or both, on the mainmast (see Figures 1 and 2).

Soon shipbuilders, notably at Boston, turned to designing larger ships with more speed. These were the three-masted, ship-rigged American clippers that came into service in time for the California gold rush of 1849. Ship after ship was crowded with those who preferred the sea passage round Cape Horn to a hazardous overland jour-

ney. Two years later (1851) gold was discovered in Australia. The demand for shipping rocketed to such heights that British shipowners placed orders with yards in the United States.

One eventual result was the lea clipper, first American and then British-built. The British tea clippers were rather smaller than the American clippers and had a narrower beam; their registered tonnage was in most cases a little more than half that of the American ships. But they were just as fast and, in some cases, faster. Since the first consignment of the yearly crop of tea gained high prices and a rich bonus on the London market, speed was more important than the amount of cargo. The captains drove the ships hard. Their additional canvas in suitable weather went far beyond the normal style of stuns'ls, with such oddities as new-style bonnets, water sails, save-alls, and jib o' jibs. They made astonishingly good passages. The "Ariel," "Taiping," and "Serica," in their remarkable race of 1866, took 98 days from Foochow to London, while the "Fiery Cross" and "Taitsing," which had started later, took 101 days. The first three ships were in the English Channel together, and they sailed up the Thames at 13 knots (nautical miles per hour) to dock on the same tide. The "Fiery Cross," however, had made the fastest day's run of all five, logging 328 nautical miles in a single 24 hours. The most famous of all clipper ships, the "Cutty Sark," is now permanently in dock at Greenwich, England.

But the brief day of the great American clipper ship was over and was fading fast for the smaller English tea clippers. These were indeed the last days of sail, for improved steamships and the opening of the Suez Canal in 1869 drove the clipper from the China tea trade in the 1870s. Instead, a number began carrying wool from Australia, even though the trade was already flourishing with large, iron-hulled ships that had been specially built for the purpose. Although these iron ships were fast, they were straight stemmed and less graceful than the clippers. They had greater length and were able to carry huge cargoes but were slim enough to move easily through the water. Although they carried about the same square footage of sail as a clipper, modern improvements enabled them to get along with much smaller crews. Later vessels were still longer and rigged as four-masted ships or, as in the case of the typical Australian grain ship, a bark, with a fore-and-aft rig on the aftermast or jiggermast.

When wool cargoes dwindled after 1890, many ships were altered and others built to bring Chilean nitrate around Cape Horn. Others fetched guano from Peru, which, as there were no loading facilities, meant back-breaking work for their crews. At the height of the nitrate trade, the harbours of Iquique, Chile, and Callao, Peru, each held a mass of ships—German, British, American, and French. Prominent among these were the fine ships of the Flying P line of Hamburg, such as the "Padua" and "Pamir," which ran a regular service with nitrate cargoes to Europe, each ship making three round voyages every two years. The opening of the Panama Canal in 1914 and the invention of artificial fertilizers killed the nitrate and guano trade for sailing vessels, and World War II finally swept away all but the last stragglers, which served in the Australian wheat trade for a few more years.

Novel developments. Throughout the last century of commercial sail, steam's ever-growing threat forced shipowners to simplify the work in big ships. Topsails and topgallants were split into upper and lower sections for easier handling, and the old chain slings holding the lower yards were replaced by new patent trusses, which allowed the yard to be braced farther aft so that the ship could sail nearer the wind without the yards fouling the shrouds. Bulky, short-lived manila hemp gave way to steel wire for stays and shrouds; iron replaced wood for the ships' hulls and, in its turn, was replaced by steel. The greatest gain, however, came from steam itself. Steam power was adopted for the capstan, for raising and lowering the sails, for weighing anchor, and for assisting the steering gear,

The largest of all sailing vessels that had no form of propulsion other than her sails was the great steel, full-

The tea clipper

u

Figure 2: Square sails. Studding sails shown astern with rigging.

Simplifying the big sailing ships

rigged ship "Preussen" of Hamburg, launched in 1902. It used steam power solely for working cargo and weighing anchor. Its five steel masts were three feet (91 centimetres) in diameter, and its main yard was 100 feet (30 metres) long. The ship itself was 433 feet (132 metres) in length, with a beam of 54 feet (16 metres).

Among wooden sailing vessels the largest was the American "Great Republic" of 1853, with four decks. The first to use steam winches to hoist its yards and the first to have double topsails, it was built as a four-masted bark for the Australian trade but was gutted by fire on the eve of its maiden voyage. Partly rebuilt and drastically cut down in size and rig, it went into service carrying gold rush passengers around Cape Horn; later, after taking part in the guano trade, it returned to passenger carrying.

The "Great Britain," largest ship afloat when it was launched in 1844, was the first passenger vessel with a screw propeller to cross the Atlantic. It had a length of 322 feet (98 metres), a beam of 51 feet (16 metres), and draft of 32 feet (ten metres) with its 3,720 tonnage. It relied heavily on the schooner-rigged sails on its six masts. Three of the masts were removed later, but it continued as a mixed steam-sail vessel through a long career. It was too large for its time and a commercial failure, though for a time it was usefully employed in laying an undersea telegraph cable across the Atlantic Ocean. It ended as a coal hulk in the Falkland Islands, but in 1970 it was towed back the 7,500 miles to England to be refitted and preserved.

Far more than twice its size was the "Great Eastern," launched in 1858. Its length was 692 feet (211 metres), beam 82 feet (25 metres), and draft 30 feet (nine metres), though it was of 18,914 tons. Also rigged as a schooner, it had both a propeller and paddle wheels, but it was sold, to end as a floating fair.

The big steel-hulled American schooner "Thomas W. Lawson," of 5,218 tons, built in 1902, had seven masts, each 195 feet (59 metres) high. In spite of its size, it had a crew of only 16, with steam winches used for sail handling. It was in service only five years when it capsized off the Scilly Isles, southwest of England.

In 1924 a wholly new kind of sailing vessel, the rotor ship, was extensively tested. Its German inventor, Anton Flettner, based his idea on the discovery that the wind pressure on a revolving cylinder was considerably greater than on a conventional sail. Flettner began by installing in a small freighter two cylinders 50 feet (15 metres) high, which were spun by an electric motor. Steering by controlling the spinning of the rotors, he reached a speed of nine and a half knots. He made further tests with three cylinders 60 feet (18 metres) high in a larger ship but found he could obtain satisfactory results only when all conditions were favourable. The idea was not pursued, and there seems to have been no other invention using wind power in such a radical way.

The end of an era. In 1775 the first successful trial of a boat driven by steam, on the Seine by Jacques P rier, foreshadowed the end of the age of sail. The sailing vessel fought long and hard, not admitting defeat for 100 years and more. One of the last rearguard actions was the struggle of a diehard Finnish skipper, Capt. Gustaf Ericson, who in the 1920s and 1930s built up a fleet of 16 sailing ships, ran them uninsured, except for their cargoes, and manned them with boys in training. The pride of Ericson's fleet, the four-masted bark "Herzogin Cecile," was finally wrecked on the rocks off the coast of Cornwall in 1936, and he died shortly afterward.

Yet there are plenty of schooners and similar fore-and-aft-rigged vessels trading or pleasure cruising about the world today. Of the big square-riggers there are more than 80 sailing the seas. One or two serve as yachts or commercial pleasure ships, but nearly all the others are used to train youngsters for the navy or the mercantile marine of 18 different nations. The U.S.S.R. has the largest fleet, with the United States next but some way behind. The Scandinavian countries have quite a number, and Indonesia has a four-masted bark. Several have been launched since World War II, notably the German bark "Georg Foch," built in West Germany in 1958 in the

same yard and of the same design as four others (two of which are now Russian, one Portuguese, and another the training cutter of the U.S. Coast Guard). Britain has only two large schooners, owned by a private and highly successful sail-training association, and a brig built for sea scouts.

Two of the European barks have been tragically lost. In 1928-29 the five-masted "K benhavn," with 40 cadets in its crew, vanished mysteriously while at sea on passage. Then, in 1958, the four-masted German "Pamir" was overwhelmed in heavy weather, leaving only six survivors of its 35-man crew and 51 cadets. Yet in both Denmark and West Germany new vessels were soon built to replace them. Despite occasional losses of a lesser kind, large and small craft, ketches, schooners, and even a square-rigged ship or two are being launched in many parts of the world to carry on the long tradition of sea and sail.

PLEASURE SAILING CRAFT

The training ships may be the last of the utilitarian sailing vessels, but a whole new and rapidly growing fleet has meantime emerged for sport and recreation. Mostly small craft, designed for coastal and inland waters, small boats are being constructed by the thousands in many parts of the world, in a variety of types and of many different materials.

Classes of boats. Sailing craft designed primarily for pleasure are yachts, other than small open boats known as dinghies. The yachts are fully or partially decked and have open cockpits. Lesser differences include a fixed keel or a centreboard that can be raised and lowered. Another difference is that many decked-over boats have a self-bailing cockpit and built-in ballast. Small vessels may be rigged as single-masted catboats, sloops, or cutters or as two-masted yawls or ketches. For small craft the rig is largely a matter of personal choice. Opinions differ on the advantages or disadvantages of various rigs in their seaworthiness, handiness, and weatherly qualities and in their performance in light airs and a strong breeze.

The Marconi, or Bermuda, rig, with its lofty fore-and-aft triangular mainsail, has now triumphed over the gaff rig, with its more or less rectangular fore and aft mainsail, for most yachts and racing dinghies. In northern European waters small boats also have a choice between the simplicity of the balanced lugsail and the standing lugsail (a four-sided sail bent to a yard that hangs obliquely on a mast and is hoisted and lowered with the sail). There is also the sliding gunter (a simple triangular sail), which has some of the efficiency of the Marconi and can be shortened without leaving a useless length of mast above it.

The old J-class sloops, which competed in the early races for the America's Cup (see BOATING AND YACHTING), were superseded, owing to their increasing cost, by the so-called 12-metre class.

The worldwide growth of interest in sailing is perhaps most evident in the increasing popularity of the multihull catamarans and trimarans. Borrowed from the Polyne-
sians, the catamaran was developed for sport sailing in England in the 1950s by two builders, working independently, and quickly gained international popularity.

The British trimaran has two outrigger floats, the one to the weather side, flying mainly clear of the water, while the leeward one acts as a stabilizer. A type of trimaran developed in the United States has much larger floats, which are bridged over and provide accommodation.

Yachting owes much to such developments as roller-reefing (shortening sail by rolling it up on the boom) and the self-steering gear, which made long-distance, single-handed sailing practical and led to the round-the-world voyages of the 1960s.

The sailboat industry. The introduction of man-made materials has had an increasing impact year by year on the sailboat industry. Boats in the early 1970s were being built mainly of glass fibre (glass-reinforced plastic), ferrocement, and steel.

Glass fibre. Glass-fibre hulls are light, strong, free of rust, and need little maintenance. The manufacturing process consists of bolting together the two halves of a

Flettner's
rotor
ship

Cata-
marans
and
trimarans

wooden mold, polishing it to a glassy surface, and then, at a fixed temperature, building it up layer by layer with successive mixtures of synthetic resin, glass-fibre matting, and a catalyst. The percentage of boats built with glass fibre advanced from 4 percent in 1955 to almost 70 percent in 1970. Some spars, and even masts, were being made of glass fibre by the 1970s.

Metal. The percentage of boats that were being built with metal hulls, using steel and aluminum together, fluctuated in the late 1960s, but the average of 3.4 percent rose with an increased proportion of steel hulls pioneered by the Dutch and increasingly built by the British.

Stainless- and galvanized-steel masts have proved satisfactory. So have aluminum masts, which, in addition to being strong and lightweight, are more versatile than spruce or pine. Laboratory experiments have been made in Britain with an alloy of aluminum and carbon fibre as a possible new material for masts.

Ferrocement. In ferrocement hull construction, a frame of light steel pipe, steel reinforcing rods, and chicken wire is first built. Cement is then forced through the frame, filling the spaces and forming a smooth hull. The ferrocement varies in thickness from $\frac{5}{8}$ to $\frac{7}{8}$ inch (16 to 22 millimetres), according to the length of the vessel, but it is immensely strong and, unlike unreinforced cement, is not brittle. It is highly resistant to shock and explosion. No maintenance is needed, and it is immune to either rot or rust.

Timber. In the 1960s manufacture of timber hulls, except for luxury yachts, fell off sharply, declining from 82.4 percent to 13.6 percent in four years.

Synthetics. Ninety percent of all sails are made of Dacron, known in Britain as Terylene. Dacron stretches a little when new, just the right amount, and has the virtue of keeping its shape. In rope or cord it is preferred to nylon for sheets and halyards, but, as with all synthetic fibres, it is liable to stretch under a steady strain. Nylon, being slightly stronger than Dacron in ropes more than $\frac{1}{4}$ inch (six millimetres) in diameter, is widely used. It is resistant to oil and alkalis, though not to all acids, whereas Dacron resists acids but is vulnerable to alkalis. As with all synthetic fibres, both are free from rot and mildew.

Polystyrene (Styrofoam) is used in a variety of ways to add buoyancy, such as being packed under the deck or molded to fit inside a mast. It is liable, however, to disintegrate when it comes into contact with petroleum products, and only a rubberized adhesive may be used to secure it in place.

New developments in boatbuilding materials and techniques are continuous, and current methods may well be superseded in the future.

Saint

The phenomenon of saintliness (*i.e.*, the quality of holiness, involving a special relationship to the sacred sphere as well as moral perfection or exceptional teaching abilities) is widespread in the religions of the world, both ancient and contemporary. Various types of religious personages have been recognized as saints, both by popular acclaim and by official pronouncement, and their influence on the religious masses (the broad spectrum of those holding wide-ranging religious beliefs) continues to be of considerable significance.

NATURE AND SIGNIFICANCE

Saints are persons believed to be connected in a special manner with what is viewed as sacred reality—gods, spiritual powers, mythical realms, and other aspects of the sacred or holy. The existence of such persons has been a widespread phenomenon throughout the religions of the world. The religious person may have various relationships with the sacred: as seer, prophet, saviour, monk, nun, priest, priestess, or other such personage. In each of these, however, a specific kind of relationship to the holy is involved. Seers, for example, have an inspirational vision of the future; prophets proclaim a revelation; saviours are entrusted with effecting redemption, liberation, or other salvatory conditions; monks and nuns lead religious lives in accordance with ascetic regulations that they generally observe as long as they live. Every one of these religious personages may simultaneously be, or become, a saint, but there is no necessary connection. Sainthood thus implies a special type of relationship to the holy, a relationship that is not automatically obtained by other religious personages through their performance of religious duties or offices.

The significance of saintly personages is generally based upon real or alleged deeds and qualities that became apparent during their lifetimes and continue to exert influence after their deaths. The special character of their feats and qualities of living is believed to arise from an especially close association with a deity or sacred power. In addition to such a relationship, sainthood also requires the existence of a sacral institution that can grant such recognition, or of a popular cult that acknowledges and posits a belief in the saint's special qualities. In institutionalized religions, such as Roman Catholicism, there is a regularized process (called canonization) by which saints are officially recognized. Canonization requires, among other things, proof that the person in question wrought miracles during his or her lifetime. On the other hand, folk belief often recognizes the saintly powers of a living or dead person long before the institutional religion acknowledges him as a saint. Nor does the lack of official recognition discourage continued veneration.

The special relationship of the saint to divine, sacred, or numinous (spiritual) powers is often enhanced by ascetic self-realization and self-negation. It does not necessarily follow, however, that the saint is an ethical example to others, though the saintliness often manifests itself in ethically outstanding deeds or qualities.

SAINTS IN EASTERN RELIGIONS

Confucianism and Taoism. Confucianism, the Chinese religion named after its 6th-century-BC founder, Confu-

Relation-
ships with
the sacred
or holy

The importance of right conduct

cious (K'ung Fu-tzu, or Master Kung), but containing many elements of pre-Confucian times, is in the main, ethically oriented. Confucius taught that right conduct was a means of acquiring ideal harmony with the Way (Tao) of Heaven and that the "holy rulers of primal times" were representative examples of such ideal conduct. In the oldest known Chinese historical work, the *Shu Ching* ("Classic of History"), such a ruler, King T'ang (11th century BC), is described as one who "possessed the highest degree of virtue, and so it came to be that he acquired the bright authority of Heaven." Thus, in Confucianism, the saintliness of its holy men lay in ethical perfection, and through the practice of ethical ideals a contact with Heaven (T'ien) was established. Confucius himself serves as an example of a man who was first regarded as a saint because of his deep wisdom and conscientious observance of ethical precepts and was even considered to be "more than human." During the Han dynasty (206 BC–AD 220) Confucius was elevated to a new status: Emperor Kao Tsu offered sacrifice at the Confucian temple, and Emperor Wu proclaimed Confucianism the official ideology of China. The titles duke (AD 1) and king (739) were further tributes to "the perfect sage." During the Tang dynasty (618–907) sacrifices were regularly offered in Confucian temples, and in 1906 Confucius was declared equal to the Lord of Heaven.

Taoism, founded by the 6th-century-BC sage Lao-tzu (Master Lao) and the second major religion native to China, is oriented toward another kind of sanctity: the attainment of a passionless unity with the Absolute. Chuang-tzu (died c. 300 BC), a mystical Taoist sage, speaks of the "pure men of early times" in his work, the *Chuang-tzu*, and characterizes them by saying that

they did not forget where they had come from, they did not care about where they should pass to; readily, they accepted what was allotted to them, peacefully they awaited their decrease. It is this that is called "not resisting the Tao" (the divine Absolute). (Tschuangtse, *Reden und Gleichnisse*. [Deutsche Auswahl], ed. Martin Buber. 1920. p. 27.)

Later, popular Taoism also incorporated into its pantheon saints who were called "true men" (*chen jen*). The "true men" were usually recluses who were close to nature and who exhibited a passive acceptance of the Way (Tao) of nature.

Shintō. Shintō, the native Japanese religion, is concerned with the veneration of nature and with ancestor worship; it does not have saints according to the standards of ethical perfection or of exceptionally meritorious performance. According to Shinto belief, every person after his death becomes a *kami*, a supernatural being who continues to have a part in the life of the community, nation, and family. Good men become good and beneficial kamis, bad men become pernicious ones. Being elevated to the status of a divine being is not a privilege peculiar to those with saintly qualities, for evil men also become kamis. There are in Shintō, however, venerated mythical saints—such as Ōkuni-nushi (Master of the Great Land) and Sukuma-Bikona (a dwarf deity)—who are considered to be the discoverers and patrons of medicine, magic, and the art of brewing rice.

Buddhism. Founded by Siddhārtha Gautama (c. 560 BC), the Buddha (or Enlightened One), Buddhism developed into three major forms in the course of its more than 2,500-year history: Theravāda ("Way of the Elders"), also called in derogation Hinayāna ("Lesser Vehicle"); Mahāyāna ("Greater Vehicle"), and, stemming from it, Vajrayāna ("Vehicle of the Thunderbolt"). A belief in saints prevails in all three groups.

Theravāda Buddhism, claiming strict adherence to the teachings of the Buddha, recognizes as saints (*arhats*) those who have attained Nirvāṇa (the state of bliss) and hence salvation from *samsāra* (the compulsory circle of rebirth) by their own efforts. The Buddha himself—having obtained Nirvāṇa ("the destruction of greed, . . . hate, . . . and illusion")—is viewed as the first Buddhist saint; he says of himself,

I am the holy One in this world, I am the highest teacher, I alone am the completely enlightened One; I have gained peacefulness and have obtained Nirvāṇa.

Disciples of the Buddha who reached Nirvāṇa after him are also considered holy men: his apostles Śāriputra and Moggallāna, converts from Brahmanism (a form of Hinduism); Ananda, the Buddha's cousin and beloved disciple; Rāhula, the Buddha's son; Nāgasena, an erudite monk; and Angulimāla, a former thief and murderer who turned to Buddhism and reached Nirvāṇa. Furthermore, in early Buddhism, there were also women regarded as holy, including Prajāpatī, the Buddha's aunt and stepmother—whose repeated requests finally caused the Buddha to permit women to enter his order—and his wife Yaśodharā.

Mahāyāna Buddhism, originating about the beginning of the Christian Era, rejected the Theravāda belief that only monks may attain salvation. In Mahāyāna belief, there is a path to redemption for all people, irrespective of their social standing. Salvation and the way to redemption are conceived in terms more liberal than those of Theravāda. Mahāyāna Buddhists believe in an otherworldly paradise that allows for personal existence and in which dwell heavenly Buddhas (those who have attained Nirvāṇa in previous worlds), and bodhisattvas ("Buddhas-to-be"). The heavenly Buddhas and bodhisattvas are believed to grant grace to sentient beings, so that salvation is no longer acquired by fleeing from the world and giving up worldly professions, but rather by faith (in the sense of trust) in the promise of a saviour deity. Thus, in Mahāyāna Buddhism, the Buddhas and bodhisattvas are viewed as the holy ones, the saints, who in compassion, attempt to aid others struggling for salvation. This concept is in striking contrast to the arhats of Theravāda Buddhism, who follow the dying Buddha's last words, "Seek your own salvation with diligence." The basic altruistic concept of Mahāyāna then is that of the helping bodhisattva. Everyone should strive for this ideal in order to save as many fellowmen as possible as a *bodhisattva*, and to bring them into the "Greater Vehicle" (Mahāyāna). Hence, the idea of faith in benevolent saints gains prominence in Mahāyāna Buddhism as a theistic religion of salvation. In Japanese Mahāyāna there are patron saints, such as Shōtoku Taishi, the regent who supported the introduction and development of Buddhism in his country in around AD 600, after it had been introduced in AD 552. Shōtoku Taishi posthumously became the patron saint of carpenters. Other saints are Nomi No Sukume, the patron saint of businessmen, and Daruma, the patron of tobacco dealers. Nichiren, the founder of the nationalistic Japanese Mahāyāna sect named after him, is considered to be the incarnation of the *bodhisattva* Viśiṣṭacāritra. The ashes of this saint are kept in a pagoda-like reliquary.

Vajrayāna Buddhism, embodying, among other views, Tantrism (a system of magical and esoteric practices), is mainly represented by Lamaism (the Buddhism of Tibet). In addition to the innumerable saints of Mahāyāna Buddhism, Lamaism also accepts as living saints those who are regarded as incarnations (tulku) of saints, scholars of the past, deities, or demons. The Dalai Lamas, heads of the Tibetan hierarchy, are viewed as reincarnations of Chen-re-zi (the bodhisattva of Mercy, Avalokiteśvara).

Jainism. The Jain religion is named after the 6th-century-BC Indian religious leader Mahāvīra (Great Hero) Vardhamāna, the Jina, or "Victor," over the bondage of life and death. Both of his honorary titles—Jina and Mahāvīra—indicate that he was regarded as an ascetic saint. According to Jain teaching, there were 23 Tirthankaras (saintly prophets or proclaimers of salvation) before Mahāvīra; today they are venerated as saints in temples containing their images. Veneration of the Holy Tirthankaras is viewed in terms of purifying the devotee morally, since these saints are but examples for the Jainas, and not actually objects of a cult.

Hinduism. Hinduism, the predominant religion of India, in a wider sense encompasses Brahmanism, a belief in the Universal Soul, Brahman; in a narrower sense it comprises the post-Buddhist, caste-ordered religious and cultural world of India. The Indian religions are by and large mystical in character; hence, even in early Hindu-

Mahāyāna saints

Differing concepts of saints in Buddhism

Significance of asceticism in the Hindu concept of saint

ism ascetics were highly honoured. Mysticism generally starts with ascetic practices as a means of eliminating a desire for worldly existence. Thus, Yājñavalkya, a sage and mystic of the *Upaniṣads* (philosophical commentaries on Vedic concepts) is addressed as a holy one, and he himself describes the nature of a redeemed person with these words, "If a man is without desires, free of desires, his vital spirits will not depart; Brahman he is and into Brahman he goes."

In later Hinduism, when the ascetics continued to be revered by the masses as *sādhus* (saints, or "good ones") and yogis (ascetic practitioners), the concept of the *avatāra* (the idea of the incarnation of a divine being in human form) served to interpret the existence of holy men. By means of this concept it was, and still is, possible to consider living and dead saints as incarnations of a deity, and also to incorporate saints of other religions into the Hindu world of belief. Thus Jesus Christ, for instance, is regarded as an *avatāra* of the god Viṣṇu (Vishnu), and the great Hindu saint Rāmakrishna is considered to be an *avatāra* of the god Śiva.

SAINTS IN WESTERN RELIGIONS

Ancient Greek religion. The ancient heroes of Greek religion may be regarded as saints. One basis for belief in heroes and the hero cult was the idea that the mighty dead continued to live and to be active as spiritual powers from the sites of their graves. Another source of the cult of heroes was the conception that gods were often lowered to the status of heroes. One of the best known heroes is Heracles, who became famous through his mighty deeds. In Greek religion, the numinous (spiritual) qualities of a person lay in such heroic deeds. Those persons killed in war might become heroes according to ancient Greek belief, and the mythical progenitor of a genetic stock also was regarded as a hero. The 3rd-century philosopher Philostratus pictures Apollonius of Tyana (1st century AD) as a philosophical saint endowed with supernatural powers and hence capable of performing miracles, such as raising the dead; he was often contrasted with Jesus as a miracle worker (see also HERO WORSHIP).

Zoroastrianism and Parsiism. Zoroastrianism, the religion founded by the 6th-century-BC Iranian prophet Zoroaster, and its modern Indian variety (Parsiism), includes the veneration of Fravashis—i.e., preexistent souls that are good by nature, gods and goddesses of individual families and clans, and physical elements. According to Zoroastrian belief, man is caught up in a great cosmic struggle between the forces of good, led by Ahura Mazdā (Wise Lord), and the forces of evil, led by Angra Mainyu, or Ahriman, the Evil Spirit. In the battle between Asha (Truth) and Druj (Lie), the Fravashis may correspond to the saints of Roman Catholicism, who can be called upon for aid in times of trouble. In the liturgical hymns called Yashts are sections devoted to more than 300 Fravashis, both male and female. Among the female saints is Hvōvi, Zoroaster's wife; among the male saints are Gayōmart, the primal man; Saoshyans, the eschatological (last times) saviour; and (in later writings) Artāy Virāf, the saint who journeyed through hell to paradise.

Judaism. The cult of saints in terms of veneration was not a part of the monotheistic religion of Israel. Saintliness, however, was an ideal which many hoped to exhibit. The model of a pious person is depicted in the righteous one of Psalm 5, "his delight is in the law of the Lord, and on his law he meditates day and night." In the Hellenistic period (c. 300 BC—c. AD 300), when many Jews were susceptible to foreign religious influences, the Hasidim (the "pious" ones), segregated themselves from the others, holding fast to the faith of their fathers.

The concept of the Hasidim gained new significance in the 18th century when Israel ben Eliezer called Ba'al Shem Tov, or "Master of the Good Name," started the modern movement called Hasidism. As opposed to the Orthodox Israelite religion with its emphasis on rationalism, cultic piety, and legalism, Ba'al Shem Tov stood for a more mystically oriented form of Judaism. He emphasized the love of God filling the world and stated that this love should find its correspondence in man, thus helping

to restore harmony between God and the world. The leaders of this movement were called the tzaddiqim ("righteous ones") and many edifying legends were told about these saints.

Christianity. Jesus and his disciples did not speak of saints; but during the period (1st to early 4th century) in which they were persecuted, Christians began to venerate the martyrs as saints. They believed that the martyrs, being sufferers "unto death" for Christ, were received directly into heaven and could therefore be effective as intercessors for the living. By the 3rd century, the veneration of martyr saints was already common.

In the Nicene Creed (AD 325), the early church called itself the "communion of saints." Here, however, the word "saint" has the broader meaning of "believer" rather than being applied strictly to a holy person or numinous personality worthy of veneration. In the 10th century, a procedure of canonization (official recognition of a public cult of a saint) was initiated by Pope John XV. Gradually, a fixed process was developed for canonization by the pope, requiring that the person must have led a life of heroic sanctity and performed at least two miracles.

Saints in the Roman Catholic Church are venerated—but not worshipped—because of their spiritual and religious significance, and are believed to be the bearers of special powers. Because of a belief in the powers of the saints, their relics are regarded as efficacious. The relics of St. Polycarp, the 2nd-century AD martyr-bishop of Smyrna in Asia Minor, are described as more precious than gems and more costly than gold. In the early church every new Christian congregation sought for relics of saints to be placed in their altars. Since the 6th century, side altars have been built in honour of particular saints. In the Eastern Orthodox Church saints also are venerated, but the process of canonization is less juridical and not always ecumenical. In some Protestant churches (Lutheran and Anglican) saints are recognized, but not venerated as in the Roman Catholic and Orthodox.

Islam. Islam is a rigorously monotheistic religion, strictly prohibiting any kind of "conjunction" (i.e., affiliation, or consortship) to Allāh. Thus the concept of sainthood was rejected. Yet even here a variegated belief in holy men arose because of the demands of popular religion. Over against the one distant God, whose almighty power and whose role as a strict judge was emphasized repeatedly, there emerged a desire for intercessors. Such were seen in saintly men who were believed to be endowed with charismatic powers (*karāmāt*), allowing them to go miraculously from one place to another far away; to wield authority over animals, plants, and clouds; and to bridge the gap between life and death. The Prophet Muhammad (died AD 632) had negated the existence of saints, but the piety of the masses "canonized" holy men while they were still living. After they died, cults of devotion arose at the sites of their graves, and pilgrimages to such sites were believed to aid the believer in acquiring help and blessing. Miraculous deeds were believed to be wrought by these "friends" (wali) of God, and as a result of this belief Islam differentiates between the wonders that Allāh performs and those of his true messengers in making opponents realize their own helplessness. The Prophet performs such miracles whereas the mere saint, the wali, is incapable of doing them.

In Islāmic mysticism, or Sūfism, the concept of the saint, or wali, is not defined in terms of extensive miracles, but rather in terms of the relationship of the person concerned to God. Men who live a life of service and obedience to Allāh are viewed as living saints, and the world is believed to owe its preservation to their intercession. Concerning such holy men, the Šūfī al-Hujwiri (died between 1072 and 1077) stated,

God has saints [*awliyā'*] whom he had distinguished especially through his friendship, and whom he has chosen to represent his kingship; He has granted them the special gift of bringing His deeds to light. He has especially favored them with [being able to do] manifold miracles [*karāmāt*], He has purified them from the corruptions of nature and freed them from servitude over against their souls which incline toward the evil, and over against their souls' desires.

Saintly powers of Muslim holy men

The Hasidim and tzaddiqim

In Islām it is believed that the saint should be remembered for his deeds rather than for his person. Thus, biographies of Islāmic saints tend to omit personal details.

MODES OF RECOGNITION

Recognition of forms of holiness

The bases of recognition. The basic motive for the belief in and veneration of saints is, primarily, the recognition by people of religious persons whom they view as holy. In order for a religious personage (*e.g.*, prophet) to be recognized as a saint, it is necessary that other people see in him the aura of holiness. The holiness recognized in him may be an impersonal sacred or spiritual power—which is often perceived in quite insignificant persons—and is believed to be present even in the bones and other material relics of a recognized holy person after his death. Religious personalities are also believed to possess a personal holiness, either bestowed upon them by divine grace or acquired through ascetism and moral discipline. Such sanctity reveals itself in the power to perform miracles.

The highest form of holiness in a holy person is reflected in the interpretation of that person as an incarnation of divine reality or as the possessor of godly nature. Divine qualities are perceived in such a person, and through him, such as the Logos (divine Word, or Reason) in Jesus.

Popular recognition. Popular recognition of saints arises out of a predilection of the religious masses (those who maintain popular belief, or folk belief, along with beliefs officially promulgated) to grasp the supernatural in that which is believed to be unusual and uncommon—*i.e.*, in the miraculous event. Thus, the religious masses long for men who can perform wonders that are awe awakening and satisfy their desire for the miraculous and mysterious. When saints perform miracles, they satisfy one of the basic religious needs of the people.

Besides the desire for miracles, there is another basic requirement of the masses, especially within monotheistic religions: the yearning for a superhuman being in human form. The one abstract God who is believed to be present everywhere and capable of helping everybody and everything is too unperceptual and remote for the average religious person. There is a tendency among the religious masses to split up the deity into many numinous beings that fulfill the desires of the people. The religious masses often have polytheistic tendencies. The term "dear saints," as the holy ones are called in Roman Catholicism, expresses an emotional relationship to those near, benevolent, heavenly, or spiritual powers that are the heirs to the ancient ethnic and patron deities of pre-Christian times. Peter and Paul, for instance, are patron saints of Rome, John is patron saint of Ephesus, and Ambrose of Milan. St. George (reduced to commemoration in 1961 and dropped from the liturgical calendar in 1969) is regarded as patron of warriors, and St. Barbara (dropped from the liturgical calendar in 1969) as patroness of miners, artillerymen, and firemen.

In the course of their histories, and as they expand, the great universal religions (*e.g.*, Christianity, Buddhism, and others) incorporate ever more people with their particular folk beliefs. As their numbers grow and their influence increases in the religious communities, the indigenous peoples retaining many earlier folk beliefs form the majority and their inclinations prevail. Since their behaviour patterns generally remain constant, their religious forms are preserved. Occasionally, religious reform movements arise within the organized mass religions. Such movements attempt to restore what is believed to be the original form of the respective religions and often turn against a belief in and veneration of saints, regarding such forms of religiosity as degenerate. This was the case in the 16th-century Protestant Reformation, and also in the Wahhiibiyah movement, an 18th-century reform movement in Islām.

Theological interpretations of popular recognition. In monotheistic religions, the belief in saints in its popular form generally contradicts orthodox teaching. Such religiosity is usually opposed and rejected or else reinterpreted in view of its ineradicability. If the latter is the case, the orthodox interpretation given the cult of saints in

order to justify it is a theological construction. In Roman Catholicism, for instance, church doctrine makes a distinction between veneration (*veneratio*, *douleia*) and adoration (*adoratio*, *latreia*). Veneration is defined as a proper attitude toward saints, whereas adoration is applicable only in connection with God. The veneration of images as practiced especially in the Eastern Orthodox Church is explained similarly. The Roman Catholic Church also teaches that the saints are representatives of God's grace on earth and that they are completely subject to his will. The vestigial remains of polytheistic beliefs and practices connected with the veneration of saints are thus theologically, though not popularly, eliminated.

Similar interpretations have been made in regard to the cult of relics in Buddhism. In Ceylon, for instance, the tooth of the Buddha is venerated. Since this practice contradicts the original teaching of the "Elders," the worship of the relic is explained as pertaining to the Buddha himself, who is the actual and true object of veneration.

A similar situation prevails in Islām. Islāmic theology acknowledged the miracles of the saints, but tried to differentiate them from the *mu'jizāt* ("miracles") of the Prophet. The miraculous deeds of the saints and the prophets are viewed similarly in that God alone bestows supernatural power in each case. But in the Muslim orthodox view, the miracles of the saints are viewed as the results of a prayer that has been answered and also as a power granted by God to perform such deeds. The miracles of the prophets, on the other hand, lie in the creation of something new, or in the transformation of the substance of a thing.

All these and similar interpretations of the belief in saints in a monotheistic religion serve to justify an existing cult. The people themselves are hardly influenced by such interpretations, however. According to many scholars, the differentiation between *douleia* (veneration) and *latreia* (worship), or between *veneratio* (veneration) and *adoratio* (adoration), has little meaning for the masses. In practice, they observe their cult of saints quite in accordance with polytheistic devotion toward gods. The supplications actually directed to the saints in the various religions can hardly be distinguished from prayers to deities, even though the saints are theologically regarded as mere intercessors having special access to God, and the answer to prayer is considered as coming from God alone. From the perspective of scholars of comparative religion, however, beings to whom prayers are dedicated are gods.

Forms of cults. The form of a cult of saints can be categorized as either indirect or direct. An indirect cult form involves the veneration of objects that stand in a magical relationship to the respective saint. In this connection there can be a veneration of the saint's relics. Such religious practices are to be understood in terms of spiritual power. Numinous power is viewed as issuing from the saint; and it is believed to be acquired by veneration or, in practice, mainly by touching (or kissing) the object itself. Another indirect cult form is the veneration of the image of the saint. According to primitive belief, there is a magical connection between the image and the original, which is itself holy. A common and widespread custom is the depositing of votive offerings, dedicated to certain saints, at holy places—temples, churches, shrines, or chapels where the supplicant can be certain of their direct presence and aid. This custom is of ancient origin—*e.g.*, the votive offerings dedicated to the healing god Asclepius in the museum of Epidaurus (Greece). This practice is still to be found in present-day popular belief in Greece or at Roman Catholic places of pilgrimage.

In these forms of indirect cult, then, saints are venerated through the medium of concrete objects. In direct veneration, on the other hand, the saint himself is addressed in invocation and praise. According to popular belief, such direct worship is most effective at the place of the predominant presence of the respective saint. This belief in the localization of the numinous, a typical element of folk belief, is to be found throughout history, from earliest times to the present. For instance, Absalom (the son of the Israelite King David) went to pay his vow to

Theological distinctions of forms of veneration

Indirect and direct cultic forms

"Yahweh of Hebron" (II Samuel) at the place of his special presence. The idea of pilgrimage is always based upon such a belief in the localized presence of numinous power.

TYPES AND FUNCTIONS OF SAINTS

Saints as moral examples. A classical illustration of the saint who is distinguished by his virtue is St. Francis of Assisi. Giving up a life of extravagance, he began in 1209, together with several friends, to actualize his ideal of the imitation of Christ by leading a life of poverty. For St. Francis, three virtues constituted the preconditions of true divine vision: poverty, ascetic chastity, and humility.

An example of a similar kind of saintliness is reflected in the person of the Indian leader and reformer, Mahatma Gandhi (1869–1948). In his life, devoted to the acquiring of freedom for India, he also lived according to three ideals. The first was *satyāgraha*, holding fast to the truth with all the powers of the spirit. Gandhi's second basic principle was *ahimsā*, which is to be understood not only in the negative sense of "not killing" but also positively as a renunciation of the self and an indulgence in "kind actions" toward all beings. His third ideal was *brahmacarya*, which often is rendered too narrowly as chastity; it is the ascetic way of life that Gandhi followed as a saint and as a statesman, hence receiving boundless veneration by the masses.

By living their lives as moral examples, saints influence the personal lives of the religious masses who attempt to emulate saintly ideals in everyday life.

Saints as prophets and reformers. Many prophets and prophetic reformers form a second group of saints. One prophet in early Christianity was Paul, who is honoured as a saint by Roman Catholics, Eastern Orthodox, and Protestants. He was a most powerful spiritual personality, decisively and significantly involved in the development of Christianity from a Jewish sect to a world religion.

The Tibetan reformer Tsong-kha-pa belonged to a completely different world from that of St. Paul. Originally, he did not want to be an innovator, but only a renewer of old religious patterns. He was mainly concerned with the restoration of the discipline and the development of the Lamaistic cult. His fame grew, and due to his activity, many monasteries were founded. The "Yellow Hat" sect was established by him. According to legend, Tsong-kha-pa was taken up to heaven before the eyes of the people. This accounts for the veneration he received, and still receives, by the Tibetan people.

Reforming. Through their reforming ideals, prophetic reformers provide goals toward which the religious masses aim, both personally and socially (or in terms of cult).

Saints as mystics. There are also saints among the great number of mystics—e.g., Bernard of Clairvaux, Gertrude the Great of Helfta, and Teresa of Avila.

At the little nunnery of Helfta near Eisleben in Germany, a centre of mysticism in the 13th century, the mystic Gertrude the Great lived. She said that Christ had appeared to her on January 27, 1281, and that though her physical condition deteriorated, her spiritual life grew. Because of her physical condition, she was all the more devoted to the work of spreading her view of the spiritual life through her writings (such as the *Messenger of Divine Love*), which reflect a life filled with the love of God and deepest thankfulness for the gift of grace granted to her. Since 1606 she has been venerated as a saint, and in 1738 her cult was permitted throughout the Roman Catholic Church.

By their devotion to the spiritual life, mystical saints point out new and contemplative directions of religious thought to the religious masses, who seldom are capable of following such a life.

Theological teachers as saints. Often numbered among the saints are certain religious personalities whose significance lies in their work as illuminating interpreters of religious tradition or as proponents of a new view of the divine or the eternal. An example from Indian religions is the great teacher (dcdrya) Śaṅkara, the repre-

sentative of Advaita (the teaching of the nonduality of divine reality). When he died at the age of 32, a short and outwardly uneventful life lay behind him. Yet even today the personality and work of Śaṅkara continue to determine the intellectual and religious life of India. Equally significant in the Christian West, and specifically in the Roman Catholic Church, is Thomas Aquinas, a Dominican scholar. Although first disputed, his work finally received general recognition, and he became recognized as the doctor *communis* ("general teacher") of the Roman Catholic Church. His significance lies in his encompassing and methodically clear theological and philosophical system, in which he reconciled the views of the ancient Greek philosopher Plato with those of his student Aristotle, antiquity with Christianity, knowledge with faith, and nature with grace. He was proclaimed a saint in 1323.

Local saints. The cults of some holy persons (local saints) are restricted to a particular locality. Though there are innumerable examples, only one will be used to illustrate this type. Brother Conrad of Parzham (in Germany), who died in 1894, was proclaimed a saint by the Roman Catholic Church in 1934 and his relics are buried in the Church of the Capuchin order at Altötting in Upper Bavaria (Germany). The veneration of this holy personality began in 1930, and today Brother Conrad is one of the most popular saints of Bavaria. The cult at his grave at times almost supplanted the cult of the wonder-working image of Maria of Altötting, whose shrine has been famous for centuries. The veneration of St. Conrad, a former gatekeeper at the Capuchin monastery of Altötting, led to a special form of invocation practiced today. Devout Catholics write detailed letters to St. Conrad as though he were still living, then place the letters in envelopes and address them to him. In the house where the saint was born, in the so-called Venushof von Parzham (Venus Court of Parzham), the cult of St. Conrad has also established itself. The room where he lived as a farm servant has been prepared as a memorial place with a little domestic altar. Local enterprise seeks to make this cult serviceable to its interests by producing lemonade made from water from a spring on the farmstead. It is sold in bottles with a picture of the saint attached.

Mythic saints. There is also a group of holy personages that can be termed mythic saints. These are holy ones who are believed to have lived on earth during mythic times and who are yet venerated. Examples of this type are the Indian saints *Kṛṣṇa* (Krishna) and *Rāma*. They are regarded as incarnations (*avatāras*) of the god Viṣṇu. *Kṛṣṇa* was perhaps a hero in early times, or a shepherd god who was associated with Viṣṇu as his human embodiment at a later period. However that may be, the saintly figure of *Kṛṣṇa* is mythic in character. In the *Purāṇas* (ancient Hindu writings), *Kṛṣṇa*'s life is narrated to peasants in the style of myth and legend. In the *Mahābhārata* (ancient Indian epic), it is told to warriors in terms of their concepts of honour and caste. Here *Kṛṣṇa* is the vassal of Prince Arjuna; in the *Bhagavadgītā* (the "Song of God," part of the *Mahābhārata*) he teaches a religious-ethical way of salvation. *Rāma* also is viewed as an incarnation of Viṣṇu. An account of his life is to be found in the *Rāmāyaṇa* (ancient Indian epic) in which there is an account of his killing the giant king *Rāvaṇa* who had abducted his wife *Sītā*.

Conclusion. As long as the religious masses demonstrate a desire or need for saintly figures—whatever their functions are conceived to be—veneration of such holy personages will continue to be practiced and will exert a religious influence even in the modern world, which has been described as oriented toward a secular, or nonreligious, value system.

BIBLIOGRAPHY. PD. CHANTEPIE DE LA SAUSSAYE, *Lehrbuch der Religions-Geschichte*, 4th ed., 2 vol. (1925), gives information, under the key-word "Heiligenverehrung" (veneration of saints), on the significance of saints in the religions of the world. Similar, though less detailed, is H. RINGGREN and A.V. STROM, *Die Religionen der Völker* (1959; Eng. trans. from the 3rd Swedish ed., *Religions of Mankind Today and Yesterday*, 1967). The cult of saints is dealt with in connection with the phenomenology of religion by G. MENSCHING in his *Die*

Brother
Conrad

Religion (1959), as well as his *Soziologie der Religion*, 2nd ed. (1968). The miraculous deeds of saints are discussed in the same author's *Das Wunder im Glauben und Aberglauben der Völker* (1957). See also W.J. BURGHARDT, *Saints and Sanctity* (1965). The characteristics and the actions of holy men in non-Christian religions are treated in the following works: R.A. NICHOLSON, *The Mystics of Islam* (1914, reprinted 1963); H.A. GILES, *Chuang Tzū, Mystic, Moralist and Social Reformer* (1926); YU-LAN FUNG (trans.), *Chuang Tzū, A New Selected Translation with an Exposition of the Philosophy of Kuo Hsiang* (1931); W.T. DE BARY et al. (comps.), *Sources of Chinese Tradition* (1960); W. FILCHNER, *Kumbum Dschamba Ling* (1933); G. VON GRUNBAUM, *Medieval Islam*, 2nd ed. (1953). In the realm of Christianity, F. HEILER, *Der Katholizismus*, 3rd ed. (1970); and P. MOLINARI, *I Santi e il loro culto* (1962; Eng. trans., *Saints: Their Place in the Church*, 1965), give information concerning the veneration of saints in folk piety. The veneration of saints in the Eastern Church is canvassed, among other works, by E. BENZ and L.A. ZANDER (eds.), *Evangelisches und orthodoxes Christentum in Begegnung und Auseinandersetzung* (1952); and by D. ATTWATER, *Saints of the East* (1963). An article summing up the various aspects of the Christian veneration of saints is R. KLAUSER, "Christliche Heiligenverehrung," in *Religion in Geschichte und Gegenwart*, 3rd ed., vol. 3 (1959). A treatment of saints in the early church may be found in B. KÖTTING, *Der frühchristliche Reliquienkult und die Besetzung im Kirchengebäude* (1965). R. KRISS and H. KRISS-HEINRICH have reviewed the Greek cult of saints in their book *Peregrinatio Neohellenika* (1955), as well as the manifold forms of the Bavarian-German veneration of holy ones in R. KRISS, *Die Volkskunde der altpfälzischen Gnadenstätten*, 2nd ed., 3 vol. (1953–56). S. BEISSEL, in his work *Die Verehrung der Heiligen und ihrer Reliquien in Deutschland bis zum Beginne des 13. Jahrhunderts* (1890), deals with the historical development of the veneration of saints in Germany. A catalog of the saints of the Roman Catholic Church and of their functions was edited by J.E. STADLER and F.G. HEIM, *Vollständiges Heiligen-Lexikon*, 5 vol. (1858–82).

(G.Me.)

Sainte-Beuve, Charles-Augustin

One of France's most prominent and influential literary critics of the 19th century. Charles-Augustin Sainte-Beuve owes much of his reputation to his unequalled sensitivity in applying historical frames of reference to the evaluation of contemporary writing.

Sainte-Beuve, oil painting by Barthélemy-Eugène Demarquay (b. 1818). In the Musée des Beaux-Arts et d'Archéologie, Boulogne-sur-Mer, France.

Romantic period. Sainte-Beuve was born at Boulogne on December 23, 1804, the posthumous only child of a tax collector. After a sheltered childhood, he completed his classical education in Paris and began to study medicine, which, however, he abandoned after a year. A talented but in no way brilliant youth, he continued his general education at his own pace, attending the University of Paris and extension institutions, and in 1825 was drawn into journalism by his former teacher, Paul Du-

bois, editor of a new liberal periodical, *Le Globe*. In its pages he wrote his first essays on the poetry of Victor Hugo and soon became a member of his literary circle of Romantic writers and poets. In his first book, *Tableau historique et critique de la poésie française et du théâtre français au XVI^e siècle* (1828), he discovered, perhaps naturally, a Renaissance ancestry for Hugo and others of his new friends. A brief visit to England in 1828 strengthened his taste for the poetry of Wordsworth and Coleridge, both of whom were then little known in continental Europe. His visit to England may also account for the appearance of elements of the style of William Cowper and George Crabbe in volumes of his own poetry, *Vie, poésies et pensées de Joseph Delorme* (1829) and *Les Consolations* (1830), which on their publication attracted some attention—not least because of their deliberate flatness and apparent uncouthness, much in contrast to the grander manner of his new friends Hugo and the poet Alfred de Vigny.

He had meanwhile developed a taste for social speculation and a concern for problems of religious experience. His social concerns first crystallized in a passing attachment to the group of reformers assembled around the doctrines of Count Claude-Henri de Saint-Simon. According to Saint-Simon's disciples, the feudal and military systems were to be replaced by one controlled by industrial managers, and scientists rather than the church were to become the spiritual directors of society. When this group in 1830 took over management of *Le Globe*, Sainte-Beuve was entrusted with drafting two manifestos, or "professions of faith"; and, although he was soon to be repelled by the sentimental excesses and intemperance of its leaders, he retained for 30 years a lingering sympathy for its vision of a technocratic society founded on the brotherhood of man. Almost simultaneously, Sainte-Beuve came under the powerful spell of a religious reformer and polemist, Félicité Robert de Lamennais, to whom for a time he looked for religious guidance. Lamennais was then the spiritual adviser of the wife of Victor Hugo, with whom Sainte-Beuve in 1831 struck up a lasting but seemingly platonic relationship of great intensity. Many of the details of this shadowy affair are more or less accurately related in the critic's privately printed volume of lyrics, *Livre d'amour*, which was, however, not published in the lifetime of either of them.

In the 1830s, in his "portraits" of contemporaries, he developed a kind of critique, novel and much applauded at the time, of studying a well-known living writer in the round and entering into considerable research to understand the mental attitudes of his subject.

By 1832 Sainte-Beuve was writing regularly for leading Parisian literary periodicals but was much hampered by his dislike for the newly established regime of King Louis-Philippe, which had aroused his anger mainly by its brutal handling of the riots of 1832. He accordingly refused several educational posts that would have relieved his poverty, fearing that they might compromise his freedom of judgment.

In 1834 he tried his hand at novel writing and published *Volupté*, an intensely introspective and troubling study of frustration, guilt, religious striving, and "renunciation" of the flesh and the devil. Like so much that he wrote—poetry, criticism, fiction—*Volupté* represented a breach with the flamboyance of current taste and won the minority approval mainly of those friends—Lamennais, the novelist George Sand, and the poet and dramatist Alfred de Musset—who recognized its subtlety or approved of its literary transmutation of his feelings for Adele Hugo.

While continuing to chronicle the intellectual "portraits" of his literary contemporaries—*Critiques et portraits littéraires* (1836–39); *Portraits contemporains* (1846)—friends or former friends, he became a member of the circle presided over by Mme Récamier, the famous hostess, and the writer and politician François-René de Chateaubriand. Sainte-Beuve celebrated the appearance of Chateaubriand's memoirs with enthusiasm, though a decade and a half later he was to write an extensive and far more detached study, *Chateaubriand et son groupe littéraire sous l'Empire*.

Social and religious concerns

Break with Romanticism. A softening of Sainte-Beuve's attitude toward Louis-Philippe's regime coincided in 1836 with an invitation from François Guizot, then minister of education, to accept a one-year appointment as secretary of a government commission studying the nation's literary heritage. Guizot's suggestion at that time that Sainte-Beuve demonstrate his eminence as a scholar by producing a major work led to *Port-Royal*, his most famous piece of writing.

In 1837 this essentially Parisian critic accepted a year's visiting professorship at Lausanne to lecture on Port Royal, the convent famous in the 17th century for advancing a highly controversial view of the doctrine of grace, loosely called Jansenism. For his lectures he produced the first version of the history of *Port-Royal*, which he published and revised over the next two decades. This monumental assemblage of scholarship, insights, and historical acumen—unique of its kind—reflects most of the varied intellectual adventures through which Sainte-Beuve had passed in the preceding ten years. Its theme ends by comprising nothing less than the study of religious and literary history of the great age of French culture, the 17th century, perceived through the lens of Jansenism.

Appointment as conservateur. On completing his year in Lausanne, Sainte-Beuve returned to Paris. Following his last major journey, to Naples and Rome, he was appointed in 1840 to a post in the French Institute's Mazarine Library, which he held until 1848. In addition to a regular gossip column that he undertook for anonymous publication by his friends in Lausanne, he continued regular essay writing. The first two volumes of *Port-Royal* had also been published when he was elected to the French Academy in 1844. By then he had already broken his earlier close links with the Romantics and was highly critical of what now appeared to him as the undisciplined excesses of that movement. He had also taken a strong stand against what he called industrial literature—the flood of popular fiction addressed (especially in serial form) to the growing readership of undistinguished reviews and newspapers of that time.

After the overthrow in 1848 of Louis-Philippe, Sainte-Beuve was not impressed by what he saw of Revolutionary democracy. Unfairly accused in the republican press of accepting secret government funds for the repair of a chimney in his apartment, he resigned his library appointment in a fit of pique, considered emigrating to London, and finally settled for a year at Liège (Belgium) as visiting professor. Here he wrote his definitive—but unfinished—study of Chateaubriand and the birth of literary romanticism and carried out research on medieval French literature.

"Causeries du lundi." Returning to Paris again in 1849, he contracted with the review *Le Constitutionnel* to furnish a weekly essay; this was the start of the famous collection of studies that he named *Causeries du lundi* ("Monday Chats"), after the review's day of publication. With few interruptions he maintained a prodigious level of literary production and research until his death 20 years later; the *Lundis* fill 15 volumes in the definitive 3rd edition and are followed by a further 13 volumes of *Nouveaux lundis*.

In these essays he tried, first, to reformulate his concept of culture, a concept based on a strong sense of tradition, stability, and decorum. To him, the highest manifestation of French culture was the world of the salons of Mme du Deffand, in pre-Revolutionary France, or Mme Récamier in his own time; but he expanded his survey to suit the larger horizons of the 19th century, also giving some attention to the contribution of other European and Oriental cultures. Not surprisingly, he welcomed the rise of Napoleon III's more dictatorial and orderly regime. In due course, his sympathy was rewarded by appointment to the chair of Latin at the Collège de France, a well-paid but largely nominal post. In his own case it remained entirely nominal, since his first lectures were interrupted by demonstrations of radical students, and he resigned his duties and salary, retaining only the title. The intended lectures were published as a full-length study of Virgil.

In 1858 Sainte-Beuve received a temporary teaching appointment in literature at the École Normale Supérieure, where he drew upon his 1848 researches to deliver a course on medieval French literature; but otherwise his whole later career was based upon free-lance essay writing.

Critical essays during the Second Empire. Under the Second French Empire, which survived him by less than a year, many of Sainte-Beuve's earlier acquaintances, now dead or in retirement, were replaced by other writers: Gustave Flaubert, Ernest Renan, the Goncourt brothers, Prosper Mérimée, Ivan Turgenev, Alexandre Dumas, Matthew Arnold, and a large number of scholars, historians, and academicians. He frequented the salon of the Emperor's cousin, the princess Mathilde, somewhat of a literary centre itself, though less formal in style than had been the salon of Mme Récamier until 1848. At the restaurant Magny he relaxed from time to time with his literary friends. He regularly attended the theatre once a week. And he continued to see old friends from time to time—including Adele Hugo, who occasionally visited him in Paris.

Nevertheless, the crushing task of researching, writing, correcting, and proofreading a 3,000-word essay for publication every Monday in effect largely prevented Sainte-Beuve from exploring in the same leisurely way as in his youth the many new trends being developed by young writers.

In religious matters, he retained (like his young friend and admirer Renan) a lively sensibility and curiosity but essayed no further commitment whatever. He was uninterested in the debates on evolution. Living a sheltered, almost monastic, bachelor existence, he paid little attention to the rise of industrialism or the economic controversies of the empire. On the other hand, his social conscience remained extremely acute. He welcomed the influence of earlier Saint-Simonian friends at the new court, and his sympathy for the underdog was reflected not only in his charitable activities but also in his support for popular education and self-help.

Politically, also, he retained a very decided independence even vis-à-vis his imperial patrons and protectors. Although in 1865 he was made a senator, he took little or no part in the formal proceedings of the upper legislative house except on one occasion. When, under heavy pressure from the church, the government banned the works of Ernest Renan from the public libraries as being subversive of good morals and religion, he prepared and attempted to deliver a withering denunciation of this violation of intellectual liberty. This brought down upon him the wrath of the princess Mathilde and the indignation of many officials and friends, but Sainte-Beuve was unrepentant. In fact, he transferred his weekly essay to an independent review.

Sainte-Beuve died on October 13, 1869, in Paris after unsuccessful bladder stone operations. For the last year of his life he had suffered considerable pain, borne courageously.

Reputation and influence. His writings were not only voluminous but also enormously influential in the world of French literature, and they continue to be consulted and used. For the study of French literature from the Renaissance to the mid-19th century, they constitute a vast and unequalled repository of information, much of it well indexed. A portion of his scholarly research has, with time, become old-fashioned, but within limits the precision of his documentation is almost always impeccable, even over details on which it has been challenged by literary opponents. This precision is due to a lifetime's habit of extreme care in documentation as well as to his fanatical respect for historical accuracy. In one of the commonplace books in which he recorded his thoughts as they came to him, he wrote:

The *Good*, the *True*, and the *Beautiful* make a fine motto, and a specious one. It has been adopted by M. Cousin for his well-known book: but dare I say it, it is not my motto. If I had a motto it would be "*Truth and Truth alone*." And let the *Good* and the *Beautiful* look after themselves as best they may.

Defense of
intellectual
liberty

Concept of criticism

This attitude lies back of a somewhat unfavourable aura that surrounds the critic's reputation as a judge. From his earliest review articles on Hugo, Sainte-Beuve was never afraid to introduce specific reservations into his most enthusiastic eulogies; and it was this liberty that in his own eyes justified his claim to uncompromising independence but also earned him the reputation of being an unreliable, or even perfidious, critic of friends. In the first years of his career the then fashionable romantic doctrine of inspiration made no provision for the role of the critic as adviser, sounding board, or judge, and it was partly the recognition of this fact that caused Sainte-Beuve to move away from Lamartine, Hugo, Vigny, George Sand, and others in the years 1834–37 and to resist the charm of these romantic spellbinders. His essay "Critical Genius" (1835) postulates a critical activity that is inquisitive, untrammelled, independent, and a contributory element in the formation of public opinion and private taste; and to this liberal conception he adhered throughout his working life.

It is sometimes claimed that Sainte-Beuve made, or wished to make, of criticism a form of comparative psychology, a botany of minds, as he himself said. This claim is based on several famous passages in *Port-Royal*. Unquestionably, he detected in the Jansenists of Port-Royal a number of family characteristics, due to common religious beliefs, shared experiences, and common values; but this was for him only one of many ways of critical study—along with textual analysis, biographical inquiry, historical contextualization, etc. Sainte-Beuve, in fact, escapes simple definition not only by the mass but also by the variety of his criticism.

MAJOR WORKS

VERSE: *Vie, poésies, et pensées de Joseph Delorme* (1829); *Les Consolations* (1830); *Pensées d'août* (1837); *Livre d'amour* (1843).

NOVEL: *Volupté* (1834).

CRITICISM: *Tableau historique et critique de la poésie française et du théâtre français au XV^e siècle* (1828); *Port-Royal*, 3 vol. (1840–48); *Critiques et portraits littéraires* (1836–39); *Portraits de femmes* (1844); *Portraits contemporains* (1846); *Causeries du lundi*, 15 vol. (1851–62); *Étude sur Virgile* (1857); *Chateaubriand et son groupe littéraire sous l'Empire* (1861); *Nouveaux lundis*, 13 vol. (1863–70); *Premiers lundis*, 3 vol. (1874–75).

TRANSLATIONS: Not all of Sainte-Beuve's works are available in English, but some useful collections include *Causeries du lundi* (selected and ed. by G. Saintsbury, 1885; Eng. trans. with introduction and notes by E.J. Trechmann, 8 vol., 1909–11; 2 vol. also by Trechmann, 1933); *Essays by Sainte-Beuve*, ed. by A. Tilley (1918); and *Sainte-Beuve: Selected Essays*, ed. by F. Steegmuller and N. Guterman (1963).

BIBLIOGRAPHY. J. BONNEROT, *Bibliographie de l'œuvre de Sainte-Beuve*, 3 vol. (1937–52), covers the huge range of textual and critical problems and also attempts to itemize what Sainte-Beuve actually read in his long career. The principal collection of manuscripts, with the bulk of the critic's notes and notebooks and many letters, is the Collection Spoelberch de Lovenjoul, Bibliothèque de l'Institut, Chantilly, France. The best editions containing the critic's last revisions are as follows: *Causeries du lundi*, 3rd ed., 15 vol. (1857–72); *Chateaubriand et son groupe littéraire sous l'Empire*, new ed., 2 pt. (1948), with useful notes by M. ALLEM; *Étude sur Virgile* (1857); *Le Clou d'or* (1881, reprinted 1920), several minor short stories; *Livre d'amour* (1904, first edition to be strictly speaking published); *Nouveaux lundis*, 13 vol. (1863–70); *Poésies complètes*, 2 pt. (1861–63); *Portraits contemporains*, new ed., 5 vol. (1869–71); *Portraits de femmes*, new ed. (1870); *Portraits littéraires*—the best edition is that of the "Pléiade Series," 2 vol. (1949 and 1951); *Port-Royal*, 3rd ed., 6 vol. (1866–67, "Pléiade"); *Premiers lundis*, 3 vol. (1874–75, "Pléiade"); *Tableau historique et critique de la poésie française et du théâtre français au XVI^e siècle*, 2nd ed. rev. (1843), with many changes from the first edition; and *Volupté*, 8th ed. (1874). The *Correspondance générale*, ed. by J. BONNEROT, 16 vol. to date (1934–70), is the most fully annotated and comprehensive collection of Sainte-Beuve's letters. A.G. LEHMANN, *Sainte-Beuve: A Portrait of the Critic, 1804–1842* (1962), based on recent research, is a study of the critic in the world of ideas and letters of his time; A. BILLY, *Sainte-Beuve: sa vie et son temps*, 2 vol. (1952–62), contains many anecdotes.

(A.G.L.)

Saint-Just, Louis de

Famous as one of the most zealous advocates of the Reign of Terror during the French Revolution, Louis de Saint-Just played a prominent, although brief, role in the National Convention and the Committee of Public Safety, as well as serving as commissioner to the armies. Many of his contemporaries acknowledged his ability but considered him a monster of pride and cruelty. Others, particularly in later generations, have viewed him as an incorruptible patriot who paid with his life for his allegiance to democracy. Some have seen in him the prototype of the rebel. These contradictions arise in part from Saint-Just's complex character and in part from an imperfect knowledge of his childhood and adolescence.

Louis-Antoine-Léon de Saint-Just was born on August 25, 1767, at Decize in central France, the son of a cavalry captain. His mother, the daughter of a wealthy local notary and a woman of egalitarian notions, wished to reduce the nobility to the level of the middle class. The family eventually moved to Blérancourt, a rural town in Picardy, the native province of his father, who died there in 1777.

After attending the College of the Oratorians in nearby Soissons, he returned to Blérancourt, a small town offering few distractions. In 1785 Saint-Just became attached to the daughter of one of the town's notaries. Her forced marriage to the son of the other notary in July 1786 marked the beginning of a crisis for Saint-Just. Hurt and angry, he fled to Paris one night in September, taking with him a few family valuables. Lodging near the Palais Royal, then the centre of a brilliant and dissolute society, he soon ran out of money. His adventure came to a sudden end when his mother, advised of the situation, had him put into a reformatory. He remained there from October 1786 to April 1787. Sobered by his experience, he decided, like so many young men of the middle class, to establish himself and enter upon a career. He became a clerk to the public prosecutor of Soissons, studied at Reims, and took his law degree in April 1788.

France at that time was shaken by the effects of a poor harvest and a hard winter, which coincided with pre-Revolutionary tremors. In 1789, Saint-Just anonymously published his first book, an epic poem, *Organt*. It was ignored by the public. A long satirical and licentious poem strewn with political allusions, it was reminiscent of Voltaire's "La Pucelle" ("The Maiden"), but it lacked the force and spirit needed for public acclaim. Perhaps Saint-Just was trying to set his own mind free rather than to achieve fame. *Organt* sometimes suggests the misadventures of Saint-Just, with his violent enthusiasms and resentments; but the eroticism is heavy, and few of the

themes of his later work appear. Saint-Just's friends scarcely mentioned it, and his enemies derided it. The book was seized by the authorities in June 1789, and, although it had been issued anonymously, Saint-Just was prudent enough to hide at a friend's home in Paris.

In the midst of the Revolutionary upheaval, Saint-Just, eager to participate, found himself ignored. Neither a Parisian nor a popular orator nor a leader of men, he was also not inclined to approve of slaughter. He did not speak of the storming of the Bastille, which he had witnessed, until a year later, when his attitude seemed reminiscent of that of the British politician Edmund Burke, who opposed the French Revolution. Saint-Just returned to his home town at the end of July. The provinces, like Paris, were in full revolt. Militia or national guard units were spontaneously forming everywhere, and Saint-Just became commander of the second unit organized in Blérancourt.

But first he had to overcome the handicap of his youth and the opposition of local cliques. As a militia commander he went to Paris for the Fête de la Fédération on July 14, 1790. He did not linger there and later spoke of it in tones of disillusionment.

Saint-Just realized that he could play the role to which he aspired in the Revolution only by election to a key post as an administrator or, preferably, as a deputy. He had, however, not reached the legally required age of 25. For most men the political clubs provided the necessary stepping-stone but not for Saint-Just, who was never a club man, doubtless because he was too overbearing. Instead, he became the municipal corporation counsel of Blérancourt, championed communal welfare and free trade, and set himself up as a spokesman for the voters. At the same time, however, he resumed his friendship with the girl whom he had been unable to marry and, in defiance of gossip, met her publicly.

He succeeded in establishing his reputation beyond Blérancourt in the district, where he was considered an energetic and able candidate for the next National Assembly. To further his candidacy, he wrote letters to politicians shamelessly flattering their self-esteem and even managed to receive the congratulations of the National Assembly after publicly burning a counter revolutionary pamphlet.

Though he was driven by ambition, his ambition was to serve the cause of the poor and the peasants, and, if he turned toward Robespierre, the most pitiless of the Revolutionaries, it was from conviction. Saint-Just now proposed directing the Revolution beyond benevolent and patriotic activity toward the making of a new society. In 1791 he finally published *Esprit de la Révolution et de la Constitution de France*. The exposition was bold, vigorous, and lofty. The brief, forceful, and elliptical formulations characterized the author. According to him, the constitution framed by the Assembly was acceptable as a first step, but the French were not yet free. Nor were they sovereign, but sovereignty of the people was acceptable only if the people were just and rational. "Law should yield nothing to opinion and everything to ethics," Saint-Just maintained. He confided to his publisher that the boldness of his exposition attracted readers and rightly added that his work, because it was based on less extensive reading than he might have wished, had the originality of a solitary thinker.

At that time Saint-Just believed himself to be on the eve of a political career, and his elimination from the Assembly as a result of his age provoked a serious crisis. "I am a slave of my adolescence!" he cried revealingly.

He then continued his reflections on the great task of building a society based on nature in which men would live together rather than merely side by side. Taking his region as a model, he observed the village communal traditions. This sojourn in the provinces directed his thinking while straining his energies.

His election to the National Convention in September 1792, shortly after he became 25, finally gave him a task cut to his measure. The new Assembly had to untangle the crisis created by the fall of the King and the invasion of France and to undertake the vast task of reconstruction. "The people have looked only for oracles and for

their happiness," he said. He was the oracle, self-assured and bold, personifying the uncompromising republican virtues. With unshakable authority he tackled financial and economic problems and, finally, military questions. His thought and style made him, with Robespierre, one of the leaders of the extreme left.

When sent on a mission to the armies, he revealed himself also as a man of action. His dreaded decisiveness was accompanied by a solicitude for the soldiers: "True happiness is found only in the comforting of the unhappy." A terror to the generals, he exercised his role of beneficent dispenser of justice throughout a series of missions to the armies that gave rise to the romanticized concept of Saint-Just.

He rose by degrees in the Convention, and beginning in May 1793 he joined the Committee of Public Safety, the small group that governed France. After playing a considerable part in eliminating both left and right deviationists, he finally supplanted the less audacious Robespierre.

The year II of the French Republican calendar (1793-94), in which Saint-Just, elected president of the Convention, passed the Ventôse (March) decrees and led the victorious attack against the Austrians at Fleurus in the Austrian Netherlands (modern Belgium) on June 26, 1794, marked the high point of his career. The Ventôse laws, by which the property of enemies of the Revolution was confiscated for the benefit of poverty-stricken patriots, were the most revolutionary act of the French Revolution, because they expropriated from one class for the benefit of another. During the same period Saint-Just drafted *Fragments sur les institutions républicaines*, far more radical proposals than the constitutions he had helped to frame; this work laid the theoretical groundwork for a communal and egalitarian society.

But his rise to power had wrought a remarkable change in Saint-Just's public personality. He became a cold, almost inhuman fanatic, bloodthirsty as even his "god" Robespierre, a man of many human weaknesses, was not. "The vessel of the Revolution can arrive in port only on a sea reddened with torrents of blood," Saint-Just once declared to the Convention. He, rather than Robespierre, showed himself to be the forerunner of the totalitarian rulers of the 20th century when he said on another occasion, "We must not only punish traitors, but all people who are not enthusiastic. There are only two kinds of citizens: the good and the bad. The Republic owes to the good its protection. To the bad it owes only death."

Dreaded, almost totally isolated, and detested, he was arrested on 9 Thermidor (July 27, 1794). Like Robespierre, he did not try to incite the Parisian sans-culottes to rise against the Convention in his defense and was guillotined the next day.

Saint-Just has, by turns, been lauded as the archangel of the Revolution or abhorred as the terrorist par excellence. Recent scholarly research has made it possible to draw the line between man and myth. Undoubtedly the Revolution changed the unruly, self-indulgent youth into a principled and decisive, though ruthless, leader. To friends he was also kind, helping them in securing positions. Yet, it is doubtful whether he had friends in the true sense, for those whom he helped attached themselves to him without becoming his equals.

Women admired his attractive appearance, and he could be very engaging when he wished. Nonetheless, he had to make notes on the conduct required "to be fortunate with women." He measured out doses of eagerness and indifference, affection and restraint, so as to make a love affair last. Yet, he could be genuinely affectionate and display real family feeling. This other Saint-Just appears in the famous portraits of Jean-Baptiste Greuze, Jacques-Louis David, and other painters.

Saint Lawrence, Gulf of

The Gulf of St. Lawrence, in southeast Canada, fringes the shores of half the provinces of that country and is a gateway to the interior of the entire North American continent. Its name is not entirely accurate, for in a hydrological context the gulf has to be considered more as a sea bordering the North American continent than as a simple river mouth. Its area is approximately 60,000 square miles (155,000 square kilometres), a little less than half that of the Baltic Sea. Its boundaries, which have always been a subject for discussion among geographers, may be taken as the maritime estuary at the mouth of the St. Lawrence River, in the vicinity of Anticosti Island, on the west; the narrow Strait of Belle Isle between Newfoundland and the mainland, to the north; and the Cabot Strait, separating Newfoundland from the Nova Scotian peninsula, on the south.

The gulf is also a relief phenomenon, for the underlying topography is in fact made up of submerged portions of the northern end of the Appalachian mountain range, as well as of the southern periphery of the vast, ancient rock mass known as the Canadian Shield. The topography of the floor of the gulf can be subdivided into several sections. First of all, there are the deepest zones: the St. Lawrence Channel and the Mingan Passage, whose orientation is toward the southeast, and the Eskimo Channel running to the southwest. Together, these channels occupy approximately one-quarter of the total area of the gulf. Then there are the submarine platforms, often less than 165 feet (50 metres) in depth, of which the most important, known as the Acadian Platform, occupies a large semicircle between the Gaspé Peninsula and Cape Breton. The relief of this area is not at all uniform because it includes such depressions as the Chaleurs Trough, shelves like the Banc de Bradelle, the Northumberland Strait, and above-water sections such as Prince Edward Island. On the far side of the axial St. Lawrence Trough are three northern elongated platforms: the Anticosti Platform, near to the island of the same name; one which skirts the low northern coast of the gulf; and finally, one lying between the Eskimo Channel and Newfoundland. The reefs on these surfaces, coupled with the hazards of fog and ice, have caused a large number of shipwrecks among the numerous vessels plying the region.

The body of water constituting the gulf is replenished not only by the local rainfall (35.5 inches [902 millimetres] annually at Cap-aux-Meules in the Magdalen Islands) but also from three great "gateways." The first of these, the maritime estuary, pours in approximately 495,000 cubic feet (14,000 cubic metres) per second of cool, soft water, and at ebb tide, a considerably larger volume of sea water, together with a formidable quantity of ice in the winter months. In the Strait of Belle Isle, which forms the second entry, the oceanographic situation is very complex. No less than seven types of water have been distinguished there, with temperatures varying from 29.1° F (−1.6° C) to 51.8° F (11° C), and a salinity fluctuating from 27.2 to 34.5 parts per thousand. The third gateway, Cabot Strait, is by far the most important; through it the Atlantic and Arctic waters enter (having already passed Newfoundland to the east), and it is through here that the major proportion of water and ice leaves the gulf.

The principal current consists of a peripheral counterclockwise circulation, which hugs the platforms of the northeast and then enters the estuary. This penetrates as far inland as the Pointe des Monts and even reaches as far as the entry of the Saguenay River into the St. Lawrence just over a hundred miles from the city of Quebec. This current continues under the name of the Gaspé Current, having three branches between the Honguedo and Cabot straits.

This circulation, as well as a weak tide, tends to mix the

waters of the gulf, but they remain stratified. In the centre of the gulf are three superimposed levels: the deep stratum (38.3° F [3.5° C] and 33.5 parts per thousand salinity), the intermediate stratum with a depth of 50 metres (165 feet) (33° F [0.5° C] and 32.5 parts per thousand salinity), and the surface stratum, which is less salty and undergoes strong seasonal thermal variations.

Ice floes constitute one of the most prominent characteristics of the gulf. Ice formation is delayed because of the salinity, the latent heat of the mass of water, and the slow passage of upstream ice; thus ice is not abundant in the gulf before mid-February. The thaw, often late, permits the Cabot Strait to have normal maritime traffic at least a month before the Strait of Belle Isle. At the end of May, the sheltered water surface between Prince Edward Island and Nova Scotia, into which the north wind drives the ice, is the last section of the gulf to be ice-free.

The life of the gulf is a function of various general conditions: light, temperature, salinity, available food, ice, etc. In addition to such organisms as the phyto-benthos and zoobenthos of the coastline and of the depths, fish such as cod and mammals such as the white whale may be distinguished. The banks and the islands of the gulf include numerous nesting places of birds, notably the Basan gannet (see also SAINT LAWRENCE RIVER; SAINT LAWRENCE SEAWAY).

(L.-E.H.)

Saint Lawrence River

The great hydrographic system connecting the source of the St. Louis River, in the U.S. state of Minnesota, with Cabot Strait, leading into the Atlantic Ocean from the extreme east of Canada, the St. Lawrence River crosses the interior of the North American continent for almost 2,500 miles (4,023 kilometres), and is of vital geographic and economic importance. It can be divided into three broad sectors. Upstream lies the Great Lakes region, with narrow riverlike sections linking the broad expanses of the lakes themselves. In the centre, from the eastern outflow of Lake Ontario, near the town of Kingston, to the Île d'Orléans, just downstream from the city of Quebec, the system passes through a more normal watercourse. From the Île d'Orléans to the Cabot Strait, between Newfoundland and Nova Scotia, the system broadens out again, first as the St. Lawrence estuary, and then, passing the island of Anticosti, as the oval shaped marine region known as the Gulf of St. Lawrence.

The article GREAT LAKES covers the first of the regions described above, and the article SAINT LAWRENCE, GULF OF treats of the marine section from Anticosti Island to Cabot Strait. The article entitled SAINT LAWRENCE SEAWAY considers the engineering, economic, and political aspects of the vast man-made improvements to the system as a whole, and the present article concentrates on the course of the St. Lawrence River from Kingston to Anticosti Island (that is, on the riverlike and estuarine portions of the system). This region, passing through the heartland of the Canadian nation, has abundant scientific documentation relating to it.

The St. Lawrence River occupies a geologically old depression that involves three great geologic regions of

Submarine relief

Ice

Origin

North America: the Canadian Shield, the Appalachian Mountains, and the intervening sedimentary rock platform. This ancient setting has been broken up by earth movements along several zones of structural weakness and has also been worn down by a number of separate cycles of erosion. Toward the end of the geologically recent Quaternary Period, the Ice Age glaciers that had occupied the depression were replaced by the Champlain Sea, which flooded the floor of the depression from about 11,400 to 9,500 years ago. The subsequent slight uplifting of the continent was enough to expel this arm of the ocean and, about 6,000 years ago, a residual riverlike watercourse was established, and the St. Lawrence—a young watercourse as rivers go—was born.

In terms of both climate and hydrology, the St. Lawrence system as a whole has several regional zones. First, in the movement downstream from the upper part of the system, some of the associated boreal character is lost; in its path from the northern streams tributary to Lake Superior down to Lake Erie, the system passes from a sub-Arctic to a more temperate southern zone. In a similar, but reverse, fashion, the eastern half of the system increases in northern character downstream; that is, from the Detroit–Windsor metropolitan area at the western end of Lake Erie to the northern coast of the St. Lawrence estuary, the climate deteriorates again to a semi-Arctic level. This basic division brings out the regional contrasts in the hydrology of the central section of the river. Lake Erie, for example, loses much water through summer evaporation, whereas the affluents feeding the estuary of the St. Lawrence are heavily influenced by snowfall characteristics. At Montreal a good part of the river flow comes from the Great Lakes; hence its remarkable regularity. At the mouth of the estuary, on the other hand, the volume of ocean water coming in at high tide is 12 times the volume of river water flowing down at low tide; and here the St. Lawrence is profoundly marine, rather than lacustrine, in character. These basic regional hydrographic traits are accentuated also by a large seasonal variation in water temperature.

Regional divisions. The regional division of the St. Lawrence raises difficult problems, and despite several works on the subject, the debate among scientists remains open. The following division has been based on such overall criteria as longitudinal gradient of the riverbed, tidal characteristics, salinity, the width of the river bottom, human geography, and animal life. Threshold zones, a dozen miles or so in length, mark the transition from one region to the next.

The St. Lawrence of the international rapids. This forms a clearly defined region extending from Kingston to above Montreal, where the presence of sudden breaks of gradient in the riverbed, the necessity of a navigable route between Montreal and southern Ontario, and the regional needs for power have led to the creation of hydroelectric stations, canals, and, of course, a significant part of the St. Lawrence Seaway. The flow volume of this section of the St. Lawrence, as measured at Cornwall, is 218,000 cubic feet per second (6,104 cubic metres per second).

Quebec Basses Terres. This region is made up of a short section with a calm and nonreversible flow. Situated for the most part in the Quebec Basses Terres area, this portion of the river course is characterized by the inflow of the system's principal tributary, the Rivière des Outaouais, by the presence of numerous islands (the Hochelaga Archipelago upstream, the Cent Îles downstream), by the development of the Greater Montreal conurbation, and also, unfortunately, by a certain degree of pollution. The development of the port of Montreal has depended upon, among other factors, the deepening of the river channel—downstream through dredging and upstream by canalization—by means of engineering projects that were begun in the 19th century. During the winter months, a thick crust of ice connects the two banks of the river, and icebreakers must open a channel in order for even a limited number of ships to reach Montreal. In earlier years, the possibilities of ice jams were great, with notable ice catastrophes occurring in 1642, 1838, and 1896.

The upper estuary. This extends from Lake Saint-Pierre to below the fle d'Orléans at Quebec. Here, the current of a freshwater tide begins to be reversible. During the winter months, the ice covering recalls the conditions at Montreal, but it also anticipates those of the middle estuary (see below), where a distinction is necessary between banked, or reef, ice, which is solid and fissured, and conglomerate ice, which moves past offshore. Topographical conditions at the river littoral, which had great military value, led to the foundation of the city of Quebec in this region, in 1608. The immediately adjacent area has been the historical cradle of the distinctive French-speaking population of Canada.

The middle estuary. From the eastern end of the fle d'Orléans to the upstream side of the confluence with its major tributary, the Saguenay, the St. Lawrence broadens but remains relatively shallow. Progressively, the water ceases to be fresh and becomes brackish, and with an east wind one may, for the first time, catch a whiff of seaweed. Tides, thrust into a narrowing channel, attain maximum height in this section. Breakaway reef ice from this area constitutes one of the major sources of ice in the downstream parts of the estuary.

The lower estuary. One of the greatest topographic alterations in the entire course of the St. Lawrence is found near the Saguenay confluence, at right angles to a submarine furrow. In this region, the river bottom exhibits a brutal break of gradient: within ten miles, all in the vicinity of the confluence, the depth of the water increases from 82 feet (25 metres) to 1,148 feet (350 metres). It is by way of this drowned valley that the cold, salt waters from downstream, classed as Arctic, enter the region. In spite of the width of the watercourse, a number of ferries connect the two banks. In contrast to the thinly settled northern bank, behind which lie the inhospitable, rugged landscapes of the ancient rock region known as the Canadian Shield, the southern frontage of the lower estuary is largely open toward its hinterland, and major roads, including the Trans-Canada Highway, lead inland toward the province of New Brunswick.

The maritime estuary. The limits of this region are, upstream, the promontory of the Pointe des Monts, and, leading to the Gulf of St. Lawrence, the island of Anticosti. (The latter, by reason of its size and its own circular currents, is an entity in its own right and cannot be considered as an element of the estuary.) Below the Pointe des Monts, the submarine valley mentioned above doubles in width, to over 50 miles. A major arm of the counter-clockwise current stemming from the Gulf of St. Lawrence, after entering the northern portion of this region, turns back to the east. The salinity found here discourages ice formation, and, on the northern shore, the port of Sept Îles—although situated much farther north than Montreal—is in fact more open to navigation. The north frontage, with a hinterland rich in iron ore and electricity-generating potential and running at right angles to this portion of the estuary, seems to have greater capacity for development.

River life. In spite of centuries of human influence, the biological world of the St. Lawrence continues to reflect natural conditions. Some clear regional distinctions must be made between not only the upper and lower sections of the system but also between the depths and the surface of the water and between the banks and the centre of the river course. Scientists have not, as yet, succeeded in identifying fully the basic life-producing conditions, the identity of the various eutrophic, or nutrition-generating, water levels, or the migrations of food supply, all of which go to make up the biomass, or life system, associated with the river. Animal life comprises fish (including the sturgeon, the smelt, and the herring), mammals (including an "Arctic" species, the beluga [white whale], and mollusks (including the mussel [mye]). A noted phenomenon, which is characteristic of all regions of the river, is the massive migration of ducks, bustards, and geese, which utilize the sandy shores or river reefs as seasonal food sources. The vegetation associated with the river undoubtedly reflects the great shrub-

by zones that extend from Lake Erie to the northeast of the Gulf of St. Lawrence, made up of deciduous forest, mixed forest, coniferous forest, and open taiga. In addition, however, it exhibits such specifically river-linked characteristics as the sandbank grasses of the freshwater section, and the plants with a high tolerance of salt found from the middle estuary onward.

Conclusion. The St. Lawrence is a mighty, unique river, estuarine over much of its course; bedded in an ancient geological depression, it drains the heart of a continent. It is at once an international, an intra-Quebec, and a multiprovincial system. An axis of regional population, it is also a **route** linking Canada, the United States, western Europe, and a large part of the rest of the world. The frontages of the six regions of the St. Lawrence River described above are not equally developed and do not maintain the same types of relationship with their hinterlands and with the outside world. Throughout its length, nevertheless, the St. Lawrence is a river retaining a great natural beauty, with landscapes beloved by all who live on its banks or make the long passage along its course.

Saint Lawrence Seaway

A massive \$466,000,000 Canadian-United States navigational project opened North America's industrial and agricultural heartlands to deep-draft ocean vessels in April of 1959. It forged the final link in a 2,342-mile waterway from Duluth, Minn., to the Atlantic by clearing a way through a 182-mile stretch of the St. Lawrence River (q.v.) between Montreal and Lake Ontario. The entire Great Lakes-St. Lawrence system, with 9,500 miles (15,300 kilometres) of navigable waterways, has come to be known as the St. Lawrence Seaway and has created a "fourth coast line" for the United States and Canada.

Efforts to sail into the heart of the continent date from 1535, when the French explorer Jacques Cartier, seeking a no thwest passage to the Orient, found his path blocked by the Lachine Rapids, west of what is now Montreal. The digging of shallow St. Lawrence canals for bateaux (long, tapering boats with flat bottoms) in 1783, the construction of the Erie Canal from Buffalo, N.Y., to the Hudson River from 1817 to 1825, the opening of the first canal around Niagara Falls in 1829, and the completion of the first lock, at Sault Ste. Marie, in 1855, all fostered the dream. But the United States proved a reluctant partner in a venture, pursued by Canada from 1913 onward, to open the Great Lakes to sea traffic. The U.S. Senate rejected the Seaway Treaty of 1932 and allowed a second treaty, signed in 1941, to remain unratified for eight years. Faced with the likelihood that Canada would proceed alone, the U.S. Congress approved participation in the project in May of 1954, and construction began just three months later.

Technology. The seaway project is considered one of man's greatest engineering feats. Locks in the seaway and Canada's Welland Canal raise and lower large ships 557 feet, the world's greatest waterway lifting operation. It takes only about 7 minutes for 22,000,000 gallons of water to pour in or out of a seaway lock, but the average locking takes about 33 minutes. The total seaway system overcomes a 602-foot drop from Lake Superior to the sea. To overcome the navigational hazard of the swift-flowing 226-foot fall of the St. Lawrence River between Lake Ontario and Montreal, and to develop its power potential, re-

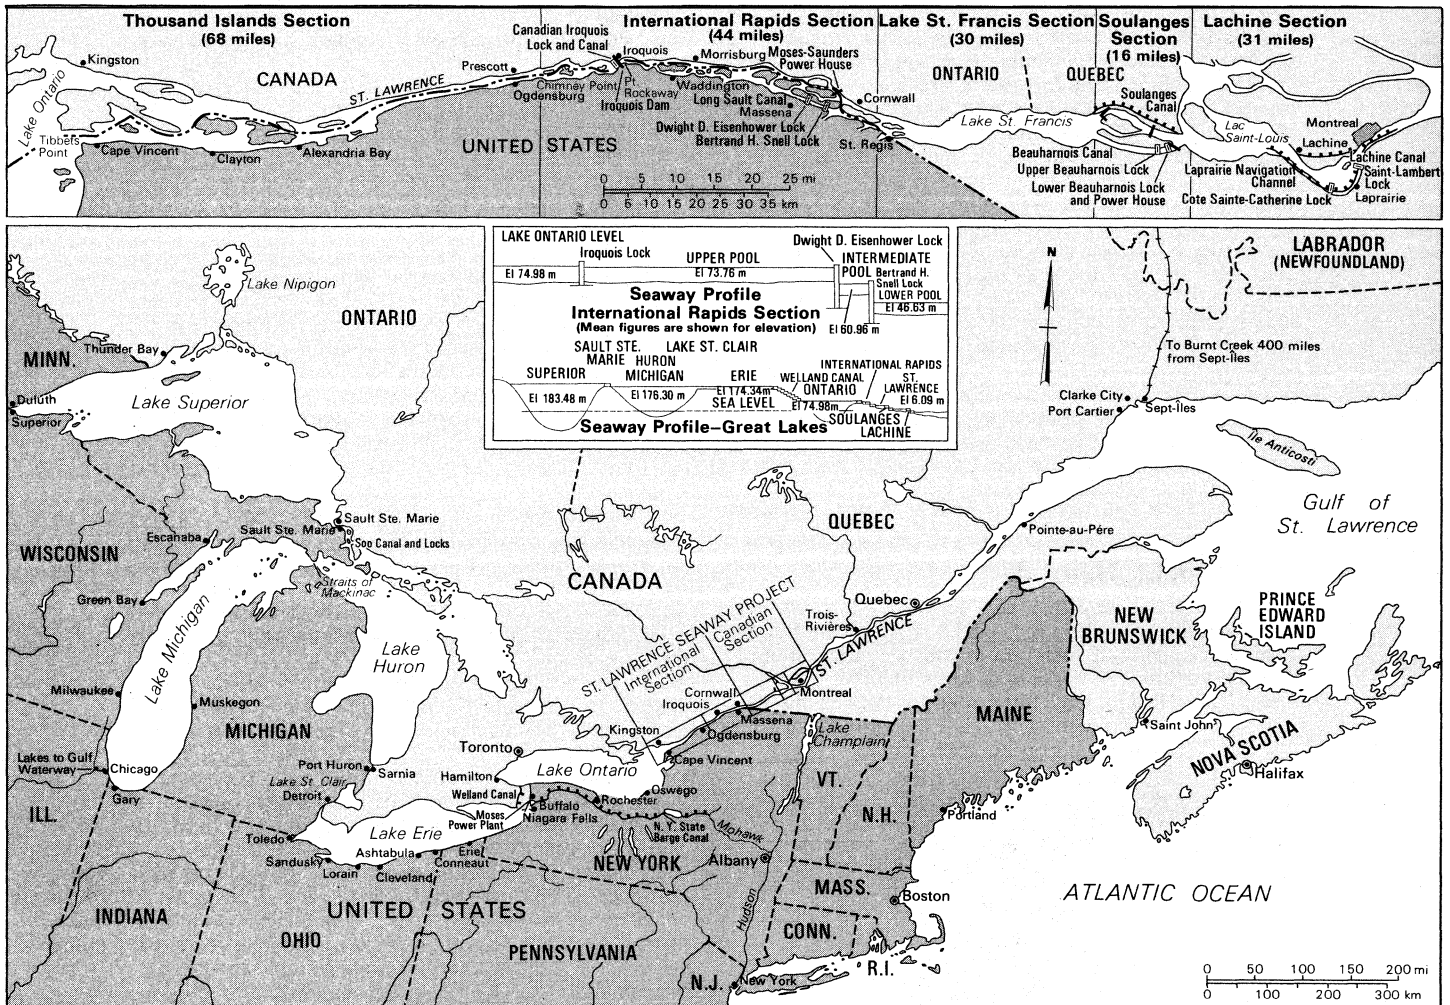

quired an investment of more than \$1,000,000,000. It employed 22,000 workers and utilized \$70,000,000 of construction equipment, enough cement to build a 1,000-mile highway and enough steel to girdle the earth. Communities containing 6,500 people had to be relocated, bridges raised, and tunnels, dikes, and roads constructed.

The navigation portion of the project included a \$332,500,000 expenditure by the Canadian government to build two canals and five locks around Soulanges and Lachine Rapids and three seaway dams, and \$133,500,000 spent by the U.S. government to build two locks, a ten-mile canal around the International Rapids, and two seaway dams, and to clear shoals from the Thousand Islands section of the river. This series of operations created a 27-foot-deep waterway, replacing six canals and 22 locks limited to 14-foot depth. Opening of the seaway required many other projects as well. The U.S. Army Corps of Engineers spent about \$200,000,000 to deepen the Straits of Mackinac, between Lake Michigan and Lake Huron; the St. Marys River, between Lake Superior and Lake Huron; the Detroit River, Lake St. Clair, and the St. Clair River, between Lake Erie and Lake Huron; and many Great Lakes harbours. Between 1913 and 1932, Canada had spent \$132,000,000 to build seven lift locks of seaway dimensions in the Welland Canal, which overcomes the 326-foot plunge of the Niagara River and Falls, between Lake Erie and Lake Ontario.

To tap the energy of the St. Lawrence River's tumbling waters, the seaway project included a power dam containing 32 hydroelectric turbine generators and two related dams to control and direct the full force of the river through the power dam. The \$600,000,000 cost and 1,600,000 kilowatts of generating capacity were shared equally by the Hydro-Electric Power Commission of Ontario and the Power Authority of the State of New York. The dams created a 30-mile lake. Generation of hydroelectric power began in July 1958.

Economic significance. Over its first decade of operation, the St. Lawrence Seaway carried more than 500,000,000 tons of cargo, worth about \$22,000,000,000, at estimated transportation savings of about \$500,000,000. By 1970, annual combined traffic through the Seaway-Welland Canal locks totalled nearly 9,000 cargo-carrying vessels, loaded with over 65,000,000 tons of freight, of which approximately 16,000,000 tons were destined for, or arriving from, overseas ports. The total tonnage was more than triple that in the seaway's first year, 1959, and foreign trade (non-U.S. and Canadian) was about seven times greater. The overall value of cargo carried approached \$5,000,000,000. As the price of approving seaway legislation, the U.S. Congress required that the project be self-liquidating, and Canada too adopted this as a national policy. Tolls were to be assessed at a rate sufficient to pay back cost of the project in 50 years, to pay annual interest on the funds borrowed to build it, and to pay all operating costs. The two nations jointly established a system of tolls, which were criticized as too high by shippers and as too low by competing ports. By the early 1970s, vessels were charged 40 cents a ton for bulk cargo, or 90 cents a ton for general cargo, to use locks between Montreal and Lake Ontario, plus 4 cents per gross registered ton of the vessel itself. There was a minimum charge of \$14 for pleasure craft and \$28 for other vessels, plus a \$3.50 charge per passenger. Each nation collects tolls in its own currency, on facilities in its territory, resulting in a split of about 73 percent of the revenue to Canada and 27 percent to the U.S. There are no tolls on the Welland Canal, but a charge per lock is made. By the mid-1970s, this was expected to amount to \$100 for cargo and passenger vessels, \$3 for pleasure craft, and \$5 for other vessels. Seaway revenue, in the first two decades of its operation, consistently fell far short of annual interest and operating costs, putting the seaway deeper in debt. By the opening of the decade of the 1970s the St. Lawrence Seaway Authority, which runs Canada's installations, had accumulated operating losses in excess of \$65,000,000, excluding over \$70,000,000 in losses, since 1959, by the Welland Canal, the latter covered by Parliamentary appropriations. The Authority had also ac-

Financial problems

accumulated a debt of nearly \$70,000,000 in unpaid interest. This boosted its total debt to over \$400,000,000. The Saint Lawrence Seaway Development Corporation, which runs U.S. operations, had an accumulated deficit of almost \$40,000,000 at the end of the 1960s. This, together with some \$23,000,000 of unpaid interest, had raised its overall debt to nearly \$160,000,000.

Financial problems have not prevented the seaway from having a major economic impact on the U.S. and Canada. A major reason for its construction was the discovery, in Quebec and Labrador, of vast iron ore deposits needed by U.S. steel mills. Canada, an importer of U.S. iron ore before the seaway, exported ore to the U.S. at an annual rate of 15,000,000 tons by the end of the 1960s—about one-fourth of all seaway volume. The second largest commodity moved was feed grains, with about 14,000,000 tons from farms on Canada's prairies and in the U.S. Midwest, shipped through the seaway at savings of six to eight cents a bushel. Major users of the seaway are vessels known as *lakers*, which are designed to the maximum limits of the seaway locks in order to facilitate an ideal two-way trade. A *laker* picks up over 1,000,000 bushels of grain in the western Great Lakes, destined for world markets, and will return with 27,000 tons of Canadian iron ore, loaded in the lower St. Lawrence. The third-largest seaway commodity is coal. About 11,000,000 tons were moved annually by the 1970s, chiefly from U.S. mines to Canadian steel mills and power plants.

Bulk commodities made up well over 80 percent of annual cargo tonnage, but vessels of more than 30 nations also used the seaway to deliver or pick up general cargoes. U.S. Midwestern manufacturers can often realize major savings on export shipments by using the seaway. For

example, a cargo of 3,784 pounds of auto parts made in Cincinnati was shipped to Stockholm from Toledo by way of the seaway at 31.2 percent less cost than if it had been shipped from New York. Through the seaway, Chicago is just 4,807 miles from London.

Problems and prospects. The Great Lakes-St. Lawrence River system is often characterized as a vast inland sea, comparable to the Mediterranean. But it suffers from difficult access and a severe winter climate that shortens the shipping season to about eight months. When constructed, the seaway would admit about 80 percent of the world's ships to this inland waterway. But its limitations of 25-foot-9-inch draft, 730-foot length, and 75-foot-6-inch beam restrict use to vessels carrying no more than about 27,000 tons of cargo, which is becoming small by world trade standards. To deepen the seaway to 35 feet would cost as much as \$5,000,000,000, and such a project would face stiff opposition from competing regions of the U.S. and Canada. Seaway tolls were subject to review early in the 1970s, but it was feared that any sharp increase would hurt traffic, leaving the seaway's revenue problems unsolved. Proposals were being considered to eliminate seaway interest payments, but the effort could falter on a broader debate as to whether charges should be made for use of all other inland waterways. Railroads are accused of hurting the seaway by charging discriminatory rates to Great Lakes ports, and the seaway faces competition from unit trains (handling fixed, equal quantities of cargo per car) and saltwater containership ports handling huge, standardized metal containers. Great Lakes ports also are installing containership facilities, but, since their initial expenditures of some \$65,000,000 on new ports when the seaway opened, cities have been

Traffic

faced with many urban problems of a higher priority than harbour facilities. In the early 1970s, studies were underway to extend the shipping season, but costs could prove prohibitive. Traffic experts predicted that seaway use would continue to grow but probably at a reduced rate. Iron ore and grain shipments also were expected to climb. The seaway could gain a major new commodity, as air pollution control regulations on sulfur content of fuels bring about substitution of heavy industrial fuel oils for coal in Midwest power plants and factories. This heavy fuel oil would have to come primarily from the Caribbean through the seaway. Despite a host of problems, the St. Lawrence Seaway is likely to continue playing an important economic role in an area containing about one-third of North America's population.

BIBLIOGRAPHY. There is no good overall survey of the Seaway. Information may be found in the annual financial reports of the Saint Lawrence Seaway Development Corp., and of the St. Lawrence Seaway Authority; in the annual traffic reports of the St. Lawrence Seaway; and in the annual reports of the Power Authority of the State of New York. Excellent articles may be found in *Seaway Review Magazine*.

Saint-Simon, Henri de

A French social reformer of the early 19th century, Claude-Henri de Rouvroy, comte de Saint-Simon, founded a religion of socialism in which he tried to combine the teachings of Jesus with ideas of science and industrialism. He attracted little attention during his lifetime, but after his death his disciples acquired considerable influence among European intellectuals.

Henri de Saint-Simon, lithograph by L. Deymaru, 19th century.

Early life

Saint-Simon was born in Paris on October 17, 1760, of an impoverished aristocratic family. His grandfather's cousin had been the duc de Saint-Simon, famous for his memoirs of the court of Louis XIV. Henri was fond of claiming descent from Charlemagne. After an irregular education by private tutors, he entered military service at 17. He was in the regiments sent by France to aid the American colonies in their war of independence against England and served as a captain of artillery at Yorktown in 1781.

During the French Revolution he remained in France, where he bought up newly nationalized land with funds advanced by a friend. He was imprisoned in the Palais de Luxembourg during the Reign of Terror and emerged to find himself enormously rich because of the depreciation of the Revolutionary currency. He proceeded to live a life of splendour and license, entertaining prominent people from all walks of life at his glittering salons. Within several years he had brought himself close to bankruptcy.

He turned to the study of science, attending courses at the Ecole Polytechnique and entertaining distinguished scientists.

In his first published work, *Lettres d'un habitant de Genève à ses contemporains* (1803), Saint-Simon proposed that scientists take the place of priests in the social order. He argued that the property owners who held political power could hope to maintain themselves against the propertyless only by subsidizing the advance of knowledge.

By 1805 he was impoverished, and the last 20 years of his life were lived mainly on the generosity of friends. He devoted himself to a long series of projects and publications through which he sought to win support for his social ideas. As a thinker, Saint-Simon was deficient in system, clearness, and coherence; but in the main his ideas represented a reaction against the bloodletting of the French Revolution and the militarism of Napoleon. He foresaw the further industrialization of the world, believing that science and technology would solve most social problems. He also proposed that the states of Europe form an association to suppress war. He had a profound influence on the social philosopher Auguste Comte (q.v.), who worked with him for a time, until, eventually, they quarrelled.

In 1823, in a fit of despondency, Saint-Simon attempted to kill himself with a pistol, succeeding only in putting out one eye.

In his last writings he sought to embody his ideas in a religion. In *Nouveau Christianisme* (1825), he argued that religion "should guide the community toward the great aim of improving as quickly as possible the conditions of the poorest class." He called upon the kings of Europe to abandon their militarism and their preoccupation with maintaining themselves in power and to return to true Christianity with its concern for the poor.

Saint-Simon died in Paris on May 19, 1825, surrounded by friends and by his disciples, who carried his message to the world in the years that followed and made him famous. The most important of these disciples were two bankers, Benjamin-Olinde Rodrigues and Barthélemy-Prosper Enfantin. Their first step, in 1825, was to establish a journal called *Le Producteur*, but it was discontinued in 1826. The movement had begun to grow, however, and before the end of 1828 was holding meetings not only in Paris but in many provincial towns. In 1828 Amand Bazard began a "complete exposition of the Saint-Simonian faith" in a long course of lectures in Paris lasting until 1830; they were well attended and won more adherents. In July 1830, revolution brought new opportunities to the Saint-Simonians. They issued a proclamation demanding the ownership of goods in common, the abolition of the right of inheritance, and the enfranchisement of women. In the following year they obtained control of the important newspaper *Le Globe*. The sect now included some of the ablest and most promising young men of France.

The Saint-Simonians formed themselves into an association arranged in three grades and constituting a society or family living together in a house in the Rue Monsigny. Before long, however, they were split by dissensions between Bazard, a man of logical and stolid temperament, and Enfantin, who wished to establish a fantastic sacredotalism with much freedom between the sexes. After a time Bazard seceded, with many of the strongest supporters of the school. A series of extravagant entertainments given by the society during the winter of 1832 reduced its financial resources and discredited it. The Saint-Simonians finally moved to a large estate belonging to Enfantin in the suburb of Ménilmontant, where they lived in a communistic society practicing chastity and poverty and wearing blue tunics and red berets. Shortly after, the chiefs were tried and condemned for offenses against the public order and morality. The movement broke up, its leaders turning to practical affairs.

The ideas of the Saint-Simonians had a pervasive influence on the intellectual life of 19th-century Europe. John Stuart Mill and Thomas Carlyle in England, Heinrich Heine in Germany, Russian literary men such as Alek-

His movement and its influence

sandr Herzen and Vissarion Belinsky, and a U.S. Socialist, Albert Brisbane, were among those influenced in one way or another by the ideas of Saint-Simon or his followers. Friedrich Engels, who, like his friend and collaborator Karl Marx, had little use for most of the French Socialists, found in Saint-Simon "the breadth of view of a genius," containing in embryo most of the ideas of the later Socialists. Felix Markham has said that Saint-Simon's ideas have a peculiar relevance to the latter part of the 20th century, when Socialist ideologies have taken the place of traditional religion among the political institutions of many countries.

BIBLIOGRAPHY

Works by Saint-Simon: Among his important works are *Lettres d'un habitant de Genève à ses contemporains* (1803), *De la Rkorganisation de la sociktd europdenne* (1814), *Du Système industriel* (1820–21), *Catckisme des industriels* (1823–24), and *Nouveau Christianisme* (1825). The standard and most complete edition of all his works is *Oeuvres de Saint-Simon et d'Enfantin*, 47 vol. (1865–78). Useful selections are *Textes choisis*, ed. by c. BOUGLE (1925); *Textes choisis*, ed. by JEAN DAUTRY (1951); and, in English, *Social Organization, the Science of Man and Other Writings*, ed. by FELIX MARKHAM (1964), which contains nearly all of *New Christianity*.

Saladin

Saladin, medieval sultan of Egypt, Syria, Yemen, and Palestine and founder of the Ayyibid dynasty, was perhaps the most famous Muslim hero of all time. Both in the East, where he has become a symbol of the wise ruler and consummate military commander, and in the West, where he has attained legendary stature as a paragon of the chivalrous enemy during the Third Crusade, Saladin's fame has outstripped the authentic, though not undramatic, facts of his life.

He was born in 1137 or 1138 into a prominent Kurdish family then at Takrīt in Mesopotamia. On the night of his birth, his father, Najm ad-Din Ayyib, gathered his family and moved to Aleppo, there entering the service of 'Imad ad-Din Zangi ibn Aq Sonqur, the powerful Turkish governor in northern Syria. Growing up in Ba'bek and Damascus, Saladin, whose full Arabic name was Ṣalāḥ ad-Din, Yūsuf ibn Ayyib (Righteousness of the Faith, Joseph, son of Job), was apparently an undistinguished youth, with a greater taste for religious studies than military training.

His formal career began when he joined the staff of his uncle Asad ad-Din Shirkihi, an important military commander under the emir Nureddin, son and successor of Zangi. During three military expeditions led by Shirkihi into Egypt to prevent its falling to the Latin-Christian (Frankish) rulers of the states established by the First Crusade, a complex, three-way struggle developed between Amalric I, the Latin king of Jerusalem, Shāwar, the powerful vizier of the Egyptian Fātimid caliph, and Shirkihi. After Shirkihi's death and after ordering Shāwar's assassination, Saladin, in 1169 at the age of 31, was appointed both commander of the Syrian troops and vizier of Egypt. His relatively quick rise to power must be attributed not only to the clannish nepotism of his Kurdish family but also to his own emerging talents. As vizier of Egypt, he received the title king (*malik*), although he was generally known as the sultan.

Saladin's position was further enhanced when, in 1171,

he abolished the Shi'i Fātimid caliphate, proclaimed a return to Sunnism in Egypt, and consequently became its sole ruler. Although he remained for a time theoretically a vassal of Nureddin, that relationship ended with the Syrian emir's death in 1174. Using his rich agricultural possessions in Egypt as a financial base, Saladin soon moved into Syria with a small but strictly disciplined army to claim the regency on behalf of the young son of his former suzerain. Soon, however, he abandoned this claim, and from 1174 until 1186 he zealously pursued a goal of uniting, under his own standard, all the Muslim territories of Syria, northern Mesopotamia, Palestine, and Egypt. This he accomplished by skillful diplomacy backed when necessary by the swift and resolute use of military force. Gradually, his reputation grew as a generous and virtuous but firm ruler, devoid of pretense, licentiousness, and cruelty. In contrast to the bitter dissension and intense rivalry that had up to then hampered the Muslims in their resistance to the crusaders, Saladin's singleness of purpose induced them to rearm both physically and spiritually.

Saladin's every act was inspired by an intense and unwavering devotion to the idea of *jihād*—the Muslim equivalent of the Christian crusade. It was an essential part of his policy to encourage the growth and spread of Muslim religious institutions. He courted its scholars and preachers, founded colleges and mosques for their use, and commissioned them to write edifying works especially on the *jihād* itself. Through moral regeneration, which was a genuine part of his own way of life, he tried to re-create in his own realm some of the same zeal and enthusiasm that had proved so valuable to the first generations of Muslims when, five centuries before, they had conquered half the known world.

Saladin also succeeded in turning the military balance of power in his favour—more by uniting and disciplining a great number of unruly forces than by employing new or improved military techniques. When at last, in 1187, he was able to throw his full strength into the struggle with the Latin crusader kingdoms, his armies were their equals. On July 4, 1187, aided by his own military good sense and by a phenomenal lack of it on the part of his enemy, Saladin trapped and destroyed in one blow an exhausted and thirst-crazed army of crusaders at Ḥaṭṭīn, near Tiberias in northern Palestine. So great were the losses in the ranks of the crusaders in this one battle that the Muslims were quickly able to overrun nearly the entire Kingdom of Jerusalem. Acre, Toron, Beirut, Sidon, Nazareth, Caesarea, Nābulus, Jaffa (Yafo), and Ascalon (Ashqelon) fell within three months. But Saladin's crowning achievement and the most disastrous blow to the whole crusading movement came on October 2, 1187, when Jerusalem, holy to both Muslim and Christian alike, surrendered to the Sultan's army after 88 years in the hands of the Franks. In stark contrast to the city's conquest by the Christians, when blood flowed freely during the barbaric slaughter of its inhabitants, the Muslim reconquest was marked by the civilized good faith and courteous behaviour of Saladin and his troops.

His sudden success, which in 1189 saw the crusaders reduced to the occupation of only three cities, was, however, marred by his failure to capture Tyre, an almost impregnable coastal fortress to which the scattered Christian survivors of the recent battles flocked. It was to be the rallying point of the Latin counterattack. Most probably, Saladin did not anticipate the European reaction to his capture of Jerusalem, an event that deeply shocked the West and to which it responded with a new call for a crusade. In addition to many great nobles and famous knights, this crusade, the third, brought the kings of three countries into the struggle. The magnitude of the Christian effort and the lasting impression it made on contemporaries gave the name of Saladin, as their gallant and chivalrous enemy, an added lustre that his military victories alone could never confer on him.

The Crusade itself was long and exhausting, and, despite the obvious, though at times impulsive, military genius of Richard I the Lion-Heart, it achieved almost nothing. Therein lies the greatest—but often unrecognized—

Rout of
the
crusaders

Early
career

Vizier
of Egypt

achievement of Saladin. With tired and unwilling feudal levies, committed to fight only a limited season each year, his indomitable will enabled him to fight the greatest champions of Christendom to a draw. The crusaders retained little more than a precarious foothold on the Levantine coast, and when King Richard set sail from the Orient in October 1192, the battle was over. Saladin withdrew to his capital at Damascus. Soon, the long campaigning seasons and the endless hours in the saddle caught up with him, and on March 4, 1193, he died. While his relatives were already scrambling for pieces of the empire, his friends found that the most powerful and most generous ruler in the Muslim world had not left enough money to pay for his grave.

(P.W.)

Sales and Excise Taxes

Sales taxes are taxes imposed upon the sale of goods and services. A sales tax levied on the manufacture, purchase, sale, or consumption of a specific type of commodity is known as an excise tax. Sales taxes are commonly classified according to the levels of business activity at which they are imposed—at the level of production or at the wholesale or retail level. Very often tax rates applied to commodities will vary according to whether the commodities are considered essential or nonessential. If the intention behind a tax is to place a burden on particular goods or to curtail consumption of such goods, it is called a sumptuary excise or a luxury tax. Many countries impose sumptuary taxes on such products as automobiles, gasoline, tobacco, alcoholic beverages, coffee, and sugar. Luxury taxes are less common because, although they are politically popular, luxury consumption is difficult to define for tax purposes and such taxes raise complex administrative problems.

Multiple sales taxes, imposed at more than one level of production and distribution, are sometimes called turnover taxes. For reasons of administration and simplicity such taxes are based on gross receipts; consequently, the taxable value at each stage includes the taxes already paid at previous stages. In order to avoid such pyramiding of taxes, some governments employ a value-added tax. This is a modified sales tax based on the net value added at each stage rather than on gross receipts. Roughly speaking, an enterprise's net value added within a given period is equal to output minus input, calculated as its total sales minus expenditure on goods and services purchased from other enterprises.

History. Excise taxes were well known in the ancient world. It is said that the Roman emperor Vespasian when

asked for the justification of a new excise on public urinals answered, "Pecunia non olet" ("money does not smell"). Excises of various kinds were important sources of public revenue in medieval Europe. In the United States, customs duties were the primary source of federal government revenue before World War I. General sales taxes are a comparatively recent innovation. Modern multistage turnover taxes were developed during and after World War I in Europe. The large-scale use of value-added taxation began when France adopted it in 1954; it was subsequently taken up in other European countries. The importance of sales and excise taxes in four countries is shown in the accompanying Table.

Sales and excise taxes in various countries. In western Europe value-added taxes existed in 1971 in Belgium, Denmark, France, Luxembourg, the Netherlands, Norway, Sweden, and the Federal Republic of Germany. Normal tax rates in those countries ranged from 10 to 23 percent. Italy and Austria introduced value-added taxes in January 1973 in place of their multistage turnover taxes. Spain had a multistage turnover tax, and Switzerland, a single-stage turnover tax. Great Britain had a purchase tax, levied at the wholesale stage upon all commodities not otherwise taxed by special excises. In most western European countries, excises on automobiles, mineral fuels, tobacco, and alcoholic beverages are among the major types of excises. A wide variety of other special excises are in use, such as taxes on coffee, sugar, salt, vinegar, matches, and amusements. In the Soviet Union and other Communist countries, general turnover taxes are among the most important sources of revenue.

In the United States, single-stage sales taxes exist in more than 40 states. Only two states have made use of multistage turnover taxes (as of 1971). Many local governments are also financed by taxes at retail level. The federal government does not levy a general sales tax; it imposes special excises on liquor, tobacco, motor fuels, automobiles, and other items. In Canada, retail sales taxes are levied in nearly all provinces; the federal government also collects a manufacturer's sales tax.

Most Latin American countries rely heavily on excises and on either turnover or sales taxes. Brazil has a manufacturer's tax and a value-added tax. Excises on tobacco, alcoholic beverages, automobiles, gasoline, and other items are the rule not only in most Latin American countries but in Africa, Asia, Australia, and New Zealand. The last two also make vigorous use of sales taxes.

In general, excise and turnover taxes have been more important in Latin countries and in the less developed world than in Scandinavia or in Anglo-Saxon countries. The latter rely comparatively more on direct taxes (income taxes) than do the Latin countries, where resistance to such direct taxation has traditionally been strong. The fact that excise and turnover taxes are easier to administer and enforce may be another reason why they are preferred in some countries. The recent adoption of value-added taxes in European countries may stem from a desire to harmonize tax systems, and perhaps also from a reaction against the rather excessive use of income taxation during World War II.

Value-added taxes in western Europe

Conditions
under
which tax
burden
can be
shifted

The burden of sales and excise taxes. It is generally assumed that sales and excise taxes are borne by the consumer. To facilitate easy collection, most such taxes are levied at the manufacturing, wholesale, or retail level. The tax burden is expected to be shifted to the last buyer in the form of a higher price. Whether the burden is shifted entirely or partly depends on market conditions. If consumers insist on having a commodity, the tax burden can be shifted to them more completely than if they are sensitive to price rises. For goods the prices of which are not much affected by quantities sold, the tax may be added to the price to a greater extent than for goods the prices of which are sensitive to the quantity factor. Usually both the supplier and the consumer share the tax burden in terms of lower profits or higher prices.

Sales and excise taxes also affect the way in which goods are allocated to different uses. Higher prices resulting from taxation may decrease the quantities produced and sold; manufacturers and sellers may have to reduce production or sales of heavily taxed commodities. In time of war or other stringency, excises and sales taxes can therefore be used as a means of reducing the production and consumption of goods that are not considered essential. It has been argued that excises interfere with the natural functioning of prices and distribution and therefore have a distorting effect on the economy. Such a conclusion, however, depends on certain assumptions as to how the economy would perform in the absence of such taxes.

More general types of taxes, such as turnover or value-added taxes, are thought to be less distorting in their effects. Single-stage sales taxes, as well as taxes on value added, if applied each at the same rate on total turnover, are assumed not to affect price relations to any marked degree.

Arguments for and against excises. Certain arguments can be advanced in favour of excise taxes. Since they are levied on specific goods, they allow the consumer to avoid them by purchasing substitutes and other nontaxed commodities. They place the burden of taxation on luxuries or nonessential goods rather than on necessities. They can also be allocated in such a way that the tax burden falls on those who receive the benefits of the tax expenditures, as the taxes on motor fuel that are used to build and maintain roads. Excise taxes, unlike taxes on income, are not thought to weaken the taxpayer's incentive to earn more. Finally, they are relatively easy to administer; the costs of collection are low.

Other arguments have been advanced against excise taxes. As mentioned above, they affect the allocation of resources in purely arbitrary ways. Also, the burden they impose is not related to the taxpayer's ability to pay. They discriminate against persons engaged in the production of the specific goods taxed.

Generally, excises are regressive in that the percentage of income spent on goods liable to taxation is higher among low-income groups. Regressiveness is often increased by the practice of applying the same tax to cheaper brands as to more expensive ones. Excises, unlike other taxes, cannot be used flexibly as a weapon for fighting inflation and maintaining economic stability.

Some of the inconveniences mentioned in connection with excises do not apply to sales taxes, but some of the advantages do not apply either. Nonselective, single-stage sales taxes do not discriminate between goods if a single flat rate is applied. On the other hand, if all goods are taxed, there is no longer a tax-influenced choice for the consumer. Sales taxes are generally more regressive than excises. Unlike excises, they cannot be related to benefits received. Multistage turnover taxes pose more serious disadvantages. Here, the amount of the tax depends on the number of turnover stages at which it is applied. Products that pass through relatively few hands on their way to the market will be taxed less than those that pass through many stages of production or distribution.

Some of the inconveniences of sales and excise taxes can be avoided by value-added taxation, in which the number of stages of turnover does not matter. The value-added tax affects neither the allocation of resources nor the price structure so long as a single tax rate is applied. It is,

however, more difficult and expensive to administer. Techniques may be simplified by using receipts that show the amount of tax at each step; each seller adds the tax to the price and acknowledges this on his bill. Each enterprise's net tax liability will be equal to the sum of all taxes it collects on goods it sells minus the sum of all the taxes it has paid on goods it has bought, the difference representing the tax on the value added by that enterprise.

Salicales

The willows and poplars together form a single, coherent family—the Salicaceae—of the distinctive order of flowering plants, the Salicales. Many grow in moist habitats, such as along riverbanks or on floodplains. The willow and the aspen have been used since the time of early man as a febrifuge (fever-controlling drug) and as basket material. Many wild animal species depend on the twigs and buds of Salicaceae species as food; others use the thickets formed by certain species as protective cover. Ecologically, members of the order are aggressive pioneers—plants that appear first in newly created habitats such as burned-over areas.

General features. Size range and diversity of structure. The aspens and poplars are trees ranging from small to very large; although some willows are medium-sized trees, often with clustered stems, most are shrubs that form thickets.

The giant of the poplars is the black cottonwood (*Populus trichocarpa*), which, in the virgin forests of the Pacific Northwest in North America, reaches a height of nearly 200 feet (60 metres) and a diameter of seven or eight feet (up to two and one-half metres). No other hardwood tree in that region reaches this size. The eastern cottonwood (*P. deltoides*) becomes nearly as large. Other species of large poplars also occur in the Northern Hemisphere, often achieving heights of 100 feet (30 metres) or more, such as the white poplar (*P. alba*) of Europe, Central Asia, and Western Siberia; the swamp cottonwood (*P. heterophylla*) of the southeastern U.S.; *P. suaveolens* from Soviet Central Asia to the Korean Peninsula; and *P. maximowiczii* of Japan, the Korean Peninsula, and Manchuria (Northeast Provinces). In addition to the great poplars and cottonwoods, the aspen group is also included in the genus *Populus*. Although exceptional individuals of the trembling aspen (*P. tremuloides*) are recorded as having reached a height of 100 feet and a diameter of three feet, they are characteristically small trees of 60 to 70 feet (about 20 metres) in height and 18 to 20 inches (46 to 51 centimetres) in diameter. A few of the willows become quite large trees, as much as 90 feet high—e.g., the crack willow (*Salix fragilis*) of Europe and western Asia. Many, such as the common osier (*S. viminalis*) or the weeping willow (*S. babylonica* and similar species), may become 15 to 30 feet high, but most willows are shrubs. Larger shrubs such as the shining willow (*S. lucida*), become 15 to 20 feet (five to six metres) high. But the great mass of willow species either form low thickets or sprawl on the surface.

Geographic distribution. The members of the Salicales are widely distributed in cool temperate areas of the Northern Hemisphere, with only a few extending into the tropics. Most of the species are relatively widespread; endemics, species restricted to a relatively small area, are virtually nonexistent. The species are prominent in the communities and habitats where they occur and, in the case of the poplars, at times form forests of great extent.

Representative plants and structures from the two genera of the willow family and order.

Drawing by R. Findahl based on (*Populus* flowers) G.H.M. Lawrence, *Taxonomy of Vascular Plants* (1957); the Macmillan Company

The two genera—*Populus* and *Salix*—are widespread in their distribution today; both are circumpolar, so that species of each have invaded the areas left by the retreating ice of the last glaciation. Thus, the balsam poplar (*P. balsamifera*), although a tree up to 90 feet (30 metres) high under favourable conditions in the central part of its range, forms low thickets at the northern limit of its range. The shrubby willows in great numbers of species and individuals have likewise moved into the Arctic and sub-Arctic upon the retreat of the ice, where they now form a prominent part of the flora. The various members of the genus *Populus* are found from the sub-Arctic tree line near the Arctic Circle southward in North America to northern Mexico and Baja California, and southward in the Old World to northern Africa and the southern slopes of the Himalayas and from sea to sea in both North America and Eurasia. Of the 35 or more species, about ten occur in North America. Two of these, the quaking aspen and the balsam poplar, extend from the Atlantic to the Pacific oceans. The other poplars of North America are more limited in occurrence; the black cottonwood, for instance, occurs only on the west coast from Baja California to Alaska and inland to the Rocky Mountains. The eastern cottonwood extends from the Great Lakes to the Gulf of Mexico and from the Central Plains to the East Coast, with but limited occurrence in the region of the Appalachian Mountains. The plains cottonwood (*P. deltoides* variety *occidentalis*), however, extends the range of the eastern cottonwood west to the Rocky Mountains.

Two basic distribution patterns of *Populus* occur in North America, the one transcontinental in formerly glaciated regions, with southward extensions predominantly in the Rockies, the other roughly from the southern limits of glaciation to the Gulf of Mexico, with the east-west boundaries of the various species set by the Atlantic Ocean, the Pacific Ocean, the north-south Rockies and Appalachians, and the Great Plains, each of which is a barrier to migration.

In the Old World there are similar wide-ranging species, such as the European aspen (*P. tremula*), which extends from Europe and North Africa to western Asia and Siberia. Other species, such as *P. koreana* of the Korean

Peninsula or *P. szechuanica* of western China, are more restricted in their occurrence.

The willows occur in such a multitude of species (300 or more) that distributional patterns are relatively obscure. There seem to be four centres of distribution in the North Temperate Zone. One is the area centring on the Bering Sea; another is central Europe; a third is the Himalayas; and a fourth is Pacific North America. In addition, there are limited occurrences of the genus in the Philippines, Madagascar, and in South America as far south as Chile. Isolated occurrences in mountains south of its region of continuous distribution are interpreted as survivals of *Salix* populations from an earlier period of colder climates, when many Arctic species grew much farther south. Another interesting type of distributional pattern is represented by very similar species pairs, or vicariads, one member of which occurs in eastern North America (such as *Salix discolor*), the other in the west (in this case, *S. scouleriana*). Some species are pronounced examples of disruption in range, such as *S. brachycarpa*, which occurs in the Rocky Mountains and then again only in the Gaspé, Anticosti, and Hudson Bay areas.

Such diverse distributional patterns are difficult to explain. The failure of active migration by members of a species after the retreat of the continental ice could have resulted in disrupted ranges. Similar disruption of the range of a single species, by ice or some other cataclysmic phenomenon, followed by genetic change in these separated populations could have produced the vicariads.

Economic importance. The outstanding and major usefulness of the members of the willow family lies in the use of the wood of the North American large-toothed aspen (*Populus grandidentata*) and the trembling aspen for high quality paper pulp. Many species of willow provide twigs for basketwork of all kinds throughout the Northern Hemisphere. On the other hand, the wood of poplars, such as the aspen of Europe (*P. tremula*), is now used more for matchsticks and matchboxes than for construction.

The wood of some willows is still much used. The British prefer the wood of *Salix alba* variety *caerulea* for the manufacture of cricket bats. The American *Salix nigra* (as well as other species) is used to produce charcoal

Willow centres of distribution

for black-powder manufacture. *Salix nigra* wood is also used for artificial limbs because of its light weight and its ability to dent without splintering. No doubt it is these qualities that make the wood useful for the soles of clogs and for the manufacture of wooden shoes and a multitude of other small domestic objects.

The tough, stringy bark obtained by stripping willow twigs is an excellent material for tying objects. It was once so important in commercial vineyards for tying up grapevines that grape growers were encouraged to grow one acre of willows for every 25 acres of vineyard. One early writer sounded the note of caution that the farmer who could not grow his own willows and reeds had better stay out of the vineyard business.

Many primitive peoples in the Northern Hemisphere discovered that the inner bark of the poplars served as a crude substitute for flour, which they used in time of famine. They also used willow leaves and bark for tanning leather.

The most important folk use of willow (and even poplar) bark—as a febrifuge—was discovered by virtually all the peoples living in the distributional range of the genus *Salix*. It was not until 1827 that the active bitter component salicin was first isolated. In 1838 salicylic acid was prepared from intermediate products obtained from salicin. Salicylic acid has a pronounced antifever and pain-controlling action. The important household medicine aspirin is a derivative of salicylic acid.

Both willows and poplars are widely used for shade trees and landscaping. The weeping willow (*Salix babylonica* and its relatives) is much used for ornamental plantings because of its gracefully drooping and generally handsome form. Another decorative tree is the Lombardy poplar (*Populus nigra* variety *italica*). The austere, columnar growth habit of the male tree made it a tremendous favourite after its introduction into Europe before 1750 and into North America in 1784. It has become a familiar roadside tree and is still much used in long row plantings as a screen.

The uses of Salicaceae to wildlife have long been recognized by the conservationist. Deer find the young shoots of aspen excellent for browsing. In fact, in the United States a deer population in excess of 15 to 20 per square mile will seriously interfere with the reproduction of the aspen crop. Aspen is also an important source of food for beaver. *Salix* and *Populus* buds form an important food source for various game birds, which also use willow brush for cover.

Natural history. Life cycle. The life cycle of poplars and willows follows the usual pattern in the flowering plants, although there are a few peculiarities. There is segregation of the sexes; male and female flowers occur on separate trees. There are, however, authenticated cases of sex reversal and also of hermaphroditism (both sexes in one individual), so that the normal unisexuality is not a constant feature, at least in some species. Furthermore, the maturation of the ovule (seed precursor) is later than that of the pollen grain; as a result, a considerable interval of time elapses between pollination and fertilization.

After the fertilized ovule has developed and the fruit, a capsule, has formed, it splits open, releasing the seeds, which float away on a parachute of silky hairs. One to 12 seeds are produced per capsule, and there are about 150 capsules per catkin (flower cluster) in *Populus tremula*; the number of catkins varies with the size of the tree, so that from 8,000 to 54,000,000 seeds may be produced by a single tree. The seeds are minute, there being about 3,500,000 per pound (after removal of the silky hairs) in *P. tremula*. A female tree thus produces millions of the seeds, which accumulate in windrows on the ground or float in masses on the water. They become attached by their silken parachutes to all sorts of rough surfaces, often clogging window screens, air conditioners, and other similar items.

Seed germination, which under natural conditions is prompt—usually in one or two days—is facilitated by the presence in the mature seed of mucilaginous hairs on a raised girdle around the base of the embryo and on the tip of the root. Growth in the seedlings is very rapid, and

reproductive maturity is often achieved in only a few years. The male and female plants then produce their flowers. The yellow and red aggregations of anthers associated with nectar-producing glands in the male flowers attract bees and other insects, which accidentally pick up the slightly rough pollen of certain species and transfer it to the flowers on the female plants. In some *Populus* species the transfer of the smooth pollen is by wind.

Ecology. The willows and poplars are generally plants of very moist habitats—riverbanks and stream banks and floodplains. The soil may be light or heavy, ranging from sandy to clay; loamy soils where the water table is a few feet below the surface are best for rapid growth. Some species, such as the swamp cottonwood (*P. heterophylla*) of the southeastern United States, thrive in swamps and sloughs where the water table is at the soil surface. Many willows grow where the soil is below water level, as along riverbanks. In apparent contrast is the Arctic tundra, in which a large number of species of shrubby willows occur; soil moisture, however, is always abundant in those places.

It is seldom that the willows or poplars form pure stands. They are more commonly associated with birches and alders, or otherwise grow as part of the understory among other larger trees.

In North America only two species of willow (*Salix nigra* and *S. atropurpurea*) and about six of poplar (*Populus balsamifera*, *P. grandidentata*, *P. trichocarpa*, *P. deltoides*, *P. tremuloides*, *P. heterophylla*) are important forest trees. The balance consists of small trees or shrubs. As shrubs, willows grow everywhere in the Arctic tundra. Some species occur in openings in various forest types, along the margins of woods, in open fields, in recently burned-over regions, in the moist and wet places of the treeless prairies, and along watercourses generally. Little detailed and experimental evidence is available, but circumstantial evidence for most of these shrubby species indicates a "demand" for light or, conversely, an intolerance of shade. The forest species as a group are among the most shade-intolerant of forest trees. Some of them, such as the balsam poplar or the black cottonwood, cannot grow in competition with other species but must be dominant, thrusting their crowns out of the canopy formed by the crowns of their associates. The large-tooth aspen of the Great Lakes region of the United States cannot reproduce in its own shade. The intolerance of competition and demand for light make these trees valuable as pioneer species, which occupy with vigour and aggressiveness areas cleared by lumbering, burning, windthrow, and other catastrophes.

In some instances, tree species, such as the aspens, form pure stands, but more frequently they are associated with other trees of the region that have similar preferences as to site. Thus the balsam poplar may be associated with birch or white spruce in the west and balsam fir and other species in the east. The large-tooth aspen may occur with a quaking aspen and balsam poplar, or to a lesser extent with jack pine, balsam fir, and gray and paper birches. The black cottonwood of the west occurs commonly with willow, white spruce, and red alder. The eastern cottonwood is often associated with American elm, burr oak, and sweet gum.

The Arctic and sub-Arctic shrubby willows form an integral part of the characteristic low, matlike vegetation of the region; occur in stream valleys, forming thickets; or grow as individuals in the lee of a rock. They are, depending on the species, virtually ubiquitous. Similarly, the various species that grow above the tree line on mountains tend to find similar habitats. Some prefer limy soil, others acid. The basic requirements are moisture during the growing season and light. The few willows that occur in the tropics, such as *Salix tetrasperma* of tropical and subtropical Asia, also are found along watercourses and on the banks of pools and lakes. The basic ecological requirements seem to be much the same as for the temperate and Arctic members of the genus.

Form and function. The outstanding anomaly in this group of plants is the simplicity of the flowers in the

Basic requirements for willow growth

Shade tree and ornamental uses

willows, which are specialized for insect pollination. No other group of flowering plants has simpler flowers and yet is insect pollinated. It has been assumed that such simplicity is intimately interrelated with wind pollination, as it is in many of the other members of the "Amentiferae," or "catkin bearers," a group of plants that includes the birches, hop hornbeams, alders, oaks, chestnuts, walnuts, and poplars. The willows, however, are so thoroughly converted to insect pollination that they have become adapted or specialized to some species of *Andrena* (solitary bees). The appearance of these bees in the spring coincides with the opening of willow catkins. Many other kinds of bees, butterflies, and flies also visit willow catkins. It is sometimes assumed that the ancestors of the willows, like the poplars today, were wind-pollinated, but that both evolved from bisexual, insect-pollinated ancestors. If so, there has been a reversion to a more primitive function by the willows.

The growth habit of the willows is woody, which in general demands a high degree of efficiency in the retention of moisture in the living cells when the leafless stems and branches are above ground during the winter. The willows and poplars have an effective waterproofing system composed of cork cells on the exposed stems. Furthermore, the winter buds are covered with one (in willow) or more (in poplar) modified leaves in the form of bud scales, often covered by a balsam-like, resinous waterproofing material. The most extreme shrubs of the exposed tundra or mountain tops supplement their waterproofing devices by sprawling close to the ground. They are often protected from desiccation and windblown ice crystals by a covering of snow. The most extreme of all sprawling willows is *Salix herbacea*, which often grows only tall enough for its buds to come to the surface of the tundra; the thin, little branches remain safely submerged the year around.

An adaptation of great value to many members of the group is the unusual facility with which the roots produce adventitious (unusual in origin) "sucker" shoots. Following the destruction of an aspen stand by fire, sprouts come up in vast numbers from the roots of the burned trees. This type of regeneration permits the aspen to continue to occupy territory from which it would otherwise become eliminated because of its intolerance to shade. A similar characteristic of many of the willows, such as the sandbar willow, permits the plants to thrive on the unstable sites provided by sandy and gravelly, often inundated, islands in rivers and shorelines of rivers and lakes.

One of the peculiar vegetative characteristics of many of the willows and poplars is the readiness with which the branchlets are abscised (cut off by specialized cells). Such branchlets, which may be carried considerable distances by water currents, provide excellent means of vegetative propagation. This is because of the readiness with which adventitious roots form on twigs of this group of plants, a phenomenon well appreciated by housewives who obtain starts of pussy willows by putting twigs in water until roots grow.

Some of the aspens possess the interesting property of having much chlorophyll—the green pigment of photosynthesis—in the bark of their trunks. As a result, photosynthesis occurs before the leaves come out in the spring and even during part of the winter. It has been suggested that, in the colder, short-season part of the range of the aspen, this property may account for its ability to thrive in what is otherwise mainly an evergreen conifer environment.

Evolution. As in the rest of the flowering plants, fossil evidence for determining the real evolutionary origins of the order Salicales is absent or, alternatively, has not been properly interpreted. *Salix* and *Populus* were already present in Europe and North America during the Cretaceous Period (from 65,000,000 to 136,000,000 years ago). The presence of *Populus* and *Salix* in the rich flora of the Tertiary (beginning 65,000,000 years ago) of Greenland and Spitsbergen, then, from the upper Oligocene (some 26,000,000 years ago) onward in central and northern Europe, suggests a southward migration. Some authorities see a similarity between the Tertiary species of *Salix*

and the species that survive today in the tropics; this suggests that the latter are primitive.

Close study of the living poplars and willows discloses a wide range of variation in some structural features and marked uniformity in others. The total of characteristics suggests a moderately advanced group of plants, which in some respects has become very highly modified. The wood is quite specialized and is far removed in its characteristics from the primitive magnolias and their tropical relatives. The leaves similarly are somewhat advanced. The woody habit rather than a herbaceous one, however, is a less specialized character.

The unisexual flowers are very small and crowded in great numbers into highly condensed spikes (*Salix*) or dangling catkins (*Populus*)—all very advanced features, as is their individual structure. The interpretation of the large number of stamens (male reproductive structures that produce pollen)—up to 50 or 60—which are spirally arranged in some poplars, is puzzling, the more so because the stamens are attached well out on a curious cuplike structure. The cup is provided with a vascular supply that is suggestive of a highly modified perianth (petals and sepals). This is interpreted to be a single flower with few to many stamens. But a quite different interpretation suggests that each stamen is a separate flower. A similar cup occurs in one of the tropical willows, but in most of them the cup found in the poplar is represented by one or more isolated nectar-producing glands, associated with few or even but a single stamen—an extreme reduction from the poplar state. In the female flowers similar cups occur in the poplars and glands in the willows, inserted in each type of flower below the pistil (female structure containing the ovules)—a primitive location for the perianth, if it is indeed a perianth. The pistil is crowned with styles (the elongated upper part of the pistil), which not infrequently have dichotomously branched—two-forked—stigmas (sticky pollen-receiving areas), another primitive feature.

The pollen also is quite advanced, especially in *Populus*, which is wind-pollinated. It has lost its superficial sculpturing, some evidence of which still remains in the insect-pollinated willows. Chalazogamy occurs in some species—*i.e.*, the pollen tube approaches the embryo sac by penetrating the base of the ovule rather than entering by the normal pathway, an opening called the micropyle. This is a rare phenomenon in flowering plants, and its significance is difficult to assess.

In one characteristic after another, therefore, varying degrees of advancement are evident that require interpretation of the order Salicales as being well along the path of specialization. But its ancestors and close relatives are a puzzle. Various suggestions have been made, such as a relationship with the families Tamaricaceae or Flacourtiaceae or, again, with the orders Caryophyllales or Papaverales or with the Betulales—Fagales order complex by way of the Hamamelidales. None can be supported with strong, positive evidence, and most of the proposals can be dismissed by pointing out a pronounced lack of consistent similarity with any of these plants. One thing is certain: the Salicales cannot be lumped with other catkin-bearing trees and shrubs to become a member of that artificial group, the "Amentiferae."

Classification. Annotated classification.

ORDER SALICALES

Woody trees or shrubs with simple, spirally arranged, tooth-margined, usually deciduous (falling) leaves that have stipules, small leaflike appendages at the base of the leafstalk. Flowers unisexual, male and female usually on separate plants. Male flowers with 1 to many stamens, vestigial pistils absent. Female flowers with a single pistil unaccompanied by vestigial stamens. Pistil composed of 4, 3, or, most often, of 2 carpels (ovule-bearing segments). Ovary superior (positioned above the other flower parts), with a single chamber and several to many ovules. Style present or absent, the number of stigmas equal to or double the number of carpels. Inflorescence (flower cluster) a characteristic cylindrical spike (a catkin or ament) that is erect (in *Salix*) or pendulous (in *Populus*). Pollination in the spring by wind (*Populus*) or insects (*Salix*). Maturation of the fruit and shedding of seed occurs in the spring. Fruit a somewhat leathery-walled capsule, splitting into as many segments as there are carpels to

Evolutionarily advanced structural features

release the minute seed, each with a tuft of cottony hair attached at the base. Seeds with a small, straight embryo, lacking endosperm, and with a thin seed coat.

Family Salicaceae

The only family of the order; it has the characters of the order. Two genera — *Populus* (poplars, aspen), with about 30 species, and *Salix* (willows) with about 320 species.

Critical appraisal. The Salicales has consistently been recognized to contain a single family, the Salicaceae. The two genera, *Populus* and *Salix*, are sufficiently similar in flowers, wood, and reproductive structures that they cannot be put into separate tribes or subfamilies. The genus *Chosenia* has been recognized by some authorities as a third genus but has few characters that distinguish it from *Salix*, in which genus it is here included.

BIBLIOGRAPHY. GEORGE H.M. LAWRENCE, *Taxonomy of Vascular Plants* (1951), an excellent introduction to the morphology and taxonomy of the Salicales; A. REHDER, *Manual of Cultivated Trees and Shrubs Hardy in North America, Exclusive of the Subtropical and Warmer Temperate Regions*, 2nd ed. rev. (1940, reprinted 1962), the authoritative treatment of those species hardy in North America; S.A. GRAHAM, ROBERT P. HARRISON, JR., and CASEY E. WESTELL, JR., *Aspens, Phoenix Trees of the Great Lakes Region* (1963), an account of the spectacular increase in importance of this "Cinderella" tree in the forest economy of the North Central United States; T.J. CROVELLO, *A Numerical Taxonomic Study of the Genus Salix, Section Stitchenses* (1968), a fine example of a very technical application of numerical taxonomy; M.J. FISHER, "The Morphology and Anatomy of the Flowers of the Salicaceae," *Am. J. Bot.*, 15:307-326, 372-394 (1928), the most complete, although technical, account of floral anatomy for this group; H. HJELMQVIST, "Studies on the Floral Morphology and Phylogeny of the Amentiferae," *Bot. Notiser, Suppl.*, 2:147-163 (1948), a different (from M.J. Fisher) point of view about floral morphology in the willow order and related groups; C. PICKERING, *Chronological History of Plants* (1879), a classic book answering the interesting question of when various members of the Salicales were first mentioned in man's history.

(E.C.A.)

Salisbury, Robert Cecil, 3rd marquess of

A British Conservative statesman, a three-time prime minister, and a four-time foreign secretary, Robert Arthur Talbot Gascoyne-Cecil, the 3rd marquess of Salisbury, was, with Gladstone and Disraeli, one of the towering political figures of the last quarter of the 19th century. Salisbury's fame rests on his successful handling of Britain's foreign affairs during a time of almost continuous crisis caused by international rivalries in Europe, Africa, and Asia. He maintained Britain's worldwide interests, always working for general peace, which among the then great powers (Germany, Britain, Russia, France, Italy, Austria-Hungary, and later Japan and the United States) remained unbroken throughout his years of office.

At home, as Conservative prime minister, he supported practical reforms on particular questions, such as housing the poor, rather than policies designed to bring about social change. Throughout his life he remained opposed to arguments in favour of democracy, believing that it was better to have a balance of "classes." He opposed Gladstone's policy of Home Rule for Ireland; instead, he followed a firm policy of maintaining law and order there while introducing some constructive reforms. This cautious reforming spirit, with its stress on the strict limitations of government, won solid electoral support and gave the Conservatives long periods in office (1886-1892; 1895-1905).

Salisbury was born at Hatfield in Hertfordshire, England, on February 3, 1830, the second surviving son of the 2nd marquess of Salisbury, who had married Frances Gascoyne, an heiress to large landed estates. His elder brother suffered from a debilitating illness all his life and died in 1865, and thus Lord Robert Cecil became heir to the estates and on the death of his father the 3rd marquess of Salisbury, in 1868. His family background allowed him easy entry into any profession but only merit and ability could ensure high office.

Robert Cecil's childhood was unhappy and lonely. He

Salisbury.

Radio Times Hulton Picture Library—Globe

was exceptionally clever but not especially strong, and he hated games. His father was conscientious but lacking in warmth. His mother, by all accounts sociable and vivacious, died when he was only ten. He was sent to Eton, where he was perpetually bullied. He was by nature pessimistic, withdrawn, and shy, but his courtesy, modesty, and fair-minded tolerance combined to make an attractive personality. Taken from school when he was 15, he was tutored privately. His love for scholarship was deep. At 18 he entered Christ Church, Oxford, but his stay was cut short by a breakdown in health. In accordance with the advice of his doctors, he set out on a long sea voyage to Australia and New Zealand. He was absent from England for almost two years. During this time his character matured. He regained his health and acquired self-confidence. He was still uncertain as to his future career; both the church and politics attracted him. When he was offered a seat in Parliament for Stamford in 1853, he chose politics and was elected to the House of Commons.

He fell in love with Georgina Alderson, but his father objected to the marriage, regarding her lack of social standing and wealth as an impediment to an alliance with the Cecil family. Nonetheless, the marriage took place in 1857. They had five sons and two surviving daughters. Salisbury was a man of strong religious faith and enjoyed a happy home life. Lady Salisbury was intelligent and sociable, and all the Cecils came to regard Hatfield as their home. Hatfield also became one of the great houses in which distinguished visitors were entertained.

During the years from 1853 to 1874, Salisbury was only briefly a government minister (secretary of state for India, July 1866 to March 1867) but resigned office in disagreement over the Conservative government's espousal of parliamentary reform. He became deeply suspicious of the new Conservative leader, Disraeli. Out of the government he was active as a member of the House of Commons and as a writer; he frequently contributed political articles to the *Saturday Review* and *The Quarterly Review*. He also interested himself in science, especially in botany and in electricity and magnetism; later he had his own laboratory built at Hatfield.

In February 1874 Salisbury was persuaded to join Disraeli's ministry and once more became secretary of state for India. During their seven years together in and out of office, Salisbury, overcoming his earlier prejudice, came to regard Disraeli with admiration and affection.

Succeeding the inept Lord Derby as foreign secretary, Salisbury first became responsible for Britain's foreign relations in April 1878, at a time of great crisis in the Balkans. It seemed probable that war might break out between Britain and Russia over the control of Constantinople. By masterly diplomacy Salisbury ensured that the

Appointment as foreign secretary

Domestic policy

Russians came to the conference table at the Congress of Berlin (June–July 1878). Disraeli occupied the limelight, but Salisbury's careful and patient diplomacy secured the essential compromises. For their success Disraeli and Salisbury were granted the Order of the Garter, the highest decoration Queen Victoria could bestow.

After Disraeli's death (1881), Salisbury was the obvious successor and led the Conservative opposition in the House of Lords. He became prime minister during the brief Conservative administration from June 1885 to January 1886. Ireland and imperial problems were the chief issues of the time. Salisbury opposed Gladstone on the question of Home Rule for Ireland and three times won the electoral support necessary to become prime minister (1886–92, 1895–1900, and 1900–02). During the greater part of these years, Salisbury combined the offices of prime minister and foreign secretary. He was not autocratic but left wide discretion to individual ministers. Weak control by the government as a whole sometimes had harmful results. This was one of the causes of the South African War (1899–1902), which occurred when Joseph Chamberlain was colonial secretary. But at the Foreign Office, Salisbury succeeded in avoiding serious conflict with the great European powers despite major crises and rivalries.

The partition of Africa largely preoccupied Salisbury's second ministry (1886–92) and remained a source of serious Anglo-French conflict until 1898, when France accepted British dominance on the Nile after the Fashoda Crisis. Salisbury was an imperialist: he believed a phase of European, preferably British, rule indispensable for the advancement of the "backward" races and had no hesitation in imposing this rule by force, as he did in the Sudan (1896–99). His foreign policy was directed toward the defense and enlargement of the British Empire. He had no sympathy for older empires, such as the Ottoman, whose rulers he regarded as corrupt oppressors. Salisbury attempted but failed to gain the cooperation of the European powers to intervene against Turkey to bring to a halt the Armenian "massacres" (1895–96). He refused to be frightened either by American threats over Venezuela (1895) or by the Kaiser's Kruger telegram sent in January 1896, after the unsuccessful Jameson raid into the Transvaal in South Africa.

During the last decade of the 19th century, when the principal powers grouped themselves into alliances, Salisbury maintained a free hand for Britain. He was opposed to alliance commitments, fearing that when the time came a democratic electorate might refuse to go to war; he also regarded alliances for Britain as unnecessary and dangerous. He did not back Chamberlain's unsuccessful efforts to conclude an alliance with Germany (1898–1901).

Recent scholarship has re-evaluated Salisbury's contribution and acquitted him of the charge of "secret diplomacy"; nor was Salisbury an "isolationist," since his diplomacy was active wherever Britain's interests extended. During the last two years of his ministry, from the autumn of 1900 until the summer of 1902, old age and ill health forced him to give up the Foreign Office, though he continued as prime minister. With Lord Lansdowne as the new foreign secretary, he saw his principles of diplomacy partially abandoned when Britain concluded an alliance with Japan in January 1902. Later that year, in July, Salisbury retired. He died on August 22, 1903.

Salisbury was the last aristocratic statesman to head a British government while in the House of Lords and not the elected Commons. He represented a tradition that passed away with him. His contemporaries recognized his greatness as a statesman. He combined a realism and clarity of view with a fundamentally ethical approach to diplomacy, which sought to conciliate and pacify while maintaining important national interests.

BIBLIOGRAPHY. The most important biography is LADY GWENDOLEN CECIL, *Life of Robert, Marquis of Salisbury*, 4 vol. (1921–32), but a projected fifth volume was never published. Sallust

A Roman politician and historian, Sallust made a unique contribution to historiography with his development of the monograph. His vivid and dramatic narratives describing Roman politics in the 2nd and 1st centuries BC and his fascination with the personalities of the leading political figures of his time influenced the great Roman historian Tacitus, among others.

Sallust (Gaius Sallustius Crispus) was born at Amiternum (now San Vittorino, near L'Aquila) in central Italy, probably in 86 BC; a late source gives his birth date as October 1. His family probably belonged to the local aristocracy, but Sallust was the only member known to have served in the Roman Senate. Thus he embarked on a political career as a *novus homo* ("new man"); that is, he was not born into the ruling class, which was an accident that influenced both the content and tone of his historical judgments. Nothing is known of his early career, but he probably gained some military experience, perhaps in the east in the years from 70 to 60 BC. His first political office, which he held in 52, was that of a tribune of the plebs. The office, designed originally to represent the lower classes, by Sallust's time had developed into one of the most powerful magistracies. The evidence that Sallust held a quaestorship, an administrative office in finance, sometimes dated about 55, is unreliable.

Because of electoral disturbances in 53, there were no regular government officials other than the tribunes, and the next year opened in violence that led to the murder of Clodius, a notorious demagogue and candidate for the praetorship (a magistracy ranking below that of consul), by a gang led by Milo. The latter was a candidate for consul. In the trial that followed, Cicero defended Milo, while Sallust and his fellow tribunes harangued the people in speeches attacking Cicero. While these events were not of lasting significance, though they did result in Pompey's appointment as sole consul, Sallust's experience of the political strife of that year provided a major theme for his writings.

In 50 Sallust was expelled from the Senate for alleged immorality on the initiative of Appius Claudius, who had close connections with Pompey and with whom Sallust had probably quarrelled. The following year Sallust sought refuge with Caesar, and, when the civil war between Caesar and Pompey broke out in that year, he was placed in command of one of Caesar's legions. His only recorded action was unsuccessful. Two years later, designated praetor, he was sent to quell a mutiny among Caesar's troops, again without success. In 46 he took part in Caesar's African campaign (with modest success), and when Africa Nova was formed from Numidian territory (modern Algeria), Sallust became its first governor. He remained in office until 45 or early 44.

Upon returning to Rome, Sallust was accused of extortion and of plundering his province, but through Caesar's intervention he was never brought to trial. The evidence is suspect: it contains few details and is in part of doubtful authenticity. It also draws moralizing contrasts between Sallust's behaviour and his censorious writings and suggests a source for the ill-gotten wealth that created the splendid Sallustian Gardens (Horti Sallustiani). Maladministration was common enough and Sallust may have been guilty. Yet the tradition about his morals seems to have originated in scurrilous gossip and by a confusion between the historian and his adopted son, Augustus' minister Sallustius Crispus, a man of great wealth and luxurious tastes who may have created the gardens. The remains of the palace where they were located—the gardens became an imperial possession—may still be seen in the Piazza Sallustia.

Sallust's political career ended soon after his return to Rome. His retirement may have been voluntary, as he himself maintains, or forced upon him by the withdrawal of Caesar's favour or even by Caesar's assassination. Cae-

sar seems not to have considered him for the consulship, nor did the Triumvirate of Antony, Octavian, and Lepidus, Caesar's heirs. Sallust may have begun to write even before the Triumvirate was formed late in 43.

Sallust was born in a time of civil war. As he grew to maturity, foreign war and political strife were commonplace; thus it is not surprising that his writings are preoccupied with violence. His first monograph, *Bellum Catilinae* (43–42 BC; *Catiline's War.*) deals with corruption in Roman politics by tracing the conspiracy of Catiline, a ruthlessly ambitious patrician who had attempted to seize power in 63 BC after suspicions of his fellow nobles and the growing mistrust of the people prevented him from attaining it legally. He was supported by certain members of the upper classes who were prompted either by ambition or by the hope of solving their financial problems by Catiline's accession to power. But he also had the backing of Italy's dissatisfied veterans, impoverished peasants, and overburdened debtors. In Sallust's view, Catiline's crime and the danger he presented were unprecedented. Indeed, alarmed contemporaries may have exaggerated the significance of the incident; yet had the government not acted as firmly as it did, a catastrophe could have occurred. Sallust describes the course of the conspiracy and the measures taken by the Senate and Cicero, who was then consul. He brings his narrative to a climax in a senatorial debate concerning the fate of the conspirators, which took place on December 5, 63. In Sallust's eyes, Caesar and Cato represented civic virtue and were the significant speakers in the debate; he regarded the deaths of these men as marking the end of an epoch in the history of the republic. A digression in this work indicates that he considered party strife as the principal factor in the republic's disintegration.

In his second monograph, *Bellum Jugurthinum* (41–40 BC; *The Jugurthine War*), he explored in greater detail the origins of party struggles that arose in Rome when war broke out against Jugurtha, the king of Numidia, who rebelled against Rome at the close of the 2nd century BC. This war provided the opportunity for the rise to the consulship of Gaius Marius, who, like Sallust and Cicero, was a "new man." His accession to power represented a successful attack on the traditionally exclusive Roman political elite, but it caused the kind of political conflict that, in Sallust's view, resulted in war and ruin. Sallust considered Rome's initial mismanagement of the war the fault of the "powerful few" who sacrificed the common interest to their own avarice and exclusiveness. Political turmoil in Rome during the late republic had social and economic causes (not overlooked by Sallust), but essentially it took the form of a power struggle between the aristocratic group in control of the Senate and those senators who enlisted popular support to challenge the oligarchy. This is the underlying framework of Sallust's schematic analysis of the events of that time—the clash between nobility, or Senate, and people, or plebs. The *Histories*, of which only fragments remain, describes the history of Rome from 78 to 67 BC. Here Sallust deals with a wider range of subject matter, but party conflict and attacks on the politically powerful remain a central concern. Hints of hostility to the Triumvirate may be detected in both *Bellum Jugurthinum* and the *Histories*.

Two "Letters to Caesar" and an "Invective Against Cicero," Sallustian in style, have often been credited, although probably incorrectly, to Sallust. A report that he wrote a speech, now lost, for Ventidius, a victorious general, in 38 BC would indicate that Sallust enjoyed a high reputation, for Ventidius would be likely to approach a currently esteemed writer. His influence pervades later Roman historiography, whether men reacted against him, as Livy (59 BC–AD 17) did, or exploited and refined his manner and views, as Tacitus (c. 56–c. 120) did. His narratives were enlivened with speeches, character sketches, and digressions; and, by skillfully blending archaism and innovation, he created a style of classic status. And to the delight of moralists he revealed that Roman politics were not all that official rhetoric depicted them to be.

Sallust is not an entirely admirable historian; his

work shows many instances of anachronisms, inaccuracies, and prejudice; the geography of the *Bellum Jugurthinum* scarcely reveals personal acquaintance with North Africa; he treats the destruction of Carthage in 146 BC as the beginning of the Roman crisis, whereas symptoms were clearly visible before that date. Nor is he a deep thinker, being content to operate with philosophical commonplaces. He makes no attack on the structure of the Roman state; his moral and political values are traditional; they commemorate the past to castigate the present. But his own experiences in politics imbued his analysis and his idiom with an energy and passion that compel the attention of readers.

Sallust died in 35 or 34 BC; a late source adds a date, May 13.

BIBLIOGRAPHY. The standard editions of the text of Sallust's works are C. SALLUSTIUS CRISPUS, *Catilina, Jugurtha, Fragmenta ampliora*, ed. by A.W. AHLBERG and A. KURFESS (1968); and *Historiarum reliquiae*, ed. by B. MAURENBRECHER, 2 fasc. (1891–93, reprinted 1967). A serviceable bibliography, though not complete, is A.D. LEEMAN, *A Systematical Bibliography of Sallust, 1879–1964*, rev. ed. (1965); it may be supplemented for works after 1964 by the successive volumes of *L'Année philologique*. D.C. EARL, *The Political Thought of Sallust* (1961), is the only substantial treatment of this subject in English. See also R. SYME, *Sallust* (1964), a comprehensive work with a useful bibliography.

(G.M.P.)

Salmoniformes

The order Salmoniformes is a diverse and complex group of fishes consisting of about 1,000 species in the fresh waters and oceans of the world. Included are the familiar trout, salmon, and pike, as well as most of the bizarre forms of fishes inhabiting the middepths of the oceans.

The framework of the order Salmoniformes in the discussion below should not be considered as a definitive taxonomic category but rather as an assemblage of diverse fishes possessing several primitive anatomical features representative of an early stage in the evolution of modern bony fishes (teleostean fishes).

GENERAL FEATURES

Evolutionary importance of the order. The significance of the order Salmoniformes as presently classified—a major departure from early schemes of fish classification—is in the evolutionary position of the group; the Salmoniformes are now considered a basal stock in the mainstream of modern bony-fish evolution. The present classification implies that the ancestors of salmoniform fishes developed several evolutionary trends in the Late Mesozoic Era, about 100,000,000 years ago, providing the necessary source of evolutionary raw material to initiate several successful evolutionary lineages, ultimately leading to most of the modern bony fishes.

The order Salmoniformes, as treated here, is based on the combined work of a British ichthyologist and several American ichthyologists, who have divided the order into eight suborders and 37 families. Constructed in this way, the order Salmoniformes brings together many extremely diverse groups. Several major alterations have recently been proposed for the classification of salmoniform fishes; thus the classification used in this article is provisional and may be subject to extensive changes when more precise information is available. The order Salmoniformes can be considered more as an evolutionary grade in the phylogeny of teleostean fishes than a well-defined taxonomic category. No single character or group of characters can distinguish all salmoniform fishes from all other fishes.

Reasons for interest in the order. The trouts, salmon, chars, whitefishes, and graylings of the family Salmonidae are the most widely known and intensively studied family of fishes. Their famed sporting qualities and excellent taste ensure their economic importance. At the other extreme, some deep-sea families of salmoniform fishes are known only to a few ichthyologists, and often only on the basis of a few imperfectly preserved specimens. The bulk of salmoniform species are fishes of the mid-depths (mesopelagic and bathypelagic zones) of the open

Divisions
of the
order

Figure 1: Body plans of salmoniform fishes of the suborders Salmonoidei, Galaxioidei, Argentinoidei, and Esocoidae.

oceans. The deep-sea salmoniforms have evolved unusual body forms and structures—such as luminous organs, telescopic eyes, complex appendages, and enormous and well-developed jaws and teeth—to cope with existence in the twilight and dark zones of the ocean and are of great interest in the study of evolutionary and developmental biology. Some of the anatomical structures evolved by the deep-sea salmoniforms are among the most striking and strange ones found in the animal kingdom.

Size range. The largest of the salmoniform fishes are members of the salmonidae and include the Pacific king salmon (*Onchorhynchus tshawytscha*) and the Danube and Siberian huchen (*Hucho hucho*), which are known to attain a weight of 50 kilograms (110 pounds) or more. The North American muskellunge (*Esox masquinongy*), of the pike family, approaches this size. The majority of the salmoniform species, however, are small. Most of the deep-sea species do not exceed 150 millimetres (six inches) in length, and many at maturity are 25 to 50 millimetres (one to two inches) long. The largest of the marine salmoniforms is one of the lancet fishes (family Alepisauridae), which may reach a maximum length of 2.1 metres (6.9 feet). The lancet fish has an elongated body with tremendously enlarged, dagger-like teeth, a fragile sail-like dorsal fin, and a soft, flaccid body. Occasionally a lancet fish migrates from the depths to the surface and may be caught by a fisherman or found washed up on a beach. Lancet fishes, like other deep-sea salmoniforms, are so highly modified that the relationships to trout and salmon are not obvious. A basic salmoniform feature, however, the small, fleshy adipose (fatty) fin situated between the dorsal fin and the tail, is found on both trouts and lancet fishes and has been inherited from a very ancient, but common, ancestor.

Most salmoniform species, including the smaller forms, are predacious fishes. Many peculiar modifications have been evolved by the small species of marine salmoniforms to allow them to capture and consume prey sometimes as large as themselves. Some of these lilliputian monsters appear to be mostly head and jaws, all out of proportion to the soft, gelatin-like body. The lack of a neck in fishes limits the mobility of the head and jaws; remarkable adaptations increase the flexibility of the head and allow a great enlargement of the mouth opening to engulf prey quickly. Several deep-sea salmoniforms lack bone on the anterior portion of the vertebral column, increasing the flexibility of the head and jaws.

Distribution and abundance. Salmoniform fishes are found in fresh water on all continents and in all of the oceans of the world. Various representatives of the trout, pike, and smelt families are indigenous to the cooler fresh waters of the Northern Hemisphere. Species of the family Salmonidae inhabit the colder waters of North America, from tributaries of the Arctic Ocean to tributaries of the Gulf of California in northwestern Mexico; in Europe and Asia, a comparable distribution is found, from the Arctic Ocean to the Atlas Mountains in North Africa and to the island of Taiwan. The Arctic char (*Salvelinus alpinus*) is the most northerly occurring of any freshwater fish. The development of an anadromous life cycle—spawning in fresh water but migrating to the sea for feeding and maturation—has allowed species of trout and salmon to extend their range greatly, particularly into fresh waters of glaciated regions after the glaciers recede and waters become inhabitable. The use of marine invasion routes allows a rapid expansion in the distribution of a species into new areas, often inaccessible to other species completely restricted to a freshwater life cycle. Species of the family Salmonidae are clearly the dominant fishes of the recently glaciated fresh waters of the Northern Hemisphere.

The pike and its allies (family Esocidae) have a distribution somewhat similar to the Salmonidae but extending neither so far north nor so far south. The pikes are completely restricted to fresh water throughout their life cycle; however, the distribution of the northern pike (*Esox lucius*) in Europe, Asia, and North America is one of the broadest distributional patterns of any fish species. Such a distribution must have been achieved when direct freshwater connections existed between the present major drainage basins and between Asia and North America. The smelts of the family Osmeridae are small fishes of Europe, Asia, and North America. Some smelts are permanent freshwater inhabitants, but the distribution of freshwater smelts is associated with relatively recent geological events; most smelts are anadromous or marine. No smelt species has penetrated far enough inland to establish a broad distribution in fresh water comparable to that of the salmonid fishes. The other salmoniform fishes with anadromous and freshwater species in the Northern Hemisphere are members of the Far Eastern families Plecoglossidae and Salangidae. In the Southern Hemisphere, salmoniform fishes ecologically similar to the trouts and smelts are encountered in the fresh waters of southern Africa, southern South America, Australia,

The
anadromous
life
cycle

New Zealand, and Tasmania. These fishes are classified in the families Galaxiidae, Retropinnidae, Aplochitonidae, and Prototroctidae (of the suborder Galaxioidi). The galaxioid fishes are typically small (100 to 300 millimetres [four to 12 inches]) marine and freshwater fishes. The family Galaxiidae contains the most species (about 35) and has the broadest distribution—in Africa, South America, Australia, New Zealand, and Tasmania. The smeltlike fishes of the family Retropinnidae comprise about six species native to Australia, New Zealand, and Tasmania. The family Aplochitonidae consists of three species in southern South America and a larva-like (neotenic) species in Tasmania. The Prototroctidae has two, troutlike species in Australia and New Zealand. Various species of Salmonidae, particularly the North American rainbow trout (*Salmo gairdneri*) and the European brown trout (*S. trutta*), have been widely introduced and successfully established in suitable waters in Africa, South America, Australia and New Zealand. When introduced into lakes with abundant food fishes but previously lacking large predator fishes, the introduced trout flourish, growing rapidly to a large size. In certain lakes in Australia and New Zealand, famed for their trophy-sized trout, the trout feed avidly on their distant relatives, species of the Retropinnidae and Galaxiidae.

The remaining 25 or more families of Salmoniformes, with about 800 species, are entirely marine, typically middepth and deep-sea fishes. Representatives are found in all oceans and all depths, but in temperate and tropical waters major concentrations occur at depths of 200 to 2,000 metres (about 650 to 6,500 feet). The tremendous abundance attained by some populations of these marine salmoniforms has become evident only with the advent of modern sonar equipment, which has detected aggregations many square kilometres in extent.

IMPORTANCE TO MAN

The economic significance of the trouts and salmon as sporting fishes and as commercial products is well-known. Governments invest heavily to maintain and increase the production of trout and salmon; hundreds of millions of trout and salmon are hatched, reared, and stocked each year for sport and commerce. A large private industry has developed, particularly in Denmark, Japan, and the United States to supply trout to markets and restaurants. With the problems of increased human population and the demands made on rivers by industry and agriculture, the challenge of perpetuating and increasing the abundance of salmon and trout has become a serious one.

The demand for trout as a sport fish far exceeds the supply in heavily populated regions. This situation, particularly in the United States, has resulted in a massive program by state and federal agencies to raise trout to acceptable size and to stock them in heavily fished waters. Such an artificial abundance, however, is a poor substitute for natural trout fishing.

Except for the pikes, the remaining freshwater salmoniforms are too small or too rare to be significant sport fish, but most are considered excellent food fish. The oceanic salmoniforms have little direct importance to man; because of their tremendous abundance, however, they form a vital link in the food chain of the oceans, providing forage for valuable predator species such as the tuna. Many of the deep-sea salmoniforms undertake daily vertical migrations, rising toward the surface layer of the ocean at night for feeding. This vertical migration exposes them to predation by larger fishes and functions in the recycling of energy in the ocean by elevating energy accumulated in the lower depths (in the bodies of the small salmoniforms) and making it available to large predators in the upper zones.

NATURAL HISTORY

Life cycle and reproduction. Virtually every type of life cycle and mode of reproduction known for fishes is exhibited by some salmoniform fishes. These life cycles range from passage of the entire life-span in the confines of a small pond or stream to migrations encompassing thousands of kilometres from a stream to the ocean and

back to the stream. Some species have a direct development stage from the egg, hatching as miniature adults, ready to fend for themselves. Most deep-sea marine species have larval stages, drastically different from the adult. Some larvae have eyes attached to long stalks from the head. Most salmoniform species consist of males and females, but several deep-sea groups are hermaphrodites, a single individual having functional testes and ovaries. Evidently, in the darkness of the ocean depths, it is advantageous for an individual to function both as male and female.

The life cycles of salmon and trouts have been intensively studied because of the economic importance of salmonid fishes. Factual information of the life cycle and reproduction is used to settle disputes between nations regarding the origin of salmon caught in the open ocean and for the intelligent management of the resource.

The life cycle and reproduction of the deep-sea salmoniforms, however, are little known except for interpretations gained from examination of a few specimens and collection of eggs and larvae. Eggs and larvae of many of the marine species have not yet been found.

Among the salmoniform fishes, only the pike family (Esocidae) and the mudminnow family (Umbridae) are completely restricted to fresh water throughout their life cycle. All other families that have freshwater representatives contain some species that enter the marine environment for growth and maturation, returning to fresh water to spawn. One species of the family Galaxiidae has a catadromous life cycle—spawning takes place in a marine environment, and the young migrate to fresh water to mature. All of the oceanic salmoniforms are completely marine throughout their life cycle.

The families Salmonidae and Osmeridae demonstrate a transition between freshwater and marine life cycles. All species of salmonids spawn in fresh water, but the Pacific pink salmon (*Onchorhynchus gorbuscha*) has reduced the freshwater stage to the spawning migration and incubation of the eggs. As soon as the eggs hatch and the yolk sac is absorbed, pink salmon fry migrate to sea. Some pink salmon may spawn in the intertidal zone at the mouths of small streams, virtually eliminating the freshwater stage in the life cycle. Other species of Salmonidae, such as the lake char, or lake trout (*Salvelinus namaycush*), the graylings (*Thymallus*), and many of the whitefishes (*Coregonus*), have completely freshwater life cycles. Life cycles may differ among closely related species or even between populations of the same species; for example, rainbow trout that go to sea and return as large, silvery individuals are called steelhead trout. A single river system may contain local resident populations of small rainbow trout—maturing, spawning, and completing a life cycle within 100 metres (about 300 feet) of the site of their birth—as well as anadromous steelhead rainbow trout returning from the ocean after a two- or three-year journey spanning several thousand kilometres. Evidently the heritable differences that govern the type of life cycle in trouts—anadromous or freshwater—are slight. Offspring from anadromous parents can be used to establish populations in completely landlocked environments, and the progeny of nonanadromous parents may go to sea if given the opportunity.

Reproductive behaviour, the type and size of the eggs laid, and the amount of parental care have been developed in each species by the process of natural selection. In an evolutionary sense, spawning success is ultimately judged by the number of mature adults resulting from any spawning act. If the eggs and larvae are exposed to a harsh and perilous environment, there is a selective advantage for a female to produce fewer but larger eggs and to provide some extra measure of protection for the developing embryos. Cold, swift rivers with sparse food, typically utilized by salmon and trouts for spawning, undoubtedly have been a major selective force in the evolution of large eggs (four to eight millimetres [0.15–0.3 inch] in diameter) and of nest-building behaviour in the trouts and salmon.

A large egg with a large yolk to supply food to the developing embryo allows for direct development—that

is, the young hatch in an advanced stage, resembling a miniature adult. In more benign environments, such as lakes and the ocean, most salmoniform fishes produce smaller but more numerous eggs, and hatching takes place when the larvae are only partially developed. In many species the larvae are quite unlike the adult form and undergo a rather striking transformation (metamorphosis). Eggs of all freshwater spawning salmoniform fishes are heavier than water (demersal eggs) and develop on or in the bottom of a stream or lake. Marine species typically have pelagic (free drifting) eggs and larvae; the eggs are of neutral buoyancy and thus drift with the currents in the surface layer of the ocean. The eggs and larvae of many deep-sea salmoniforms have not yet been described, and in some species the eggs and larvae may be associated with the ocean bottom.

As far as known, all salmoniform fishes lay eggs and have external fertilization (oviparous fishes). In several of the deep-sea salmoniform families, in which hermaphroditism is common, it is not known if the species are self-fertilizing.

Some of the deep-sea salmoniforms have luminescent organs, one of the functions of which probably is sexual recognition. In the lantern fishes (Myctophoidi), the light organs are arranged in distinctive patterns that distinguish males and females of a species.

Behaviour and locomotion. Only the freshwater salmoniform fishes can be studied in any detail by direct observation. Most of what is known about the deep-sea species is based on preserved specimens, and, for most species, behaviour and locomotion can only be surmised from an examination of the morphology and anatomy.

The generalized body form of trout and salmon is characteristic of active, swift-moving fishes. A trim, fusiform body, powerful caudal (tail) muscles, and a well-developed tail combine to propel the fish against strong currents with a minimum of resistance and to give it the ability to leap barrier falls as high as three metres (ten feet) or more.

Predatory fishes that dart out to grasp their prey are exemplified by the pike, in which the dorsal fin is situated posteriorly on the body to act more as a rudder than a keel. The pikelike body form has been evolved independently many times among predatory fishes such as the barracuda (*Sphyræna sphyraena*, of the order Perciformes). Among the deep-sea salmoniforms, however, certain predatory species are sedentary and have only

weak swimming ability. Such fish remain immobile until unsuspecting prey ventures close enough to be grasped. Some evidently use a luminous lure to attract their prey.

A peculiar type of locomotion is encountered among the barracudinas (family Paralepididae), marine salmoniforms of the suborder Myctophoidi. The barracudina swims in a vertical plane, darting up and down with the head oriented downward.

The behaviour of a fish toward other members of its species can be highly variable. Often, predator species are territorial and aggressive, whereas plankton-feeding species typically form schools and do not function normally unless they are close to other members of their species. Although behaviour patterns are largely innate and species-specific, striking differences occur between closely related species. Pink salmon fry, on hatching, seek each other and form schools prior to seaward migration. The young of the coho, or silver salmon (*Oncorhynchus kisutch*), however, establish territories and aggressively attack other young cohos that invade their territory. This difference in aggressive behaviour is associated with the longer period of freshwater life and limited food supply experienced by the coho salmon.

One fascinating aspect of the behaviour of trout and salmon is their homing instinct—i.e., the ability to return to the stream of their birth after migrating thousands of kilometres in the ocean for one to three years. Homing to the site of birth for reproduction is apparently a rather universal trait among the Salmonidae. Trout, char, and whitefishes in lakes segregate into discrete populations during the spawning season, each at a specific site.

It is now generally accepted that the sense of smell plays the major role in guiding an anadromous trout or salmon to its precise natal stream once it enters a river drainage from the ocean. How it finds the mouth of the river system leading to the natal stream from the open ocean is not yet understood; celestial navigation and detection of fields of gravity by some unknown means have been hypothesized. Several senses besides smell may be used to locate the natal stream. Cutthroat trout (*Salmo clarki*) in Yellowstone Lake, Wyoming, have been found to be able to return to their spawning stream after experimental blocking of the senses of smell and sight.

Homing behaviour has allowed the development of discrete populations among anadromous species of salmon and trout. Different life-history characteristics can be maintained because different populations segregate for

Homing
by trout
and
salmon

Adapta-
tions of
predators

spawning, and individuals of a population spawn only with each other, perpetuating hereditary traits. In major river systems such as the Columbia and Fraser in North America, one species may include several distinct races, each having different life cycles; such a situation greatly complicates the management of a species.

Ecology. As with other aspects of the biology of salmoniform fishes, the ecology of species of the family Salmonidae is best known. All species of salmonid fishes evolved in clear, cold water, and they thus require pure, well-oxygenated, cold water; for this reason salmonid fishes are the first species to suffer when water quality is degraded. Other freshwater salmoniforms, although not quite so sensitive to water quality as the salmonid fishes, are also susceptible to the inimical effects of man-induced environmental degradation.

Most salmoniform fishes are predators, feeding on other fish and large invertebrates. The process of evolution, however, works to modify and adapt species for certain ecological specializations in order to exploit a variety of food resources. In the lakes of the Northern Hemisphere, several whitefish species (*Coregonus*) are comparable, ecologically, to the herrings in the ocean. Such whitefishes, which are often called freshwater herrings, cruise the open water of lakes, filtering out minute organisms by straining the water through a fine mesh of gill rakers—minute bony elements attached to the gill arches. The sheefish, or inconnu (*Stenodus leucickthys*), a large, predatory whitefish of the Arctic, demonstrates that evolution for ecological adaptation is occasionally reversible: the adults feed on other fish and have evolved a pikelike body shape and large, powerful jaws, the development of teeth taking precedence over that of the gill rakers; the sheefish is quite unlike the typical whitefish from which it has evolved.

There probably has been strong selection for freshwater salmoniforms to utilize the marine environment for feeding. All groups except the esocoid fishes (pike family and related groups) have species that migrate to the ocean for feeding. This presents a problem of osmotic regulation in waters of different salinities. The physiology of most fishes is fixed for life in fresh water or in the sea, but most of the freshwater salmoniforms are able to live in the sea because they can excrete excess salts through cells in the gills. They also possess well-developed kidneys, which, in the freshwater environment, handle the excess of water that diffuses into their blood via the gills.

Little is known of the ecology of the wholly marine salmoniforms. They may be ecologically grouped by the depths that they inhabit and by their feeding preference. Those found in the twilight zone of the ocean (200–1,000 metres [650–3,300 feet]) consist of plankton feeders and predators. The plankton feeders typically are more active and have a more fully developed and functional swim bladder than is typical of the predatory forms.

Because virtually all primary food production in the oceans takes place in the upper, sunlit layer, the deep-sea fishes live in a food-poor environment. At first, it may seem contradictory that they are able to maintain such numerical abundance; certain features of the biology of the deep-sea salmoniforms, however, allow them to attain great numbers. The body of the typical oceanic salmoniform is feebly developed, appearing to consist of little more than gelatinous material. The skeleton and muscles are reduced, so that little energy is needed to maintain the body. Many of the deep-sea species make nightly migrations to the food-rich surface zone for feeding. The species inhabiting the deepest parts of the ocean must depend on a food supply that filters down from above. This food is concentrated in a narrow bottom layer (the benthic zone), with the result that the benthic species may attain a relatively high abundance.

FORM AND FUNCTION

Features of the generalized salmoniform. External characteristics. The tremendous range of structural diversity found in salmoniform fishes has already been mentioned. Comparisons of some of the extreme morphological and physiological modifications with a generalized,

standard type can be useful in understanding the evolutionary trends leading to certain specializations. A trout of the genus *Salmo*, such as a rainbow trout or brown trout, can serve as a "standard" for the form and function of salmoniform fishes. The nonspecialized morphology and physiology of a typical trout species allow it to utilize diverse ecological niches during its life. A trout's diet consists of a variety of organisms, and its habitat may vary from small streams, large rivers, or lakes to the ocean. The body and fins are streamlined and symmetrical; the body is covered with small, smooth (cycloid) scales; the fins are formed from soft supporting rays, without spines. A small, fleshy adipose fin is located between the dorsal fin and the tail. The dorsal fin is located midway along the body on the dorsal surface. On the ventral surface, the paired pectoral fins are directly posterior to the head, the paired pelvic (or ventral) fins are directly beneath the dorsal fin, and the single anal fin is positioned beneath the adipose fin. The well-developed tail (caudal fin) connotes a powerful swimming ability. The presence, absence, rearrangement in position, and modifications in size, shape, and function of the various fins are characteristic of the numerous families of Salmoniformes.

Digestive system. The structures associated with feeding and digestion denote the diversity in a trout's diet. The mouth is fairly large with moderate development of nonspecialized teeth on the jaws and on several bones within the mouth. An adult trout can capture and consume a fish about one-quarter its own length without undue difficulty. Feeding on invertebrate organisms, as small as a few millimetres (perhaps 0.2 inch) in length, is facilitated by the gill rakers on the surface of the gill arches; they strain small organisms from a stream of water passing over the gills and funnel them to the esophagus. The well-defined muscular stomach opens by a valve into the intestine. A series of fingerlike appendages opens off of the intestine immediately posterior to the stomach. These appendages, called pyloric ceca, secrete enzymes and provide additional digestive areas to the intestine. Among closely related species of the family Salmonidae, there is a tendency for the more predacious species to have more numerous pyloric ceca. Generalizations relating pyloric cecal development to diet cannot be extended, however, to other fishes. The highly predacious pikes of the genus *Esox* completely lack pyloric ceca, whereas the algae-eating ayu (*Plecoglossus altivelis*, family *Plecoglossidae*) probably has more numerous ceca than any other fish, up to 400 or more.

Sense organs. Because vision is important in the life of a trout, the eyes are well developed; the retina possesses both rods (for vision in dim light) and cones (for perceiving more acute images and for colour vision). The sense of smell is also highly developed.

The lateral line nervous system functions as a pressure receptor and a direction finder for objects that move, such as another fish. The lateral line might be considered as a remote sense of touch; it does not, however, function in hearing low-frequency sound waves as was once believed. It has been demonstrated that sound waves are well below the threshold necessary to stimulate the lateral line cells. In trout, the lateral line consists of a series of connected sensory cells (neuromasts) with tiny, hairlike projections. These cells are embedded under the scales along the midline of the body and open to the surface through pores in the scales. An extension of the lateral line system on the head consists of a ramification of sensory canals. In some deep-sea salmoniforms living in the absence of the effects of sunlight, other senses are needed to compensate for vision in perceiving the environment, and the neuromast sensory cells may be exposed on raised papillae, thus increasing their sensitivity.

The swim bladder (or air bladder) has a hydrostatic function, adjusting internal pressure to maintain a weightless condition of neutral buoyancy at various depths. The trouts have a primitive type of swim bladder with a connecting duct from the bladder to the esophagus. The duct is an evolutionary holdover from an ancestor in which the swim bladder was mainly an accessory

Abundance of deep-sea species

The lateral line system

respiratory organ. Many salmoniform fishes lack the duct, and several deep-sea marine species lack a swim bladder altogether.

Departures from the generalized body plan. From the primitive body plan exemplified by the trouts, it is possible to derive all of the specialized body types of other salmoniform fishes by the elimination of some structures and by the modification, exaggeration, and rearrangement of others.

The pike is an example of a specialized predator whose diet, after the first year of life, consists almost entirely of other fishes. Its success depends on how effectively it captures and consumes other fishes, and its whole morphology and physiology are directed toward this end. A pike has an elongated body with a large head and large, powerful jaws. Its mouth is armed with large, canine-like teeth that can handle large prey. Patches of teeth on the gill arches replace the typical gill rakers. Vision is the primary sense used by pike to detect and capture prey. The visual centre of the brain (optic lobe) is more highly developed than are the centres of smell (olfactory lobes). The eyes have a high proportion of cones to rods in their retinas and are positioned to provide partial binocular vision (*i.e.*, the eyes are aimed in the same direction), sighting down grooves on the snout to aim at moving prey. The body form and position of the fins are specialized for swift, darting movements. The dorsal fin is placed posteriorly, over the anal fin, and, as is typical of other salmoniform fishes with posteriorly oriented dorsal fins, the adipose fin is absent.

The most extraordinary modifications in the basic salmoniform body plan are found among the marine species of the middepths and great depths of the ocean. The more striking adaptations include luminous organs, eyes specialized to function in dim light, feeding adaptations allowing some predatory species to kill and eat a fish as large as themselves, and drastic departures in body shape and fin development.

Bioluminescence, the production of chemical light by living organisms, is widespread in nature. Among vertebrate animals, only marine fishes have light organs. Light organs (or photophores) are encountered in many diverse groups of fish. These structures apparently have been evolved independently several times in different groups of fish. It is believed that light organs of fish have evolved from mucous cells of the skin. Salmoniform fishes, particularly species in the suborders Stomiatoidei and Myctophoidei, have developed some elaborate and highly complex light-producing systems. Some structures have lenses, reflectors, and eyelid-like shades. In addition to light cells on the sides of the body, luminous tissue may be found on the head, around the eyes, on fin rays and barbels, and on the ventral surface; in the myctophoid family Paralepididae, an internal duct makes the whole fish glow. The great diversity in the type and position of light organs suggests that they must serve different functions in the groups possessing them. In the family Searsiidae (suborder Alepocephaloidei), a large sac on the shoulder emits a display resembling a shower of sparks when the fish is disturbed. Such a structure probably is a defensive mechanism. Light organs on the head may help in locating food, and those on elongated dorsal fin rays or chin barbels may lure prey. Sexual recognition and territorial behaviour are other suggested functions. Although not all marine salmoniform fishes have light organs, the latter are typically found in species that spend most of their life in the lower twilight and upper dark zones of the ocean. The effects of sunlight essentially disappear at about 700 metres (2,300 feet); the maximum abundance of luminous fishes occurs at about 800 metres (2,600 feet).

There are some parallels in the development of eyes and light organs in fishes correlated with the depth at which the species lives. Perhaps the most sensitive of all vertebrate eyes is found in fishes inhabiting the dim twilight zone of the ocean; the eyes, specialized to function at very low light intensity, may be greatly enlarged. The retina typically consists entirely of rods with golden pigment to increase sensitivity to blue light of the light spec-

trum (the last part of the visual light spectrum to be filtered out in water). Another adaptation found in some marine salmoniforms for concentrating weak light is tubular eyes. Fish with tubular eyes appear to be wearing exaggerated goggles. Tubular eyes are aimed in the same direction (binocular vision) and may be directed straight ahead or directly upward. Two sets of retinas are associated with tubular eyes, one on the side of the shaft and one in the normal position at the base. The two sets of retinas function to enlarge the field of vision. A most unusual modification of the eyes is found in the myctophoid genus *Ipnots* (family Ipnotidae), which appears to be eyeless; however, a thin, transparent bony plate on top of the head covers a mass of retinal cells. Evidently such an eye functions to perceive faint luminescence at great depths. Larval stages of a few salmoniforms have eyes extended out from the body on stalks, which are resorbed when the eyes assume a normal position during metamorphosis.

Some grotesque fishes are found among the predatory stomiatoidei and myctophoids. The teeth may be developed into tremendously enlarged fangs, which may be likened to daggers, spears, or sabres. The gape of the jaws is sufficiently large to engulf a prey as large as the predator. Stomiatoidei predators have a peculiar modification of the anterior vertebral column, which remains unossified, resulting in a flexible jointlike mechanism allowing the head to snap back and enlarge the gape. To allow the swallowing of large prey, the body is soft, distensible, and usually lacks scales; the stomach is highly elastic.

EVOLUTION AND CLASSIFICATION

Evolutionarily important taxonomic characters. Studies of the skeletal system (osteology) and comparative anatomy have produced most of the information used in the classification of salmoniform fishes. At present, however, the taxonomy of Salmoniformes is not well defined because no character or group of characters is exclusive to salmoniform fishes, and little consistent difference in characters occurs among the suborders.

The fishes grouped in Salmoniformes possess a mosaic of primitive characters from which it is possible to derive most of the more advanced orders of teleostean fishes. Both evaluation of the hypothetical evolutionary branching sequences to denote relationships and judgment concerning the primitive or derived (advanced) state of a character are based on an evolutionary principle that a structure lost or highly modified during evolution will never be re-evolved in its original condition; for example, the adipose fin, the mesocoracoid bone of the pectoral skeleton, and teeth on the maxillary bone of the jaw are considered to be primitive salmoniform characters. The absence of these characters represents an advancement; evolutionary lines that have lost these features therefore could not have been ancestral to fishes that possess one or more of these characters. No family of Salmoniformes has all of the primitive characters, but the families Salmonidae and Osmeridae have most of them.

The primitive dentition pattern of the ancestral salmoniform would be with teeth on the premaxilla and maxilla (bones of the upper jaw) and on the dentary bone of the lower jaw, with the maxilla clearly dominant over the premaxilla in forming the gape of the upper jaw. Inside the mouth, on the upper surface, teeth would be on palatine and pterygoid bones on each side and on the median vomerine bone. On the lower surface of the mouth, teeth would cover the tongue and occur on a plate overlying the basibranchial bones (between the gill arches). Many separate lines of salmoniforms show evolutionary advancement for the loss of teeth and the dominance of the premaxilla over the maxilla, with loss of teeth on the maxilla.

The primitive structure of the pectoral girdle, associated with the ventral position of the pectoral fin, consists of an additional supporting bone—the mesocoracoid. The advanced condition, related to a more dorsally positioned pectoral fin, is the loss of the mesocoracoid.

The primitive salmoniform condition of the caudal skeleton has three separate vertebral centra (the centrum

Luminescent organs

Eye adaptations in deep-sea forms

Skeletal features

is the main body of the vertebra) and associated bony elements functioning in support of the bony plates (hypural plates), which form the base of the tail. Such a structure is a vestige of the upturned tail (heterocercal tail) characteristic of a more primitive stage of fish evolution. Other such vestiges found in some salmoniform fishes include abdominal pores (minute ducts from the body cavity to the exterior), remnants of a preteostean type of intestine (spiral valve), and the absence of oviducts in females. Evolution in several salmoniform lines has reduced by fusion the three supporting caudal vertebrae to two or, more commonly, one. The primitive type of salmoniform swim bladder is connected to the esophagus by a duct. The absence of the duct or absence of the swim bladder is the advanced state. The primitive salmoniform had pyloric ceca on the intestine—a variable trait among living species. The light organs of some marine salmoniforms are an advanced character and are considered to be derived from mucous cells.

Annotated classification. The classification presented here is based on that of P.H. Greenwood *et al.*, with some modifications incorporated from more recent publications. These alterations consist of transferring the family Salangidae from the suborder Galaxioidei to the suborder Salmonoidei, placing the family Bathylaconidae in the suborder Alepocephaloidei (eliminating the suborder Bathylaconoidei), and the recognition of two additional families: Prototroctidae (in the suborder Galaxioidei) and Searsiidae (in the suborder Alepocephaloidei).

ORDER SALMONIFORMES

A diverse group of fishes with a mosaic of primitive characters. Typically fusiform or elongated predatory fishes. Adipose fin usually present; dorsal fin and pelvic fins typically placed midway along body; fin rays without true spines; pectoral fin generally in ventral position. Scales, if present, typically smooth (cycloid). Light organs present in several marine families. Caudal skeleton with 1 to 3 vertebral centra functioning in support of tail. Fossils from Cretaceous.

Suborder Salmonoidei

About 100 species; 10–150 cm long; freshwater, anadromous, or marine; Northern Hemisphere. Adipose present in all species; swim bladder with open duct; maxilla dominant over premaxilla in upper jaw; no light organs; intestine with pyloric ceca (except Salangidae); tail support on 3 distinct vertebral centra in Salmonidae, fused into single element in other families. Suborder includes the families Salmonidae (including Coregonidae and Thymallidae), salmons, trouts, charrs; Osmeridae, smelts; Plecoglossidae, ayu; and Salangidae, icefishes.

Suborder Galaxioidei

About 50 species; 7.5–40 cm long; freshwater, anadromous, or catadromous; Southern Hemisphere. Adipose fin absent in Galaxiidae, present in other families; swim bladder with or without duct; relationship of maxilla and premaxilla variable among genera. Light organs absent. Pyloric ceca present or absent. Tail support on 1 or 2 vertebral centra; mesocoracoid bone of pectoral girdle absent; teeth present on mesopterygoid bone in roof of mouth. Suborder contains the families Galaxiidae, no group name; Retropinnidae, New Zealand smelts; Aplochitonidae, South American trouts; and Prototroctidae, New Zealand "grayling."

Suborder Esocoidae

Ten species; 5–150 cm long; freshwater; Northern Hemisphere. Adipose fin lacking; swim bladder with open duct; maxilla without teeth; pyloric ceca lacking; pectoral girdle without mesocoracoid bone; tail support on 3 separate vertebral centra; 2 sets of paired ethmoid bones on snout region of skull. Suborder includes the families Esocidae, pikes; and Umbridae (including Dallidae), mudminnows.

Suborder Argentinoidei

About 50 species; 3–40 cm long; marine; worldwide. Adipose fin present on most species; swim bladder without duct or absent entirely; maxilla and premaxilla reduced, without teeth; light organs present in several species; tail support on 2 vertebral centra. Suborder includes the families Argentinidae (including Xenophthalmichthidae and Microstomatidae), argentines; Bathylagidae, deep-sea smelts; and Opisthoproctidae (including Dolichopterygidae, Macropinnidae, Winteridae), barreleyes.

Suborder Stomiatoidei

About 350 species; 2.5–45 cm long; marine; worldwide. Adipose fin present or absent, some species with both a dorsal and a ventral adipose fin; swim bladder without duct

or absent entirely; maxilla the dominant bone of the upper jaw; some species with greatly enlarged, depressable teeth; anterior vertebrae sometimes unossified; light organs present in most families; members of some families with chin barbel, which may be a highly elaborate structure; tail support on single vertebral centrum. Suborder includes families Stomiidae, scaly dragonfishes; Gonostomatidae, bristlemouths; Sternopychidae, hatchetfishes; Astronesthidae, snaggletoothed fishes; Melanostomiidae, scaleless dragonfishes; Chauliodontidae, viperfishes; and Idiacanthidae, black dragonfishes.

Suborder Alepocephaloidei

About 120 species; 3–70 cm long; marine, deep-sea; worldwide. Adipose fin lacking; swim bladder lacking; teeth small; intestine with pyloric ceca. Light organs present in some species (on raised papillae). Tail supported by 3 vertebral centra. Suborder contains the families Alepocephalidae, batfishes; Bathypriidae, deep-sea tube-shoulders; and Bathypriidae.

Suborder Myctophoidei

About 470 species; 2.5–200 cm long; marine; worldwide. Adipose fin usually present; swim bladder, if present, with duct. Premaxilla dominant over maxilla in upper jaw; no mesocoracoid bone in pectoral girdle. Light organs present in all species of family Myctophidae, but absent in species of most other families; tail support on single vertebral centrum. Suborder includes the following 15 families: Myctophidae, lantern fishes; Aulopodidae, thread-sail fishes; Synodontidae, lizard fishes; Harpodontidae, bombay duck; Chlorophthalmidae, green-eyes; Bathypteroidae, spider fishes; Ipnopidae, grid-eye fishes; Paralepididae, barracudinas; Omosudidae, hammerjaw; Alepisauridae, lancet fishes; Anotopteridae, javelin fish; Evermannellidae, sabre-toothed fishes; Scopelosauridae, paperbones; Neoscopelidae, blackchin; Scopelarchidae, pearleaves.

Critical appraisal. Previous schemes of fish classification have been based mainly on the work of the British ichthyologist C.T. Regan and the Soviet ichthyologist L.S. Berg. Both Regan and Berg grouped most of the generally primitive fishes with soft fin rays and smooth scales in an order with the herring family, Clupeidae. Regan called this order Isospondyli, and Berg used the name Clupeiformes. Such a classification considered Isospondyli or Clupeiformes as the most primitive of the teleostean fishes and as ancestral to all other advanced orders of Teleostei. The work of Greenwood and his colleagues clearly demonstrated that the classifications of Regan and Berg were without evolutionary reality, that the fishes classified as Clupeiformes or Isospondyli, as formerly arranged, were not all derived from a common ancestor but consisted of several unrelated groups. The true herrings (family Clupeidae and their direct derivatives) possess some unique characters, such as the structures involved with the connection of the swim bladder to the inner ear, not found in any other teleostean fishes; the herrings thus are not very likely to have been the progenitors of all other modern teleosts. The order Salmoniformes was created to remove several diverse groups of dubious relationships from the order Clupeiformes; these groups are thus considered as the basal stocks in the evolutionary radiation of teleostean fishes. The order Iniomi of Regan (Scopeliformes of Berg) was placed as a suborder, Myctophoidei, in Salmoniformes. It should be emphasized, however, that this taxonomic revision has added little new knowledge concerning the relationships among the various suborders grouped in Salmoniformes. At present no coherent picture of evolutionary affinities among the suborders and with other orders has emerged. Undoubtedly the present interpretation of Salmoniformes will undergo major revisions in the future both in structure and in its implications regarding the evolutionary links leading to other teleostean orders. Publications by D.E. Rosen and by the British ichthyologist Colin Patterson consider new evidence and a more critical interpretation of previous data; they have separated the suborder Myctophoidei from the Salmoniformes into the order Myctophiformes and have suggested that the suborder Giganturoidei of the order Cetomimiformes should be placed in Salmoniformes. The myctophoid fishes are well separated from other salmoniforms, having undergone their own evolution at least since Cretaceous times (about 100,000,000 years ago)—fossils of four families are known from Cretaceous depos-

Alternate views on the nearest relatives of the salmoniforms

its—and recognition of the order Myctophiformes seems justified.

Hopefully, new evidence will be forthcoming from future studies providing new insights into the evolutionary events that transpired from 50,000,000 to 100,000,000 years ago and resulted in the evolution of the various families and suborders of Salmoniformes. From such evidence, a better understanding of the ancient divergences leading to the bulk of the present teleostean fishes should follow. Ichthyologists may have exploited anatomical characters to the limit of potential information yield, but it is to be expected that new fossil finds of extinct, intermediate groups will yield valuable information.

New techniques for examining chromosomes and comparing their number, size, shape, and content and for comparing the structure of certain evolutionally stable protein molecules are promising approaches for the interpretation of evolution.

Salt and Salt Production

Salt, sodium chloride (symbol, NaCl), is a mineral substance of great importance to man. The mineral form, halite or rock salt, is sometimes called common salt to distinguish it from a class of chemical compounds called salts.

Salt is essential to the health of men and animals. Table salt, used universally as a seasoning, is fine-grained and of high purity. To ensure that this hygroscopic substance will remain free-flowing when exposed to the atmosphere, small quantities of sodium aluminosilicate, tricalcium phosphate, or magnesium silicate are added. Iodized salt—that is, salt to which small quantities of potassium iodide have been added—is widely used in areas where iodine is lacking from diet, a situation which can cause swelling of the thyroid gland, commonly called goitre. Livestock also require salt; it is often made available in solid blocks.

Table 1: Properties of Salt

Chemical formula	NaCl (sodium chloride)
Physical form at room temperature	colourless, transparent, or translucent cubic crystals
Hygroscopicity	salt is hygroscopic; <i>i.e.</i> , it absorbs atmospheric moisture and in pure form will lump together unless countermeasures are taken
Density	2.165 times as heavy as water at 0° C (32° F)
Melting point	800° C (1,472° F)
Solubility	100 parts by weight of water dissolve 36.0 parts of salt at 20° C (68° F); 39.1 parts at 100° C (212° F); and 39.7 parts at 107° C (222° F), the boiling point of a saturated solution; salt is also soluble in glycerin, slightly soluble in alcohol or liquid ammonia, and insoluble in concentrated hydrochloric acid
Sodium chloride hydrate	if a saturated solution of salt in water is cooled below 0.10° C (32.18° F), a crystalline hydrate (NaCl·2H ₂ O) separates
Electrolysis of salt	under the influence of an electric current, molten salt decomposes to form metallic sodium and chlorine; its aqueous solutions form caustic soda and chlorine

The meat-packing, sausage-making, fish-curing, and food-processing industries use salt as a preservative or seasoning or both (see also FOOD PRESERVATION). It is employed for curing and preserving hides, and as a brine for refrigeration.

In the chemical industry, salt is required in the manufacture of sodium bicarbonate (baking soda), sodium hydroxide (caustic soda), hydrochloric acid, chlorine, and many other chemicals. Salt is also employed in soap, glaze, and porcelain enamel manufacture and enters into metallurgical processes as a flux (a substance promoting fusing of metals).

When applied to snow or ice, salt lowers the melting point of the mixture. Thus, large amounts are used in northern climates to help rid thoroughfares of accumulated snow and ice. Salt is used in water-softening equipment that removes calcium and magnesium compounds from water.

HISTORY

In some parts of the Western Hemisphere and in India, salt was introduced by Europeans. In parts of central Africa it is still a luxury available only to the rich. Where men live mainly on milk and raw or roasted meat (so that its natural salts are not lost), sodium chloride supplements are unnecessary; nomads with their flocks of sheep or herds of cattle, for example, never eat salt with their food. On the other hand, peoples with largely cereal, vegetable, or boiled meat diets require supplements of salt.

The habitual use of salt is intimately connected with the advance from nomadic to agricultural life, a step in civilization that influenced the rituals and cults of almost all ancient nations. The gods were worshipped as the givers of the kindly fruits of the earth, and salt was usually included in offerings consisting wholly or partly of cereal elements. Such offerings were prevalent among the Greeks and Romans and among a number of the Semitic peoples.

Covenants were ordinarily made over a sacrificial meal, in which salt was a necessary element. The preservative qualities of salt made it a peculiarly fitting symbol of an enduring compact, sealing it with an obligation to fidelity. The word salt thus acquired connotations of high esteem and honour in ancient and modern languages. Examples include the Arab avowal "There is salt between us," and the Hebrew expression "to eat the salt of the palace," and the modern Persian phrase *namak harām*, "untrue to salt" (*i.e.*, disloyal or ungrateful). In English the term "salt of the earth" describes a person held in high esteem.

Salt contributes greatly to our knowledge of the ancient highways of commerce. One of the oldest roads in Italy is the Via Salaria (Salt Route) over which Roman salt from Ostia was carried into other parts of Italy. Herodotus tells of a caravan route that united the salt oases of the Libyan Desert. The ancient trade between the Aegean and the Black Sea coasts of southern Russia was largely

dependent on the salt pans (ponds for evaporating seawater to obtain salt) at the mouth of the Dnepr (Dnieper) River, and on the salt fish brought from this district.

The economic importance of salt is further indicated by the prevalence, even down to the present, of taxes on salt and government salt monopolies. In Oriental systems of taxation high, oppressive imposts on salt are customary, with the result that salt usually reaches the consumer in an impure state largely mixed with earth.

Cakes of salt have been used as money in Ethiopia and elsewhere in Africa, and in Tibet. In the Roman army an allowance of salt was made to officers and men; in imperial times, this *salarium* (from which the English word "salary" is derived) was converted into an allowance of money for salt. (F.O.W.)

OCCURRENCE

Seawater. Though the material which gives seawater its salty flavour is comprised of many substances, sodium chloride, or common salt, is by far the predominant compound. On the assumption that each gallon (about four litres) of seawater contains 0.231 pound (about 105 grams) of salt and that on the average rock salt is 2.24 times as dense as water, it has been estimated that if the oceans of the world were completely dried up they would yield at least 4,500,000 cubic miles of rock salt, or about 14% times the bulk of the entire continent of Europe above high-water mark.

Seawater contains on the average about 3 percent salt, the actual concentration varying from about 1 percent (in the polar seas) to 5 percent. Enclosed seas such as the Mediterranean and Red seas contain a higher proportion of salt than does the open ocean at the same latitude. Irrespective of the source of the seawater, salt obtained by evaporation of seawater has the following composition: sodium chloride 77.76 percent; magnesium chloride 10.88 percent; magnesium sulfate 4.74 percent; calcium sulfate 3.60 percent; potassium chloride 2.46 percent; magnesium bromide 0.22 percent; and calcium carbonate 0.34 percent.

Natural brines. Brine is water containing a high concentration of salt. Natural brines of commercial importance are found in the Dead Sea, Austria, France, Germany, India, the United States, and Great Britain. Salt in brines is nearly always accompanied by chlorides and sulfates of potassium, calcium, and magnesium; carbonates and the element bromine are often present as well.

Table 2 gives the composition of some concentrated natural brines used for salt production.

The Dead Sea, which covers an area of 393 square miles (1,020 square kilometres), contains approximately 12,650,000,000 tons of salt. The Jordan River, which contains only 35 parts of salt per 100,000 parts of water, adds 850,000 tons of salt to this total each year. The composition of Dead Sea water is given in Table 3.

The concentration of salts in the Dead Sea varies from 270 to 300 parts per thousand to a depth of 130 feet (40 metres); it increases gradually from 130 to 330 feet, and remains a fairly constant 332 parts per thousand below 330 feet. Dead Sea water is relatively free from sulfates and has a high proportion of potassium and bromine. Because atmospheric conditions are favourable to evaporation by means of sunlight (solar evaporation) for about eight months of the year, the production of salt, potassium, and bromine is feasible in the Dead Sea area. The

process used for recovery of salt and potash is similar to that described below under *Salt Manufacture*. The Indian brines at Khārāghoda resemble seawater in the character of their dissolved salts, but are much more concentrated and in some cases virtually saturated; that is, they have dissolved all the salt they can.

Table 3: Composition of Dead Sea Water

item	surface water	deep water (250 ft)
Specific gravity	1.1651	1.2356
Sodium chloride	6.11%	7.20%
Potassium chloride	0.85%	1.25%

Magnesium chloride	9.46%	13.73%
Calcium chloride	2.63%	3.82%
Calcium sulfate	0.11%	0.05%
Total solids	19.54%	26.66%

Certain natural brines occurring in England and the United States are of special interest because they contain salts, such as the chlorides of barium and strontium, not usually found in brines. Special processing methods are required to produce salt from such brines. In Great Britain, these unusual brines are found at great depths during test drillings for petroleum, while in the United States, they occur in deep wells in several places.

Rock salt. Rock salt is crystalline sodium chloride, called halite by mineralogists. It occurs widely in the form of rock masses and beds and is abundant in rocks from all geological periods. Because of its great solubility in water, it occurs under extremely thick cover in humid regions, but lies close to the surface in arid regions.

All major rock-salt deposits originated from the evaporation of seawater at some time during the geologic past. Seventy-eight percent of the mineral matter in normal seawater is sodium chloride. Upon evaporation of about nine-tenths of the volume of seawater, rock salt is precipitated. Calcium sulfate (gypsum and anhydrite) and potassium and magnesium salts are also precipitated. Deposits are found in beds from a few feet to many hundreds of feet thick. The ages of these beds range through much of geologic time. Because evaporation of a large quantity of seawater leaves only a small amount of salt, it is theorized that many extremely thick rock-salt beds were deposited in partly enclosed arms of the seas in which evaporation was greater than the inflow of salt

water. A barrier on the sea floor at the entrance to the basin prevented the outflow of the concentrated saline water.

Such bedded salt deposits occur in the Punjab Salt Range in Pakistan and in Iran, but are little exploited. Similar deposits in the United States and in Canada are extensively worked for industrial and domestic use. Other important salt deposits, usually classified by the age of the surrounding rock, exist in Germany, Nova Scotia, the sub-Carpathian region extending from Poland through Hungary and Romania, the Soviet Union, the United States, and the province of Szechwan, China, where salt wells have been in existence for more than 2,000 years.

Salt domes

Another economically important type of rock-salt deposit is the salt domes (*q.v.*), which were formed when earth pressure forced up plugs of rock salt measuring approximately a mile across. The domes appear to result from pressure, which pushes the salt up through the rocks from depths as great as 50,000 feet (15,000 metres). Many domes occur at shallow depths, and are extensively mined. Domes in the sub-Carpathian region of Europe have been worked since ancient times. The North German Plain has many domes, extensively mined, which are thought to have originated below 6,000 feet (1,830 metres); domes are also abundant along the U.S. Gulf Coast. Rock salt may be obtained from domes by the usual mining methods or by drilling wells into the salt strata and pumping water down to dissolve the salt; the brine is then returned to the surface where it is processed like natural brine. (F.O.W./J.M.Hi./R.H.Ra.)

SALT MANUFACTURE

At one time almost all the salt used in commerce was produced from the evaporation of seawater, and sea salt still is a staple commodity in many maritime countries, especially where the climate is dry and the summer of long duration. Commercial salt is manufactured from rock salt, and from seawater and other natural and artificial brines. Most of the artificial brines are obtained by pumping water into underground salt beds. A considerable amount of brine itself is used directly in industrial countries.

Manufacture from rock salt. The beds of rock salt are mined or quarried by the usual excavation methods, depending upon the depths and thicknesses of the deposits and upon local conditions. The mined rock salt sometimes is dissolved and the salt manufactured by treatment of the brine, as described below. The method affords opportunities for purification of the salt. When the rock salt is of a high degree of purity, as in Poland and the United States, the salt may be ground, screened, and marketed without further processing. The salt is mined in large lumps which are first crushed, then more finely ground and screened by size into various grades; the salt is then bulk-loaded into trucks, hopper cars, or barges, or loaded into bags for further handling. Bulk handling has been greatly facilitated by the use of anticaking agents which allow the salt to be stored uncovered and outdoors without becoming a hard mass again.

Manufacture from seawater and brines. Only a certain quantity of salt will dissolve in water at any given temperature. Once the solution contains as much salt as it can hold, it is said to be saturated; any further additions of salt will not dissolve.

Evaporation is the reverse of this process. When an aqueous solution of several salts (seawater, for example) is evaporated, each of the salts precipitates as it reaches its point of saturation in the solution. Thus the different salts in seawater will precipitate at different times, forming layers on the bottom of the evaporating pond. For seawater and many brines, the order of deposition is calcium carbonate, calcium sulfate, sodium chloride, magnesium sulfate, potassium magnesium chloride, and magnesium chloride.

Solar evaporation. In maritime countries where there is a negative evaporation rate—*i.e.*, the amount of water evaporating exceeds the amount of rainfall by at least 30 inches (about 75 centimetres)—salt is produced by solar evaporation from seawater. The processes used are

similar in general principle from country to country, but details of equipment vary from sophisticated in the United States, the Bahamas, France, and Africa to quite primitive in India and most of the developing nations. There is no solar salt production in Canada, Great Britain, Germany, and Iceland.

A preliminary concentration is usually accomplished by allowing the seawater to flow through a series of gates constructed of wood or a combination of wood and concrete into a series of shallow ponds separated by dikes. In these ponds, the solution is concentrated to a specific gravity of about 1.22; this means that a given volume of brine is 1.22 times as dense as a given volume of pure water. At this stage, suspended impurities such as sand, clay, and the less soluble salts such as calcium carbonate, or chalk, and calcium sulfate are removed. Solar evaporation of the Dead Sea water is hastened by adding dye to the water. The dye permits more heat to be absorbed from sunlight in thinner layers of brine so that shallow ponds may be used and the penetration of brine into the ground is reduced.

Once it has been concentrated, the brine is run through a series of crystallizing pans, usually four in number, where the salt is deposited. In the first crystallizing pan, the brine is concentrated to a specific gravity of 1.23 and remains partly contaminated with calcium sulfate. The specific gravity of the solution in the pan increases slowly during crystallization of the salt, reaching 1.24 in the second pan. In the third pan, the specific gravity of the solution reaches 1.25; the salt deposited there contains small amounts of magnesium sulfate as an impurity. The final solution, termed bitterns, has a specific gravity of 1.25–1.26 and is used in some countries (United States and Israel) in the manufacture of potash, bromine, epsom salts (magnesium sulfate), and magnesium chloride.

In developing countries, the salt in each crystallizing pan is raked into rows and allowed to drain for several days, after which it is collected into heaps, drained again, lifted from the pans, and finally dried. In the industrial countries, the salt is harvested mechanically, washed with saturated brine, dewatered, washed with fresh water, then stored for further processing or direct sale.

Use of artificial heat. In areas where bedded deposits can be solution mined, evaporated salt is recovered from these solutions with artificial heat. Some evaporated salt is also made from natural brine or solar salt. Formerly, brine was concentrated in open pans over fire. More recently, steam-jacketed vessels have been used. The largest amount of salt produced in the colder climates is rock salt. The largest amount of evaporated salt is produced by multiple-effect vacuum evaporators, and an important quantity is made in so-called open crystallizers or grainers that produce a type of crystal preferred for use in some of the food industries. The brine, natural or artificial, is first pumped into settling tanks, where calcium and magnesium compounds may be removed by chemical treatment. In grainer operations the settled and filtered brine is delivered to the grainer, a long open trough heated with steam coils. The brine is fed into the grainer at approximately the same rate that evaporation is taking place and at a temperature only slightly below that of the brine in the grainer. The residue of brine, or bitterns, may be removed continuously, once a day, or less often. Evaporation occurs at the surface of the liquid and the crystals originate there. They remain at the surface, held up by the surface tension of the brine. The crystal grows at the top edges, becoming a small inverted hollow pyramid, or hopper. Eventually the hopper sinks and ceases to grow. When the crystals are recovered, the salt is largely in the form of flakes, hence the name flake salt.

When multiple-effect evaporators are used, the vacuum in each vessel is adjusted so that the vapour from the first vessel is hot enough to boil the brine in the second; the vapour from the second supplying the heat to operate the third vessel or effect. The brine is usually sent through the stages or effects in succession, although in the case of salt manufacture, fresh brine may be fed to each stage if desired. With open pans, 10,000 to 12,000 pounds (4,500

Flake salt

The
Alberger
process

to 5,400 kilograms) of steam are required to produce one ton (900 kilograms) of salt. With triple-effect evaporation, 1,400 pounds (630 kilograms) of steam produce one ton of salt.

The Alberger process is partially a vacuum-pan and partially a grainer operation in which cubic crystals are formed in the solution fed to the grainer pans by a partial vacuum-pan evaporation. These seed crystals in the grainer produce a salt that is a mixture of the grainer-type flake and the flake grown on seed crystals. About 3,000 pounds (1,350 kilograms) of steam are required to produce one ton of salt. Salt from the Alberger process is centrifuged (spun) from the brine and then dried. Table salt may have small amounts of aluminum calcium silicate, calcium silicate, magnesium silicate, tricalcium silicate, magnesium carbonate, or tricalcium phosphate added to keep it free-flowing. Iodized salt has potassium iodide added. In some countries yellow prussiate of soda, to prevent caking, is added in minute amounts as regulated by the government. (F.O.W./R.H.Ra.)

PRODUCTION STATISTICS

Salt production is one of the world's most widely distributed mineral industries. Outputs vary with the population and industrial activity of each country. The major part of the production of heavily populated countries such as India and China is for food uses. The United States, on the other hand, uses several times as much salt for industry as it does for food. The leading producing countries are China, France, India, Italy, the Soviet Union, the United Kingdom, the United States, and West Germany.

World production of salt increased 67 percent in the ten years up to 1970, when it reached 156,365,000 tons. Of that total, the United States produced 44,804,000 tons, or about 29 percent. Solar evaporation of seawater accounted for 45 percent of world production. (F.O.W.)

BIBLIOGRAPHY. A general reference on this subject is G.L. ESKEW, *Salt, the Fifth Element: The Story of a Basic American Industry* (1948). A more technical reference is D.W. KAUFMANN (ed.), *Sodium Chloride: The Production and Properties of Salt and Brine* (1968). Highly technical references on salt geology, geochemistry, mining, rock mechanics, solution mining, and underground storage are given in the proceedings of the *Symposium on Salt*, ed. by A.C. BERSTICKER (1963). Later volumes in the "Salt Symposium Series" with the same scope as the first are JON L. RAU (ed.), *Second Symposium on Salt*, 2 vol. (1966); and JON L. RAU and LOUIS F. ELLWIG (eds.), *Third Symposium on Salt*, 2 vol. (1970). A factual survey of salt deposits of the world by countries is given in STANLEY LAFOND, *Handbook of World Salt Resources* (1969). The authoritative work in English on the deposition and geologic history of salt deposits is H. BORCHERT and R.O. MUIR, *Salt Deposits* (1964). The best source for statistics on salt production and markets is the U.S. BUREAU OF MINES, "Salt," in the *Minerals Yearbook* (1970).

(R.H.Ra./J.M.Hi./F.O.W.)

Salt Domes

A salt dome is a largely subsurface geologic structure that consists of a vertical cylinder of salt (including halite and other evaporites) a kilometre or more in diameter, embedded in horizontal or inclined strata. In the broadest sense, the term includes both the core of salt and the strata that surround and are "domed" by the core. Similar geologic structures in which salt is the main component are salt pillows and salt walls, which are related genetically to salt domes, and salt anticlines, which are essentially folded rocks pierced by upward migrating salt. Other material, such as gypsum and shale, form the cores of similar geologic structures, and all such structures, including salt domes, are known as diapiric structures, or diapirs, from the Greek word *diaperein*, "to pierce." The embedded material in all instances appears to have pierced surrounding rocks. Upward flow is believed to have been caused by the following: gravity forces, in situations where relatively light rocks are overlain by relatively heavy rocks and the light rocks rise like cream to the surface; tectonic (earth-deformation) forces, in situations where mobile material (not necessarily lighter) is literally

squeezed by lateral stress through less mobile material; or a combination of both gravity and tectonic forces.

Salt domes are one of a number of kinds of salt structures whose interrelationships are shown diagrammatically in Figure 1. "Classic" salt domes develop directly from

Figure 1: Interrelationships of salt structures (see text).

bedded salt by gravitational stress alone. Salt domes also may develop from salt walls and salt anticlines, however. In the latter case, the development of the domes results from superposition of gravitational stress on salt masses that initially developed due to tectonic stress. Salt domes can exist in any sedimentary basin that contains thick salt buried beneath a thick sequence of sedimentary rocks or subject to tectonic stress or both. In some areas, salt domes are valuable as sources of oil, natural gas, sulfur, salt, and potash.

This article treats the characteristics, mode of origin, and world distribution of salt domes. For further information on the origin of the salts involved, see **EVAPORITES**; and for the economic and geological significance of these structures, see **PETROLEUM**; **NATURAL GAS**; **SALT AND SALT PRODUCTION**; **SULFUR PRODUCTS AND PRODUCTION**; and **ROCK DEFORMATION**. The latter article presents a discussion of the various types of folds and faults that are relevant to salt domes as well as more detail on the tectonic and gravitational stresses involved in salt dome formation.

PHYSICAL CHARACTERISTICS OF SALT DOMES

A salt dome consists of a core of salt and an envelope of surrounding strata. In some areas, the core may contain "cap rock" and "sheath" in addition to salt.

The size of typical salt domes (including cap rock and sheath) varies considerably. In most cases, the diameter is a kilometre or more and may range up to more than ten kilometres. The typical salt dome is at least two kilometres high (in the subsurface), and some are known to be higher than ten kilometres. Many individual salt domes actually are salt spires that are connected to much larger massifs of salt at depth. Four domes in the Caillou Island–Bay Marchand area of coastal Louisiana rise from a salt massif that measures 43 by 20 kilometres at a depth of 6 kilometres. This massif contains over 1,000 cubic kilometres of salt above 6 kilometres and, depending upon the depth to the base and shape of the bottom of the massif, possibly over 5,000 cubic kilometres of salt in total. Many of the salt walls of the North German–North Sea area are 3 to 5 kilometres wide, 2 kilometres high, and over 50 kilometres long.

The salt core. The cores of salt domes of the North American Gulf Coast consist virtually of pure halite (sodium chloride) with minor amounts of anhydrite (calcium sulfate) and traces of other minerals. Layers of white pure halite are interbedded with layers of black halite and anhydrite. German salt dome cores contain halite, sylvite, and other potash minerals. In Iranian salt domes, halite is mixed with anhydrite and marl (argillaceous limestone) and large blocks of limestone and igneous rock.

The interbedded salt–anhydrite and salt–potash layers are complexly folded; folds are vertical and more com-

The size
of domes

Mineral
content

plex at the outer edge of the salt. In German domes, when relative age of the internal layers can be deciphered, older material is generally in the centre of the salt mass and younger at the edges. Study of halite grains in some Gulf Coast salt domes indicates a complex pattern of orientation that varies both vertically and horizontally in the domes. Mineral grains in the centre of a Caspian salt dome are vertical; those at its edge are horizontal.

Cap rock. Cap rock is a cap of limestone–anhydrite, characteristically 100 metres thick but ranging from 0 to 300 metres. In many cases, particularly on Gulf Coast salt domes, the cap can be divided into three zones, more or less horizontally, namely, an upper calcite zone, a middle transitional zone characterized by the presence of gypsum and sulfur, and a lower anhydrite zone. These zones are irregular and generally are gradational with each other, although in some instances the contact between gypsum and anhydrite is quite abrupt. Cap rock is generally believed to develop from solution of salt from the top of the salt core; this leaves a residue of insoluble anhydrite that is later altered to gypsum, calcite, and sulfur. Presumably, solution takes place in the circulating (shallow) water zone; deeply buried domes with cap rock must have been shallow at some former time and subsequently buried.

Shale sheath. Shale sheath is a feature that is common to many Gulf Coast salt domes. In shape, it may completely encase the salt (like a sheath), or it may be limited

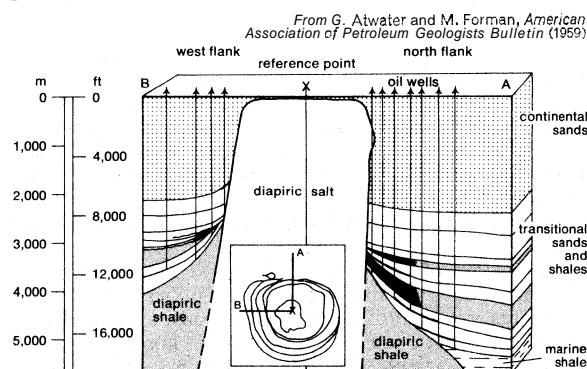

Figure 2: North and west flanks of Weeks Island salt dome in Iberia Parish, Louisiana, showing relationship of the shale sheath to the dome.

to the lower portions of the salt. It is most common on the deeper portions of salt domes whose tops are near the surface or on deeply buried salt domes. The fluid pressure within the shale is significantly greater than that within the surrounding rocks, and the stratification (bedding planes) of the shale is distorted. Fossils in the shale are older than in surrounding sediments, indicating that the shale came from an older, and therefore deeper, layer.

Surrounding sediments. The strata around salt cores can be affected in three ways: they can be uplifted, they can be lowered, or they can be left unaffected while surrounding strata subside relatively. Uplifted strata have the structural features of domes or anticlines; characteristically they are domed over or around (or both) the core (including cap and sheath if present) and dip down into the surrounding synclines. The domed strata are generally broken by faults that radiate out from the salt on circular domes but which may be more linear on elongate domes or anticlines with one fault or set of faults predominant. Lowered strata develop into synclines, and a circular depression called a rim syncline may encircle or nearly encircle the domal uplift. Unaffected strata develop into highs surrounded by low areas. These highs, called remnant highs or turtleback highs, do not have as much vertical relief as the salt domes among which they are interspersed. Present-day structure of strata around salt domes may not in every instance coincide with the present-day position of the salt. This offset relationship suggests that late uplift of the salt dome shifted its centre compared with early uplift.

Geophysical properties. Salt domes have some unique properties, compared to their surrounding rocks, and for

Figure 3: Plan view of the Weeks Island salt dome. Contours represent the elevations of an overlying sandstone formation.

From Atwater and Forman, *American Association of Petroleum Geologists Bulletin* (1959)

this reason they can be detected by geophysical methods. Salt has a specific gravity of 2.2, whereas sedimentary rocks, such as sandstone and compacted shale, have a density of 2.5. Because gravitational attraction is related directly to mass, the forces of gravity are weaker in the vicinity of a salt dome; thus they provide a negative gravity anomaly when compared with gravity values of the surrounding terrain. Shock waves are propagated through salt faster than through sandstone and shale; this serves as another means of detecting salt bodies. Because seismic waves are partially reflected at the interface between low-velocity and high-velocity material, a salt dome will reflect shock waves. High-velocity sandstone that becomes uplifted around a salt dome will also reflect shock waves and thus suggest the existence of the dome.

ORIGIN OF SALT DOMES

The number of theories proposed by geologists to explain the origin of salt domes has been even larger than the number of types of salt domes observed in nature. In general, salt structures associated with folds have been linked with the same forces that caused the folding. Salt structures in areas without any apparent folding, however, puzzled early geologists and gave rise to a bewildering series of hypotheses. In the late 19th century, the volcanic theory held sway as a hypothesis of origin for Gulf Coast salt domes. This was followed by a group of theories that in some way were associated with deposition from solution. From 1912 to 1934 there followed a period during which flow of salt was generally accepted as a factor in structural development, but the motivating force behind salt flow was the centre of considerable geologic debate. It was suggested in Sweden that the upward movement of salt was caused by the buoyancy of the salt itself, but a number of German scientists proposed that salt domes developed as the result of tectonic forces. An American geophysicist, L.L. Nettleton, revised the buoyancy concept in 1934, formulated the fluid mechanics theory, and demonstrated that upward movement can result from density differences alone. It is now generally agreed that salt structures (and diapiric or piercement structures in general) develop as the result of gravitational forces, tectonic forces, or some combination of these forces, at the same time or with one force following the other. Whatever the precise circumstance, development of diapiric structures requires a rock that flows.

Flowage of rocks. Although rock flow is difficult to visualize because of slow rates of movement, its results can be clearly seen: stonework that sags, mine and tunnel openings that flow shut, and glaciers of rock salt that

Domed strata, rim synclines, and other structures

Theories of folding and buoyancy

Conditions
and rates
of salt flow

move down mountainsides with all the features of glaciers of ice. Given very long periods of time and the relatively high temperature and pressure due to depth of burial, considerable movement of a relatively plastic material such as salt can result. A movement of one millimetre a year, for example, over a period of 1,000,000 years (a short period geologically) would produce a net movement of 1,000 metres. The most common rocks that flow are halite, sylvite, gypsum, and high-pressure shale. These rocks also have densities that are lower than consolidated rock such as sandstone, and if buried by sandstone they would be gravitationally unstable. All of them are deposited by normal processes of sedimentation (see *SEDIMENTARY ROCKS*) and are widespread in sedimentary strata. Thick salt is especially common and has been found in rocks from Precambrian to Holocene (the last 10,000 years, approximately) in age; great thicknesses of it are, in fact, now being deposited.

Mechanics of growth. Study of models and natural salt structures have led to a reconstruction of the sequence of events in the development of salt domes, as shown in Figure 4. First, thick salt is deposited and buried by dens-

Figure 4: Developmental stages of shallow piercement salt dome. Initial stage is shown at top.

er sedimentary strata. The salt and overlying strata become unstable and salt begins to flow from an undeformed bed to a rounded salt pillow. Flow continues into the centre of the pillow, doming the overlying strata; at the same time the area from which the salt flowed subsides, forming a rim syncline. The strata overlying the salt, because they are literally spread apart, are subject to tension, and fractures (faults) develop. Eventually, the salt breaks through the centre of the domed area, giving rise to a plug-shaped salt mass in the centre of domed, upturned, pierced strata. Upward growth of the salt continues apace with deposition of additional strata, and the salt mass tends to maintain its position at or near the surface. If the salt supply to the growing dome is exhausted during growth, development ceases at whatever stage the dome has reached, and the dome is buried. In models, as in nature, movement of the light material does not take place until it has been covered by some critical thickness of heavy material. This amount appears to depend upon the density contrast between the two materials and their

relative mobility. In nature, as in models, some discontinuity in the overburden appears necessary to localize movement; such discontinuities may be faults, folds, or stratigraphic variations.

WORLD DISTRIBUTION

Salt structures develop in any sedimentary basin in which thick salt deposits were later covered with thick sedimentary strata or tectonically deformed or both. With the exception of the shield areas, salt structures are widespread; Figure 5 shows the world distribution of salt structures. By their very nature, the classic salt domes generated by gravitational instability alone are limited to areas that have not been subject to significant tectonic stress. Some salt domes do, however, occur in regions that were subject to tectonic stress. Three of the many areas of salt structures in the world are representative of all; these are the Gulf of Mexico region of North America, the North German–North Sea area of Europe, and the Iraq–Iran–Arabian Peninsula of the Middle East.

Gulf of Mexico region. The Gulf of Mexico region contains more than 500 known salt structures in a circle of land and water 1,000 miles in diameter; this circle consists of eight sub-basins around its outer portion and two in its central portion. Starting in Mississippi and moving counterclockwise around the Gulf, the rimming basins are the East Central Basin, the North Louisiana Basin, the East Texas Basin, the Rio Grande Basin, the Sabinas Basin of northeastern Mexico, the Veracruz and Tabasco–Campeche basins of southern Mexico, and the Cuban Basin. The two central basins are the Texas–Louisiana Coastal Basin, which extends from the coastal lowlands to beyond the continental shelf, and the Sigsbee Basin, which is the deepest portion of the Gulf of Mexico. In all the basins, Cretaceous–Tertiary sediments (from about 136,000,000 to 4,500,000 years in age) are thick; they may be ten kilometres or thicker in the Coastal Basin. In all of the basins except the Sabinas and the Cuban basins, evidence of tectonic activity is lacking. In all of the basins, the salt is probably Triassic–Jurassic (from 225,000,000 to 136,000,000 years ago) in age and may have been part of one large saline basin. Salt structures on the outermost rim of the Gulf region, where the salt was originally thin, are generally salt swells or salt anticlines. Salt structures toward the centre of the region are generally cylindrical or spire-shaped salt domes.

The salt domes of the Coastal Basin, despite their possible connection at depth to a massif or to bedded salt, can be classified according to the relationship that they bear to the encasing sedimentary strata. For the purposes of classification, the sedimentary rock is divided into three zones: an upper zone of sandstone, approximately 1,500 metres thick; a middle zone of interbedded sandstone and shale, 2,000 metres thick, which is the primary reservoir zone for oil and gas; and a lower zone of shale, extending from a depth of 3,500 to 10,000 metres.

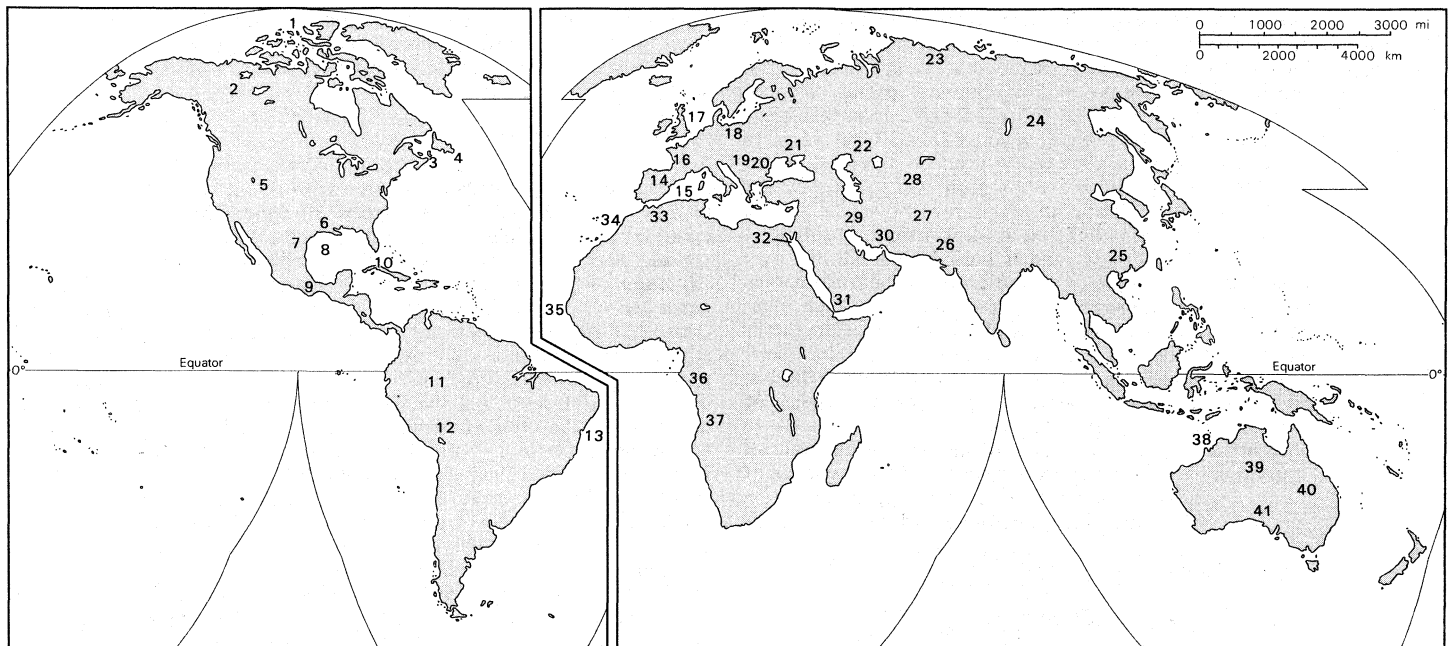

Salt domes that do not reach above the lower shales are called deep or nonpiercement types because they do not pierce the interbedded sandstone and shale of the middle zone. These salt domes may be plug or spire-shaped at depth, but they produce only simple, relatively unfaulted domes in the middle zone. They have no cap rock but generally have some sheath above and on the side of the salt. Oil and gas are found above the salt.

Salt domes that penetrate the middle sandstone and shale zone but not the upper sandstone zone are called intermediate or semipiercement domes. The strata of the middle zone are domed above the salt and are pierced and dragged up by it. The strata around the salt core have a complex radial fault pattern, and those above it have a complex network of faults like a pane of shattered glass. Cap rock is rare, but sheath is present in many instances both above and beside the salt. Oil and gas are found both above and beside the salt.

Salt domes that pierce the middle zone and extend into or through the upper zone are called shallow or piercement salt domes. The strata of the middle zone are dragged up around the cores and have a typical radial fault pattern. Cap rock is common on the top of these

domes, but sheath is limited to the deep flanks of the core. This type of dome traps oil and gas on the sides of the core and in the cap rock; some domes that reach the surface are mined for salt. In the coastal swamps and on the floor of the Gulf of Mexico, shallow salt domes cause circular uplifts. These uplifts form round "islands" or areas of high ground a kilometre in diameter in the swamps—hence the "islands" of Louisiana such as Weeks Island and Avery Island.

North German-North Sea area. The North German-North Sea area contains more than 300 salt structures beneath the North Sea and the land areas of Denmark, Germany, and the Netherlands. Three types of salt structure are present: salt pillows, salt walls, and salt domes.

The salt walls and salt domes rise from depths of 2,500 to 4,000 metres and pierce Triassic to Recent strata. The salt, mostly Permian (225,000,000 to 280,000,000 years ago) in age, is thought to have had an original thickness of up to 1,200 metres. Movement of the salt appears to have taken place from Triassic time onward. Two views have been expressed on the origin of these salt structures. Some believe that the structures are due to gravitational forces alone, whereas others claim that the structures owe their characteristics, position, and development to presalt structural trends and postsalt tectonic deformation. Recent geophysical surveys indicate that the strata below the salt of many salt structures are undeformed; this suggests that at least some of the structures are not of tectonic origin. The alignment of salt features with structural trends, however, suggests that regional tectonics did play some role in the origin of many of the structures present.

A particularly interesting feature of many of the German salt domes is an upward bulging of the salt. This

overhang of the salt (also present on some Gulf Coast salt domes) gives the domes an appearance of a mushroom, and in some cases oil is trapped beneath it. The origin of overhangs is probably connected with a decrease in confining pressure near the surface, which would allow the salt mass to spread laterally. In some cases, it may represent a fossil salt glacier. Oil and gas are trapped in sands and limestone associated with German and North Sea salt domes in many ways: above the salt, beside the salt, under the salt overhangs, in stratigraphic traps away from the salt, and in turtleback highs between salt domes. Salt pillows predominate in English parts of the North Sea, whereas salt walls predominate in northern Germany, and salt domes in southern Germany and in the North Sea between England and Norway.

The Middle East. Salt structures exist in four principal areas in the Middle East. Circular and elongate salt masses of tectonic origin occur in northern and central Iran near Tehran and in southwest Iran in the foothills of the Zagros Mountains; and circular, gravity-induced salt domes occur in southern Iran and the Persian Gulf and in Yemen and the Red Sea.

More than 150 salt domes have been mapped in southern Iran and the Persian Gulf. They consist of a core of Cambrian salt (500,000,000 to 570,000,000 years old), are in a basin with a thick sequence of sedimentary rock, and appear to have been unaffected by tectonic forces. The salt core has penetrated more than 5,000 metres of sedimentary strata, largely Cretaceous and younger in age. In the Persian Gulf, these domes form spectacular, multicoloured islands, the best known of which is Hormuz Island. Some of the domes on land form mountains of salt that are 1,000 metres high and salt glaciers that flow from the

Salt mountains and salt glaciers

Salt pillows, walls, and domes

mountaintops to the valleys. Most of the salt cores are about three kilometres in diameter, but, due to flow of salt away from the centre, salt may cover an area of more than 60 square kilometres. The southern Iran and Persian Gulf salt domes contain blocks of limestone, gypsum, and igneous rocks; many of these blocks exceed 100 metres in diameter. No oil or gas are found on these salt domes.

ECONOMIC SIGNIFICANCE OF SALT DOMES

Salt domes make excellent traps for hydrocarbons because surrounding sedimentary strata are domed upward and blocked off. Major accumulations of oil and natural gas are associated with domes in the United States, Mexico, the North Sea, Germany, Romania, and the U.S.S.R. In the Gulf Coastal Plain of Texas and Louisiana, salt domes have produced 6,000,000,000 barrels of oil and will be a major source of hydrocarbons for many years to come. Huge new supplies of oil have recently been found in salt dome areas off the coast of Louisiana. Some individual salt domes in this region are believed to have reserves of over 500,000,000 barrels of oil. Salt domes in northern Germany have produced oil for many years. Exploration for salt dome oil in the North Sea is extending production offshore, and it is possible that salt domes in the North Sea may ultimately supply Europe's oil and gas needs.

The cap rock of shallow salt domes in the Gulf Coast contains major quantities of elemental sulfur. By the early 1970s, 170,000,000 tons had been produced by the Frasch process (the sulfur is melted by injecting hot water in wells and is then pumped to the surface), and 70,000,000 additional tons were known to exist; exploration is continuing. Salt domes are major sources of salt and potash in the Gulf Coast and Germany; halite and sylvite are extracted from domes by underground mining and by brine recovery.

Salt domes have recently been utilized for underground storage of liquefied propane gas. Storage "bottles" are made by drilling into the salt and then forming a cavity by subsequent solution. Such cavities, because of their impermeability, also have been considered as sites for disposal of radioactive wastes. In 1962 an atomic device was successfully detonated inside the Tatum salt dome of Mississippi, suggesting the potential use of domes for this purpose.

Salt Range

The Salt Range is a range of hills and low mountains between the valleys of the Indus and Jhelum rivers in the northern part of the Punjab region of Pakistan. It derives its name from extensive deposits of rock salt that form one of the richest salt fields in the world. The range is approximately 186 miles (300 kilometres) long from east to west, and its width, in the central and eastern parts, is from five to 19 miles. Its average height is 2,200 feet, and its highest altitude, at Sakesar mountain, is 4,992 feet (1,522 metres). In addition to the salt deposits, mined from ancient times, the Salt Range contains coal, gypsum, and other minerals.

Physiography. The landform is that of a range of low mountains from which the top strata have been removed by erosion. Forming the southern terrace of the Potwar Plateau (1,700 feet), southwest of Rāwalpindi, it consists of two unsymmetrical, parallel ridges divided by a longitudinal valley. The southern slopes of both ridges are steep; the northern slopes are slanting. The northern ridge (a *cuesta*—*i.e.*, a sloping plain, culminating at the upper end at the crest of a cliff), with an average height of from 2,300 to 2,600 feet and with very steep southern

slopes, is the lower. In the west and east, the Range divides into separate mountain masses, or massifs. West of Sakesar the course of the Range swings to the northwest, with low, longitudinal ranges. The Indus River breaks through the ranges at Kālābāgh, flowing between vertical cliffs inaccessible to communication. The summits of the Salt Range are slanting, hilly, and plateau-like. The highest peaks are Sakesar, in the west, and the massif Chel (Chail), 3,700 feet (1,128 metres), in the east. On the northern slope, a system of deep ravines (badlands) has developed.

Structurally, the Salt Range is a highly upheaved block of the northwestern part of the Indian Platform, or Shield, raised to a significant height along the southern fracture, with the sedimentary strata sloping uniformly to the north. The incline of the strata in the central part is around 10°, and in the western, eastern, and northern parts it is up to 45°.

The structural characteristics are well expressed in the topography: the course of the range follows the trend of basic structural elements, the steepness of the southern slopes reflects the fracture and uplift of the block, and the slanting surface corresponds to the slant of the strata. At the time of the upheaval of the Salt Range, beginning in the mid-Tertiary Period (about 26,000,000 years ago), the ancient river system was dislocated. The present main watershed does not coincide with the axis of the largest upheavals of the southern ridge but follows the lower crest of the northern slope. During the upheaval of the Salt Range, lateral cutoffs arose in the longitudinal valley in connection with which the valley lost its sharp, continuous course. The depth of the valley is 600–1,000 feet; the transverse section is sharper in the valleys cut through limestones and dolomites (the narrow ones up to 15–30 feet at the bottom) than in those cut through the sandstones and clay slates (150 or more feet). The foot of the southern ridge is marked by a sloping (1°–2°) zone of loose slope wash (alluvial) taluses with a width of a mile or more. The water of the temporary rivers and streams is absorbed by this debris. The rivers of the northern slope belong to the Sikan River Basin on the Potwar Plateau. There are small lakes of karstic (sinkholes formed by underground erosion) or eolian (wind-formed basins) origin without external drainage, including the beautiful salt lake, Kallar Kahir. The water level of Lake Nammal is maintained by a dam. The Nammal River does not reach the Indus River but disappears into the Indus alluvial plain. In the east, only the Bhura River has a constant flow into the Jhelum River. The undercurrent of the river has cut a wide trough on exit from the ravine.

Stratigraphy. The sedimentary mantle in the northwestern part of the Indian Platform in the region of the Salt Range is represented by thick deposits of Late Precambrian, Paleozoic, and Mesozoic times (*i.e.*, from more than 65,000,000 to 570,000,000 years ago). In the eastern part there are layers of Late Precambrian, Cambrian (from 570,000,000 years ago), and Permian (280,000,000 years ago) deposits, and in the western part there are Mesozoic (65,000,000 to 225,000,000 years ago) and Early Tertiary (25,000,000 to 65,000,000 years ago) deposits. The Precambrian deposits are represented by the widely known salt-bearing strata cropping out along the southern slope of the range, which have an overall thickness of more than 1,600 feet. In the lower part they contain marl, gypsum, and bituminous argillite (a slaty shale). In the central part are located the main strata of salt. The upper part of the strata includes dolomites (magnesium-rich limestones), gypsum, and bituminous argillites. The Precambrian layer is topped by obliquely laminated sandstones up to 650 feet thick. One school of geologists has held that the saline deposits are of Tertiary age on the basis of their superior position in relation to other deposits in the western part of the range, interpreting their underlying position in the central part as resulting from an overthrust of the older sandstones.

Deposits of the Lower Cambrian (thickness around 700 feet) are represented by argillites with interlayers of dolomites and limestones, dolomitic sandstones, and bright red argillites with interlayers of sandstones. With the high stratigraphical variance above are located rubbly con-

Recon-

salt-
bearing
strata

Relief
and
structure

glomerates appearing as deposits of the Permian (225,000,000 to 280,000,000 years ago) glaciers. The conglomerates are overlapped by argillites and sandstones (thickness from 65 to 650 feet) and a layer (around 1,000 feet) of limestone and marl with abundant fauna. Triassic (190,000,000 to 225,000,000 years ago) deposits in the lower part are represented by a stratum of limestones, marls, and sandstones of a thickness of 160–260 feet. In the central part, thin-layer dolomites and sandstones from 80 to 400 feet thick are located. In the eastern parts of the range, red laterites (porous, claylike, iron-rich rocks) are characteristic for the Upper Triassic deposits. Limestone layers in the eastern parts of the range contain more clay, and the overall thickness of the Triassic in this direction diminishes. Jurassic (136,000,000 to 190,000,000 years ago) deposits with a thickness of 500 to 600 feet are represented by varicoloured terrestrial rocks in the lower part and limestones and dolomites in the upper part. Cretaceous (65,000,000 to 136,000,000 years ago) deposits have developed only in the western part of the range and are represented by argillites and sandstones up to 500 feet thick. Clays, limestones, and sandstones of the Early Tertiary with layers of coal, widely developed on the northern slope of the range, occur with more ancient deposits. Overall thickness of the Early Tertiary is from 500 to 1,800 feet.

Along the northern edge of the range a thick (up to several thousand feet) stratum of varicoloured continental deposits of Miocene (from 26,000,000 years ago) to Recent (10,000 years ago) age consisting of conglomerates, coarse stones, sandstones, and clays developed.

Climate. The climate of the Salt Range is continental and arid, changing from tropic to subtropic. Tropical air prevails during all seasons of the year, except the cold winter months, when the relatively cool polar air penetrates at the tail end of high-pressure systems (cyclones). This is a cold, damp season. During summer, precipitations are connected with the equatorial, moist, southwestern (Indian) monsoon, which reaches the limits of its occurrence in West Punjab but brings the largest amounts of precipitation (more than 50 percent annually).

Average temperature in June is 77°–81° F (25°–27° C); in January it is 54° F (12° C) (at the highest peaks it is 63°–66° F [17°–19° C] and 41°–43° F [5°–6° C]). On the average, annual amounts of precipitation in the east are from 20 to 24 inches; in the west they are from 14 to 18 inches. The ultimate maximum of precipitation occurs in summer, during the second half of July and in August. Annual evaporation is more than 80 inches. Evaporation exceeds precipitation even during rainy seasons. Weather during winter is unstable. Warm, dry days alternate with cold, rainy days with northwestern winds (from December through February); frosts and snowfalls occur. The spring is dry and warm. Strong winds are not infrequent, giving rise to dust storms. Mist clings for several days. The dustiness of the air falls abruptly with the first monsoon rains in the second part of the summer. In years of intensive distribution of monsoons, the number of rainy days during the two moist months is more than 20; in years of slight distribution it is less than ten. In September the rains cease, and the temperature gradually falls toward the beginning of October. In the end of October and November, nights may be cold (down to 41° F). Northwestern winds become stronger, accompanied by dust winds and mist, as in the dry months of spring.

Soil. Soil-forming rocks appear as residual mantles (weathering crusts). Insufficient moisture leads to the formation of rocky crusts, usually rubble. Primitive soils are widely distributed; in the outcrop of bedrock there is lithosol (skeletal soils), and, on the continually restored taluses and alluvial fans of the plain at the foot of the southern mountains, there is soft and imperfectly consolidated soil washed down from the slopes (regosol). The soils of the Salt Range belong to the cinnamonic, or cinnamon-coloured, soil type with claying at a depth from 8 to 16 inches, which is characteristic for the types. At upper levels, claying is reduced because of the drying out of the soil in nonrainy seasons. The contents of humus, which penetrates deeply down the cross section, is around

2 percent. At high humidity the calcareous layer is found at some depth; at lower humidity, calcareousness is seen beginning with the surface. Water-soluble salts are few. The soils of the Salt Range are not saline, a condition that is connected with good drainage. The exception is a narrow strip of alluvial fans with efflorescences of salt at the foot of the southern spur, where there is active erosion of salt-bearing strata. Occurrences of alluvial soils are not large, being confined to the longitudinal valley between the northern and southern ridge and to the small sections of terraces in the river valleys of the northern slope. Destruction of vegetation and excessive pasturing of cattle have led to an increase of areas of eroded soils and badlands.

The use of land for agriculture is limited because of a lack of water for irrigation. Small sections on the slopes and in the longitudinal valleys are being terraced for cultivation of irrigated crops using the water of lakes and springs. In the valleys dry farming prevails.

Vegetation. In the flora of the Salt Range there are both African–Arabian and Mediterranean elements. Before the loss of the natural vegetation, the area was covered in the south by xerophyte (drought-resisting) thin forests and in the north chiefly by savannas. At present a small mass of thin forest has been preserved by conservation on the southeast of the Salt Range. Among the forest trees are acacia, pine, wild olive, and others. The trees are low (up to 33 feet) with deciduous leaves. Other characteristic vegetation includes spurge (*Euphorbia*) and camel thorn and other scrubs and brushwood. The grasses burn out in April or May.

Mineral resources. On the southern slope of the Salt Range are located the largest deposits of rock salt in Pakistan, at Khewra, Warcha, and Kālābāgh. Salt deposits smaller in importance occur at Jatta, Bahādur Khel, and Kharak. Coal deposits are found at Dandot, Pidh, and Makarwrl Kheji. Traces of petroleum content are associated with limestone and sandstone deposits in the western part of the Salt Range. In the salt-bearing series in the eastern part of the Salt Range, layers of bituminous shales and dolomites are found. In the eastern parts, too, occur beds of bauxite (aluminum-bearing laterite).

Large deposits of high-grade gypsum and anhydrite, an important calcium mineral, are traced from Jalalpur Kālābāgh and the district of Khewra-Dawdot. Economically, the salt and coal mines and limestone quarries are the most important.

Human resources and prospects. The only population centre of any size associated with the Salt Range is Jhelum, headquarters of the district of that name that encompasses the range and stretches north to Rāwalpindi. Most of the towns in the range itself serve the mines and quarries. The Salt Range divides the district of Gujrrit, to the southeast, from the districts of Jhelum, Attock, and Rriwalpindi, the four districts together making up the Rriwalpindi Division, which occupies the north of Pakistan.

The main ethnic groups of the region are the Pandzhabt, Dzhat, and Aran peoples, who speak Indian languages (mainly Lakhnda). While there is marginal farming in the valleys and on the few terraces and some animal husbandry on the overgrazed hillsides, the principal occupation is salt mining.

Although the Salt Range has been a barrier to travel and communication, its modest peaks have never presented a challenge to explorers or mountain climbers.

The future economic and social development of the Salt Range appears to depend on the future development of the Rriwalpindi Division, and especially on the development of the Jhelum District.

BIBLIOGRAPHY. Two standard works—M.B. PITHAWALLA, *An Introduction to Pakistan: Its Resources and Potentialities* (1948); and O.N.K. SPATE, *India and Pakistan*, 2nd ed. (1957)—contain some information on the Salt Range. K.S. AHMAD, *A Geography of Pakistan* (1964), is a popular work that mentions some characteristics of the range. The geology of the range is covered by AUGUST GANSSER in *Geology of the Himalayas* (1964).

Rock salt and coal deposits

Farming, animal husbandry, and mining

Salvation

Salvation is the deliverance or redemption of man from such fundamentally negative or disabling conditions as suffering, evil, finitude, and death. In some religious beliefs it also entails the restoration or raising up of the natural world to a higher realm or state. The idea of salvation is a characteristic religious notion related to an issue of profound human concern.

NATURE AND SIGNIFICANCE

It could be argued reasonably that the primary purpose of all religions is to provide salvation for their adherents, and the existence of many different religions indicates that there is a great variety of opinion about what constitutes salvation and the means of achieving it. That the term salvation can be meaningfully used in connection with so many religions, however, shows that it distinguishes a notion common to men and women of a wide range of cultural traditions.

The fundamental idea contained in the English word salvation, and the Latin *salvatio* and Greek *sōtēria* from which it derives, is that of saving or delivering from some dire situation. The term soteriology denotes beliefs and doctrines concerning salvation in any specific religion, as well as the study of the subject. The idea of saving or delivering from some dire situation logically implies that mankind, as a whole or in part, is in such a situation. This premise, in turn, involves a series of related assumptions about human nature and destiny.

Objects and goals. The creation myths of many religions express the beliefs that have been held concerning the original state of mankind in the divine ordering of the universe. Many of these myths envisage a kind of Golden Age at the beginning of the world, when the first human beings lived, serene and happy, untouched by disease, aging, or death and in harmony with a divine Creator. Myths of this kind usually involve the shattering of the ideal state by some mischance, with wickedness, disease, and death entering into the world as the result. The Adam and Eve myth is particularly notable for tracing the origin of death, the pain of childbirth, and the hard toil of agriculture, to man's disobedience of his maker. It expresses the belief that sin is the cause of evil in the world, and implies that salvation must come through man's repentance and God's forgiveness and restoration.

In ancient Iran, a different cosmic situation was contemplated, one in which the world was seen as a battleground of two opposing forces: good and evil, light and darkness, life and death. In this cosmic struggle, mankind was inevitably involved, and the quality of human life was conditioned by this involvement. Zoroaster, the founder of Zoroastrianism, called upon men to align themselves with the good, personified in the god Ahura Mazdā, because their ultimate salvation lay in the triumph of the cosmic principle of good over evil, personified in Ahri-man. This salvation involved the restoration of all that had been corrupted or injured by Ahri-man at the time of his final defeat and destruction. Thus the Zoroastrian concept of salvation was really a return to a Golden Age of the primordial perfection of all things, including man. Some ancient Christian theologians (e.g., Origen) also conceived of a final "restoration" in which even devils, as well as men, would be saved; this idea, called universalism, was condemned by the church as heresy.

In those religions that regard man as essentially a psychophysical organism (e.g., Judaism, Christianity, Zoroastrianism, Islam), salvation involves the restoration of both the body and soul. Such religions therefore teach doctrines of a resurrection of the dead body and its reunion with the soul, preparatory to ultimate salvation or damnation. In contrast, some religions have taught that the body is a corrupting substance in which the soul is imprisoned (e.g., Orphism, an ancient Greek mystical cult; Hinduism; and Manichaeism, an ancient dualistic religion of Iranian origin). In this dualistic view of human nature, salvation has meant essentially the emancipation of the soul from its physical prison or tomb and its return to its ethereal home. Such religions generally explain the incarceration of the soul in the body in terms

that imply the intrinsic evil of physical matter. Where such views of human nature were held, salvation therefore meant the eternal beatitude of the disembodied soul.

Christian soteriology contains a very complex eschatological program (regarding the final end of man and the world), which includes the fate of both individual persons and the existing cosmic order. The return of Christ will be heralded by the destruction of the heaven and earth and the resurrection of the dead. The Last Judgment, which will then take place, will result in the eternal beatitude of the just, whose souls have been purified in purgatory, and the everlasting damnation of the wicked. The saved, reconstituted by the reunion of soul and body, will forever enjoy the Beatific Vision; the damned, similarly reconstituted, will suffer forever in hell, together with the devil and the fallen angels. Some schemes of eschatological imagery, used by both Christians and Jews, envisage the creation of a new heaven and earth, with a New Jerusalem at its centre.

Means. The hope of salvation has naturally involved ideas about how it might be achieved. These ideas have varied according to the form of salvation envisaged; but the means employed can be divided into three significant categories: (1) the most primitive is based on belief in the efficacy of ritual magic—initiation ceremonies, such as those of the ancient mystery religions, afford notable examples; (2) salvation by self-effort, usually through the acquisition of esoteric knowledge, ascetic discipline, or heroic death, has been variously promised in certain religions—Orphism, Hinduism, Islām, for example; and (3) salvation by divine aid, which has usually entailed the concept of a divine saviour who achieves what man cannot do for himself—as in Christianity, Judaism, Islām.

BASIC CONTEXT

The cosmic situation. *Time.* Study of the relevant evidence shows the menace of death as the basic cause of soteriological concern and action. Salvation from disease or misfortune, which also figures in religion, is of a comparatively lesser significance, though it is often expressive of more immediate concerns. But the menace of death is of another order, and it affects man more profoundly because of personal awareness of the temporal categories of past, present, and future. This time-consciousness is possessed by no other species with such insistent clarity. It enables man to draw upon past experience in the present and to plan for future contingencies. This faculty, however, has another effect: it causes man to be aware that he is subject to a process that brings change, aging, decay, and ultimately death to all living things. Man, thus, knows what no other animal apparently knows about itself, namely, that he is mortal. He can project himself mentally into the future and anticipate his own decease. Man's burial customs grimly attest to his preoccupation with death from the very dawn of human culture in the Paleolithic Period. Significantly, the burial of the dead is practiced by no other species.

The menace of death is thus inextricably bound up with man's consciousness of time. In seeking salvation from death, man has been led on to a deeper analysis of his situation, in which he has seen in his subjection to time the true cause of the evil that besets him. The quest for salvation from death, accordingly, becomes transformed into one for deliverance from subjugation to the destructive flux of time. How such deliverance might be effected has been conceived in varying ways, corresponding to the terms in which the temporal process is imagined. The earliest known examples occur in ancient Egyptian religious texts. In the so-called Pyramid Texts (c. 2400 BC), the dead pharaoh seeks to fly up to heaven and join the sun-god Re on his unceasing journey across the sky, incorporated, thus, in a mode of existence beyond change and decay. A passage in the later Book of the Dead (1200 BC) represents the deceased, who has been ritually identified with Osiris, declaring that he comprehends the whole range of time in himself, thus asserting his superiority to it.

The recognition that mankind is subject to the inexorable law of decay and death has produced other later

Resurrection and immortality

Man's
deliver-
ance from
time and
death

attempts to explain its domination by time and to offer release from it. Such attempts are generally based on the idea that the temporal process is cyclical, not linear, in its movement. Into this concept, a belief in metempsychosis transmigration of souls can be conveniently fitted. For the idea that souls pass through a series of incarnations becomes more intelligible if the process is seen as being cyclical and in accordance with the pattern of time that apparently governs all the forms of being in this world. The conception has been elaborated in various ways in both Eastern and Western religions. In Hinduism and Buddhism, elegantly imaginative chronological systems have been worked out, comprising *mahāyugas*, or periods of 12,000 years, each year of which represented 360 human years. In turn, 1,000 *mahāyugas* made up one kalpa, or one day in the life of *Brahmā*, and spanned the duration of a world from its creation to its destruction. After a period of quiescence, the world would be re-created by *Brahmā* for another kalpa. The purpose of this immense chronological scheme was to emphasize how the unenlightened soul was doomed to suffer an infinite series of incarnations, with all of their attendant pain of successive births and deaths. In the Orphic texts of ancient Greece, man's destiny to endure successive incarnations is significantly described as "the sorrowful weary Wheel," from which the Orphic initiate hoped to escape through the secret knowledge imparted to him.

Nature. As an alternative interpretation to this view of man's fatal involvement with time, the tragedy of the human situation has also been explained in terms of the soul's involvement with the physical universe. In some systems of thought (e.g., Hinduism and Buddhism), the two interpretations are synthesized; and in such systems it is taught that, by accepting the physical world as reality, the soul becomes subject to the process of time.

Man's
deliver-
ance from
the body
and the
natural
world

Concentration on the soul's involvement with matter as being the cause of the misery of human life has generally stemmed from a dualistic view of human nature. The drawing of a sharp distinction between spirit and matter has been invariably motivated by a value judgment: namely, that spirit (or soul) is intrinsically good and of transcendent origin, whereas matter is essentially evil and corrupting. Through his body, man is seen to be part of the world of nature, sharing in its processes of generation, growth, decay, and death. How his soul came to be incarcerated in his corruptible body has been a problem that many myths seek to explain. Such explanations usually involve some idea of the descent of the soul or its divine progenitor from the highest heaven and their fatal infatuation with the physical world. The phenomenon of sexual intercourse has often supplied the imagery used to account for the involvement of the soul in matter and the origin of its corruption. Salvation has thus been conceived in this context as emancipation from both the body and the natural world. In Gnosticism and Hermeticism—esoteric theosophical and mystical movements in the Greco-Roman world—and the teaching of St. Paul deliverance was sought primarily from the planetary powers that were believed to control human destiny in the sublunar world.

Man's responsibility. The idea that man is in some dire situation, from which he seeks to be saved, necessarily involves explaining the cause of his predicament. The explanations provided in the various religions divide into two kinds: those that attribute the cause to some primordial mischance and those that hold man to be himself responsible. Some explanations that make man directly responsible represent him also as the victim of the deceit of a malevolent deity or demon.

Because death has been universally feared but rarely accepted as a natural necessity, the mythologies of many peoples represent the primeval ancestors of mankind as having accidentally lost, in some way, their original immortality. One Sumerian myth, however, accounts for disease and old age as resulting from the sport of the gods when they created mankind. In contrast, the Hebrew story of Adam and Eve finds the origin of death in their act of disobedience in eating of the tree of knowledge of good and evil, forbidden to them by their maker. This

causal connection between sin and death was elaborated by St. Paul in his soteriology, outlined in his letter to the Romans, and formed the basis of the Christian doctrine of original sin. According to this doctrine, through seminal identity with Adam, every human being must partake of the guilt of Adam's sin, and even at birth, a child is already deserving of God's wrath for its share in the original sin of mankind and before it acquires the guilt of its own actual sin. Moreover, because each individual inherits the nature of fallen humanity, he has an innate predisposition to sin. This doctrine of man means that no person can, by his volition and effort, save himself but depends absolutely upon the saving grace of Christ.

Wherever a dualistic view of human nature has been held, it has been necessary to explain how ethereal souls first became imprisoned in physical bodies. Generally, the cause has been found in the supposition of some primordial ignorance or error rather than in a sinful act of disobedience or revolt—i.e., in an intellectual rather than a moral defect. According to the Hindu philosophical system known as Advaita Vedānta, a primordial ignorance (*avidyā*) originally caused souls to mistake the empirical world for reality and so become incarnated in it. By continuing in this illusion, they are subjected to an unceasing process of death and rebirth (*saṃsāra*) and all of its consequent suffering and degradation. Similarly, in Buddhism, a primordial ignorance (*avijjā*) also started the "chain of causation" (*paṭiccasamuppāda*) that produces the infinite misery of unending rebirth in the empirical world.

METHODS AND TECHNIQUES

Ritual. The means by which salvation might be achieved has been closely related to the manner in which salvation has been conceived and to what has been deemed to be the cause of man's need of it. Thus in ancient Egypt, where salvation was from the physical consequences of death, a technique of ritual embalment was employed. Ritual magic has also been used in those religions that require their devotees to be initiated by ceremonies of rebirth (e.g., Baptism in water in Christianity, in bull's blood in rites of Cybele) and by symbolic communion with a deity through a ritual meal in the Eleusinian Mysteries, Mithraism, and Christianity (communion).

Knowledge. Religions that trace the ills of man's present condition to some form of primordial error, or ignorance, offer knowledge that will ensure salvation. Such knowledge is of an esoteric kind and is usually presented as divine revelation and imparted secretly to specially prepared candidates. In some instances (e.g., Buddhism and Yoga), the knowledge imparted includes instruction in mystical techniques designed to achieve spiritual deliverance.

Devotion and service. Whenever mankind has been deemed to need divine aid for salvation, there has been an emphasis on a personal relationship with the saviour-god concerned. Such relationship usually connotes faith in and loving devotion and service toward the deity, and such service may involve moral and social obligations. Judaism, Christianity, Islām, and the bhakti cults of India afford notable examples. Christianity adds a further requirement in this context: because human nature is basically corrupted by sin, God's prevenient (antecedent, activating) grace is needed before man's will can be disposed even to desire salvation.

VARIETIES OF SALVATION IN WORLD RELIGIONS

Ancient Egypt. The Pyramid Texts of ancient Egypt provide the earliest evidence of man's quest for salvation. They reveal that by about 2400 BC a complex soteriology connected with the divine kingship of the pharaohs had been established in Egypt. This soteriology was gradually developed in concept and ritual practice and was popularized; i.e., the original royal privilege was gradually extended to all of the classes of society, until by about 1400 BC it had become an elaborate mortuary cult through which all who could afford its cost could hope to partake of the salvation it offered. This salvation con-

Moral and
intellectual
defects

Post-mortem salvation through Osiris

cerned three aspects of postmortem existence, as imagined by the ancient Egyptians, and, in the concept of Osiris, it involved the earliest instance of a saviour-god. An elaborate ritual of embalment was designed to save the corpse from decomposition and restore its faculties so that it could live in a well-equipped tomb. This ritual imitated the acts that were believed to have been performed by the gods to preserve the body of Osiris, with whom the deceased was ritually assimilated. The next concern was to resurrect the embalmed body of the dead person, as Osiris had been resurrected to a new life after death. Having thus been saved from the consequences of death, the revived dead had to undergo a judgment (presided over by Osiris) on the moral quality of his life on earth. In this ordeal, the deceased could be saved from an awful second death only by personal integrity. If he safely passed the test, he was declared *maa kheru* ("true of voice") and was admitted to the beatitude of the realm over which Osiris reigned.

This Osirian mortuary cult, with its promise of postmortem salvation, was practiced from about 2400 BC until its suppression in the Christian Era. In some respects, it constitutes a prototype of Christianity as a salvation religion.

Hinduism. Running through the great complex of beliefs and ritual practices that constitute Hinduism is the conviction that the soul or self (*atman*) is subject to *saṃsāra*—i.e., the transmigration through many forms of incarnation. Held together with this belief is another, *karman*—i.e., that the soul carries with it the burden of its past actions—which conditions the forms of its future incarnations. As long as the soul mistakes this phenomenal world for reality and clings to existence in it, it is doomed to suffer endless births and deaths. The various Indian cults and philosophical systems offer ways in which *mokṣa* or *mukti* ("release"; "liberation") from the misery of subjection to the inexorable process of cosmic time may be attained. Basically, this liberation consists in the soul's effective apprehension of its essential unity with Brahman, the supreme *Ātman* or essence of reality, and its merging with it. Most of the ways by which this goal may be attained require self-effort in mastering meditation techniques and living an ascetic life. But in the devotional (*bhakti*) cults associated with Viṣṇu (*Vishnu*) and Śiva (*Shiva*), an intense personal devotion to the deity concerned is believed to earn divine aid to salvation.

Buddhism. Buddhism accepts the principles of *saṃsāra* and *karman* (Pāli, *kamma*) but it differs in one important respect from the Hindu conception of man. Instead of believing that an *atman*, or soul, passes through endless series of incarnations, Buddhism teaches that there is no such pre-existent immortal soul that migrates from body to body. According to it, each individual consists of a number of physical and psychical elements (*khandhas*) that combine to create the sense of personal individuality. But this combination is only temporary, and is irreparably shattered by death, leaving no element that can be identified as the soul or self. By a subtle metaphysical argument, however, it is maintained that the craving for personal existence generated by the *khandhas* causes the birth of another such personalized combination, which inherits the *karma* of a sequence of previous combinations of *khandhas*.

The Enlightenment won by Gautama Buddha was essentially about the cause of existence in the phenomenal world, from which suffering inevitably stemmed. Buddhist teaching and practice have, accordingly, been designed to acquaint men with their true nature and situation and enable them to free themselves from craving for existence in the space-time world and so achieve *Nirvāṇa*. Traditionally, this goal has been presented in negative terms—as the extinction of desire, attachment, ignorance, or suffering—creating the impression that Buddhist salvation means the complete obliteration of individual consciousness. In one sense this is so; but in terms of Buddhist metaphysics, ultimate reality transcends all the terms of reference relevant to existence in this world.

Theoretically, the Buddhist initiate should, by his own effort in seeking to eradicate desire for continued exist-

tence in the empirical world, achieve his own salvation. But as Buddhism developed into a popular religion in its *Mahāyāna* ("Greater Vehicle") form, provision was made for the natural human desire for assurance of divine aid. Consequently, belief in many saviours, known as *bodhisattvas* ("Buddhas-to-be") developed, together with elaborate eschatologies concerning human destiny. According to these, before the ultimate achievement of *Nirvāṇa*, the faithful could expect to pass through series of heavens or hells, according to their merits or demerits and the intensity of their devotion to a *bodhisattva*.

Judaism. Because Judaism is by origin and nature an ethnic religion, salvation has been primarily conceived in terms of the destiny of Israel as the elect people of Yahweh, the God of Israel. It was not until the 2nd century BC that there arose a belief in an afterlife, for which the dead would be resurrected and undergo divine judgment. Before that time, the individual had to be content that his posterity continued within the holy nation. But even after the emergence of belief in the resurrection of the dead, the essentially ethnic character of Judaism still decisively influenced soteriological thinking. The apocalyptic faith, which became so fervent as Israel moved toward its fateful overthrow by the Romans in AD 70, conceived of salvation as the miraculous intervention of Yahweh or his Messiah in world affairs. This saving act would culminate in the Last Judgment delivered on the nations that oppressed Israel and Israel's glorious vindication as the people of God. From the end of the national state in the Holy Land in AD 70, Jewish religion, despite the increasing recognition of personal significance, has remained characterized by its essential ethnic concern. Thus, the Exodus from Egypt has ever provided the typical imagery in terms of which divine salvation has been conceived, its memory being impressively perpetuated each year by the ritual of the Passover. The restoration of the holy nation, moreover, always has been linked with its Holy Land; and Hebrew literature, both in biblical and later forms, has lovingly described the establishment of a New Jerusalem and a new Temple of Yahweh ("the Lord"), whether it be in this world or in some new cosmic order. Into this new order, the rest of mankind, repentant and purified, will be incorporated; for the original promise made to the patriarch Abraham included all of the men within the divine blessing. In the Book of Zechariah, the ultimate salvation of mankind is graphically envisaged: the Gentiles, in company with the Jews, will return to serve God in an ideal Jerusalem.

Christianity. Christianity has been described as the salvation religion par excellence. Its primary premise is that the incarnation and sacrificial death of its founder, Jesus Christ, formed the climax of a divine plan for mankind's salvation. This plan was conceived by God consequent on the Fall of Adam, the progenitor of the human race, and it would be completed at the Last Judgment, when the Second Coming of Christ would mark the catastrophic end of the world. This soteriological evaluation of history finds expression in the Christian division of time into two periods: before Christ (BC) and *Anno Domini* (AD)—i.e., the years of the Lord.

The evolution of the Christian doctrine of salvation was a complicated process essentially linked with the gradual definition of belief in the divinity of Jesus of Nazareth. In Christian theology, therefore, soteriology is an integral part of what is termed Christology. Whereas the divinity of Jesus Christ has been the subject of careful metaphysical definition in the creeds, the exact nature and mode of salvation through Christ has not been so precisely defined. The church has been content to state, in its creeds, that Christ was incarnated, crucified, died, and rose again "for us men, and for our salvation."

The basic tenets of Christian soteriology may be summarized as follows: man is deserving of damnation by God for the original sin, which he inherits by descent from Adam, and for his own actual sin. But because sin is regarded as also putting man in the power of the devil, Christ's work of salvation has been interpreted along two different lines. Thus his crucifixion may be evaluated as a vicarious sacrifice offered to God as propitiation or

Salvation through Yahweh's action and power

Salvation through Christ

Salvation through Enlightenment or *bodhisattvas*

atonement for human sin. Alternatively, it may be seen as the price paid to redeem man from the devil. These two ways of interpreting the death of Christ have provided the major themes of soteriological theory and speculation in Christian theology. Despite this fluidity of interpretation, belief in the saving power of Christ is fundamental to Christianity and finds expression in every aspect of its faith and practice.

Islām. Muhammad regarded himself as "a warner clear," and as the last and greatest of a line of prophets whom Allāh had sent to warn his people of impending doom. Although the word *najāt* ("salvation") is used only once in the Qurʾān, the basic aim of Islām is salvation in the sense of escaping future punishment, which will be pronounced on sinners at the Last Judgment. Muhammad did teach that Allāh had predestined some men to heaven and others to hell; but the whole logic of his message is that submission to Allāh is the means to salvation, for Allāh is merciful. Indeed, faithful submission is the quintessence of Islām (Arabic "submission") as the name itself signifies. Although in his own estimation Muhammad was the prophet of Allāh, in later Muslim devotion he came to be venerated as the mediator between God and man, whose intercession was decisive.

Zoroastrianism and Parsiism. According to Zoroaster, a good and evil force struggled for mastery in the universe. Man had to decide on which side to align himself in this fateful contest. This dualism was greatly elaborated in later Zoroastrianism and Parsiism, which derived from it. Good, personified as the god Ormazd, and evil, as the demonic Ahriman, would contend for 12,000 years with varying fortune. At last Ormazd would triumph, and Saoshyans, his agent, would resurrect the dead for judgment. The righteous would pass to their reward in heaven, and the wicked be cast into hell. But this situation was of temporary duration. A meteor would later strike the earth, causing a flood of molten metal. Through this flood all would have to pass as an ordeal of purgation. The sensitivity of each to the anguish would be determined by the degree of his guilt. After the ordeal, all men would become immortal, and all that Ahriman had harmed or corrupted would be renewed. Salvation thus took the form of deliverance from postmortem suffering; for ultimate restoration was assured to all after suffering the degree of purgation that the nature of their earthly lives entailed.

BIBLIOGRAPHY. For recent and comprehensive studies of the subject, S.G.F. BRANDON, *Man and His Destiny in the Great Religions* (1962), provides extensive documentation and bibliographies; important aspects of salvation are specially dealt with in his *History, Time and Deity* (1965) and *The Judgment of the Dead* (1967), also well-documented and including bibliographies. S.G.F. BRANDON (ed.), *The Saviour God* (1963), comprises 15 essays by specialists in the major religions; C.J. BLEEKER (ed.), *Anthropologie religieuse* (1955), also contains 15 specialized essays (in English, French, and German) that relate to salvation in various religions. J. HASTINGS (ed.), *The Encyclopaedia of Religion and Ethics*, vol. 11 (1921), provides a series of articles on salvation in various religions; these articles are valuable, but are necessarily dated in both material and approach. The German encyclopaedia *Die Religion in Geschichte und Gegenwart*, 3rd ed., vol. 2, col. 576–600 (1958), gives a useful survey under "Erlöser" and "Erlösung," but attention is heavily concentrated on the Christian theological issues. A valuable and well-documented study of the subject in Hebrew, Greco-Roman religions, and early Christianity may be found in T. KLAUSER (ed.), *Reallexikon für Antike und Christentum*, vol. 5, col. 54–219 (1964). ADOLF VON HARNACK'S monumental *Lehrbuch der Dogmengeschichte*, 3rd ed., 3 vol. (1893; Eng. trans., *History of Dogma*, 7 vol., 1900, reprinted 1961), traces the development of Christian soteriology; G. AULEN, *Christus Victor* (1931), deals particularly with early classical interpretation of Christ's soteriological role; L.W. GRENSTED, *A Short History of the Doctrine of the Atonement* (1920, reprinted 1962), is a reliable concise guide. Aspects of salvation in the religions concerned are treated in the following books: R.C. ZAEHNER, *Hinduism*, 2nd ed. (1966) and *The Dawn and Twilight of Zoroastrianism* (1961); E.J. THOMAS, *The History of Buddhist Thought*, 2nd ed. (1951); and A.J. WENSINCK, *The Muslim Creed* (1932).

(S.G.F.B.)

Samarkand

Samarkand, a town and *oblast* (province) centre in the Uzbek Soviet Socialist Republic, U.S.S.R., was one of the great cities of Central Asia during the Middle Ages. It lies at an altitude of about 2,330 feet (710 metres) in the valley of the Zeravshan River, 168 miles (270 kilometres) southwest of Tashkent by rail and about 155 miles (249 kilometres) north of the Afghanistan frontier (population of the city, 1970 census [prelim.] 267,000).

History. Samarkand is one of the oldest cities of Central Asia. In the 4th century BC, then known as *Maracanda*, it was the capital of Sogdiana and was captured (329) by Alexander the Great. In the 6th century AD it was part of a Turkish kingdom. At the beginning of the 8th century it was conquered by the Arabs, and in the 9th and 10th centuries it was ruled by the *Sāmānids* of Persia. From the 11th century to the Mongol invasions, Samarkand was ruled by various Turkic peoples. In the 11th century it was conquered by the *Qarakhanids* (*Karakhanids*) and later by the *Seljuq Turks*; in the 12th century by the *Karakitai*; and in the 13th century it was annexed to the kingdom of *Khwarezm* (*Khorezm*). In 1220 it was captured and destroyed by Genghis Khan. In 1365 the city revolted against the Mongol emirs, and at the end of the 14th and the beginning of the 15th centuries, it was the capital of the empire of Timur. During this period Samarkand was the most important economic and cultural centre of Central Asia. In 1500 it was conquered by the Uzbeks, the Muslim people of the Golden Horde, and came under the dominion of the *Shaybānīd* dynasty, who in the middle of the 16th century transferred their capital to Bukhara. Samarkand later became part of the khanate of Bukhara. During the 17th and 18th centuries, as a result of attacks by nomad tribes and by the Iranians, Samarkand underwent a serious economic crisis, and from the 1720s until the 1770s it was uninhabited. In 1868 it was occupied by Russian troops and became a part of the Russian empire as capital of the *Zeravshan District*, which in 1887 became the Samarkand Province. When the Uzbek S.S.R. was constituted in 1924, Samarkand became its capital until 1930.

Major features. The old city of Samarkand, as opposed to the "new town" built after the Russian conquest of 1868, took shape in the Middle Ages. Its plan consisted of streets converging toward the centre from six gates in the five-mile-long, 11th-century walls. The walls and gates were destroyed after the capture of the town by the Russians, but the plan of the medieval period is still preserved. Here are to be found monuments of Central Asian architecture in which the developments of six centuries can be observed. The earliest of these are the five small 14th-century edifices (in the collection of mausoleums known as the *Shāh-e Zendah*) and the *Rūhābād* mausoleum dating from the middle of the 14th century. In the time of Timur (*Tamerlane*), the congregational mosque of *Bībī-Khānom* (his Chinese wife) and the mausoleum of Timur himself, known as the *Gūr-e Amīr*, were built. To the second half of the 15th century belongs the Ak Saray tomb with a superb fresco of the interior. A fine example of the town-planning culture of Central Asia is *Rīgēstān Square* with its group of monumental buildings: the *madrasahs* (Muslim schools) of *Ulūgh Beg* (1417–20), *Shirdar* (1619 to 1635/36), and *Tilakari* (mid-17th century), which border the square on three sides. In the environs of Samarkand are the tomb of 'Abd-e Darūn (15th century), the mausoleum of *Chopān-Atā* (mid-15th century), the mausoleum of 'Eshrat Khān, the ruins of a 16th-century aqueduct leading to the Zeravshan River, the mosque of *Namāzgāh* (17th century), the *madrasah* at the tomb of *Khoja Ahrār* (built 1630–36 by a Samarkand architect *Dūst Mohammad*), and the *khānegāh* (cloister) at the tomb of 'Abd-e Bīrūn (1633–34). The main features of the 15th- to 17th-century monuments are the splendid portals, the vast coloured domes, and the remarkable exterior decoration in majolica, mosaic, marble, and gold. The new town, construction of which began in 1871, has expanded considerably during the Soviet period; and public buildings, houses, and parks have been built. There are Uzbek and Russian theatres, a uni-

versity (established 1933), and higher educational institutions for agriculture, medicine, and trade.

Samarkand's commercial importance, which in ancient and medieval times derived from its location at the junction of trade routes from China (the "silk road") and India, declined during the 17th and 18th centuries but greatly increased with the coming of the railway in 1896. Samarkand then became an important centre for the export of wine, dried and fresh fruits, cotton, rice, silk, and leather. Under the Soviet regime, industry has been expanded and, although mainly based on agriculture (e.g., cotton ginning; silk spinning and weaving; fruit canning; production of wine, clothing, leather and footwear, and tobacco), also includes the manufacture of tractor and automobile parts and cinema apparatus.

Samarkandskaya (Samarkand) oblast. The *oblast*, formed in 1938, is divided into 16 *rayony* (districts). Its area is 11,270 square miles (29,200 square kilometres), and its population mainly Uzbek but includes Tadzhiks, Russians, and Ukrainians. More than one-quarter of the population lives in the three towns of Samarkand, Katta-Kurgan, and Dzhizak. The *oblast* is drained by the Zeravshan River and includes the Nuratau and Ak-Tau mountain ranges in the north. In the southwest is the Karmabchul Steppe. The geological structure includes marble, granite, limestone, gypsum, and other valuable building materials and minerals. The climate is continental and is noted for the amount of sunshine and the absence of cloud cover. There is no frost during 200 days in the year. The economy, mainly agricultural, includes cotton and fruit growing and sericulture in the Zeravshan Valley; elsewhere there is dry wheat farming. Karakul sheep and goats are bred. Extensive irrigation systems have been developed. The *oblast* is traversed by the Krasnovodsk-Tashkent railway to an extent of 200 miles and there are about 5,000 miles of motor roads.

Samoa

The Samoa Islands, situated in the eastern Pacific Ocean about 1,600 miles northeast of New Zealand, 2,700 miles

east of Australia, and 2,200 miles southwest of the Hawaiian Islands, are among the westernmost islands of Polynesia. The archipelago is divided administratively into two parts—American Samoa and Western Samoa. American Samoa, a dependency of the United States, consists of the six islands east of the 171° W meridian. Western Samoa, a self-governing nation that until 1962 was a United Nations trust territory administered by New Zealand, consists of the nine islands west of that meridian.

American Samoa, with a total land area of 76 square miles (197 square kilometres), includes the inhabited islands of Tutuila, Tau, Olosega, Ofu, and Aunuu and two uninhabited coral atolls named Rose Island. Swains Island (inhabited), a coral atoll 210 miles northwest of Tutuila and geographically not a part of the archipelago, was made a part of American Samoa in 1925. Western Samoa, with a total land area of 1,097 square miles (2,841 square kilometres), includes the inhabited islands of Upolu, Savai'i, Manono, and Apolima, and the uninhabited islands of Fanuatapu, Namua, Nuutele, Nuulua, and Nuusafee. The capital of American Samoa is Pago Pago, on Tutuila; the capital of Western Samoa is Apia, on Upolu.

The landscape. *Relief features.* Except for the coral atolls, the islands are rocky and were formed by volcanic activity that progressed from east to west within the past 7,000,000 years. The islands of American Samoa are thus the oldest geologically. The main island of Tutuila, with an area of 53 square miles, rises steeply above deep inlets, of which the most notable is Pago Pago Harbour, which almost divides the island in two. Its highest peak is Matafao (2,142 feet [653 metres]).

The largest island of Western Samoa is Savai'i (662 square miles); its highest peak is Silisili (6,096 feet [1,858 metres]). There have been two eruptions from Savai'i volcanoes in historic times, the most recent in 1905. The other large island is Upolu (433 square miles), which has five uninhabited, offshore islets. Manono and Apolima lie between the two main islands.

Apart from cliffs formed by recent lava flows, all of the islands are ringed by coral reefs and shallow lagoons. The volcanic soils are easily exhausted by farming but support a lush natural vegetation which varies from plantations of taro, coconut, breadfruit, and other food crops on the coast to rain forest and mountain rain (or mist) forest further inland.

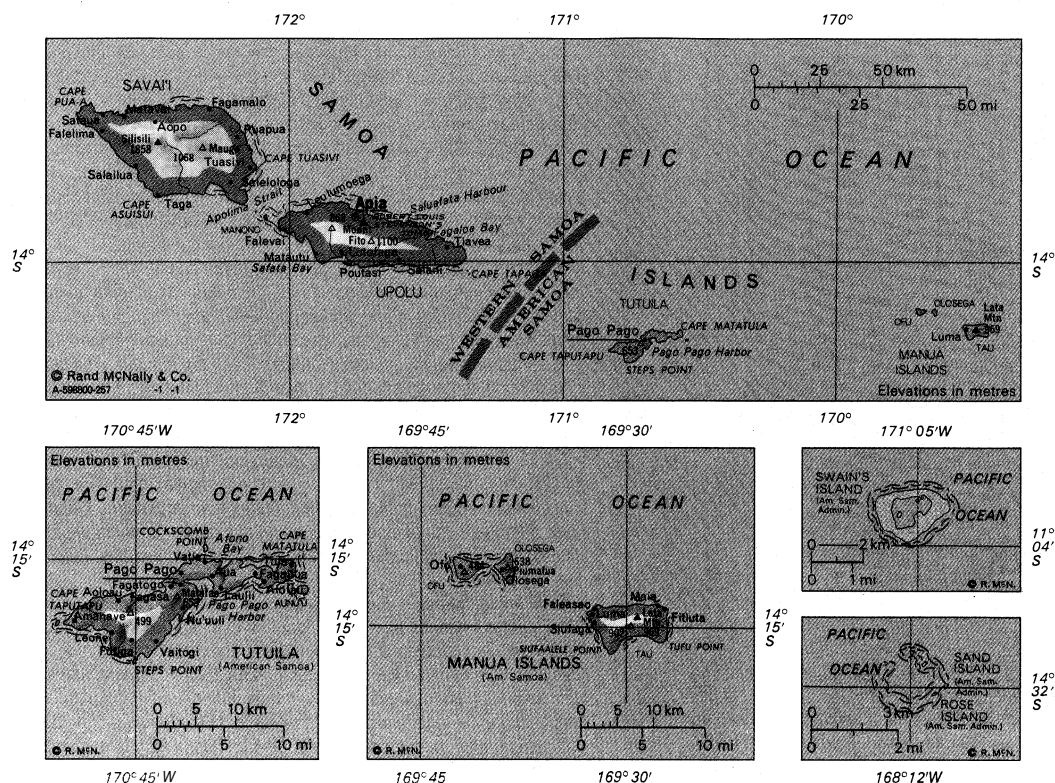

Climate. Rainfall varies from over 100 inches on the coasts to 300 inches inland, but porous soils and rocks make water supplies unreliable. Hence, coastal wells are the only water source for almost half the rural population. Temperatures are unusually constant, the monthly mean varying only 1.2° F (0.7° C) from an average of 79° F (26° C). The southeast trade winds prevail, varying occasionally to northerlies during the wet season, from November to March. Hurricanes are liable to occur between May and November.

Animal life. The islands are not rich in animal life. Nevertheless, of the 53 species of birds, at least 16 are unique, including a rare tooth-billed pigeon. The only native mammals are the flying fox and smaller bats. There are several lizards and two harmless snakes of the boa family. Rats, wild cattle, and pigs have been introduced. There are centipedes and millipedes, scorpions, spiders, and a rich insect life. A United Nations-South Pacific Commission project has been studying methods to control the rhinoceros beetle, which attacks the copra crop.

People and population. The Samoan people are of eastern Polynesian stock. Their language, believed to be the oldest of the Polynesian tongues, is closely related to the Maori, Tahitian, Hawaiian, and Tongan languages. Within the villages, close kinship ties have traditionally bound individuals into a sternly collectivist society. Elected family leaders called *matai* (titled chiefs or orators) form village or district councils to administer group affairs. Extended blood ties linked family or village groups; beyond the social framework of well-regulated village life a network of allegiances arose, with the major families striving for supremacy and regularly plunging

Village

culture

Commer-
cial
import-
ance

the islands into warfare. The material culture was utilitarian, and most artifacts are unadorned. There appears to have been no dominant priestly class; family elders performed the rituals of a pantheistic religion.

While European contact and the introduction of a cash economy have produced some changes in values and traditional authority, preservation of the culture has become a shibboleth amongst Samoan leaders, particularly in Western Samoa; many outward features of rural life have thus remained virtually unchanged. The Christian churches were easily absorbed into the village social structure; sanctuaries of cathedral proportions made of coral cement dot the most remote settlements. The Congregational Christian Church (formerly the London Missionary Society) is predominant, followed by the Methodist and the Roman Catholic faiths, and the Church of Jesus Christ of Latter-day Saints mission.

The population of American Samoa in 1970 was over 27,000; of these 4,000 lived in Pago Pago and Fagatoga, and 21,000 on Tutuila Island. It was estimated that an additional 20,000 American Samoans were living in Hawaii and in California. Out of the total population of Western Samoa of 149,000, one-fifth lived in Apia and three-quarters on Upolu Island. Many Western Samoans lived overseas, perhaps as many as 20,000 of them in New Zealand.

The economy. *American Samoa.* The United States administration, with about 3,000 employees, is the main employer. Tuna canning (by American-owned canneries) and tourism are major industries, in addition to those in the retail business sector. The canneries are supplied by a fleet of about 150 oriental vessels and employ about 1,000 Samoans to process the catch. Tourists in 1971 totalled nearly 30,000. A major hotel is owned by a corporation, whose shareholders are mostly Samoan. One other hotel is in operation, and more are planned, and the government has formed a development bank to encourage the establishment of light industry.

Apart from the cultivation of copra on the outlying islands, agriculture is not widely practiced, although family gardens provide subsistence crops to supplement cash wages. Fewer than 200 acres are under commercial cultivation, mostly vegetable gardens for local markets.

Social legislation ties American Samoa more closely to U.S. costs of living than its South Pacific neighbours,

Western Samoa. Fish and timber are the only exploitable large-scale natural resources. A United States company opened a large veneer and lumber operation on Savai'i in 1971; and fisheries research and promotion is in progress. The growing of cash crops for local sale or export has been difficult; individual commercial enterprise is not suited to the communal way of life. Despite this, such export crops as copra, cocoa, and bananas, nevertheless provide strong support for the economy.

The balance of payments position is favourable, assisted by a growing tourist industry, now second in economic importance only to copra, and to the receipt of remittances from family members overseas, particularly in New Zealand.

Tourism was increasing in the early 1970s. To encourage the industry, a new airstrip and a road from the airport to Apia have been built with the aid of an Asian Development Bank Loan, and more hotel projects are planned in addition to those now operating.

Transport. Regular shipping services link the islands with ports abroad; international airlines operate flights to and from the United States, New Zealand, and Fiji. The principal trade and transport links are with Hawaii and California to the north, and Fiji, New Zealand, and Australia to the south.

Administration and social conditions. *American Samoa.* American Samoa is an unincorporated, unorganized territory, the people of which are United States nationals but not citizens. The territory is administered by the United States Department of the Interior, which appoints the governor.

Under the islands' second constitution, adopted in 1966, the Fono (bicameral legislature) is autonomous in its disposition of local revenues. The 21 members of the House of Representatives are elected by universal suffrage; the minimum voting age is 18. The 18 senators are chosen by councils of chiefs, in accordance with Samoan custom. The 1970 Commission on Future Political Status recommended that the present status be retained but that the governor and senate be elected. An unofficial delegate to the Congress of the United States was elected in 1970. Apart from Swains Island, the islands are divided into three administrative districts (each with an appointed district governor), which are subdivided into a total of 14 counties. Chiefs representing each family form village and district councils. This autonomous village control is linked with the central government through three district governors appointed by the governor. Each village has a Samoan magistrate with authority to adjudicate on minor misdemeanours.

Administration: Western Samoa. In 1962 Western Samoa became the first independent Polynesian state, and in 1970 it joined the Commonwealth of Nations. The constitution provides for parliamentary government. There were originally two heads of state, with the provision that when one died the other would continue as sole head of state for life, after which the head of state would be elected by the Parliament for a five-year term. The present surviving head of state is Malietoa Tanumafili II. The prime minister is elected by the Parliament and appoints a cabinet of eight other ministers from elected members.

The parliament has 45 Samoan members, and two representing the Individual Voters, who are mixed blood or non-Samoan citizens claiming European status and enjoying universal suffrage. In the 41 Samoan electorates, only chiefs are eligible as candidates or voters, but they in their turn have been chosen by consensus of their entire family. In each village, chiefs form a council to run their own affairs, and there is little contact with the central government.

Education. Education is compulsory between the ages of six and 18 in American Samoa; 36 percent of the population is of school age. Televised instruction over six channels, given mostly by teachers and technicians from the United States, is available to local schools. In Western Samoa more than half the population is under the age of 15; although education is not yet free or compulsory, most children receive a primary education. Selected pupils are sent to government or mission high schools.

Prospects for the future: Western Samoa. There is a need to diversify the economy to support the fast-growing population—expanding at a rate of 2.9 percent a year. To meet this need research is being pursued with help from the United Nations Development Program, from New Zealand, and other sources. Some secondary industries have already been established. These, along with beef farming, food processing, canning, tourism, and

the cultivation of export crops will form the mainstay of the economy in the foreseeable future. At the same time a family-planning campaign is being instituted to prevent a booming population from lowering the standard of living.

A major aim of Samoan leaders is to create jobs in order to lessen the emigration of young people to Hawaii and the United States mainland. Such growth in industry would also enable the territory to provide more of its own revenue, and thus diminish reliance on the United States subsidies, thus tying living costs less closely to those in the United States. The retention of Samoan control over land is the main bulwark against radical changes in the life-style of both the Samoans.

BIBLIOGRAPHY. The traditional way of life in the Samoas is described most definitively in A.F. KRAMER, *Die Samoa-Inseln*, 2 vol. (1902–03); and SIR PETER H. BUCK, *Samoan Material Culture* (1930). The customs of the people are discussed in MARGARET MEAD, *Coining of Age in Samoa* (1928, reprinted many times); and F.M. and M.M. KEESING, *Elite Communication of Samoa: A Study of Leadership* (1956). For historical reference, see R.P. GILSON, *Samoa 1830 to 1900: The Politics of a Multi-Cultural Community* (1970); and J.A.C. GRAY, *Amerika Samoa: A History of American Samoa and Its United States Naval Administration* (1960); and for political development in Western Samoa, J.W. DAVIDSON, *Samoa mo Samoa* (1967). Geographical publications are JAMES W. FOX and KENNETH B. CUMBERLAND (eds.), *Western Samoa: Land, Life, and Agriculture in Tropical Polynesia* (1962); and MYRTLE J. ASHMOLE, *Guide to the Birds of Samoa* (1963), practically the only reference for natural history. Modern development in the islands is dealt with in F.M. KEESING, *The South Seas in the Modern World*, rev. ed. (1945); and D. PITT, *Tradition and Economic Progress in Samoa* (1970); the WOLF MANAGEMENT SERVICES, *Economic Development Plan for American Samoa* (1967); and the DEPARTMENT OF ECONOMIC DEVELOPMENT, APA, *Western Samoa: Second Five-Year Development Plan* (1970).

(P.R.C.)

Samuel

Samuel, the most outstanding religious hero in the history of Israel between Moses and David, is represented in the Old Testament in every role of leadership open to a Jewish man of his day—seer, priest, judge, prophet, and military leader; his greatest distinction, however, was his role in the establishment of the monarchy. Although no exact dates can be given for him, he was a contemporary of Saul, the first king of Israel, who is placed by historians roughly in the period 1050–1010 BC.

Information about Samuel is contained in the First Book of Samuel. The ancient designation of the two books of Samuel does not indicate that he is the author (in fact, his death is related in I Sam. 25) or the hero of the books; indeed, it is difficult to deduce what the title was intended to mean.

Samuel, the son of Elkanah (of Ephraim) and Hannah, was born in answer to the prayer of his previously childless mother. In gratitude she dedicated him to the service of the chief sanctuary of Shiloh, in the charge of the priest Eli; as a boy Samuel received a divine oracle in which the fall of the house of Eli was predicted (I Sam. 1–3). When he became an adult, Samuel inspired Israel to a great victory over the Philistines at Ebenezer (chapter 7). The proposal of the elders of Israel to install a king was indignantly rejected by Samuel as infidelity to Yahweh, the God of Israel (chapter 8). By the revelation of Yahweh, however, he anointed Saul king and installed him before all Israel (chapters 9–10). Saul was vindicated as king by his leadership of Israel in a campaign against the Ammonites (chapter 11); after this, Samuel retired from the leadership of Israel (chapter 12). He reappeared, however, to announce the oracle of Yahweh rejecting Saul as king, once for arrogating to himself the right of sacrifice (chapter 13) and a second time for failing to carry out the law of the ban—a primitive institution by which persons or objects were devoted to the deity, normally by destruction—against the Amalekites (chapter 15). By the oracle of Yahweh, Samuel secretly anointed David as king (chapter 16). He then faded into the background, appearing at the sanctuary

Samuel's
priestly
leadership

Increase
in
tourism

of Naoth (chapter 19). He died, and his ghost was evoked by a necromancer, or sorceress, at the request of Saul; he then announced a third time the rejection of Saul (chapter 28).

Samuel thus appears as a leader in all Israel; his leadership is exercised in war and law, but his authority is basically religious, mostly prophetic, although with some features of priestly authority. He appears at first as being hostile to the monarchy and then as being favourable to it. He is the spokesman of Yahweh in the election both of Saul and of David. Yet, the picture is not entirely straightforward, and a close examination of the material, as conducted by a large number of critical historians, reveals inconsistencies that raise questions about both the history of Samuel and the sources in which this history has been preserved. The same examination reveals that none of the material in its present form was contemporary with the events; if one source is taken as controlling, then the other materials lose all historical value.

The "pro-monarchic" and "anti-monarchic" sources

The two major divergences lie in those passages that critics call the "pro-monarchic" source (I Sam. 9:1–10:16) and the "anti-monarchic" source (I Sam. 8 and 10:17–27). The word source here means tradition rather than a hypothetical document that can be reconstructed. In the pro-monarchic account of the rise of Saul, Samuel is an obscure village seer (with distinct evidence of occult practices). The institution of the monarchy and the election of the King occur according to the will of Yahweh as revealed to Samuel. The story of the anointing, however, has no story of accession to complete it; instead, there is the account of Saul's victory over the Ammonites. Examination discloses that this is still another account of Saul's rise without an anointing story; Saul is chosen king as the judges—the leaders of the Israelites during their conquest of the land of Canaan—were chosen, by a charismatic display of military courage and leadership. Samuel was very probably intruded into this narrative.

The anti-monarchic account presents a different kingship, a different Saul, and a different Samuel. Samuel is a figure known through "all Israel" (a term of uncertain meaning at this period); his authority rests on his position as judge. The institution of kingship comes not from divine revelation but from the request of the elders of Israel, and this request is treated by Samuel as rebellion against Yahweh. The king is chosen not by divine election but by lot, implying that no special qualities were required, and the bashful candidate has to be summoned from a hiding place. This story is related to the account of Samuel as judge in chapters 7 and 12, and he is clearly presented as the last of the judges; it is indicated that the system of the judges was rejected by the Israelites not because of its failure but because of their worldliness. This tradition has two questionable features: Samuel is the only judge who is a permanent magistrate as well as a military leader, and his victory over the Philistines in chapter 7 cannot be historical.

The story of the birth and vocation of Samuel is regarded by critics as legendary because of a number of obviously unhistorical features. The narrative is the major piece in establishing the role of Samuel as a prophet, but it is questionable whether the "prophet" as a distinct religious figure had emerged at this early date. The story is also at the root of the priestly role imposed on Samuel at a later date in I Chron. 6; but this is an effort to explain in terms of the later priesthood the sacred functions performed by Samuel.

There are also two traditions in the account of the rejection of Saul by Samuel. The first story (chapter 13) is motivated by Saul's assumption of the prerogatives of the priesthood. It is quite unlikely that either the powers of the king or the prerogatives of the priest were as closely defined as this in the early period. The second story (chapter 15) is motivated by the failure of Saul to observe the ethic of the holy war. This story does not exhibit the same improbability. It seems that there was a firm tradition of a split between the two men but an inexact memory of the details of the incident.

There must have been some reason why Samuel was

important enough to be remembered for a major role in the establishment of the monarchy. Yet, his roles as prophet, seer, and judge are all incredible in certain respects, apart from the fact that each of them is considerable. The problem may be resolved by identifying a role for Samuel that receives only passing mention because it no longer existed when this material was written. This is his leadership of the sons of the prophets, a group of young men organized for ecstatic worship. Indications are that they were a group of fanatical religious and national conservatives. That they were young and active gave Samuel a base of power that was physical as well as moral. As conservatives, they must have been torn between the threat to Israel posed by the Philistines and the promise that the new political system, alien to religious and national traditions, offered against this threat. This internal division in Israel is reflected in the person of Samuel, who stood with most Israelites on both sides of the question.

BIBLIOGRAPHY. Two recent histories of Israel, JOHN BRIGT, *A History of Israel*, pp. 163–172 (1959); and MARTIN NOTH, *Geschichte Israels*, 3rd ed. (1956; Eng. trans., *The History of Israel*, 2nd ed., pp. 168–176, 1960), represent the two dominant schools of thought in Israelite historiography. H.W. HERTZBERG, *Die Samuelbücher*, 2nd ed. (1960; Eng. trans., *I & II Samuel: A Commentary*, 1964), is the most recent thorough study of the texts on which the history depends, and deals with both criticism and exegesis.

(J.L.McK.)

Sand Sheets and Sand Dunes

A dune is a mound of windblown sand. The smallest dunes are about a metre (three feet) high and cover about ten square metres (107 square feet); the largest may be over 400 metres (1,300 feet) high and cover several square kilometres. Large areas of gently undulating sandy surfaces with low local relief are called sand sheets. Because aerial photography shows these to have **dunelike** patterns and other evidence shows them to be wind-blown, it is appropriate to describe them with dunes.

True sand dunes are found in very arid areas and are the result of the movement of sand grains by the wind under the influence of gravity. They are comparable to other forms that appear when a fluid moves over a loose bed, such as subaqueous "dunes" on the beds of rivers and tidal estuaries **and** sand waves on the continental shelves beneath shallow seas and are known as "bedforms." True dunes must be distinguished from dunes formed in conjunction with vegetation. The latter cover relatively small areas on quite humid coastlands and also occur on the semi-arid margins of deserts. True dunes cover much more extensive areas, primarily in the great sand seas (ergs), some of which are as big as France or Texas, but they also occur as small isolated dunes on hard desert surfaces. Sand sheets are poorly mapped, but some are probably almost as extensive as some of the great sand seas.

In the last 2,000,000 years or so the areas of very low rainfall in which true dunes form expanded once or twice into areas that are now more humid. The best evidence for these changes is the presence of sand seas that are now immobilized by vegetation. Dunes were not uncommon in the geological past, and at certain times there were deserts as extensive as modern ones. Rocks formed by the solidification of ancient sand seas occur, for example, in the walls of the Grand Canyon, Arizona; in the west Midlands of England; and in southern Brazil.

This article treats dune formation, fixed and mobile dunes and their patterns, and the basic characteristics of sand sheets and sandy terrains. For further information on the arid environment in general, see DESERTS. See also WIND ACTION; PLAYAS, PANS, AND SALINE FLATS for discussions of deflation or erosion by the wind.

DUNE FORMATION

An understanding of sand dunes requires a basic knowledge of their sands, the winds, and the interactions of these main elements; these factors will be treated in **turn**.

Sands. Dunes are almost invariably built of particles of sand size. Clay particles are not usually picked up by

Samuel's importance

the wind because of their mutual coherence, and if they are picked up they tend to be lifted high into the air. Only where clays are aggregated into particles of sand size, as on the Gulf Coast of Texas, will they be formed into dunes. Silt is more easily picked up by the wind but is carried away faster than sand, and there are few signs of dunelike bed forms where silt is deposited, for instance as sheets of loess (*q.v.*). Particles coarser than sands, such as small pebbles, only form dunelike features when there are strong and persistent winds, as on top of some sea cliffs in Peru. Even larger particles, such as small boulders, can only be moved by the wind on such slippery surfaces as ice or wet saline mud and never form into dunes.

Common dune sands have median grain diameters between 0.02 and 0.04 centimetres (0.008 and 0.016 inches). The maximum common range is between 0.01 and 0.07 centimetres. Most dune sands are well sorted, and a sample of sand from a dune will usually have particles of very similar size. The sand on sand sheets, however, is poorly sorted and often bimodal; that is, it is a mixture of coarse sands, often about 0.06 centimetres in diameter, and much finer sands, with few particles of intermediate size. Windblown (eolian) sands, especially the coarser particles, are often rounded and minutely pitted, the latter giving the grains a frosted appearance when seen under a microscope.

Minerals
in
windblown
sand

Most windblown sand is composed of quartz. Quartz exists in large quantities in many igneous and metamorphic rocks in crystals of sand size. It tends to accumulate when these rocks are weathered away because quartz resists chemical breakdown better than most minerals, which are taken away in solution. Most of the great sand seas occur in continental interiors that have been losing soluble material for millions of years; as a consequence, quartzose sandstones are common. These sandstones are eroded by rainwash and stream runoff, processes that are spasmodic but violent in deserts. The eroded products are transported to great interior basins where they are deposited. These alluvial deposits are the sources of most wind-blown sand. Quartz also predominates in most coastal dune sands, but there usually are considerable mixtures of other minerals in such dunes.

Dune sands not composed of quartz are rarer but not unknown. Near volcanic eruptions in Tanzania, for example, dunes are built of volcanic dust. In many arid areas, gypsum crystals of sand size are deposited on the floors of ephemeral lakes as the water dries out; they are then blown like sand to form dunes. Gypsum dunes occur in New Mexico, northern Algeria, and southwestern Australia. Some coastal dunes are built of broken shells, as in the western Isles of Scotland, or of broken coral, as in the West Indies. These carbonate sands are sometimes re cemented after deposition to become hard and rocklike. In desert and coastal dunes, heavy minerals are often sorted out and may occur in commercial concentrations, as does rutile on the southeastern Australian coast.

Winds. Winds have three sources of variation that are important, namely, direction, velocity, and turbulence. Most of the great deserts are found in the subtropical areas of high atmospheric pressure, where the winds circulate in a clockwise direction in the Northern Hemisphere and a counterclockwise direction in the Southern Hemisphere. The high-pressure systems tend to dip down to the east so that winds are stronger there, a pattern mirrored by the dunes. Poleward of these circulation systems are the zones of eastward moving depressions in which there are generally westerly winds that mold the dunes of the North American and Central Asian deserts and of the northwest Sahara. The boundaries between these two circulation systems migrate back and forth seasonally so that complicated dune patterns are found in the zones of overlap. Only a few deserts, such as the Thar Desert of India, are affected by monsoonal wind systems. Some dunes are built by local winds, as in coastal Peru. Coastal dunes in the temperate latitudes may sometimes be built by local winds, but in general they are built to greater heights on west coasts by the westerly winds.

The direction of the wind at any one place in the desert

is affected by a number of local factors. Winds are particularly channelled around topographical features, such as the Tibesti Massif in the Sahara, so that dunes are affected by different winds on different sides of the obstruction.

The pattern of wind velocity also is important. Like many natural phenomena, wind velocities have a log-normal distribution: there is a large number of moderate breezes, and a diminishing number of increasingly more violent winds. The greatest volumes of sand are probably moved by winds somewhat in excess of the median wind velocities. Strong winds often blow from a particular direction, as in the southern Sahara, where the strong winds of the sandstorms come predominantly from one direction and are responsible for the undulations of the sand sheets because they alone can move coarse sands. Lighter winds blow from several different directions, and the dunes, being of finer sand, are therefore affected by several winds.

Wind
velocity
patterns

The wind is retarded near the surface by friction. Above the ground the wind velocity increases rapidly. The near-surface velocity must rise above a certain threshold value before sand will be picked up, the value of this depending on the size of the sand grains; for example, a wind of 12 kilometres per hour (7 miles per hour) measured at a height of 10 metres (33 feet) is required to move sands 0.02 centimetre (0.8 inch) in diameter, and a 21-kilometre-per-hour (13-mile-per-hour) wind is required to move 0.06 centimetre (0.24 inch) sands. Once sand movement has been initiated by such a wind it can be maintained by lower wind speeds. Because instantaneous wind speeds in eddies can rise well above the average velocity, turbulence also is important, but it is difficult to measure. The amount of sand moved by a wind is a power function (exponential factor) of the windspeed; for example, a 10-kilometre-per-hour (6-mile-per-hour) wind carries 13 grams per hour (0.39 ounce per hour), a 20-kilometre-per-hour (12-mile-per-hour) wind carries 274 grams per hour (8 ounces per hour), and a 30-kilometre-per-hour (18-mile-per-hour) wind carries 1,179 grams per hour (35 ounces per hour). A wind of a particular velocity will move fewer larger than smaller grains.

Growth of a dune. The dune-forming process is complex, but an introductory account can be given based on the example of a single desert dune on a hard desert surface.

Three quarters of the sand carried by the wind moves as a mass of jumping (saltating) grains; the remaining quarter moves slowly along the surface as creep, kept in motion by the bombardment of the saltating grains. Saltating sand bounces more easily off hard surfaces than off soft ones so that more sand can be moved over a pebbly desert surface than over a smooth or soft one. Slight hollows or smoother patches will reduce the amount of sand that the wind can carry, and a small sand patch will be initiated. If it is large enough, this patch will attract more sand.

The wind adjusts its velocity gradient on reaching the sand patch; winds above a certain speed decrease their near-surface velocity and deposit sand on the patch. This adjustment takes place over several metres, the sand being deposited over this distance, and a dune is built up. The growth of this dune cannot continue indefinitely; the windward slope is eventually adjusted so that there is an increase in the near-surface velocity up its face to compensate for the drag imposed by the sandy surface. When this happens, the dune stops growing and there is no net gain or loss of sand.

As the dune grows, the smooth leeward slope steepens until the wind cannot be deflected down sharply enough to follow it; the wind then separates from the surface leaving a "dead zone" in the lee into which falls the sand brought up the windward slope. When this depositional slope is steepened to the angle of repose of dry sand (about 32°), this angle is maintained and the added sand slips down the slope or slip face. When this happens, the dune form is stabilized, and the dune moves forward as a whole, sand being eroded from the windward side and deposited on the lee.

Angle of
repose and
the slip
face

If, from meteorological measurements the regional rate of sand flow can be calculated, and if it is assumed that the dune has a simple cross section that migrates forward without change of form, a formula for the rate of movement of a dune that agrees with actual measurements can be derived. In Peru dunes have been observed to move at 30 metres per year (100 feet per year), and in California rates of 25 metres per year (82 feet per year) have been measured.

Dune patterns. Thus far it has been assumed that the wind is a homogeneous stream of air blowing from one constant direction. If this were so, long straight dunes oriented at right angles to the wind would result. But most dunes are neither straight nor at right angles to the wind, and this indicates that the winds are not a uniform stream or that they blow from different directions.

Barchan dunes (small crescent-shaped sand bodies) occur in areas where the regional wind blows consistently from one direction. Their crescentic shape must be due to spatial variations in wind velocity and the regular repetition of dune shapes and spacings when they are close together indicate that the variations in the wind are also regular. This is a property common to all bed forms. It is thought that flow of a fluid (air or water) arranges itself in long spiral vortices parallel to the direction of flow, which, with zones of faster and slower velocities arranged transverse to the flow, gives a regular sinuous pattern on the bed.

Where there is a continuous sand cover, a varied dune pattern results from the pattern of flow. The main forms are transverse ridges composed of alternating crescentic elements, like barchans, facing downwind, and other crescentic elements facing upwind. These enclose between them a regular pattern of small hollows. Superimposed on this are small straight ridges parallel with the flow. These elements form a network pattern that is extremely common in the great sand seas. The slip faces reach a maximum height of about 10 metres (33 feet), and the dunes are about 100 metres (330 feet) apart.

An important feature of sandy terrains is that their forms occur at a number of distinct sizes. Large features are covered with smaller ones, and the smaller ones are covered with ripples. Between these size groupings there are no features of intermediate size. This is an example of bed-form hierarchy; the two most important groups in this particular hierarchy are the dunes, which are seldom higher than about 20 metres (66 feet) or more than about 200 metres (660 feet) apart, and *draa* (a north Saharan term for large sand features), which can be over 200 metres high and are usually over one kilometre (0.6 mile) apart. In the larger sand seas there is usually a massive skeleton of *draa* sometimes arranged parallel to the apparent flow, in long ridges, and sometimes transverse to it in great sand waves. The *draa* are usually covered with a dune pattern. Within each of the size groups of the hierarchy (ripples, dunes, or *draa*) there are variations in size depending on grain size and wind velocity; for example, whereas most ripples are

Sand dunes in irregular patches that rise as high as 600 feet from the ground, Libyan Desert.

Aero Service Corporation, Division of Litton Industries

spaced only a few centimetres apart, "mega-ripples," built in very coarse sand, are spaced almost as far apart as small dunes; and whereas most dunes are about 100 metres apart, the low undulations of coarse sand on sand sheets are up to 500 metres apart.

Other dune forms can be related to variations in the overall wind direction, usually on a seasonal cycle. There is some evidence for example, that the linear seif dune, which has steep slopes on either side and a sharp sinuous summit, occurs in areas where two or more sand-carrying winds blow at an acute angle to each other, the alignment of the seif being that of the resultant of these winds. Seif, however, can have very puzzling patterns, such as two crossing directions, and meanders, which must be explained in other ways. Most seif occur in open desert resting on a coarse sand sheet.

In some areas, winds from opposed directions blow at different seasons. In the San Luis Valley in Colorado, for example, westerly winds bring sand from the west for most of the year, but on the eastern side of the valley the sands meet easterly winds at some seasons, so that "reversing dunes" are formed, in which the slip faces face first in one direction and then in the other.

In the northwestern Sahara, the sand seas have a complex pattern of intersecting *draa* ridges, probably built by consistent seasonal combinations of winds, blowing over thousands of years. Where these patterns are particularly complex, they break up into regularly spaced pyramidal dunes of great size.

Distinct dunes are formed around topographic obstructions. Sheltered zones are found on the lee of small hills into which the sand migrates from the wind to form one or two trailing seif-like dunes, depending on the width of the hill. If the wind meets a high scarp or large hill massif, an "echo dune" is deposited on the upwind side separated from the scarp by a rolling eddy of air that keeps a corridor free of sand. Many oases and routeways are found in this kind of corridor. Echo dunes are the largest dunes in the desert, sometimes reaching a height of more than 400 metres (1,300 feet).

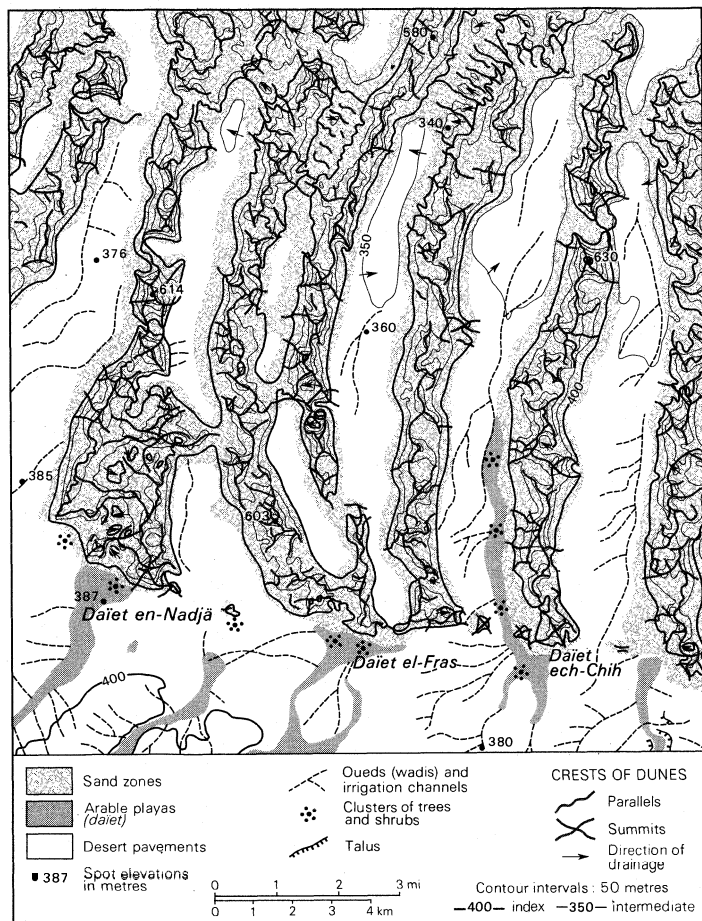

Most sand sheets (known in the Sahara as *serir*) have coarse bimodal sands and low undulating dune forms. Where there are large amounts of coarse sand, the *serir* may be almost completely flat. Some thin drifts of sand are found where the desert floor is too rough to allow dunes to form.

The role of vegetation. Dunes on coasts and in semi-arid areas have distinctive forms of two kinds: those built up around vegetation and those formed when the plant cover is destroyed. Winds blowing off a beach carry sand inland where the stems and fronds of plants slow it down so that the sand builds up a shore dune parallel to the beach. Some plants are adapted to live in these conditions, and in fact thrive on the continued supply of nutrients; marram grass (*Ammophila arenaria*), a native of north-western Europe, is one of the best known of these dune-adapted plants and has been introduced to many coasts expressly to stabilize the dunes. On coasts where it did not exist before introduction, such as in the northwestern United States or on desert or wet tropical coasts where sand-fixing plants do not thrive, there are no typical shore dunes.

The supply of sand for dune formation is renewed on the beach by longshore drift in the sea. A wide tidal range, exposing a wide foreshore, encourages dunes, but on lakes such as Lake Michigan, the role of tides can be played by fluctuations in lake levels. Some shore dunes, for instance, in southwestern France, can grow to very great heights; but as with desert dunes, there is a stable height beyond which growth stops. On shores that are themselves being built out by the sea, a series of dunes parallel to the shore often forms. Dunes also form around plants in the desert where these are fed by subterranean water. The usual dune forms in such instances are isolated mounds around each plant and are known as coppice dunes or nebkha.

Shore dunes, even when vegetated, are very unstable. Breaches in the plant cover are enlarged by the wind into blowouts facing the wind. These are then further enlarged by erosion, often down to a hard bed or the water table; the sand blown out of them covers and kills the plants downwind so that a free dune may form, which then moves downwind, leaving trailing edges of sand on either side to form a U-shaped, or parabolic dune, eventu-

ally stabilized again with vegetation. A series of these dunes moving downwind may form "nested parabolics."

In semi-arid areas, hollows may be eroded by the wind in a similar way, and the eroded material then forms a U-shaped lunette on the downwind side. If the hollow is filled with water draining off the land, salt crystals, deposited when the water dries up, loosen the other depositors of the lake bed. Clay, silt, sand, and salt are then blown onto the lunette, which is later stabilized by recrystallization of the salts or by plants. Lunettes are found in west Texas, northern Algeria, and southern Australia.

Extensive as the active sand seas are, there are areas of dunes fixed by vegetation that are nearly as extensive. They serve as undeniable evidence that the areas in which they are found were once more arid and are interesting because they indicate the nature of former climatic changes and because they are of much more use to man than free dunes.

Fixed dunes occur in cool temperate climates such as North America or northern and eastern Europe, where they were formed beyond the edges of the ice during the last glaciation, when conditions were evidently cool and dry and when winds were intensified around the ice sheets. They also occur on the edges of the tropical and subtropical deserts, where they formed when the deserts expanded during the Pleistocene Epoch (10,000 to 2,500,000 years ago), and on the edges of the Soviet and Chinese deserts. On the North American high plains, in Hungary, and in Mongolia, the fixed sands have a cover of rich grassland. In Poland they are covered with coniferous forest. On the southern edges of the Sahara the grassland of the desert margins merges into a zone in which the gum arabic tree (*Acacia senegal*) is dominant and then into zones of thick impenetrable bush with broadleaved species in which the rainfall may reach 1,000 millimetres (40 inches) a year. Patterns of vegetation that are similar to those in the southern Sahara are found on the edges of the Kalahari, Indian, and Australian deserts.

The dune patterns on these fixed sands bear a close resemblance to those in active sand seas, except that their forms are rounded and subdued. Because relationships between the winds and forms of the active sands can only be assumed, conclusions about the changes in wind patterns since the fixed sands were formed must be tentative. In The Sudan, for example, it seems likely that the wind and rainfall belts were both some 450 kilometres (270 miles) south of their present positions at the height of the dune-building period. In Poland at the turn of the century, there were lengthy arguments between those who believed that the fixed dunes were barchans formed by strong easterly winds and those who, it now seems correctly, saw the accumulations as parabolic dunes formed by westerly winds.

Some coastal dunes also yield evidence of formerly different conditions. Ancient lake shores are shown to have existed in North Dakota, to the south of modern Lake Chad, and to the west of the lower White Nile by a series of fixed shore dunes. On the coasts of California, the modern dunes are formed on top of ancient dunes, which were connected with a different sea level in the recent past. In the Bahamas, carbonate dunes were built when the sea level was lower, and they since have been cemented and flooded by the sea to form the bases of many islands. In southeastern Australia, a whole series of ancient ridges is visible evidence for a progressive retreat of the sea.

SAND TERRAINS

Characteristics. The firm, gently undulating sand sheets that are ideal for motor transport contrast with the variable topography and treacherous surfaces of dunes; the latter are difficult to traverse even on camel. Dune surfaces have great contrasts in firmness due mainly to the way in which the sand is laid down. Most of the body of a dune consists of sand laid down on the slip face, for as the dune moves forward this sand is constantly being re-exposed on the windward slope. These beds are very soft, in contrast to the flatbedded sands

Fixed dunes

laid down on top of the dune and in the intervening hollows.

In few of the great sand seas are there extensive continuous areas of dunes. There are usually many corridors of firm sand sheet or desert floor on which travel is easy and routes often follow these in a tortuous pattern.

The surfaces of coastal and fixed dunes need to be treated with caution; the plant cover is usually fragile, and when it is destroyed by the passage of a few hooves or wheels, the sand beneath becomes a loose and difficult surface.

One valuable property of windblown sands is that they are highly permeable to water. The actual infiltration rate depends on several things: water penetrates more quickly into the slip-face-bedded sands than into flatbedded sands and into well sorted better than poorly sorted sands (since fine particles fill up the spaces between the coarse ones in the latter); and some humus substances can reduce the wettability of the soils if they coat the sand particles. Most sandy soils imbibe water easily, however, and the high air content of the upper soil insulates the water from evaporation. Plants, too, can remove water more easily from sandy than from heavier soils, and thus sandy soils often support the densest plant cover in arid and semi-arid areas. Sandy terrains have virtually no surface drainage.

Coastal dunes in temperate climates provide poor dry soils, but their permeability means that they can be used as storage reservoirs for domestic and industrial water supplies, as they are, to great advantage, in The Netherlands.

Economic importance. Although many desert sand seas are relatively unexplored, it is probable that they are of little agricultural or industrial value. They occur in areas of extreme aridity, most of which have been arid for millions of years, and their lack of vegetation cannot be attributed to depredation by man. Even if water became readily available, their poorly permeable soils would make them difficult to cultivate. They are unlikely to contain many mineable concentrations of minerals. Although gypsum sands are mined at present, they are of very limited extent; quartz for use as building sand and in glass manufacture occurs in vast quantities, but it is remotely situated, and foreseeable demands are quite likely to be minute when compared to the vastness of the sands.

Sand seas will probably be opened up in other ways. Many of the rocks beneath the barren sands do have valuable deposits of oil or minerals, and many are being opened up for the first time by prospecting and mining. As the world's population expands and as some of it becomes more affluent and claustrophobic, sand seas will probably become vast recreation parks as they are already in the United States. Dunes have many advantages for recreation: they have variety; they can absorb many people in relative privacy; they are virtually indestructible; they can be exciting for such sports as racing or exploring with especially equipped vehicles such as "dune buggies"; and they are dry and absorbent and for that reason are hygienic.

Fixed dunes, on the other hand, support very dense agricultural populations, as in northern Nigeria and Senegal, where they produce huge amounts of groundnuts (peanuts). In Nebraska, pasture lands on fixed sands produce some of the world's finest cattle. Settled systems of agriculture, however, are less common on fixed sands than seminomadic cattle herding, although cattle grazing has its dangers on these soils. In recent years cattle numbers have grown very rapidly, and although deep wells have opened up new areas, overgrazing around the wells has meant that the vegetation cover has often been completely removed and consequently the sands have started to move again. Local customs have made it difficult to find the best plan for the wise use of these lands, but properly managed they provide a rich potential source of protein.

Temperate coastal dunes are seldom of use agriculturally, being more used for forestry or recreation. Too many

human feet, however, like too many cattle hooves, can destroy the plant cover and so lead to blowouts and the loss of nearby agricultural land in the subsequent burial by moving sand. In The Netherlands, for example, this has to be watched very carefully because the dunes provide an essential protection from the sea for the farmland and cities behind. Coastal dunes occur near many large cities and are therefore convenient, if not ideal, building land. Parts of Liverpool, Ostend, The Hague, Durban, and much of San Francisco are built on coastal dunes. In some places the higher dunes are used as a convenient water reservoir for such cities.

Sandstones

The weathering of rocks into their constituent mineral grains yields great quantities of sand-sized particles. This material is carried down rivers to the coast where it accumulates as dunes on beaches and as submarine bars, deltas, and other offshore deposits. Gradual consolidation converts such sand deposits into sandstone, which is one of the sedimentary rocks (*q.v.*).

Sandstones generally are defined as consisting mainly of grains between 0.06 and 2 millimetres (0.00234 and 0.078 inch) in diameter; they grade on the one hand into conglomerates (*q.v.*) and breccias and on the other into siltstones and shales (*q.v.*). When the proportion of shell fragments, oolites, and other biogenic material increases, they also grade into limestones.

Most sandstones are resistant to erosion, and they form about one-fourth of the sedimentary rocks of the earth's crust and thus create the backbone of many mountain ranges, such as the Appalachians, Carpathians, Pennines, and Appenines. Sandstone beds that are gently folded or nearly horizontal tend to form plains and uplands on which poor soils develop.

There are three basic components of sandstones. These are (1) detrital grains, mainly transported, sand-sized minerals such as quartz and feldspar; (2) a detrital matrix of clay or mud, which is absent in "clean" sandstones; and (3) a cement that is chemically precipitated in crystalline form from solution and that serves to fill up original pore spaces. The conversion of any sediment to rock is called diagenesis. Most diagenesis is caused by cementation, but some occurs by the recrystallization of clay minerals (*q.v.*). Some sandstones that have no cement and little or no clay matrix are loose enough to be crushed with the fingers. Sandstones bonded with calcite or iron oxide cements are moderately hard. The hardest of all sandstones are those in which the pore spaces have been completely filled with chemically precipitated quartz cement, particularly if this quartz is in crystallographic continuity with detrital quartz grains. In this event, the quartz has the strength that would be attributable to a single mass. The original, detrital quartz grain is separated from the overgrowth by a thin line of water bubbles, clay, or hematite (iron oxide). These thoroughly cemented, quartz-rich rocks, or quartzites, form some of the hardest, most resistant rocks in the earth's crust. The Tuscarora Quartzite of Silurian (395,000,000 to 420,000,000 years ago) age, for example, makes the high ridges in most of the Appalachian Mountains.

Other minerals that may occur as cement in sandstones include feldspar, gypsum, barite, dolomite, opal, pyrite,

Sandstone components and colour

Agriculture on fixed dunes

and chert, among others. Deep burial of sandstones may produce more unusual cements, such as zeolites (*q.v.*) or chlorite, and the original clay matrix may be recrystallized to micas (*q.v.*). Electron luminescence examination of thin sections of such formations can reveal special features of cementation that are not visible by any other means. For the identification of very fine-grained or complex minerals such as clays or zeolites, X-ray diffraction may be necessary.

The colour of a sandstone depends upon its detrital grains and bonding material. An abundance of potassium feldspar often gives a pink colour; this is true of many arkoses, which are feldspar-rich sandstones. Fine-grained, dark-coloured rock fragments, such as pieces of slate, chert, or andesite, however, give a salt-and-pepper appearance to a sandstone. Iron oxide cement imparts tones of yellow, orange, brown, or red, whereas calcite cement imparts a gray colour. A sandstone consisting almost wholly of quartz grains cemented by quartz may be glassy and white. A chloritic clay matrix gives a greenish-black colour and extreme hardness; such rocks are called **gray-wackes** (*q.v.*).

Sandstones occur in strata of all geologic ages. Much of man's understanding of the depositional environment of ancient sandstones comes from detailed study of sand bodies forming today. One of the clues to the origin is the overall shape of the entire sand deposit. Inland desert sands today cover vast areas as a uniform blanket; some ancient sandstones in beds a few hundred feet thick but 1,000 or more miles in lateral extent, such as the Mesozoic Nubian Sandstone of North Africa, also may have formed as blankets of desert sand. Deposits from alluvial fans (*q.v.*) form thick, fault-bounded prisms. River sands today form "shoestring-shaped" bodies, tens of feet thick, a few hundred feet wide, up to 100 or more miles long, and usually oriented perpendicularly to the shoreline. In meandering back and forth, a river may construct a wide swath of sand deposits, mostly accumulating on meander-point bars. Beaches, coastal dunes, and barrier bars also form "shoestring" sands, but these are parallel to the shore. Deltaic sands show a fanlike pattern of radial, thick, finger-shaped sand bodies interbedded with muddy sediments. Submarine sand bodies are diverse, reflecting the complexities of underwater topography and currents. They may form great ribbons parallel with the current; huge submarine "dunes" or "sand waves" aligned perpendicularly to the current; or irregular shoals, bars, and sheets. Some sands are deposited in deep water by the action of density currents (*q.v.*), which flow down submarine slopes by reason of their high sediment concentrations and, hence, are called turbidity currents. These characteristically form thin beds **interbedded** with shales; sandstone beds often are graded from coarse grains at the base to fine grains at the top of the bed and commonly have a clay matrix.

BEDDING STRUCTURE

One of the most fruitful methods of deciphering the environment of deposition and direction of transport of ancient sandstones is detailed field study of the sedimentary structures.

Bedding in sandstones may be tens of feet thick, but it can range downward to paper-thin laminations, expressed by layers of clays, micas, heavy minerals, pebbles, or fossils. Flagstone breaks in very smooth, even layers a few inches thick and is used in paving. Thin, nearly horizontal lamination is characteristic of many ancient beach sandstones. Bedding surfaces of sandstones may be marked by ripples (almost always of subaqueous origin), by tracks and trails of organisms, and by elongated grains that are oriented by current flow (fossils, plant fragments, or even elongated sand grains). Sand grain orientation tends to parallel direction of the current; river-channel trends in fluvial sediments, wave-backwash direction in beach sands, and wind direction in aeolian sediments are examples of such orientation.

A great variety of markings, such as flutes and scour and fill grooves, can be found on the undersides of some sandstone beds. These markings are caused by swift cur-

rents during deposition; they are particularly abundant in sandstones deposited by turbidity currents.

Within the major beds, cross-bedding is common. This structure is developed by the migration of small ripples, sand waves, tidal-channel large-scale ripples, or dunes and consists of sets of beds that are inclined to the main horizontal bedding planes. Almost all sedimentary environments produce characteristic types of cross-beds; as one example, the lee faces of sand dunes (side not facing the wind) may bear cross-beds as much as 100 feet (35 metres) high and dipping 35°. This structure can be seen in modern desert dunes and in ancient dune sandstones such as the Jurassic Navajo Sandstone of the western United States. Cross-bedding that forms in river sands is generally six inches to three feet (0.174 to 1.04 metres) high and dips at angles of about 20°. Careful regional mapping of such cross-beds has contributed enormously to understanding of the directions of old shorelines, location of ancient landmasses, flow of river systems, and former wind belts.

Some sandstones contain series of graded beds. The grains at the base of a graded bed are coarse and gradually become finer upward, at which point there is a sharp change to the coarse basal layer of the overlying bed. Among the many mechanisms that can cause these changes in grain size are turbidity currents, but in general they can be caused by any cyclically repeated waning current.

After the sand is deposited, it may slide downslope or subside into soft underlying clays. This shifting gives rise to contorted or slumped bedding on a scale of inches to many tens of feet. Generally these are characteristic of unstable areas of rapid deposition.

Local cementation may result in concretions of calcite, pyrite, barite, and other minerals. These can range from sand crystals or barite roses to spheroidal or discoidal concretions tens of feet across.

The fossil content also is a useful guide to the depositional environment of sandstones. Desert sandstones usually lack fossils. River-channel and deltaic sandstones may contain fossil wood, plant fragments, fossil footprints, or vertebrate remains. Beach and shallow marine sands contain mollusks, arthropods, crinoids, and other marine creatures, though marine sandstones are much less fossiliferous than marine limestones. Deep-water sands are frequently devoid of skeletal fossils, although tracks and trails may be common. The fossils are not actually structures, of course, but the living organisms are able to produce these. Burrowing by organisms, for example, may cause small-scale structures, such as eyes and pods or tubules of sand.

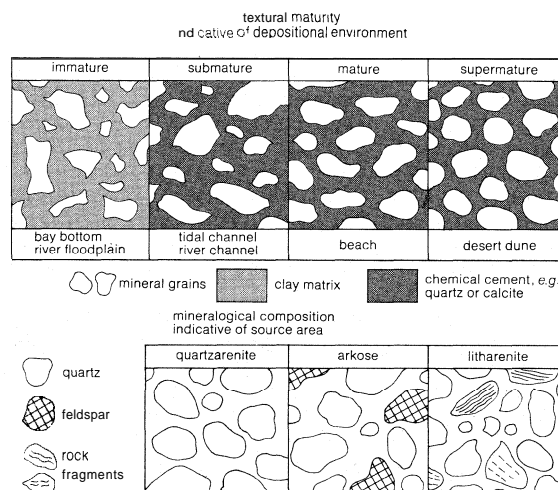

TEXTURES

The texture of a sandstone is the sum of such attributes as the clay matrix, the size and sorting of the detrital grains, and the roundness of these particles. To evaluate this

Graded beds, slump structures, and fossils

Formation of sandstones today

Bedding-plane markings and cross-bedding

Textural maturity and mineralogical composition of sandstones from various environments.

Degree of
textural
maturity

property, a scale of textural maturity that involved four textural stages was devised in 1951. These stages are described as follows.

Immature sandstones contain a clay matrix, and the sand-sized grains are usually angular and poorly sorted. This means that a wide range of sand sizes is present. Such sandstones are characteristic of environments in which sediment is dumped and is not thereafter worked upon by waves or currents. These environments include stagnant areas of sluggish currents such as lagoons (*q.v.*) or bay bottoms or undisturbed sea floor below the zone of wave or current action. Immature sands also form where sediments are rapidly deposited in subaerial environments, such as river floodplains, swamps, alluvial fans, or glacial margins. Submature sandstones are created by the removal of the clay matrix by current action. The sand grains are, however, still poorly sorted in these rocks. Submarine sandstones are common as river-channel sands, tidal-channel sands, and shallow submarine sands swept by unidirectional currents. Mature sandstones are clay free, and the sand grains are subangular; but they are well sorted, that is, of nearly uniform particle size. Typically, these sandstones form in environments of current reversal and continual washing, such as on beaches (*q.v.*). Supermature sandstones are those that are clay free; well sorted; and, in addition, those in which the grains are well rounded. These sandstones probably formed mostly as desert dunes, where intense aeolian abrasion over a very long period of time may abrade sand grains to nearly spherical shapes.

Grain-size
analysis

More detailed study of texture, first accomplished in 1898, involved grain-size analysis, and the establishment of the following grain-size terms: 1–2 mm (0.039–0.078 in.), very coarse sand; 0.5–1.0 mm (0.019–0.039 in.), coarse sand; 0.25–0.5 mm (0.009–0.019 in.), medium sand; 0.125–0.25 mm (0.0045–0.009 in.), fine sand; and 0.062–0.125 mm (0.0022–0.0045 in.), very fine sand. For purposes of analysis, the cement is removed chemically, and the sandstone is carefully broken down into its constituent detrital grains. These grains are then filtered through a stack of sieves with fixed, decreasing mesh size. Size can also be measured by allowing the grains to settle in a water column (the larger grains settle more rapidly). From these analyses a size frequency distribution showing the weight of grains in each size class can be constructed. Often an analysis of a beach or river sand will show a typical Gaussian curve or bell-shaped size distribution. A logarithmic transformation (the ϕ scale) invented in 1934 greatly facilitates statistical analysis. The main parameters it measures are mean size, standard deviation (a measure of sorting), skewness (symmetry of the frequency distribution), and kurtosis (peakedness).

Such information is useful in identifying depositional environments. For example, dune sands in all parts of the world tend to be in the 0.12–0.25 millimetre (0.0022–0.0045 inch) mean size range, because sand of that size is easiest to move by winds. Desert floor sediments tend to be bimodal or polymodal, with two (or more) abundant sizes of grains with a gap in between. Dune and beach sands exhibit the best sorting, and river and shallow marine sands are less well sorted. Such sediments as glacial tills, river-floodplain deposits, and submarine sands in areas of sluggish currents have much poorer sorting. Skewness serves to separate beach sands, which are often negatively skewed (with a tail of coarse grains), from dune and river sands, which tend to be positively skewed (with a tail of fine grains). Kurtosis is valuable in identifying sediments that have come from a mixture of two materials, such as beach sands blown into a muddy lagoon.

Shape
and
roundness

Careful analysis of grain roundness and grain shape also can aid in distinguishing the high-abrasion environments of beach and especially dune sands from those of fluvial or marine sands. Rounding takes place much more rapidly in sands subjected to wind action (*q.v.*) than in water-laid sands. In general, coarser sand grains are better rounded than finer grains because the coarser ones hit bottom more frequently and also hit with greater impact during transport. Sand grains may also have polished, frosted,

pitted, or otherwise characteristic surfaces. These depend on the grain size, the agent of transport, and the amount of chemical attack. For example, polish can occur on medium-grained beach sands and fine-grained desert sands and can also be produced chemically by weathering processes.

MINERAL COMPOSITION

Mineralogical study of sandstones has proceeded along two distinct lines. One method involves cutting a thin section (0.03 millimetre [0.0012 inch] thick) from the rock for examination of the mineralogy, cementation, texture, and structures with a petrographic microscope. This thin section approach was first used in the 1870s. Another method is to disaggregate the sand and place the grains in a heavy liquid such as bromoform (density about 2.8). This concentrates the heavy minerals that are present in minute amounts (0.01 to 1 or 2 percent of the rock) for detailed microscopic study. These methods offer valuable clues to source area composition.

Although sandstones may be composed of any mineral, the most common mineral is quartz (SiO_2), which comprises about 80 percent of the average sandstone; a few sandstones, however, lack quartz entirely, whereas others contain more than 99 percent quartz. Microscopic study reveals a great many types of quartz, recognizable by their appearance in polarized light and by inclusions of gas or liquid bubbles or other substances. Volcanic quartz, various types of metamorphic quartz, hydrothermal quartz, and other varieties are known. Other detrital minerals of common occurrence are the feldspars and micas. The abundance of these chemically less resistant silicates has been used as a climatic indicator. Sand-sized fragments of older fine-grained rocks (e.g., chert, slate, basalt) are common in many sandstones. Clay matrix, if present, may consist of the minerals illite, kaolinite, montmorillonite, or clay-sized micas. Some marine sandstones contain an abundance of pellets of glauconite (green-sands) or phosphates in the form of bones, teeth, scales, or chemical precipitates. These sands are useful as fertilizers.

CLASSIFICATION OF SANDSTONES

There are many different systems of mineralogic classification of sandstones. The system presented here is that

By courtesy of R.L. Folk

(Top left) Cambrian quartzarenite, cemented with calcite and typical of those formed originally as dune sands. (Top right) Silurian Tuscarora quartzite, a former beach sand. Quartz sand grains are well rounded and are completely cemented by quartz overgrowths visible as clear rims around the "dusty" detrital nuclei. (Bottom left) Submature calcilithite of the Ordovician Marathon Formation. (Bottom right) Chert-arenite consisting of about 50 percent quartz and 50 percent chert (finely speckled). It probably is a channel sandstone derived from older sedimentary rocks. (All photographs magnified about 50 X.)

of R.L. Folk (1966), based upon the concepts of P.D. Krynine, an American sedimentologist, and others. In it sandstones are divided into three main groups based on percentages of quartz, feldspar, and rock fragments. Clays are considered only in the textural part of the name (*e.g.*, clayey fine sandstone), and cements and accessory minerals are handled by descriptive adjectives. Rocks whose sand grains consist of more than 95 percent quartz are termed quartzarenites. If the sand grains consist of more than 25 percent feldspar, the rock is termed arkose; if the feldspar content is between 5 and 25 percent it is "subarkose." Sandstones with more than 25 percent rock fragments are called litharenites and are further subdivided according to the nature of the rock fragments (see below). "Sublitharenite" contains 5 to 25 percent rock fragments.

(Top left) Immature Devonian quartzarenite with clay matrix. This rock originated from turbidity-current deposition in a deepwater marine basin. (Top right) Precambrian subarkose with angular and poorly sorted grains. (Bottom left) Devonian phyllarenite consisting of about 50 percent quartz and 0 percent metamorphic rock fragments (speckled grains). (Bottom right) Carboniferous volcanic arenite with clay matrix and poorly sorted grains of volcanic rock fragments containing tiny feldspar laths. This sandstone was deposited in an island arc area. (All photographs magnified about 50 \times .)

Quartzarenites

Quartzarenites are usually white but may be any other colour; cementation by hematite, for example, makes them red. They are usually well sorted and well rounded (supermature) and often represent ancient dune, beach, or shallow marine deposits. Characteristically, they are ripple marked or cross-bedded and occur as very widespread thin blanket sands. On chemical analysis, some of these are found to contain more than 99 percent SiO_2 (silicon dioxide, or silica). Most commonly they are cemented with quartz, but calcite and iron oxide are also common cements.

This type of sandstone is widespread in stable areas of continents surrounding the craton (a stable area), such as central North America (St. Peter Sandstone, Ordovician), central Australia, or the Russian Platform, and are particularly common in Paleozoic strata. Quartzarenites have formed in the past when large areas of subcontinental dimensions were tectonically stable (not subject to uplift or deformation) and of low relief, so that extensive weathering (*q.v.*) could take place, accompanied by prolonged abrasion and sorting. This process eliminated all the unstable or readily decomposed minerals such as feldspar or rock fragments and concentrated pure quartz together with trace amounts of such resistant heavy minerals as zircon and tourmaline. Occasionally, deeply subsiding basins adjoining stable cratons were filled with many thousands of feet of quartzarenite. Quartzarenites also form in geosynclines (large

depositional troughs that are loci of mountain building) if the source area is sufficiently stable to permit beach abrasion and chemical weathering to remove rock fragments and feldspars. Apparently this was the origin of the Tuscarora Quartzite (Silurian) of the Appalachians.

Arkosic sandstones are of two types. The most common of these is a mixture of quartz, potash feldspar, and granitic rock fragments. Chemically, these rocks are 60–70 percent SiO_2 and 10–15 percent aluminum oxide (Al_2O_3), with significant amounts of potassium (K), sodium (Na), and other elements. This type of arkosic sandstone, or arkose, can form wherever block faulting of granitic rocks occurs, given rates of uplift, erosion, and deposition that are so great that chemical weathering is outweighed and feldspar can survive in a relatively unaltered state. These rocks are usually reddish, generally immature, very poorly sorted, and frequently interbedded with arkose conglomerate; alluvial fans or fluvial aprons are the main depositional environments. The Triassic Newark Group of Connecticut is a classic example of this type of arkosic sandstone.

Arkoses also form under desert (or rarely Arctic) conditions in which the rate of chemical decomposition of the parent granite or gneiss is very slow. These arkoses generally are well sorted and rounded (supermature) and show other desert features, such as aeolian cross-beds (of wind origin), associated gypsum, and other evaporitic minerals. The Precambrian Torridonian Arkose of Britain is thought to be of desert origin. Basal Sands deposited on a granitic-gneissic craton (stable continental interior) are also usually arkosic. Subarkose sandstones (*e.g.*, Millstone Grit, Carboniferous of England) have a feldspar content that is diminished by more extensive weathering or abrasion or by dilution from nonigneous source rocks.

Less commonly, arkoses may contain plagioclase feldspar (sodic to calcic types) as the dominant variety. These generally result from volcanic activity and are frequently associated with volcanic rock fragments and a chlorite matrix.

Litharenites occur in several subvarieties, but they are normally gray or of salt-and-pepper appearance because of the inclusion of dark-coloured rock fragments. Most commonly, fragments of metamorphic rocks such as slate, phyllite, or schist predominate; this dominance produces the phyllarenite variety of sandstone. If volcanic rock fragments such as andesite and basalt are most abundant, the rock is a volcanic arenite. It is termed a vitric arenite if glass predominates. These sandstones are transitional to tuffs (derived from volcanic dust and ash). Finally, if chert or carbonate rock fragments prevail, the rock is a chert arenite or calclithite. Texturally immature litharenites of Paleozoic age (225,000,000 to 570,000,000 years ago), if deposited in flysch sequences (rapidly deposited sands in Alpine zones) and involved in tectonic activity, may become extremely hard and have a dark greenish-black colour. These rocks are further described and discussed in the article GRAYWACKES.

Litharenites are a diverse family of rocks that in general were formed by rapid deposition under unstable tectonic conditions. Among the subvarieties, the phyllarenite is most common. It is a typical sandstone of geosynclines in which a low-rank (low temperatures and pressures of origin) metamorphic source of fold mountains with slates and phyllites has been exposed. These sandstones are usually rich in mica and texturally immature; the SiO_2 content is 60–70 percent; Al_2O_3 is 15 percent; and potassium, sodium, iron, calcium, and magnesium are present in lesser amounts. Most examples are deposited as fluvial apron, deltaic, coastal-plain, and shallow marine sandstones, interbedded with great thicknesses of shale and frequently with beds of coal or limestone. If laid down in an oxidizing environment, such as a well-drained river system, they are reddish (*e.g.*, Devonian Catskill Formation of New York or the Devonian Old Red Sandstone of England). Many sandstones of the Appalachians are phyllarenites, and they are common in the Carpathians and many other mountain chains. Heightened abrasion in the beach environment eliminates the soft rock fragments, and the rock

Arkosic sandstones

Litharenites and graywackes

may pass into a subphyllarenite; these are often good oil reservoirs, such as the Devonian Bradford Sand of Pennsylvania.

Volcanic arenites occur mainly in unstable, island-arc volcanic regions, such as the Paleozoic Tasman Geosyncline of Australia, and they also are deposited as continental beds derived from the erosion of volcanic terranes. Chert arenites and calcilithites result from rapid erosion of uplifted chert and carbonate mountain tracts, respectively. Many of these are alluvial fan deposits that front areas of intense faulting. Calcilithites are common among the younger sandstones of the Alps and Slovak Carpathians.

The study of heavy minerals reveals many details about changes in source area and climate and aids in the correlation of sandstones. Quartzarenites contain only the most durable and chemically stable heavy minerals, such as tourmaline, zircon, and magnetite; yet these minerals may be present in a great number of varieties based upon colour, shape, and inclusions. Arkose and litharenite specimens often have upward of 20 species of heavy minerals, such as rutile, pyroxene, epidote, amphibole, kyanite, staurolite, and monazite. More than 100 heavy minerals are known to occur in sandstones, and in some places (Florida, Brazil, Queensland) they form black sand beaches from which the minerals can be commercially mined. In sea-bottom sediment, heavy minerals occur in distinct geographic provinces, indicating derivation from diverse source areas and revealing the direction of marine currents.

Special
types of
sandstones

Certain types of sandstones are defined by special features; they may have any mineral composition and form in a wide range of environments. Flysch was originally a European term for thick sequences of rhythmically interbedded sandstone and shale in beds a fraction of an inch to several feet thick. Most workers in geology believe that the sands have been deposited by turbidity currents; the beds are thought to fill deep-water marine geosynclines with rapid sediment influx fed by rising mountain chains.

Molasse is also a European term. It refers to sandstones that are deposited on top of flysch. They are coarser grained than flysch; tend to be shallow marine, fluvial, or alluvial fan deposits; and are thought by workers to represent the peak of the mountain-building, when mountains are at their maximum height. In theory, as a mountain chain rises, the resulting deposits should grade from deep-water dark shales into flysch sands and shales, and finally into continental, molasse sands and conglomerates. Redbed is a general term referring to red shales, sandstones, and conglomerates. The problem of the significance and origin of the red colour has intrigued geologists for more than 100 years. Doubtless this type of sediment can originate in many ways, the only requisite being survival of the red hematite (iron oxide) pigment in an oxidizing environment. Redbeds form in many environments, from alluvial fans to fluvial, deltaic, and shallow marine areas. Some geologists think that redbeds are the result of hot desert climates, whereas other scientists believe that hot humid climates with seasonal rainfall are responsible for them; still other investigators think that they are caused by postdepositional alteration not necessarily related to climate.

USES OF SANDSTONES

Sandstone
reservoirs

The most valuable aspect of sandstone depends on its natural storage capacity for underground fluids: water, oil, and natural gas. Many sandstones contain an interconnected spongelike network of tiny pores. Porosity is a measure of the total volume of holes in the rock and may range up to 35 percent for some sandstones, although an average oil sand has 10–20 percent porosity. Permeability is a measure of the rate at which a fluid may pass through a rock and is greater if the pores are large and well interconnected. Both permeability and porosity are at a maximum in coarser sands that are well sorted and lack both clay matrix and chemical cement. Many sandstones are so tightly bonded with clay or cement that they are for practical purposes devoid of useful porosity and are use-

less as fluid reservoirs (see also PETROLEUM; GROUND-WATER).

Approximately half the world's oil comes from sandstone strata. A typical porous sandstone is folded and faulted by tectonic movements. One common site of occurrence of oil is in anticlines (arch-shaped folds), where in the three fluids arrange themselves in order of density, with water filling the pores at greatest depths, then oil, and finally gas on top. Early oil prospectors concentrated on searching for oil in anticlines. Another type of oil trap is one in which a sandstone gradually decreases in porosity in a lateral direction, and the migration of oil is stopped at the porosity-permeability barrier where an oil pool may accumulate. Most good oil sands are of deltaic, beach, or shallow marine origin.

Sandstones provide a very valuable reservoir of water. The Dakota Sandstone in the western United States provides artesian-well water for a widespread area of the Great Plains. After the water falls as rain in the Rocky Mountains and percolates into the surface outcrop of the Dakota Sandstone there, then it travels through the sandstone underground for 1,000 miles (1,600 kilometres) to the east, where (through deep wells) it is brought to the surface for use in irrigation. Sandstone aquifers (water-bearing strata) are of great importance in most developed countries.

An important use of sandstones is in the construction industry. Relatively clay-free, little-cemented sands or sandstones are crushed and sieved for use in concrete, plaster, or as fill in the manufacture of bricks, asphalt paving, etc. Such sandstones should be free of soft constituents such as slate fragments and reactive minerals such as pyrite or opal. Sandstones that are readily split (such as flagstones) and of attractive colour are used as building stone (e.g., Triassic arkose "brownstone" of New York) or paving stones. Such sandstones should be resistant to weathering and should have easy workability combined with high crushing strength. A former use was as millstones and grindstones (Millstone Grit of England; Berea Sandstone of Ohio).

Building
stone and
glass
sands

Glass sand requires easily crushable, medium-grained quartzarenite sandstones of the highest purity, often over 99 percent SiO_2 and particularly low in iron oxides and aluminum (under 0.1 percent and 0.2 percent, respectively). The Devonian Oriskany Sandstone of West Virginia and Pennsylvania supports an important glass industry. Ganister is a tough, quartz-cemented sandstone used as firebrick in industrial furnaces.

Certain sandstones are used as a source of commercially valuable heavy minerals (titanium, zirconium, rare earths), and some sandstones in the American Southwest are cemented with uranium minerals and form a valuable ore of this element.

San Francisco

San Francisco holds a secure place in the United States' romantic dream of itself—a cool, elegant, handsome, worldly seaport whose steep streets offer breathtaking views of one of the world's great bays. San Franciscans, according to the dream, are sophisticates whose lives hold full measures of such civilized diversions as music, art, and good food. Their city is a magic place, almost an island, saved by its location and its history from the overpowering ugliness that allegedly afflicts so much of the rest of urban California.

For all the truth there may be in this picture, there is, of course, also another San Francisco in which the per capi-

Flavour
of the
city

Central San Francisco and (inset) its metropolitan area.

ta consumption of alcohol is the highest of any U.S. city, the suicide rate is twice the national average, and the divorce rate is several times that of New York City. San Francisco is clearly a city in which the tensions between the dream and the reality have, from its beginnings, demanded a high price.

Furthermore, since World War II, San Francisco has had to come to grips with the common urban problems of the latter half of the 20th century: pollution of both the air and the water; the uglification that comes from ram-

nant building, violence, and vandalism; and the decay of the inner city. San Francisco has been shrinking as families, mainly white, mainly middle class, have moved to its suburbs, leaving the city to a population that, viewed statistically, tends to be older, less married, more probably less white than the stereotype has it. Every third San Franciscan is, in the sterile term of the census taker, "nonwhite"—black, Oriental, Filipino, Samoan, or American Indian. Many others are immigrants from Spanish America. Their dreams increasingly demand a

realization that has little to do with the romantic dream of San Francisco.

But both the dreams and the realities are important, for they are interwoven in the fabric of the city that might be called Paradox-by-the-Bay.

THE GROWTH OF THE METROPOLIS

The explorers and early settlers. It is extraordinary that the site of San Francisco should have been discovered by land instead of from the sea, for San Francisco Bay is one of the most splendid natural harbours of the world, and great captains and explorers sailed unheeding past the entrance—Juan Rodríguez Cabrillo (1542–43), Sir Francis Drake (1578), Sebastián Vizcaino (1602). In 1769 a scouting party from an expedition led by the Spanish explorer Gaspar de Portola looked down from a hilltop onto a broad body of water, the first white men known to have seen San Francisco Bay. It was not until August 5, 1775, that the first Spanish ship, the “San Carlos,” commanded by Lieut. Juan Manuel de Ayala, turned eastward between the headlands, breasted the ebbing tide, and dropped anchor just inside the harbour mouth. (Though it is possible that Drake may have entered the bay, most evidence is against it.)

Settlers from Monterey, under Lieut. José Joaquín Moraga and the reverend Francisco Palóu, established themselves at the tip of the San Francisco peninsula the next year. The military post (which remains in service as the Presidio of San Francisco, a major U.S. Army installation) was founded September 17, 1776, and the Mission San Francisco de Asís (later renamed the Mission Dolores) heard its first mass on October 9.

Almost half a century later, a village sprang up on the shore of Yerba Buena Cove, two miles east of the mission. The pioneer settler was an Englishman, Capt. William Anthony Richardson, who in 1835 cleared a plot of land and erected San Francisco's first dwelling—a tent made of four pieces of redwood and a ship's foresail. In the same year, the United States tried unsuccessfully to buy San Francisco Bay from the Mexican government, having heard reports from whalers and captains in the hide-and-tallow trade that the great harbour held bright commercial possibilities. Richard Henry Dana, whose ship entered the bay in 1835, recalled in *Two Years Before the Mast* (1840) that “If California ever becomes a prosperous country, this bay will be the centre of its prosperity.”

The Americans had to wait only another 11 years. After fighting began along the Rio Grande, Capt. John B. Montgomery sailed the sloop of war “Portsmouth” into the bay on July 10, 1846, anchored in Yerba Buena Cove, and went ashore with a party of sailors and marines to raise the U.S. flag in the plaza. On January 30, 1847, Yerba Buena was renamed San Francisco, which was regarded as a more propitious name for the town's future development.

The white population of Yerba Buena had been reported as 25 to 30 in 1844. In 1846, the school board counted 700 whites (half of them American) and 150 Indians, Negroes, and Hawaiians. Two years later, just before the discovery of gold on the American River, the town had grown to about 200 shacks and adobes inhabited by about 800 white people.

The city of the '49ers. With the discovery of gold, the history of San Francisco picks up pace and direction. The modest village was at first almost entirely deserted as its population scrambled inland to the Mother Lode, and then it exploded into one of the most extraordinary cities ever constructed. Some 40,000 gold hunters arrived by sea, another 30,000 plodded across the Great Basin, and still another 9,000 moved north from Mexico. By 1851, more than 800 ships rode at anchor in the cove, deserted by their crews.

Everybody except the miners got rich. Eggs sold for \$1 apiece, and downtown real estate claimed prices that would almost hold their own in the inflation of the 1970s. Until the bubble burst in the Panic of 1857, 50,000 San Franciscans became rich and went bankrupt, cheated and swindled one another, and took to the pistol and knife all

too readily. As *The Sacramento Union* noted in 1856, there had been “some fourteen hundred murders in San Francisco in six years, and only three of the murderers hung, and one of these was a friendless Mexican.” Two vigilance committees (1851 and 1856) responded to the challenge with crude and extralegal justice, hanging four men apiece as an example to the others.

In 1859 silver was discovered in the Nevada Territory. The exploitation of the Comstock Lode, which eventually yielded \$300,000,000, turned San Francisco from a frontier boomtown into a metropolis whose leading citizens were bankers, speculators, and lawyers who dressed their ladies in Paris gowns and ate and drank in splendid restaurants and great hotels.

San Francisco then was by all accounts an intoxicating city whose many charms moved the historian-moralist B.E. Lloyd to advise parents in 1876

to look closer to their daughters, for they know not the many dangers to which they are exposed . . . and to mildly counsel their sons, for when upon the streets of this gay city they are wandering among many temptations.

The 1860s and 1870s saw the birth of the modern San Francisco, which has for 100 years laid claim with some justice to being the Athens, Paris, and New York of the West but which never completely lost the mark of its wild beginning. As Rudyard Kipling was to observe after he visited the city in the 1890s, “San Francisco is a mad city, inhabited for the most part by perfectly insane people whose women are of remarkable beauty.”

San Francisco's growth in the first half of the 20th century was shaped by two cataclysmic events. The first of these was the great earthquake and fire of 1906, which destroyed the central business district. Between 1906 and 1910, however, the city rebuilt atop its ashes. The other cataclysm was World War II, during which hundreds of thousands of servicemen passed through San Francisco on their way to the war in the Pacific, and some 500,000 war workers settled temporarily in the cities around the bay. This was the beginning of the great postwar surge in the area's permanent population, which saw San Francisco become the centre of a metropolitan area of nine counties and more than 4,000,000 people.

THE CONTEMPORARY CITY

Physical characteristics. *Layout of city and bay.* Hilly, roughly square, and 44.6 square miles (116 square kilometres) in area, San Francisco occupies the northern tip of a peninsula. To its south are the bedroom suburbs of San Mateo County; to the east and northeast is the bay; to the west and northwest lies the Pacific Ocean.

The most prominent of San Francisco's famous hills are Twin Peaks, Mt. Davidson, and Mt. Sutro, all over 900 feet (270 metres) in height. The best known are Nob Hill, where the wealthy “nobs” built extravagant mansions in the 1870s, and Telegraph Hill, which once looked down on the Barbary Coast, a neighbourhood alive with gaudy wickedness. Thanks to the pioneer planners' prejudice in favour of a squared-off grid, the downtown streets march intrepidly up precipitous slopes, terrifying newly arrived drivers, making the cable cars something more than sentimental anachronisms, and providing splendid views of the bay.

San Francisco Bay is a drowned river valley, submerged during the melting of the last glacial ice sheet. Enthusiastic and profitable filling of the tidelands has reduced its area from about 700 square miles in 1880 to a mere 435 square miles at mean high tide. More than half of the bay is still fillable, but in 1965 the state legislature created the Bay Conservation and Development Commission to control further landfill projects. At its widest point, the bay measures 13 miles and, at its deepest, in the Golden Gate channel, 357 feet. The maximum daily flow of water through the Golden Gate into the Pacific is seven times the flow of the Mississippi River at its mouth.

Within the 93.1 square miles of water lying inside the city limits are the natural islands of Alcatraz and Yerba Buena and man-made Treasure Island, created for a world's fair in 1939 and soon turned into a naval base. Alcatraz (Spanish: “pelican”) was from 1934 until 1962

The hills and dizzying streets

The San Francisco Bay Area. At upper right is the San Francisco-Oakland Bay Bridge, which tunnels through Yerba Buena Island.

George Hunter

the most notorious maximum-security, "escape-proof" prison in the United States. In 1970, after the decaying cell blocks had been given up by the Federal Bureau of Prisons, the island was invaded by a multi-tribal force of Indians who asserted their rights to abandoned federal property until they were forcibly evicted in 1971.

Climate. Winter in San Francisco is rainy and mild, the spring sunny and mild, the summer foggy and cool, and the fall sunny and warm. The average mean minimum temperature is 51° F (11° C), the average mean maximum, 63° F (17° C). The mean rainfall, almost all of which occurs between November and April, is about 21 inches (790 millimetres). The sun shines during two-thirds of the possible daylight hours. The most characteristic feature of the weather, however, is the summer fog, which lies low over the city until midday, creating consternation among the tourists shivering in seersuckers and cotton prints. This fog is a phenomenon of temperature contrasts created when warm, moist ocean air comes in contact with cold water welling up from the ocean bottom along the coast.

Building and nature's demolition. The central business district, the financial district, North Beach, and Chinatown occupy the site of the Gold Rush city, expanded by progressive fillings along the waterfront. The bones of many a ship deserted in 1849 now lie under business buildings several blocks inland. To the west, at the approach to the Golden Gate Bridge, lies the Presidio, green and parklike although it is still a military garrison. South of the Presidio are the 1,017 acres of Golden Gate Park, reclaimed from a onetime sandy desert. The rest of San Francisco is largely comprised of the neighbourhoods, from Pacific Heights, in which the old, monied families live, to Hunter's Point, which is 86 percent black.

In the late 1960s and early 1970s, a great change, which has been described as the Manhattanization of San Francisco, became apparent and has been both welcomed and excoriated. The financial district in particular has seen one tall building after another rise in a city in which, for generations, few buildings were higher than 20 stories. Among the new skyscrapers are the Bank of America

building (52 stories) and the Transamerica Corporation building (48 stories and a 212-foot spire), which rises to a point like a fantastically elongated pyramid. Between 1967 and 1969 the total valuation of authorized high-rise projects in the Bay Area rose from \$18,500,000 to \$226,100,000. As the architect Frank Lloyd Wright once noted: "Only San Francisco could survive what you people are doing to it."

Concern has also arisen from the experience that San Francisco shares with no other U.S. city—destruction by earthquake. Severe quakes had been felt in 1864, 1898, and 1900, but it was not until 5:13 AM of April 18, 1906, that the rocky masses of the San Andreas Fault, the greatest fracture anywhere on the Earth's crust, heaved violently and doomed San Francisco as it then existed. The quake was followed by a fire that destroyed the centre of town and burned on until April 21, when the ashes were wetted down by rain. Four square miles, making up 512 blocks in the centre of town, were gone, along with 28,000 buildings and a total property value of about \$500,000,000. Perhaps 700 people died; 250,000 were left homeless. Survivors camped in Golden Gate Park. An Eastern newspaperman, celebrating the survival of a local distillery, composed the verse, "If, as they say, God struck the town/ For being over-frisky./ Why did He burn the churches down/ But spare Hotaling's whisky?"

The lore of the earthquake and fire has become overlaid with much sentiment, but in recent years seismologists and structural engineers have been reminding San Franciscans that it could happen again. There have been charges that the new office towers could not withstand another quake like the one in 1906 and that the next great rumbling of the San Andreas Fault may take a vastly greater toll.

The people. The 1970 census counted some 716,000 San Franciscans, less than the 740,000 of 1960 and the 775,000 of 1950. By ethnic group, the 1970 population included 511,000 whites, 96,000 blacks, 59,000 Chinese, 25,000 Filipinos, 12,000 Japanese, 2,900 American Indians, and 10,000 people of other origins. Among the

The great earthquake and fire of 1906

The ethnic polyglot and ghettos

whites were 51,602 people with Spanish surnames, most of them comparatively recent immigrants. The original settlers—the Spanish and Mexican families who held land grants on the shores of the bay—disappeared into the mists of history, done out of their holdings by aggressive and land-hungry Americans.

Americans and Europeans. The pattern of immigration into San Francisco during the latter half of the 19th century was significantly different from that of anywhere else in the United States. The waves of newcomers included not only native-born Americans moving west but also Europeans arriving directly by ship without previous Americanization along the Eastern Seaboard. The demography of the Gold Rush city was summed up concisely by a real-estate firm that advertised that it could "transact business in the English, French, German, Spanish and Italian languages."

San Francisco remains one of the two most European of American cities—New Orleans is the other—and surely the most Mediterranean. The Italians are still the dominant European minority, with 41,000 Italian-born San Franciscans reported in 1970, followed by Germans, Irish, and British.

The blacks. Before World War II about 20,000 blacks lived in the entire Bay Area, about 4,000 of them in San Francisco. The 24-fold increase during the next 30 years was set in motion by the war, which brought at least 500,000 war workers to the Bay Area's shipyards and other industries. Among them were tens of thousands from the South, who settled mainly in San Francisco, Oakland, and Richmond. In San Francisco they moved into the old "carpenter gothic" houses in the blocks around Fillmore Street, vacated when the Japanese were driven into wartime internment camps. The Fillmore district and the Hunter's Point housing project are decaying slums afflicted with the full gamut of social problems that come from poverty, inadequate education, unemployment, official neglect, and all the frustrations that grow out of desperate conditions of life. An increasing number of black men and women have become prominent in the city's life, however—a state assemblyman, a county supervisor, the president of the school board, a newspaper publisher, and numerous clergymen, educators, physicians, and civil servants.

The Chinese. Chinatown, which is said to be the largest Chinese community outside of Asia, is also probably the least understood minority community in the city. The colourful shops and restaurants of Grant Avenue mask a slum of crowded tenements and sweatshops that has the highest population density in an already densely populated city. Increasingly, those Chinese who can escape do so, into North Beach, hitherto predominantly Italian, onto the nearby slopes of Russian Hill, or into the Richmond district north of Golden Gate Park. Those who cannot move include many recent immigrants from Hong Kong, trapped by their ignorance of English.

The Japanese. Never as large as Chinatown, the Japanese community of San Francisco was wiped out at a single stroke by the infamous Executive Order 9066 of 1942, which sent them, foreign-born and native alike, into "relocation centers" that were, in all but name, concentration camps. The present centre of the Japanese community is Japan Town (Nihonmachi), a few blocks east of Fillmore Street. There, an ambitious new trade and cultural centre has risen, with restaurants, a hotel, shops, and business establishments. Though the rising generation of Japanese-Americans go to Japan Town as visitors, bound for a birthday dinner or to buy imported goods, their own roots are elsewhere.

The Spanish-speaking. Few visitors see the Mission district, which is a great irony, because the historic origins of the city extend to Spain and Mexico and the Spanish-speaking population rivals the Chinese as the second-greatest ethnic minority.

Before World War II the Mission district, named for the Mission Dolores, was principally blue collar and Irish. The Irish have largely been replaced by Spanish-speaking immigrants, mainly from Central America and Mexico. Living among them are pockets of American Indians and

Samoans. Hampered by language and cultural difficulties, the Spanish-speaking San Franciscans are found in service occupations such as restaurants and hotels, from which they are struggling to escape.

The Filipinos. The Filipino community, despite its size, is virtually invisible, for, unlike the minorities who live in clearly defined neighborhoods, the Filipinos impinge on the visible city only in the form of a few blocks of modest shops on the edge of Chinatown. Culturally and educationally handicapped in a world in which the power lies with English-speaking whites, they have yet to assert themselves.

Economic life. The Gold Rush and the Cornstock madness established San Francisco as the premier city of the West, known from the Oregon border to the pueblo of Los Angeles simply as the City. It is still a great port, the financial and administrative capital of the West, and a substantial centre for commerce and manufacturing.

In 1970, San Francisco employed more people in the service occupations (over 110,000) than in any other officially reported category. This reflects, among other things, the importance of tourism in the city's economy. Wholesale and retail trade followed and then governmental employment; finance, insurance, and real estate; transportation, communications, and utilities; manufacturing and construction. The total figure came to some 535,000 employed workers. The total personal income of San Franciscans in 1969 represented an increase of about 68 percent over that of 1960.

From its beginnings as a port of call in the hide-and-tallow trade and, later, as the home port of the Pacific whale fishery, San Francisco has always been acutely conscious of the importance of shipping. A century ago, ships sailed around Cape Horn or from the Isthmus of Panama, and "steamer day" was a civic institution; after 1914, cargo and passenger vessels arrived from the East by way of the Panama Canal. In 1867, the Pacific Mail Steamship Company opened the first transpacific service, sailing from San Francisco to Yokohama and Hong Kong.

Imports and exports passing through the San Francisco Customs District in 1969 made the combined ports of San Francisco Bay—San Francisco, Oakland, Alameda, Sausalito, and Stockton—the eighth most active international port in the country. As in the case of other material things, however, San Francisco has fallen behind Los Angeles, which ranks even higher. The chief source of imports was Japan, holding a giant 33 percent of the trade, followed by West Germany. In 1969 the greatest number of ships arriving flew the U.S. flag, followed by vessels of Norwegian and Japanese registry.

Manufacturing is the main source of wage and salary income in the Bay Area. In San Francisco, in which manufacturing is a lesser source of income, the principal industries are food processing and printing and publishing, while the aerospace and electronics industries are strong in the cities of the peninsula.

A financial centre since the first pinch of gold dust was exchanged for hard cash, San Francisco is the seat of the Pacific Coast Stock Exchange—which opens at 7:00 AM in order to keep pace with New York City's Wall Street—as well as the headquarters of such banks as the Bank of America, the largest in the country. In banking activity, San Francisco ranks second only to New York.

San Francisco has, rightly, the reputation of being a strong union town. Older union members still remember Bloody Thursday, July 5, 1934, when two strikers were killed in a pitched battle with police along the waterfront. The strike spread from the longshoremen and seamen until 127,000 union workers walked off their jobs in a general strike. The settlement brought the longshoremen their first union hiring hall. Continuing union strength was evident in the prolonged dock strike of 1971–72.

Transportation and services. Los Angeles long ago surrendered unconditionally to the automobile; San Francisco has on occasion rebelled and found it possible to oppose "progress." A monument to this revolt is the elevated Embarcadero Freeway, which stops dead as if sliced off by a guillotine. Again, angry citizens in 1964 defeated the state highway commission when it threat-

Components of the economy

Financial leadership

ened to run a freeway through the "panhandle" of Golden Gate Park.

Among the serious problems that remain is periodic smog, produced mainly by the more than 2,000,000 cars in the area. (An air-pollution-control district was formed in 1955.) Another is that access to San Francisco from its commuter towns is largely by a network of freeways that are anything but free at rush hours. Travel from the East Bay cities of Oakland and Berkeley and from Marin County to the north is over two great but overburdened bridges. Completed in 1936, the 4¼-mile-long San Francisco-Oakland Bay Bridge consists of two silver spans, one suspension and one cantilever, that meet at Yerba Buena Island and that on an average day in 1970 carried about 165,000 cars. The orange-red Golden Gate Bridge, leading north to Marin County, followed in 1937. On an average day in 1970 it carried 90,000 cars. A pure suspension bridge, its 4,200-foot centre span was, until recently, the longest such span in the world.

Until the ferries were doomed by the bridges, San Francisco was served by a great network of ferry routes whose splendid vessels were said to deliver more passengers, about 50,000,000 a year, to the Ferry Building at the foot of Market Street than arrived at any other transportation depot except Charing Cross in London. Only after the bridges began to choke with traffic did San Franciscans realize what they had lost, and the ferries are now returning, on a smaller scale, between San Francisco and Marin County.

A much greater undertaking is the 75-mile-long inter-urban rapid-transit system known as BART (Bay Area Rapid Transit), beginning operations in the summer of 1972. Operating between San Francisco and the East Bay through a four-mile underwater tube, BART is the first system of its sort, part subway and part elevated, to be built in half a century, but it does not resemble the older systems in all respects. Comfortable, computerized automatic trains running at speeds up to 80 miles an hour are a major feature.

Situated at the head of a peninsula, San Francisco has always been a dead-end for rail traffic, with the transcontinental trains (the first westbound train arrived over the tracks of the Central Pacific on September 6, 1869) discharging their passengers in Oakland, whence they were carried to San Francisco by ferry and, in recent times, by bus. As in the rest of the country, the railroad's importance has been declining since World War II. For carrying goods, trucking has largely taken over.

Owned and operated by the municipal government, San Francisco International Airport is located seven miles south of the city-county limits, on a filled site on the southwestern shore of the bay. In 1970, the combined Bay Area airports ranked fourth in passenger traffic among the metropolitan areas of the United States. Since 1934 San Francisco's principal source of water has been the Hetch Hetchy Reservoir, 167 miles away, in the High Sierra. Other sources are the Calaveras Reservoir in Alameda County and reservoirs in San Mateo County to the south. The Hetch Hetchy project required the damming of a valley almost as splendid as that of Yosemite National Park and the construction of tunnels, one 25 miles long, through the Coast Range. In 1902 the first high-voltage line transmitting hydroelectric power was completed between a powerhouse on the Mokelumne River and San Francisco, some 180 miles away. Since then, the Bay Area has developed a network of hydroelectric plants on the rivers of the interior as well as a steam-powered plant on Monterey Bay.

Government and politics. Unlike any other California city, San Francisco (incorporated 1850) has a consolidated city-county government. The 1932 freeholders' charter, under which the city-county still operates, provides the mayor with strong executive powers but delegates substantial authority to a chief executive officer (appointed by the mayor) and a controller. The legislative authority is lodged with an elected board of supervisors. The other key officials are the superintendent of schools and the manager of utilities, both appointed.

Within recent memory, the government of San Francis-

co has been reasonably efficient and reasonably honest. It was not always so. Survivors of the earthquake can still recall the scandal that erupted in 1906 when it was discovered in the course of planning the rebuilding of the city that the mayor, a handsome violinist named Eugene Schmitz (the "hero of the hour" after the disaster), had become the creature of a political boss named Abe Ruef and both were indicted for extortion. Ruef eventually doing penance in San Quentin Prison.

Present-day civic issues are concerned less with the possibility of corruption than with the implications of the high-rise building boom and with the certainty that the minority groups have been given seats farther down the banquet table than their white neighbours. Although the city has yet to elect a black, Chinese, or Spanish-speaking mayor, advances have been made on the board of supervisors and the school board and, increasingly, in other civic bodies.

Along with their pro-labour sentiments, San Franciscans have traditionally leaned toward the Democratic Party.

Cultural life. Higher education. Although strictly speaking they cannot be counted as San Francisco institutions, the greatest universities in the Bay Area are the University of California, located across the bay in Berkeley, and Stanford University, down the peninsula in Palo Alto. Within San Francisco, the most noted institution of higher education is California State University, San Francisco (formerly San Francisco State College), which was founded as a normal school in 1899 but has achieved national prominence for its academic excellence and for a prolonged campus strike that came close to destroying it as a functioning institution in 1968-69. Other colleges are the University of San Francisco (Jesuit), Lone Mountain College (also Catholic), City College (a two-year public college), and the California School of Fine Arts.

Music and theatre. San Francisco is the home of two major musical organizations. Since World War II the San Francisco Symphony has been conducted by a Frenchman, Pierre Monteux, a Spaniard, Enrique Jorda, an Austrian, Josef Krips, and a Japanese, Seiji Ozawa whose spirited style is widely admired. The San Francisco Opera enjoys an early season so that its leading singers may fulfill their commitments at New York's Metropolitan Opera. With the exception of the American Conservatory Theatre (ACT), a resident repertory group, the professional theatre is virtually nonexistent. The surviving downtown theatres are occupied largely by the touring casts of Broadway successes.

The visual arts. One of the amiable illusions held by San Franciscans is that theirs is a great city for artists. But no matter how many painters and sculptors live and work in the city, few are visible from beyond its boundaries. It has been cruelly observed that if San Francisco's three museums were to be combined, the city would then have one good second-rate museum. A possible exception to the asserted mediocrity is the collection of Far Eastern art at the M.H. de Young Museum in Golden Gate Park.

Literature. The greatest writer to make San Francisco his home was the young man who arrived as Samuel L. Clemens in 1861 and, after working as a newspaper reporter, left town as Mark Twain in 1864. Other notables of the past century have included Frank Norris, Ambrose Bierce, Bret Harte, Jack London, and Robert Louis Stevenson, who lived in great poverty in a boarding house. The current population of writers includes many reputable practitioners, a number of whom are affiliated with the creative writing program on the San Francisco campus of California State University.

Popular culture. A most vital part of San Francisco culture from the beginning has been found in its restaurants, hotels, and drinking places. To this must be added the popular culture of the ethnic enclaves—Chinatown, the Italian community of North Beach, the black culture of the Fillmore, Japan Town, the Russian colony along Clement Street, and the Spanish-speaking Mission district.

San Francisco's greatest contribution to the nation's life in recent years, however, had nothing to do with either its

The civic
present
and past

The
once-busy
ferries

ethnic cultures or with its officially anointed institutions—or, indeed, as has been suggested, with the emergence of the "topless" dancer in a North Beach nightclub in 1964. Instead, it was the unheralded appearance in 1967 of the "flower children," a generation of youngsters, long of hair and usually grubby in appearance, who declared themselves in headlong flight from the Great Society and preached the saving graces of peace and love. Unhappily, as the 1960s turned into the 1970s, the main street of their capital, the Haight-Ashbury district, turned into an ugly and dangerous marketplace for drugs.

San Francisco also emerged, for a period in the late 1960s, as the capital of rock music, which achieved national prominence for the San Francisco sound of such groups as the Jefferson Airplane, the Grateful Dead, and the Quicksilver Messenger Service, as well as such individual performers as Janis Joplin.

Problems and prospects. As it progressed through the 1970s, San Francisco faced a critical period that, in the popular phrase, could be described as an identity crisis. In the general low opinion in which San Franciscans held Los Angeles could be detected not only a dislike for the ugliness and brashness of the city to the south but also envy and perhaps even fear of its vitality. San Francisco itself was still handsome, elegant, and worldly, but all too often its admiration was turned to its own past, while a perceptible apathy could be sensed when it faced the future. Middle class white residents and commuters tended to share the beguiling dream that San Francisco was "everybody's favourite city," and that it was still, as it had been to the muckraking newspaperman Will Irwin in the early 1900s, "the gayest, lightest-hearted, most pleasure-loving city of the Western continent." The hard reality of San Francisco in the 1970s was still in the process of being defined.

BIBLIOGRAPHY. For accounts of the early history of San Francisco, the serious reader should not be discouraged by the voluminousness and variousness of the works of the historians HUBERT HOWE BANCROFT and THEODORE H. HITTELL, the latter of whom is particularly readable. FRANK SOULE, JOHN H. GIBON, and JAMES NISBET, *The Annals of San Francisco* (1854), is invaluable; while B.E. LLOYD, *Lights and Shades of San Francisco* (1876), is both vivid and divertingly moralistic. HERBERT ASBURY, *The Barbary Coast* (1934, reprinted 1968), is the classic account of the underworld; while JULIA COOLEY ALTROCCHI, *The Spectacular San Franciscans* (1949), is a useful social history. Of the many books about the earthquake and fire of 1906, WILLIAM BRONSON, *The Earth Shook, the Sky Burned* (1959), is a first-rate work of historical reconstruction. The FEDERAL WRITERS' PROJECT, *San Francisco: The Bay and Its Cities* (1940), although out of date, remains a useful starting point. MEL SCOTT, *The San Francisco Bay Area: A Metropolis in Perspective* (1959), is the best systematic description of the area, with particular emphasis on planning. Of the many books that celebrate the distinctive flavours of San Francisco life, ROBERT O'BRIEN, *This Is San Francisco* (1948); and HERB CAEN, *Only in San Francisco* (1960), are recommended. SART FRANCISCO BAY (1957), by the naturalist-conservationist HAROLD GILLIAM, is both authoritative and evocative. JOHN HASKELL KEMBLE, *San Francisco Bay: A Pictorial Maritime History* (1957), contains a splendid collection of drawings and photographs from the earliest days to the present.

(K.La.)

Sankara

Sankara, medieval Indian philosopher and exegete, Hindu theologian and religious leader, was the most famous exponent of the school of the Indian religious philosophy known as Vedānta. He affirmed that there is only one true reality (Brahman), an eternal principle that is the source of all things, and that all differentiations, plurality, and change are illusory. This school of thought has exercised a deep and wide influence upon religion, philosophy, and culture in India for many centuries.

There are at least 11 works that profess to be biographies of Sankara. All of them were composed several centuries later than the time of Sankara and are filled with legendary stories and incredible anecdotes, some of which are mutually conflicting. Today there are no materials with which to reconstruct his life with certainty.

His date of birth is naturally a controversial problem. It has been customary to assign him the birth and death dates of 788–820. But the dates 700–750, grounded on a recent study, are more acceptable at present.

According to one tradition, Sankara was born into a pious Nambūdiri Brahmin family in a quiet village called Kālaḍi on the banks of the Cūrṇā (or Pūrṇā, Periyār) River, Kerala, southern India. He is said to have lost his father, Sivaguru, early in his life. He renounced the world and became a *sannyāsin* (ascetic) against his mother's will. He studied under Govinda, who was a pupil of Gauḍapāda. Nothing certain is known about Govinda, but Gauḍapāda is notable as the author of an important Vedānta work, *Māṇḍūkya-kārikā*, in which the influence of Mahāyāna Buddhism—a form of Buddhism aiming at the salvation of all beings and tending toward nondualistic or monistic thought—is evident and even extreme, especially in its last chapter.

A tradition says that Siva, one of the principal gods in Hinduism, was Sankara's family deity and that he was, by birth, a Śākta, or worshipper of Sakti, the consort of Siva and female personification of divine energy. Later he came to be regarded as a worshipper of Siva or even as incarnation of Siva himself. His doctrine, however, is far removed from Saivism and Śāktism. It is ascertained from his works that he had some faith in, or was favourable to, Vaisnavism, the worship of the god Viṣṇu. It is highly possible that he was familiar with Yoga (one of the classical systems of Indian philosophy, as well as a technique to achieve salvation). A recent study has suggested that in the beginning he was an adherent of Yoga and later became an Advaitin ("advocate of non-dualism").

Biographers narrate that Sankara first went to Kāśī (Vārāṇasī), a city celebrated for learning and spirituality, and then travelled all over India, holding discussions with philosophers of different creeds. His heated debate with Mandana Miśra, a philosopher of the Mīmāṃsā ("investigation") school, whose wife served as an umpire, is perhaps the most interesting episode in his biography and may reflect a historical fact; that is, keen conflict between Sankara, who regarded the knowledge of Brahman as the only means to final release, and followers of the Mīmāṃsā school, which emphasized the performance of ordained duty and the Vedic rituals.

Sankara was active in a politically chaotic age. He would not teach his doctrine to city dwellers. The power of Buddhism was still strong in the cities, though already declining, and Jainism, a nontheistic ascetic faith, prevailed among the merchants and manufacturers. Popular Hinduism occupied the minds of ordinary people, while city-dwellers pursued ease and pleasure. There were also epicureans in cities. It was difficult for Sankara to communicate Vedānta philosophy to these people. Consequently, Sankara propagated his teachings chiefly to *sannyāsin*s and intellectuals in the villages, and he gradually won the respect of Brahmins and feudal lords. He enthusiastically endeavoured to restore the orthodox Brahmanical tradition without paying attention to the *bhakti* (devotional) movement, which had made a deep impression on ordinary Hindus in his age.

It is very likely that Sankara had many pupils, but today only four are known (from their writings): Padmapāda, Sureśvara, Toṭaka (or Troṭaka), and Hastāmāla. Sankara is said to have founded four monasteries, at Śringeri (south), Puri (east), Dvārakā (west), and Badarīnātha (north), probably following the Buddhist monastery (*vihāra*) system. Their foundation was one of the most significant factors in the development of his teachings into the leading philosophy of India.

More than 300 works—commentative, expository, and poetical—written in the Sanskrit language, are attributed to him. Most of them, however, cannot be regarded as authentic. His masterpiece is the *Brahma-sūtra-bhāṣya*, the commentary on the *Brahma-sūtra*, which is a fundamental text of the Vedānta school. He also wrote commentaries on the principal *Upaniṣads*, which are certainly all genuine, with the possible exception of the commentary on the *Śvetāśvatara Upaniṣad*. The commentary on

the *Māṇḍūkya-kārikā* was also composed by Sankara himself. It is very probable that he is the author of the *Yoga-sūtra-bhāṣya-vivaraṇa*, the exposition of Vyāsa's commentary on the *Yoga-sūtra*, a fundamental text of the Yoga school. The *Upadeśasāhasrī*, which is a good introduction to Sankara's philosophy, is the only non-commentative work that is certainly authentic.

Śaṅkara's style of writing is lucid and profound. Penetrating insight and analytical skill characterize his works. His approach to truth is psychological and religious rather than logical. He was a prominent religious teacher rather than a philosopher. His works reveal that he was not only versed in the orthodox Brahmanical traditions but also was well acquainted with Mahāyāna Buddhism. He is often criticized as a "Buddhist in disguise" by his opponents because of the similarity between his doctrine and Buddhism. Despite this criticism, it should be noted that he made full use of his knowledge of Buddhism to attack Buddhist doctrines severely or to transmute them into his own Vedāntic nondualism, and he tried with great effort to "vedanticize" the Vedānta philosophy, which had been made extremely Buddhist by his predecessors. The basic structure of his philosophy is more akin to Sāṅkhya, a philosophic system of nontheistic dualism, and the Yoga school than to Buddhism.

It is said that Sankara died at Kedārnātha in the Himalayas. The Advaita Vedanta school founded by him has always been pre-eminent in the learned circle of India. His doctrine has been the source from which the main currents of modern Indian thought are derived.

BIBLIOGRAPHY. Among the biographies of Śaṅkara written in Sanskrit, VIDYARANYA, *Śaṅkaradigvijaya* (14th century) in verse, is best known, though legendary. T.M.P. MAHADEVAN, *Homage to Śaṅkara* (1959), gives a short account of Śaṅkara's life based upon the traditions. s. RADHAKRISHNAN, *Indian Philosophy*, vol. 2 (1958), contains a brief but fairly critical biography and a detailed account of his works and philosophy.

(Se.M.)

San Marino

Situated on the slopes of Monte Titano, on the Adriatic side of central Italy between the Romagna and the Marche regions, the Republic of San Marino is surrounded on all sides by the Republic of Italy. It centres on the capital of the same name. The republic's area of 23.5 square miles (61 square kilometres) makes it the smallest independent state in Europe after Vatican City and Monaco and the smallest republic in the world. It is linked with the Italian Republic by a treaty of friendship and a customs union.

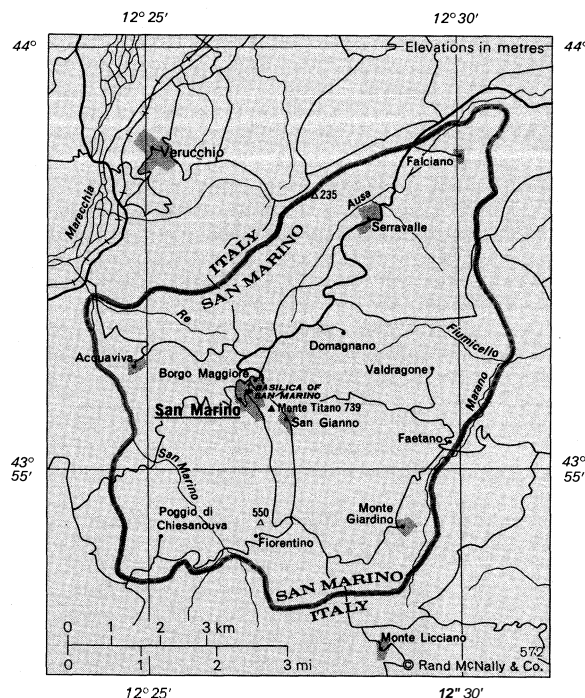

C.Bo.

History. The Republic of San Marino traces its origin to the early 4th century AD when, according to tradition, St. Marinus and a group of Christians settled there to escape persecution. By the 12th century San Marino had developed into a commune ruled by its own statutes and consuls. The commune was able to remain independent despite encroachments by neighbouring bishops and lords, largely because of its isolation and its mountain fortresses. Against the attacks of the Malatesta family, who ruled the nearby seaport of Rimini, San Marino enjoyed the protection of the rival family of Montefeltro, who ruled Urbino. By the middle of the 15th century it was a republic ruled by a Grand Council—60 men taken from the Arengo, or assembly of families. Warding off serious attacks in the 16th century (including an occupation by Cesare Borgia), San Marino survived the Renaissance, a relic of the self-governing Italian city-states. Rule by an oligarchy and attempts to annex it to the Papal States in the 18th century mark the history of the decline of the republic.

When Napoleon invaded Italy he respected the independence of the republic and even offered to extend its territory (1797). The Congress of Vienna (1815), at the end of the Napoleonic Wars, also recognized its independent status. During the 19th-century movement for Italian unification, San Marino offered asylum to revolutionaries, among them Giuseppe Garibaldi. After Italy became a national state, a series of treaties (the first in 1862) confirmed its independence. (Ed.)

Landscape. The territory has an irregular rectangular form with a maximum length of eight miles, northeast to southwest; it is crossed by the Marano and Ausa (Aussa) streams, which flow into the Adriatic Sea, and by the stream of San Marino, which falls into the Marecchia River. The landscape is dominated by the huge, central limestone mass of Monte Titano (2,424 feet [739 metres]); hills spread out from it on the southwest, whereas the northeast part gently slopes down toward the Romagna plain and the Adriatic coast. The silhouette of Monte Titano, with its three summits crowned by ancient triple fortifications, may be seen from many miles away. Correspondingly, the panorama from the top of Titano is superb and enchanting: on one side the azure Adriatic, as far as the Yugoslav coastline on clear days, and on the other, the green hills of Montefeltro and the serried ranges of the Apennines.

Monte Titano

SAN MARINO

The climate is mild and temperate, with maximum temperatures of 79° F (26° C) in summer and 19° F (−7° C) in winter. Annual rainfall ranges between about 22 inches (560 millimetres) and 32 inches (810 millimetres). Vegetation is typical of the Mediterranean zone, with variations due to altitude, and includes olive, yine, oak, vine, ash, poplar, fir, and elm and many kinds of grasses and flowers. Besides domestic and farmyard animals, moles, hedgehogs, foxes, badgers, martens, weasels, and hares are found. Indigenous birds and birds of passage are plentiful.

The capital, San Marino, is set, like an eyrie, high on the western side of Monte Titano, beneath the fortress crowning one of its summits, and is encircled by triple walls. It has about 4,000 inhabitants and is the goal of many tourists.

Borgo Maggiore, lower down the slope, was for centuries San Marino's commercial centre, and Serravalle, beneath its castle of the Malatesta family, is agricultural and industrial. Most of the nine districts (*castelli*) remain agricultural, but industrial concerns are beginning to intrude on the centuries-old forms of agricultural life. In Borgo Maggiore and San Marino, new construction is spreading and penetrates the ancient centre.

Population. Although traces of human presence from both prehistoric and Roman times exist in the territory, Monte Titano and its slopes are known to have been populated, with certainty, only after the Dalmatian stone-cutter St. Marinus, traditional founder of the San Marino state (AD 301), came to the Titano to escape the

emperor Diocletian's persecution of Christians. San Marino's population (7,080 in the first census [1864]) is now about 19,000, of whom more than 3,000 are non-San Marino citizens and, in a strong majority, Italian citizens. More than 20,000 San Marino citizens, or Sammarinesi, are resident abroad, principally in Italy, the United States, France, and Argentina. The increase in the population is due not only to births but also to the re-entry of citizens from abroad. The average birthrate at the beginning of the 1970s was 16.9 percent, the death rate, 8.5 percent.

Almost all the people are Catholics. The official language is Italian. A widely spoken dialect has been defined as Celto-Gallic, akin to the Piedmont and Lombardy dialects as well as to that of Romagna. A characteristic of the San Marino dialect, as compared with the others of the same origin, is its singular homogeneity, due to long isolation.

Economy. The territory has no mineral resources, for the centuries-long quarrying of Monte Titano stone and the craft that depended upon it have become exhausted. The republic's economy, therefore, relies entirely upon its inhabitants' enterprise. Its principal resources are, in order of importance, industry, tourism, commerce, agriculture, and crafts.

Industry, only recently set up, employs nearly 3,000 people and produces principally building materials, paints and varnishes, paper, metalwork, textiles, clothing, furniture, rubber and leather footwear, ceramics, china, food and confectionery products, liqueurs, cosmetics, and sanitary articles.

Tourism is the sector that has seen the greatest expansion, with more than 2,400,000 visitors in 1969, mostly on day trips, from April to October; and it makes a major contribution to the inhabitants' resources. Alongside this form of excursion tourism, a convention-type tourism, based on the recently opened, modern Congress Palace, and, although still on a modest level, a residential tourism are developing.

Commerce flourishes on account of the high standard of living and in conjunction with the tourist trade. It is also encouraged by free trade agreements, which form, in fact, a customs union between the republic and Italy.

Agriculture, although no longer the principal economic resource in San Marino, has not shown any major decrease in production: wheat, maize (corn), and barley are the chief crops; dairying and livestock also are important.

Industry includes characteristic and interesting handicraft articles in ceramics and wrought iron, modern and reproduction furniture, and fine printing. The issue of new postage stamps is a useful source of revenue.

Transport. The San Marino road network totals 137 miles. The territory is connected with Italy by three main roads and by a dual-carriageway highway to nearby Rimini. Motorcoach services connect San Marino with its districts and with Rimini and, in summer, directly with other centres on the Adriatic coast. In summer, too, a helicopter service operates from Rimini to Borgo Maggiore. The capital is reached from Borgo Maggiore by means of a funicular.

The state. The San Marino constitution, originating from the Statutes of 1600, provides for the following instruments of government: the Great and General Council (Parliament), the captains regent (*capitani regenti*, heads of state and of the administration and presidents of the parliamentary assembly), the Council of Twelve (appellate judicial body), and the Congress of State (a council of ministers). The Great and General Council has 60 members, elected every five years by all adult citizens. It has legislative and administrative powers and nominates every six months the two captains regent, who hold office for that period and may not be elected again until three years have elapsed. The Congress of State is composed of ten members, elected by the Great and General Council from among its members, and constitutes the central organ of executive power. Each member has charge of a ministerial department.

Judicial power is entrusted to judges who must not be

San Marino citizens. One judge, called a commissioner of the law, attends to civil cases; an additional commissioner of the law acts in preliminary hearings of criminal cases and lesser criminal cases. The first-grade penal judge presides over criminal cases involving heavier penalties. Appeal lies, in the first instance, with civil and criminal appeals judges.

San Marino has no army but a military corps (the Great and General Council Guard, the Uniformed Militia, the Fort Guard), who today serve on parade during ceremonies at the republic's national festivities. Public order is maintained by the gendarmerie.

Social organization. San Marino can boast of provisions for social security. The state finds employment for those who cannot find work with private concerns; when this is not possible (during winter or a slack period), workers receive unemployment pay equal to 60 percent of their salary. Against a social security contribution, all citizens receive free, comprehensive medical care, assistance in sickness, accident, and old-age, as well as family allowances. The state aids home ownership through its buildings schemes. Education is free up to 14 years of age. For higher level schooling, the state grants aid to students attending universities and institutions outside San Marino. Children up to the age of 12 are guaranteed an annual seaside holiday; and two private mountain establishments, subsidized by the state, welcome young people and adults during the summer.

Cultural life. Tangible signs of life in centuries past live on in San Marino: from the three "fortresses" that surmount Titano's three summits to the triple wall that encircles the city of San Marino, a reminder of the long, hard struggle to defend its freedom; from the public and private buildings with their simple, austere lines to the narrow, winding streets; from the captains regent's costumes to the many-coloured uniforms of the Uniformed Corps; from the folklore shows, such as the Crossbowmen's Contest, to the country fetes.

The State Archives, Government Library, State Art Gallery, St. Francis' Church and Convent, and the Museum of Antique Weapons possess precious relics of the life and history of the republic and evidence of art and culture.

The outlook. San Marino is a tiny state with 17 centuries of history, known more to collectors of its magnificent stamps than for Abraham Lincoln's words "Your country is one of the most honoured in all history." It maintains with jealous pride some medieval institutions in its administration, but it is neither a museum nor a lifeless relic left by history but a community awake to the needs of the present-day world, aware of the new demands being made, and seeking a clear-cut answer in spite of its scanty resources to the human, civil, and social problems that today challenge every state.

BIBLIOGRAPHY. NEVIO MATTEINI, *Repubblica di San Marino, guida storia artistica* (1966), is a useful guide. There is no work devoted specifically to the geography of San Marino. For geology, see GIULIANO RUGGERI, "Geologia di San Marino," in *Studi Sanmarinesi*, pp. 3-9 (1960). On the flora, the monograph by R. PAMPANINI, *Flora della Repubblica di San Marino* (1930), is a fundamental work. The following cover the history of the state: GINO ZANI, *Il territorio e il castello di San Marino attraverso i secoli* (1963); PAUL AEBISCHER, *Essai sur l'histoire de Saint Marin des origines à l'an mille* (1962); and MARINO FATTORI, *Ricordi storici della Repubblica di San Marino*, 8th ed. (1956). On art, CARLA NICOLINI, *Pittura e scultura a San Marino* (1965), should be consulted. Descriptive works in English include: VIRGINIA WALES JOHNSON, *Two Quaint Republics, Andorra and San Marino* (1913); GILES PLAYFAIR and CONSTANTINE FITZGIBBON, *The Little Tour: Andorra, Monaco, Liechtenstein, San Marino* (1954); CHARLES L. SHERMAN, *The Five Little Countries of Europe: Luxembourg; Monaco, Andorra, San Marino, Liechtenstein* (1958); and C. NEVILLE PACKETT, *Guide to the Republic of San Marino* (1964).

San Martin, José de

South American soldier and statesman and national hero of Argentina, José de San Martín led rebel troops in freeing Chile and Peru of Spanish domination. Together

Importance of tourism

High level of social security

San Martin, portrait by F. Bouchot (1800–42). In the West Point Museum, New York.

By courtesy of the West Point Museum Collection, United States Military Academy

with Simón Bolívar, he was the major architect of South American independence.

San Martín is believed to have been born on February 25, 1778, at Yapeyú, formerly a Jesuit mission station in Guaraní Indian territory, on the northern frontier of Argentina. There his father, Juan de San Martín, a professional soldier, was administrator. His mother, Gregoria Matorras, was also Spanish. The family returned to Spain when José was six. From 1785 to 1789 he was educated at the Seminario de Nobles in Madrid, leaving there to begin his military career as a cadet in the Murcia infantry regiment. For the next 20 years he was a loyal officer of the Spanish monarch, fighting against the Moors in Oran (1791); against the British (1798), who held him captive for over a year; and against the Portuguese in the War of the Oranges (1801). He was made captain in 1804.

The turning point in San Martín's career came in 1808, following Napoleon's occupation of Spain and the subsequent patriotic uprising against the French. For two years he served the Seville junta that was conducting the war on behalf of the imprisoned Spanish king Ferdinand VII. He was promoted to the rank of lieutenant colonel for his conduct in the Battle of Bailén (1808) and was elevated to command of the Sagunto Dragoons after the Battle of Albuera (1811). Instead of taking up his new post, he sought permission to go to Lima, the capital of the viceroyalty of Peru, but travelled by way of London to Buenos Aires, which was the principal centre of resistance in South America to the Seville junta. There, in the year 1812, San Martín was given the task of organizing a corps of grenadiers against the Spanish royalists centred in Peru who threatened the revolutionary government in Argentina.

One explanation for this startling change of allegiance on the part of a soldier who had sworn a fealty to Spain is that it was prompted by British sympathizers with the independence movement in Spanish America and that San Martín was recruited through the agency of James Duff, 4th earl of Fife, who had fought in Spain (and who caused San Martín to be made a freeman of Banff, Scotland). In later years, San Martín averred that he had sacrificed his career in Spain because he had responded to the call of his native land, and this is the view taken by Argentinian historians. Undoubtedly, peninsular Spanish prejudice against anyone born in the Indies must have rankled throughout his career in Spain and caused him to identify himself with the criollo (creole) revolutionaries.

In the service of the Buenos Aires government, San Martín distinguished himself as a trainer and leader of soldiers, and, after winning a skirmish against loyalist forces at San Lorenzo, on the right bank of the Paraná (February 3, 1813), he was sent to Tucumán to reinforce, and ultimately replace, General Belgrano, who was being hard pressed by forces of the Viceroy of Peru. San Martín realized that the Rio de la Plata provinces would

never be secure so long as the royalists held Lima, but he perceived the military impossibility of reaching the centre of viceregal power by way of the conventional overland route through Upper Peru (modern Bolivia). He therefore quietly prepared the masterstroke that was his supreme contribution to the liberation of southern South America. First, he disciplined and trained the army around Tucumán so that, with the assistance of gaucho guerrilleros, they would be capable of a holding operation. Then, on the pretense of ill health, he got himself appointed governor intendant of the province of Cuyo, the capital of which was Mendoza, the key to the routes across the Andes. There, he set about creating an army that would link up with the soldiers of the patriotic government in Chile and then proceed by sea to attack Peru. To his disappointment, when the first stage of this plan was nearing completion, loyalist forces recaptured Chile (although the Chilean liberator, Bernardo O'Higgins, was able to escape to Mendoza). This made it necessary for San Martín to fight his way across the formidable barrier of the Andes. This was accomplished between January 18 and February 8, 1817, partly by a double bluff, which caused the Spanish commander to divide his forces in order to guard all possible routes, and more especially by careful generalship that ensured the maximum concentration of force at the enemy's weakest point, backed by adequate supplies. San Martín's skill in leading his men through the defiles, chasms, and passes—often 10,000 to 12,000 feet (3,000 to 4,000 metres) above sea level—of four Andean cordilleras has caused him to be ranked with Hannibal and Napoleon. On February 12, he surprised and defeated the royalists at Casas de Chacabuco and took Santiago, where he refused the offer of the governorship of Chile in favour of Bernardo O'Higgins (who became supreme director) because he did not wish to be diverted from his main objective, the capture of Lima. Nevertheless, it took him over a year to clear the country of royalist troops. He finally routed the remaining 5,300 on April 5, 1818, at the Battle of Maipú.

The next stage of San Martín's plan involved the creation of the Chilean Navy and the accumulation of troop ships. This was accomplished, despite shortage of funds, by August 1820, when the rather shoddy fleet, consisting mainly of armed merchant ships, under the command of Thomas Cochrane (later 10th earl of Dundonald), left Valparaíso for the Peruvian coast. Cochrane, whom San Martín found a cantankerous colleague, had failed the year before to take the chief port, Callao, which was well-defended. The port was therefore blockaded, and the troops landed to the south near Pisco; from this point they could threaten Lima from the landward side. True to his cautious nature, San Martín resisted the temptation to assault the capital, which was defended by a superior force, and waited for almost a year, until the royalists, despairing of assistance from Ferdinand VII (who had since been restored to the Spanish throne), withdrew to the mountains. San Martín then entered Lima, the independence of Peru was proclaimed on July 28, 1821, and the victorious commander was made protector.

San Martín's position was nevertheless insecure. He had broken with his supporters in Buenos Aires when, against their wishes, he insisted on pressing on to Lima; he was unsure of the loyalty of the Peruvian people and of the backing of some of his officers, many of whom suspected him of dictatorial or monarchical ambitions; and he lacked the forces to subdue the royalist remnants in the interior. Moreover, Simón Bolívar, who had liberated the northern provinces of South America, had annexed Guayaquil, a port and province that San Martín had hoped would opt for incorporation in Peru. He therefore decided to confront Bolívar. The two victorious generals met, ostensibly on equal terms, on July 26, 1822, at Guayaquil. What passed between them in their secret discussions is unknown, but what is clear is that San Martín hurried back to Lima, a disappointed man. There, seriously ill, faced by recriminations and overt disaffection, he resigned the protectorship on September 20. The rest of his life was spent in exile with his daughter, in Brussels, Paris, and Boulogne-sur-Mer, wisely avoiding any further

Campaign across the Andes

Capture of Lima

Meeting with Bolívar

Change of allegiance

involvement in the anarchic situations that marred the early history of the newly independent nations. He died in Boulogne-sur-Mer on August 17, 1850.

San Martín's abiding contribution to the cause of independence in the Rio de la Plata, Chile, and Peru was the military skill that he had acquired in his long career in the Spanish Army. He knew how to train and inspire soldiers, how to lead them, and how to avoid involvement with the enemy until he was sure of superiority on every count. Above all, the boldness of his plan to attack the viceroyalty of Lima by crossing the Andes to Chile and going on by sea, and the patience and determination with which he executed it, was undoubtedly the decisive factor in the defeat of Spanish power in southern South America. Whether at Guayaquil he consciously made a great renunciation of personal ambition so that Bolívar, and with him the cause of independence, might triumph, or whether he went into voluntary exile because Bolívar made it clear that he was not prepared to help Peru so long as San Martín remained in control, remains an unresolved historical problem.

BIBLIOGRAPHY. The basic documents on San Martín's career will be found in *Documentos del archivo de San Martín*, 12 vol. (1910–11). The classic biography is BARTOLOME MITRE, *Historia de San Martín y la emancipación sudamericana*, 2nd ed., 4 vol. (1890 and later reprints), of which WILLIAM PILLING, *The Emancipation of South America* (1893), is an abridged translation. RICARDO LEVENE, *El genio político de San Martín* (1950), summarizes the known facts. The controversial meeting that occurred between Simón Bolívar and San Martín at Guayaquil is examined in two articles in the *Hispanic American Historical Review*: GERHARD MASUR, "The Conference of Guayaquil," 31:189–229 (1951), and VICENTE LECUNA, "Bolívar and San Martín at Guayaquil," 31:369–393 (1951).

Santa Catarina

Santa Catarina, one of the 22 states of Brazil, is situated in the southern part of the country. It is bounded on the north by the state of Paraná, on the south by the state of Rio Grande do Sul, on the east by the Atlantic Ocean, and on the west by Misiones territory of Argentina. One of the smaller Brazilian states, it has an area of 37,060 square miles (95,985 square kilometres) and a population, in 1970, of more than 2,900,000. The capital is Florianópolis, located on coastal Santa Catarina Island. The region was given various names by early Spanish and Portuguese cartographers; the name Santa Catarina is said to have been given in honour of St. Catherine of Alexandria by the Italian navigator Sebastian Cabot, when he was in the service of Spain.

History. Santa Catarina was part of a larger hereditary captaincy (district administered by a captain) established by the Portuguese crown in 1532, although the first Portuguese settlement, at what is today the port of São Francisco do Sul near the Paraná border, was not made until 1648. Interior highland prairies were used for cattle raising, and early in the 18th century trading posts were opened along the cattle trails leading across the plateaus toward the coastal towns and the northern markets.

The captaincy of Santa Catarina was created in 1738 to serve as an outpost in the Portuguese–Spanish territorial wars. It was governed from Rio de Janeiro by the military until 1822, when Brazil became an empire independent of Portugal. A revolution that spread northward from Rio Grande do Sul in 1839 created the short-lived Republic of Santa Catarina. One of the participants was Giuseppe Garibaldi (*q.v.*), who married a Brazilian, Anna Maria Ribeiro da Silva, and in later decades led the battles that unified his native Italy.

During the 19th century a considerable immigration of non-Portuguese peoples occurred. Germans arrived as early as 1829 and came in great numbers during the 1850s, settling along the coastal valleys and founding the cities of Blumenau, Joinville, and Brusque. Many Italians immigrated after 1875, and Poles, Ukrainians, and Russians arrived in the 1880s. African slaves comprised about 10 percent of the population in the 1870s; they were emancipated in 1888. Santa Catarina became a state

of Brazil when, in 1889, a republic was proclaimed to replace the empire; Florianópolis was designated as the capital.

The physical environment. Behind the seacoast a great escarpment rises like a mountain wall; the state has little level ground. Its highest point is Campo do Padres, at 6,000 feet (1,800 metres) in altitude, located in the southeast part of the state. There are two principal river systems, one formed by the coastal rivers flowing eastward to the coast, the other flowing south to the Uruguay River, which forms part of the state's southern border.

Rainfall is heavy, ranging from 47 to 97 inches annually; temperatures range from a summer high of about 69° F (21° C) to a winter low of about 48° F (9° C). Although much of the original forest cover, which consists of mixed tropical and subtropical vegetation, has been cleared, there are extensive reforestation programs that are now being pursued.

Santa Catarina is among the less developed Brazilian states, and the rugged aspect of its land is a handicap to diversification of the economy and modernization of rural life.

The people. About 95 percent of the population of more than 2,900,000 are white, the remainder predominantly Negro and Indian. The Portuguese spoken by the majority has also influenced the languages spoken by the descendants of the various immigrant groups. More than 70 percent of the people are Roman Catholic; there are also several Protestant sects, and spiritualism has much influence, principally in urban areas.

Administration. The administration of the state is centralized, in accordance with Brazil's 1967 constitution, in a governor, who is assisted by several secretaries of state. There is a 35-member assembly representing the various regions of the state. There is also a tribunal of justice. The 197 municipalities are administered by local governors, or *prefeitos*, who are either elected or nominated. Each municipality also has a municipal chamber that is composed of seven to 15 members, who are known as *vereadores*.

Social conditions. There have been elementary schools in Santa Catarina for centuries, but secondary education became prevalent in the interior only in the 20th century. Higher education was introduced in 1919, and a number of universities are located in the major cities, the most prominent being the Federal University of Santa Catarina, in Florianópolis.

A prominent feature of state welfare is the public housing program. There are about 150 hospitals throughout the state, and about 700 doctors and an additional 1,000 medical personnel serve the population.

Economy. The manufacture of wood products forms a major part of Santa Catarina's industry; these products include processed wood, furniture, and charcoal. Brazil's best coal is mined about 70 miles northwest and southwest of Tubarão on the southern coast. Fishing and fish processing are important, as also are cattle raising and other forms of food production and processing. There is rather low productivity, however, which is caused by a scarcity of skilled labour and a lack of knowledge of modern marketing techniques.

Transportation. The road system dates from the colonial era but has been modernized during the mid-20th century. Two national highways cross the state from north to south and one from east to west. Secondary roads from the main producing areas are linked to these highways. A railway line crosses the centre of the state from south to north but is no longer of major significance; there are also some minor branch lines. River and sea transport is poorly developed. The principal ports are São Francisco do Sul, Itajaí, Florianópolis, Imbituba, and Laguna. The local airports are at Florianópolis, Joinville, Joaçaba, Cricúma, Caçador, Chapécó, and Navegantes. An international airport is under construction at Navegantes.

Cultural life and institutions. The theatre is popular in Florianópolis and Blumenau; there are 12 museums and more than 300 libraries in the state. There are nine daily newspapers, two television stations, and 61 radio sta-

gration

Education

tions. The state Institute of History and Geography has been in existence since 1896 and the Academy of Letters since 1920. Traditional folk dancing is a favourite activity, and folk arts and crafts are widely practiced. Public festivals celebrate a number of Catholic saints. When religious processions are held, it is a common practice to cover the roads with carpets of flowers.

(W.F.P.)

Santalales

The Santalales, or sandalwood order of flowering plants, consists chiefly of members either partially or entirely parasitic on other plants. The order is of interest from several points of view. The true sandalwood (*Santalum album*) and some of its near relatives play an important role in the practices of various religious groups in the Orient. The oil distilled from its wood continues to be of commercial importance and is used as a body ointment and a constituent of many soaps and perfumes. The European mistletoe (*Viscum album*) is thought to have had special ritual significance in Druidical ceremonies and lives in folklore today, its special status as the Christmas mistletoe having come from Anglo-Saxon times. *Phoradendron serotinum*, somewhat similar to its European counterpart, is an acceptable substitute in North America.

GENERAL FEATURES

The order contains trees up to 60 feet (18 metres) high and many shrubs and perennials, but no shorter lived annuals or biennials. The smallest member of the order is the dwarf mistletoe (*Arceuthobium minutissimum*), one of the smallest of all vascular plants, its flowering stems extending from the host plant for no more than about three millimetres (about 1/8 inch).

Distribution and abundance. The great majority of species in the order are tropical and subtropical, but a number of genera, especially in the families Santalaceae and Loranthaceae, have temperate representatives. There are no truly Arctic species, although *Geocaulon* (Santalaceae) occurs north to the shores of Hudson Bay and to north of Inuvik in Canada. Of the mistletoe genera only *Arceuthobium* of the Northern Hemisphere is present in both the Old and New Worlds. In other large families in the order, such as the following, geographic distribution is more limited: Erythropalaceae (Southeast Asia); Cardiopteridaceae (Indo-Malayan); Dipentodontaceae (Southeast Asia); Medusandraceae (tropical West Africa); Myzodendraceae (southern tip of South America); and Cynomoriaceae (Mediterranean). Many of the parasitic forms are restricted in occurrence, but some of the smaller species may be extremely abundant and widespread, as in *Arceuthobium*, *Phoradendron*, and *Comandra*.

Importance. The economic importance of the order focusses on the sale of mistletoe, the use of sandalwood products, and the destructive effects of various parasitic mistletoes.

Mistletoe branches are gathered in rural areas of many central and western European countries and shipped to larger cities, to reach the market during the week before Christmas. In North America most of the commercially important mistletoe is harvested in Texas, New Mexico, and Oklahoma.

The use of sandalwood products is varied and goes back to the dawn of history. Sandalwood was known as long ago as 1700 BC (Egypt), and its use in the Far East is probably older. It is used as a ceremonial burning material during religious rites (especially burials) of Hindus, Buddhists, Parsis, and Moslems in Southeast Asia. The wood is also of excellent quality for wood carvings. The famous sandal oil is slowly distilled from the wood, that of older roots being especially high in oil content. Used for centuries as a body ointment, it has more recently been found to be extremely useful in fixing such delicate and quickly vanishing fragrances as jasmine. Both the United States and France import significant amounts of sandal oil from Australia and India, respectively, for use in the manufacture of perfumes and soaps. Because of the high cost of sandalwood, various substitutes are offered locally, some from closely related members of the fami-

lies Santalaceae or Olacaceae in the sandalwood order (as in the Australian *Eucarya spicata* and the Indian genus *Ximenia*); others from quite unrelated families of other orders (as in *Erythroxylum* of the family Erythroxylaceae in India and the Venezuelan genus *Amyris* in the family Rutaceae). The best sandal oil is derived from the wood of *Santalum album*, a tree extensively planted in Southeast Asia. The most important industry is centred in the Indian state of Mysore where it has been a state monopoly for many years. In Hawaii, the rise of King Kamehameha in the 19th century has been credited to the income from local sandalwood, which was exported to the Orient.

Although the great majority of species in the sandalwood order are parasitic upon other vascular plants, only the mistletoes cause serious damage to economically important plants. Primitive agricultural practices in many tropical areas frequently take little account of the occasionally very great populations of mistletoes on cacao, rubber, citrus, and many other trees, especially fruit. The genus *Dendrophloe* in the Indian region, and *Struthanthus* in tropical America can be especially bothersome. *Viscum album*, the Christmas season mistletoe, malforms ornamental trees in many European countries, thus decreasing their value. The dwarf mistletoes, *Arceuthobium americanum*, *A. douglasii*, *A. campylopodum* and *A. vaginatum*, in western North America are among the most serious forest pathogens (causes of diseases) because they attack most of the conifers in the region to varying degrees. Numerous *Phoradendron* species in the United States are also important pathogens of several trees, including walnut, oak, and some conifers.

NATURAL HISTORY

Predominance of parasitism. By far the most interesting evolutionary development in the order is the phenomenon of parasitism. More than half of the species in the order are parasitic, including all known members of the following families: Santalaceae, Loranthaceae, Viscaceae, Eremolepidaceae, Myzodendraceae, Cynomoriaceae, and Balanophoraceae. In addition, the genera *Cansjera* (Opiliaceae), *Olex*, *Ptychopetalum*, and *Ximenia* (Olacaceae) are known to be parasitic.

The most obvious evidence of parasitism lies in the occurrence of the haustorium, a specialized absorbing organ that penetrates into living host tissues and functions to transfer various materials from the host into the parasite.

In certain advanced species an extensive invasion of host tissues takes place. The intrusive organ becomes fragmented and branches out through the softer tissues of the host. This development is especially noteworthy in most members of the family Viscaceae, and probably in the genus *Phacellaria* (Santalaceae). In certain species of dwarf mistletoe (*Arceuthobium*) parasitic on conifers, a threadlike system develops internally and may reach into the growing point of the host. The host tree responds to such an all-pervasive parasite attack by developing a striking abnormal bushy growth at its top, known as a 'witches' broom'.

The degree to which the parasitic species is dependent on the host is poorly understood but is probably high for most species, even obligatory under natural conditions. Chlorophyll is present in all species except those of the families Cynomoriaceae and Balanophoraceae, which are completely dependent on parasitism for nutrition. Studies with radioactive isotopes indicate that the more reduced forms, such as *Arceuthobium*, have a greater dependence on the host compared with greener and more leafy parasites such as *Phoradendron*.

Dispersal. In the treelike or shrubby species of the order, the nutlike or drupelike fruits are probably spread by birds or other animals. It has been known since Roman times, however, that a rather special relationship exists between mistletoes and birds. The fleshy, one-seeded berries of mistletoes are eaten by a great variety of birds. The extremely viscous seeds pass through the digestive tract unharmed and, when voided on a suitable object, will sometimes germinate and become established on

Witches' broom response of host plants

Birds as agents of dispersal

Sandal oil

a new host tree. Outside the mistletoe families, *Phacellaria*, and possibly some other santalacean, tree-inhabiting genera have evolved a similar dependence upon bird dispersal. In most mistletoes, the degree of dependence on this partnership is complete.

Several mistletoes, however, are not dependent upon birds. The Australian treelike mistletoe *Nuytsia floribunda* has winged, dry nuts, which hold no interest for birds. The minute fruits of the family Myzodendraceae bear long, hairy structures that attach themselves to leaves and branches of the host tree. These seeds are probably wind dispersed. In the dwarf mistletoe genus *Arceuthobium* (Viscaceae), the fruit is explosive, and the sticky bullet-shaped seed may travel up to 15 metres (49 feet) with astonishing velocity (initially, 24 metres per second [79 feet per second]) before adhering to a new host branch.

FORM AND FUNCTION

Vegetative characters. One of the most remarkable vegetative characters of the sandalwood order is the **haustorium**, a specialized absorbing organ that attaches to other plants and provides a means by which the parasite obtains water and nutrients from the victimized host plant. The typical young haustorium is a small bell-like or even clamplike organ, which attaches by its lower surface to a suitable host. From the central tissues of the anatomically complex haustorium a small intrusive, wedgelike organ grows out toward and into the host tissues, where it undergoes further development. The mature haustorial organ is characterized by a partial fusion of the xylem, or water conducting tissues, of host and parasite. The bell-like shape of the original haustorium soon disappears during expansion of the host-parasite contact zone. The size of the haustorium ranges from about one millimetre in most species up to one foot in diameter in the exceptionally large, mature *Psittacanthus* haustorium. The *rosas de palo*, or *flores de palo*, sold as curiosities in Mexico, consist of the abnormally developed wood of the host tree where these large haustoria were once attached.

Few generalizations can be made about other vegetative characters. Nearly all species have simple leaves lacking stipules, and only a few bear surface hairs on the leaves or stems. In many parasites of the order, including, among others, all members of the family Balanophoraceae, leaves are reduced to scalelike organs. Even among species with well-developed leaves, including the temperate-climate woody species the evergreen habit predominates and leaf fall in autumn is rare.

Flower and fruit characters. The flower may have both petals and sepals as in any typical flower, or, as is common in many members of the order, one or both of these sets of flower structures may be entirely lacking. The male parts of the flower, the stamens, usually occur in numbers equalling the number of petals and are positioned directly opposite the lobes of the petals rather than between adjacent ones. The female structure, the ovary, is positioned in the flower embedded in tissues below the region where the petals and sepals are attached, or it may be positioned higher up in such a way that the sepals and petals are located at its base. The first condition, termed inferior ovary is the type that predominates in the order. Inside the ovary, two to several ovules, or developing seeds, are present. Sometimes these ovules lack the tissues that are destined to become seed coats in later development.

The fruit ranges from rather large nuts in many members of the Olacaceae family to exceedingly minute fruits in the Balanophoraceae family. Almost invariably, the seed is solitary and contains special nutrient tissue, the endosperm. In especially the parasitic groups a trend toward reduction of seed coats and embryos is evident, resulting in a propagative unit that in some groups is different from a typical seed. In most mistletoes a portion of the ovary wall supplies the viscous layer of this "seed."

Evolution and paleontology. There is no significant fossil record for the order Santalales, and evolutionary considerations must therefore be based upon contemporary members.

Floral characteristics in representative families of the sandalwood order.
Drawing by R. Findahl

CLASSIFICATION

Distinguishing taxonomic features. The order Santalales as defined by most authorities consists of an apparently unnatural (*i.e.*, unrelated by descent from a common ancestor) association of the Santalales core families with various other small families, the number and assortment of which depend upon the authority consulted. It is, therefore, virtually impossible to describe meaningful characteristics held in common by all members of the order. In the restricted conception of the order the primitive olacacean complex (families Olacaceae, Opiliaceae, Schoepfiaceae) plus the families Loranthaceae and Santalaceae predominantly contains species with bisexual flowers; all other derived (*i.e.*, related by descent from primitive complex) families have unisexual flowers only (families Viscaceae, Myzodendraceae, Eremolepidaceae). Leaves are without stipules except in the families Dipentodontaceae and Medusandraceae. Leaves are simple in all families except Cardiopteraceae, in which palmately lobed leaves occur. In more advanced parasites, the leaves are often reduced to small scales. Ovules are few, frequently only one or two, and their attachment to the ovary tends to be on a central column unsupported except at its base. Seeds of nearly all have nutritive tissues called endosperm for the use of the developing young plant at germination.

Annotated classification. The extremely variable composition of this order and the apparently unnatural assemblage of families, even in many recently proposed systems, makes an acceptable grouping of families by relationship impossible. The following annotated classification, therefore, consists of two parts: (1) Santalales, in the restricted sense, including all families of some indisputable relationship to Santalaceae, and (2) an alphabetical list of various other families placed at some time in Santalales by one or more responsible authorities.

ORDER SANTALALES

Woody plants ranging from a few millimetres to 15 m (49 ft) or more in height, mostly parasitic on the branches of trees or on the roots of perennial plants. Leaves simple, entire, and without stipules (small leaflike appendages at the base of the leaf stalk) alternate or opposite. Corolla (petals) and calyx (sepals) usually 5- or 4-parted (*i.e.*, the number of petals and/or sepals is either 5 or 4) but the calyx greatly reduced in

some families and completely absent in others. Stamens as many as the perianth (sepals and petals) members or petals, in the latter case mostly opposite the petals. Ovary superior or (more commonly) inferior, ovules or embryo sacs few and basal, ovules frequently greatly reduced.

Family Aptandraceae

A small family of trees with the general characters of Olacaceae and usually included in that family. The calyx enlarges after fertilization to enclose the entire fruit; filaments are fused to form a tube surrounding the style. Equatorial America, Africa, and southwest Asia.

Family Eremolepidaceae

A small neotropical family of mistletoes parasitic on various tree species. Leaves alternate; in 1 genus (*Eubracion*) reduced to scales. Inflorescences spikelike or catkin-like, flowers small and drab, unisexual. Fruit a 1-seeded berry. Three genera and about 10 species. Only recently revived, the family in the past has been part of Viscaceae or Loranthaceae.

Family Loranthaceae (in the broad sense)

Trees or shrubs parasitic on branches of trees, rarely on roots of smaller vascular plants. Leaves usually opposite and evergreen. Flowers unisexual (subfamily Viscoideae) or bisexual (most of subfamily Lorantheidae). Stamens opposite petals, ovary inferior, giving rise to a (usually) viscous single seed disseminated by birds. Corolla 2- to 7-parted (*i.e.*, there are 2 to 7 petals), calyx absent (subfamily Viscoideae) or reduced to rimlike outgrowth (subfamily Lorantheidae). Embryo sacs embedded in ovarian papilla representing joined, reduced ovules. Seed with endosperm in nearly all species. A largely tropical family, only some genera being established in temperate zones, especially of the Northern Hemisphere (*Arceuthobium*, *Viscum*, and *Phoradendron* in particular). The family has been regarded as a single family through most of its history, commonly known as the mistletoe family. Two clear subfamilies have been recognized, Lorantheidae and Viscoideae. Recent authors agree in separate familial status for each, the 3 genera *Eremolepis*, *Aiztidaphne*, and *Ezbrachion* sometimes being removed from Viscoideae to form the family *Eremolepidaceae*. Loranthaceae in the broad sense contains about 75 genera and 1,300 species.

Family Loranthaceae (in the restricted sense)

A nearly exclusively tropical family of mistletoes parasitic mostly on branches of trees. Some are, or can be, terrestrial trees up to 10 m high, parasitic on roots of even small herbaceous plants (*e.g.*, *Nuytsia* from Western Australia, *Gaiadendron* from tropical America). Leaves usually evergreen and opposite. Flowers mostly bisexual, calyx reduced to a rimlike structure called a calyculus, corolla usually 4-, 5-, or 6-parted (*i.e.*, there are 4, 5, or 6 petals), each petal bearing a basally attached stamen. Ovary inferior, ovules reduced to a knoblike basal placenta, or embryo sacs originating in receptacular tissue. Fruit a 1-seeded berry (except *Nuytsia*) disseminated by birds. Some 65 genera and 850 species, the most important centre of distribution being from tropical Asia to New Guinea and Australia.

Family Myzodendraceae

Mistletoe-like plants parasitic on *Nothofagus* (false beech) in southern South America. Leaves small and deciduous or squamate, inflorescences catkin-like. Flowers reduced to 2 or 3 stamens or a minute ovary, perianth virtually absent. Fruit a small achene (a small, dry, 1-seeded, nonsplitting fruit with a tight, thin seed coat) with 3 long, feathery modified stamens. One genus and about 10 species.

Family Octoknemaceae

A problematic family maintained in several systems. One of the 2 constituent genera (*Octoknema*) has recently been placed in the Olacaceae family, the other (*Okoubaka*) with Santalaceae.

Family Olacaceae

A tropical and subtropical family of trees and shrubs 3 of which (*Ola*x, *Ximenia*, and *Ptychopetalum*) are known to be parasitic on roots of other plants. Leaves simple, alternate. Inflorescence usually a raceme (a simple elongate flower cluster having flowers on stalks, the lowermost flowers maturing first), sometimes catkin-like, and flowers bisexual. Calyx reduced to calyculus, frequently expanding greatly in fruit. Corolla 3- to 6-parted. Stamens 1 to 3 times as many as petals and opposite them, or more numerous and in varying positions, surrounded by a disklike rim or nectary. Ovary inferior to superior, with a central stalk from which 3 ovules are suspended. Fruit a 1-seeded drupe or nut. The family contains 25 genera and 250 species unless it is united with the related Opiliaceae, making then a total of 33 genera and 310 species.

Family Opiliaceae

A family sharing most characters with Olacaceae, but distinguished from it by the usual absence of the calyculus or calyx,

and by an apparent fragmentation of the nectary-like disk into frequently staminode-like units. Petals 4 to 5, each with an opposite stamen. One genus (*Cansjera*) is known to be parasitic. Opiliaceae is perhaps more properly added to Olacaceae to which, in any case, it is very closely related. Eight genera and 60 species.

Family Santalaceae (sandalwood family)

Named after the true sandalwood, *Santalum album*. Small parasitic herbs, shrubs, or trees with mostly alternate leaves. Inflorescence variable, flowers mostly bisexual. Perianth of 1 whorl of 3 to 5 stamen-bearing members. Ovary mostly inferior, containing 1 to 3 ovules suspended on a twisted basal stalk, or embedded in an ovarian papilla as in mistletoes. Fruit a 1-seeded drupe or nut. About 30 genera and 400 species, mostly tropical or subtropical.

Family Schoepfiaceae

An infrequently recognized family containing the single genus *Schoepfia*, more commonly placed in Olacaceae. Separation as a family has been justified on the basis of the apparent absence of a calyculus and the inferior position of the ovary. *Schoepfia* has perhaps 25 species, mostly tropical.

Family Viscaceae

A mistletoe family parasitic on branches of trees. Leaves mostly opposite, in many species reduced to scales. Flowers unisexual; perianth of 1 whorl of 2 to 5 members, each bearing a stamen, the latter reduced to a sessile anther (anther having no stalk) in some genera. Ovary inferior, with ovarian papilla containing 2 embryo sacs. Fruit a 1-seeded berry with viscous seed, the endosperm often containing chlorophyll. Including *Eremolepidaceae*, the family contains 11 genera and about 450 species, mostly tropical. The European mistletoe, *Viscum album*, is the best known member of the family.

FAMILIES FREQUENTLY PLACED IN SANTALALES BUT OF UNCERTAIN AFFINITIES

Family Balanophoraceae

Mushroomlike parasites on the roots of trees or shrubs. Chlorophyll absent; leaves reduced to fleshy scales or absent. Inflorescence usually unbranched, fleshy, bearing many minute, unisexual flowers. All species in tropical areas except the Mediterranean *Cynomorium coccineum* (the Maltese fungus of the Crusaders), which is sometimes placed in a separate family, *Cynomoriaceae*. Probably not related to the family Santalaceae. About 100 species in 16 genera.

Family Cardiopteridaceae

(or Cardiopterygaceae or Peripterygiaceae)

Green climbing plants with small bisexual flowers, superior ovary, and winged fruits. A single genus (*Peripterygium*) with 3 species. Southeast Asia to Queensland.

Family Cynomoriaceae

See under Family Balanophoraceae.

Family Cytinaceae

Two genera (*Cytinus* and *Bdallophyton*) of wholly parasitic species, normally included in family Rafflesiaceae.

Family Dipentodontaceae

A single genus and species of deciduous small trees, native to southwestern China and adjacent India. Little in common with Santalales, and probably related to the family Flacourtiaceae in the order Violales.

Family Erythralaceae

Liana-like shrubs with simple leaves and slender divided inflorescences of bisexual flowers. Fruit nutlike, with a long stripe, and completely enclosed by a persistent calyx. One genus, with perhaps 2 species; tropical Asia. The family is not satisfactorily placed in Santalales and shows similarities with the families Icacinaceae and Celastraceae, both in the order Celastrales. Included in Olacaceae in earlier works.

Family Grubbiaceae

A South African family of shrubs at one time regarded as santalalean but now believed to belong to the orders Ericales, Pittosporales, or some other group. Two genera, 5 species.

Family Hydnoraceae

A small family of 2 genera with 2 species each, in arid South America and eastern Africa. Leafless parasites on roots of various plants. Only individual fleshy flowers emerge from the soil. The fruit is a pulpy mass with numerous minute seeds. The family is related to the family Rafflesiaceae but probably not to Santalales.

Family Medusandraceae

Trees with simple alternate leaves and catkin-like inflorescences of bisexual flowers. A single genus and species of obscure affinities. West Equatorial Africa.

Family Peripterygiaceae

See under Family Dipentodontaceae.

Family Rafflesiaceae

A small family of about 50 species of mostly tropical, chlorophyll-less parasites in most cases reduced to no more than (sometimes very large) flowers that emerge from a mycelium-like absorptive organ embedded within host tissues. In older systematic treatments Rafflesiaceae (and the related Hydnoraceae) were commonly placed in Santalales, but recent authors have realized the artificiality of this position and now place it in the order Rafflesiales.

Critical appraisal. The order Santalales, in the broad sense, is clearly a miscellaneous collection of families many of which are of uncertain affinity. Following detailed analysis, some of these families may eventually be placed in different orders related to but outside the order Santalales. Others (Cynomoriaceae, Balanophoraceae) seem to be included mainly because of their parasitism and extreme reduction and are not likely to remain in the vicinity of Santalales. Other parasitic families (Hydnoraceae, Rafflesiaceae) were at one time placed in the order for similar reasons. When stripped to families of undoubted relationship there remain five to nine families, depending on taxonomic judgment. The olacacean complex (families Olacaceae and Opiliaceae, including Apandraceae and Schoepfiaceae) is very inadequately known. Nearly all authors agree that other families in the order are traceable to Olacaceae-like ancestors, although the exact lineages are not completely agreed upon. The more common concept visualizes a descent of all mistletoe-like plants (Loranthaceae, Viscaceae, Myzodendraceae, Eremolepidaceae) from Olacaceae, via Santalaceae. This particular evolutionary pathway has logical obstacles, except for Viscaceae. Separate evolutionary lines from the olacacean complex to each of Eremolepidaceae, Myzodendraceae, Santalaceae, and Loranthaceae is perhaps a more accurate concept of descent. Viscaceae as a separate family might be derived from ancestral members of the Santalaceae family.

BIBLIOGRAPHY. J. KUIJT, "Mutual Affinities of Santalean Families," *Briftonia*, 20:136-147 (1968), a historical resumé of the composition of Santalales, with an exposition of newly conceived evolutionary relationships, *The Biology of Parasitic Flowering Plants* (1969), a worldwide treatment of all parasitic groups of angiosperms, with special sections on history, folklore, haustorium, physiology, evolution, and each parasitic group; B.A. BARLOW, "Classification of the Loranthaceae and Viscaceae," *Proc. Linn. Soc. N.S.W.*, 87:51-61 (1969), a formal recognition of two mistletoe families, and natural grouping within each; A. TAKHTAJAN, *Flowering Plants: Origin and Dispersal* (1969; Eng. trans. from the 2nd Russian ed., 1961), a recent book treating plant relationships at the level of families and orders; J. HUTCHINSON, *The Families of Flowering Plants*, vol. 1, *Dicotyledons*, 2nd ed. (1959); A. ENGLER and K. PRANTL, *Die natürlichen Pflanzenfamilien*, 2nd ed., vol. 16b (1935), the only recent, detailed coverage of the plant kingdom. Vol. 16b contains chapters, written by various specialists, on all important santalean families, including Balanophoraceae, Hydnoraceae, and Rafflesiaceae.

Santayana, George

George Santayana was an early-20th-century philosopher, novelist, and man of letters, the speculative naturalism and critical Realism of whose thought was expressed in prose of great formal beauty. At once a Skeptic and a humanist, Santayana gave a rich and perceptive account of human experience—ethical, social, religious, and artistic—skillfully interweaving themes that modern technical philosophy keeps apart.

Career at Harvard and in England. George Santayana was born of Spanish parents on December 16, 1863, in Madrid. He never relinquished his Spanish citizenship, and, although he was to write in English with subtlety and poise, he did not begin to learn that language until taken to join his mother in Boston in 1872. Santayana was to reside in New England for most of the ensuing 40 years. He went through the Boston Latin School and Harvard College, graduating summa cum laude in 1886. He then spent two years studying philosophy at the University of Berlin before returning to Harvard to complete his doctoral thesis under the Pragmatist William

Santayana.

James. He joined the faculty of philosophy in 1889, forming with James and the Idealist Josiah Royce a brilliant triumvirate of philosophers. Yet his attachment to Europe was strong. He spent his summers in Spain with his father, visited England, and spent his sabbatical leaves abroad: at Cambridge, in Italy and the East, and at the Sorbonne.

At Harvard he began to write. *The Sense of Beauty* (1896) was an important contribution to aesthetics. The essay is concerned with the nature and elements of man's aesthetic feelings and holds that to judge that anything is beautiful is "virtually to establish an ideal"; and the understanding of why something is thought to be beautiful enables one to distinguish transitory ideals from those that, springing from more fundamental feelings, are "comparatively permanent and universal." The vital affinity between such aesthetic faculties and man's moral faculties is illustrated in Santayana's next book, *Interpretations of Poetry and Religion* (1900), particularly in the discussion of the poetry of Robert Browning, which is a model of its kind.

The Life of Reason (1905-06) was a major theoretical work consisting of five volumes. Conceived in his student days after a reading of Hegel's *Phenomenology of Spirit*, it was described by Santayana as "a presumptive biography of the human intellect." The life of reason, for Santayana as for Hegel, is not restricted to purely intellectual activities, for reason in all of its manifestations is a union of impulse and ideation. It is instinct become reflective and enlightened. The theory is given practical illustration in a series of essays, gathered into two volumes: *Three Philosophical Poets: Lucretius, Dante, and Goethe* (1910); and *Winds of Doctrine* (1913), in which the poetry of Percy Bysshe Shelley and the philosophies of Henri Bergson, a French evolutionary philosopher, and of Bertrand Russell are discussed.

Santayana was appointed a full Harvard professor in 1907. In 1912, however, while he was in Europe, his mother died, and he sent in his resignation from there. He never returned to America, although several attractive offers were made by Harvard in an attempt to draw him back.

Santayana's resignation astonished his colleagues, for it came at the height of his career. All of his books were admired and influential, and there seemed to be an intimate connection between them and his teaching. Clearly, he was a gifted teacher: interested in his students, devoid of pedantry, and with a superb capacity for analyzing philosophies and related poetry with lucid sympathy while judging them by standards that remained rational and humane. His resignation, nevertheless, can be seen as inevitable: he disliked the academic straitjacket; he wished to devote himself exclusively to his writing; and he was ill at ease in America. His Latin heritage and allegiance gave to his thinking a striking range and perspective, but the net result was to make him want "to say plausibly in English as many un-English things as possible." From the strain of doing this, he was thankful to escape.

Early writings

When World War I began, Santayana was in Oxford, and he settled there for the duration. Though he enjoyed the friendship of several eminent people, the war saddened him, and he led a secluded life. *Egotism in German Philosophy* appeared in 1916, making clear his strong allegiance to the Allied cause; he also wrote a number of popular essays centring on the English character and countryside. At the end of the war he was offered a life membership in Corpus Christi College, Oxford, but he declined.

Career in Rome. In 1924 he settled permanently in Rome. The atmosphere was congenial to a native-born Catholic who, though evolving into a philosophical materialist for whom the world of spirit was wholly ideal and nonexistent, had always admired the Catholic and classical traditions. Three new books consolidated his reputation as a humanist critic and man of letters, and this side was brought to perfect expression in a novel, *The Last Puritan* (1935).

The bulk of his energies in the interwar years, however, went into speculative philosophy. *Scepticism and Animal Faith* (1923) marks an important departure from his earlier philosophy and serves as "a critical introduction" to and résumé of his new system developed in the four-volume *Realms of Being* (1928, 1930, 1937, 1940), an ontological (nature of being) treatise of great concentration and finish. In these later works Santayana enhanced his stature as a philosopher by achieving greater theoretical precision, depth, and coherence. *Scepticism and Animal Faith* conveys better than any other volume the essential import of his philosophy. It formulates his theory of immediately apprehended essences and describes the role played by "animal faith" in various forms of knowledge.

In *Realms of Being* extraordinarily complex points are elucidated with luminous succinctness, although the general reader is deterred by their technicality and by the aestheticism inherent in a view of Truth as simply "that segment of the realm of essence which happens to be illustrated in existence." "The realm of essence," in Santayana's system, is that of the mind's certain and indubitable knowledge. Essences are universals that have being or reality but do not exist. They include colours, tastes, and odours as well as the ideal objects of thought and imagination. "The realm of matter" is the world of natural objects; belief in it rests—as does all belief concerning existence—on animal faith. Naturalism, the dominant theme of his entire philosophy, appears in his insistence that matter is prior to the other realms.

Such a philosophy enabled Santayana to accept imperceptibly another onset of war. He took rooms in a Catholic nursing home and began a three-volume autobiography, *Persons and Places* (1944, 1945, 1953). When Rome was liberated in 1944, the 80-year-old author found himself visited by an "avalanche" of American admirers. By now he was immersed in *Dominations and Powers* (1951), an analysis of man in society; and then with heroic tenacity—for he was nearly deaf and half blind—he gave himself to translating Lorenzo de' Medici's love poem, "Ambra," during which he was overtaken by his last illness. He died on September 26, 1952, a few months before his 89th birthday, and was buried, as he had wished, in the Catholic cemetery of Rome in a plot reserved for Spanish nationals.

MAJOR WORKS

PHILOSOPHY: *The Sense of Beauty* (1896); *The Life of Reason; or the Phases of Human Progress* (1905–06), five volumes consisting of *Reason in Common Sense*, *Reason in Society*, *Reason in Religion*, *Reason in Art*, and *Reason in Science*; *Scepticism and Animal Faith* (1923); *Realms of Being* (1927–40), four volumes consisting of *The Realm of Essence*, *The Realm of Matter*, *The Realm of Truth*, and *The Realm of Spirit*; *Dominations and Powers* (1951).

CRITICAL WRITINGS: *Interpretations of Poetry and Religion* (1900); *Three Philosophical Poets: Lucretius, Dante, and Goethe* (1910); *Winds of Doctrine* (1913); *Egotism in German Philosophy* (1916); *Philosophical Opinion in America* (1918); *Character and Opinion in the United States* (1920); *Platonism and the Spiritual Life* (1927); *Some Turns of Thought in Modern Philosophy* (1933); *The Idea of Christ in the Gospels* (1946).

OTHER WORKS: *The Last Puritan* (1935), a novel; *Persons and Places*, 3 vol. (1944–53), autobiography.

BIBLIOGRAPHY. There is no full-length biography of Santayana, but GEORGE W. HOWGATE, *George Santayana* (1938), and DANIEL CORY, *Santayana: The Later Years* (1963), together provide a detailed portrait that may be supplemented by DANIEL CORY (ed.), *The Letters of George Santayana* (1955), and by Santayana's three-volume autobiography, *Persons and Places* (1944–53). A comprehensive study of Santayana's philosophy, and in particular of his later ontology, has still to be written, but of special interest among book-length studies of his moral philosophy are: WILLARD E. ARNETT, *Santayana and the Sense of Beauty* (1955); MILTON K. MUNITZ, *The Moral Philosophy of Santayana* (1939); and JACQUES DURON, *La Pensée de George Santayana: Santayana en Amérique* (1950), which contains a detailed list of book reviews and articles on Santayana up to 1950. Two volumes bring together most of the shorter critiques of Santayana's philosophy: P.A. SCHILPP (ed.), *The Philosophy of George Santayana* (1940); and JOHN LACHS (ed.), *Animal Faith and Spiritual Life* (1967). The contents are of uneven quality, but there are informative essays by Bertrand Russell, Justus Buchler, and several others. An admirably detailed article on Santayana's critique of Idealism and Pragmatism is TIMOTHY L.S. SPRIGGE, "Santayana and Verificationism," *Inquiry*, 12: 265–286 (1969). Editorial introductions to the following collections of Santayana's work provide interesting appraisals of his achievement as humanist and social and literary critic: NORMAN HENFREY (ed.), *Selected Critical Writings of George Santayana* (1968); RICHARD COLTON LYON (ed.), *Santayana on America* (1968); and DOUGLAS L. WILSON (ed.), *The Genteel Tradition* (1967), in which is traced the historical influence of that phrase as coined and given conceptual currency by Santayana in 1911.

(N.V.He.)

Santiago

Santiago is the capital and major city of the Republic of Chile. It is also the capital of Santiago province and the country's largest industrial centre. Located in north central Chile, the city has grown rapidly during the 20th century and has developed into the sprawling urban complex known as Greater Santiago, which covers an area of 132 square miles (342 square kilometres) with a complex of residential areas, industrial zones, and slums. Its national importance is reflected in its metropolitan population of about 2,780,000—almost one-third of the nation's inhabitants.

Santiago is plagued by the urban problems of overcrowding, air and water pollution, lack of services, and the economic and social consequences of the migration of city residents to the ever-expanding suburbs. It is also the object of rivalry from other Chilean cities that desire more development for themselves. It has always been Chile's principal city, however, and its continued position as the major economic and cultural centre of the country seems assured.

History. The city was founded as Santiago del Nuevo Extremo (Santiago of the New Frontier) in 1541 by the Spanish conquistador Pedro de Valdivia. The area was inhabited by the Picunche Indians; who were placed under the rule of the Spanish settlers who formed the city. The original city site was limited by the two surrounding arms of the Mapocho River and by Huelén (renamed Santa Lucía) Hill to the east, which served as a lookout.

Santiago was the original headquarters of the Spanish governor of Chile and has been the nation's capital throughout its history. As they were created, various governmental, military, ecclesiastic, and cultural institutions were established there. These included the Town Council (founded 1541), the archbishopric (1561), the Royal Court (1609)—a subsidiary of the Spanish Royal Court, the University of San Felipe (1747), the Mint (1743), and the Court of the Consulate (1795), which served both commercial and judicial functions.

During the period of Spanish domination, growth was slow. In 1700, the city covered one and a half square miles and had a population of 10,000. A century later it had expanded to almost three square miles and had 25,000 residents. Its checkerboard outline was maintained until the early 1800s, when it grew to the north, to the south, and especially to the west. The south shore of the

Carl Frank

Mapocho River was drained and converted into a public promenade, now the Alameda Bernardo O'Higgins. The more densely inhabited neighbourhoods formed a suburban area to the north of the river called La Chimba.

At the beginning of the struggle for independence in 1810, the city covered nearly four square miles and had 35,000 inhabitants. It suffered little during the War of Independence (1810–18), since the decisive Battle of Maipú took place outside the city limits. Santiago was named the republic's capital in 1818; it became the seat of the National Congress, the Supreme Court of Justice, the University of Chile, the ministries, and the municipal theatre. Thus, during the remainder of the 19th century, the wealth of the nation flowed into Santiago.

Prosperous saltpeter, copper, and coal magnates and absentee landlords moved to the capital, living in upper income neighbourhoods such as Cousiño Park. Middle income areas also developed. By 1900 the city's population had reached 250,000, with its area extended over 11 square miles.

During the 20th century, Santiago has grown rapidly and in an unplanned fashion. The absorption of nearby villages and towns has caused enormous increases in expenditure and has resulted in a sharpening of economic and cultural differences between the capital and other Chilean cities. By 1960, Greater Santiago covered 132 square miles and housed nearly 2,000,000 inhabitants.

The contemporary city. *The city site.* Santiago lies in a depression formed by the coastal mountain range, the Cordillera Occidental to the west, the Chacabuco Ridge to the north, and the towering Andes to the east. Its elevation is about 1,700 feet (520 metres) above sea level. The city centre covers an area of 21 square miles. It is triangular in shape, with Santa Lucía Hill forming the eastern tip of the triangle, the Mapocho River forming its northern border, and the Avenida Bernardo O'Higgins—or the Alameda—forming its southern boundary. Together with its surrounding suburbs, Greater Santiago spreads out in all directions over the Mapocho River's alluvial plains, but is confined on the east by the Andes. By 1970, the metropolitan area extended to the towns of Colina to the north, Buin to the south, Melipilla to the west, and Cajón del Maipo to the east.

Climate. The climate resembles that of the Mediterranean. Summer occurs between October and March; it is warm and dry with an average January temperature of 68° F (20° C). The annual average rainfall of 15 inches

occurs mainly in winter, when high humidity and low temperatures result in penetrating cold; the average July temperature is 46° F. Fog is common in winter.

Vegetation and animal life. The original vegetation consisted of grasses and brambles. It has largely disappeared within the city but can be found at the edges of the suburbs, especially to the east in the Andean foothills. Remnants of the original forests of peumus (a laureaceous plant bearing edible fruit) and litre (a hardwood tree with poisonous leaves) are found at Manquehue to the northeast and Peñalolén to the east.

In addition to the sparrows and pigeons introduced from Europe, there are indigenous birds such as the fieldfare, gold finch, *tiuque* (a bird of prey), and turtle dove. Rodents such as the rat and spiny mouse occur in the surrounding rural area.

The city layout. Greater Santiago includes 18 different *comunas* (districts). They are Santiago, Conchalí, Renca, Quilicura, Providencia, Las Condes, Nufioa, La Reina, San Miguel, La Florida, La Granja, La Cisterna, Puente Alto, San Bernardo, Pirque, Quinta Normal, Maipú, and Las Barrancas. Until 1960 each community enjoyed complete autonomy, but since then the degree of autonomy has been reduced with the introduction of the Intercommunity Regulating Plan of Santiago, which harmonizes city development. The suburbs have nevertheless continued to expand, and the outlying districts are not under the plan's control.

Santiago's checkerboard plan of rectangular city blocks has spread monotonously over the flat valley and has partly climbed up the Andean piedmont and the spur of the coast mountains. Apart from the basic triangular shape of the city, the city map resembles a misshapen star, whose five points correspond to the main highways, along which homes have been built.

The *centro*, or downtown area, the city's original nucleus, is centred on the Plaza de Armas and the Barrio Cívico, which contain a concentration of high-rise buildings primarily intended for administrative and commercial use and only secondarily for residences. The *barrio alto*, or high district, includes the upper-income communities of Providencia (6,658 feet), Las Condes (2,719 feet), and La Reina (1,827 feet), which are located on the elevated ground of the Andes foothills. The altitude of the area is a symbolic socioeconomic segregating barrier. Its occupants are largely managers, high-level professionals, and members of the business community.

Neighbourhood districts

Social stratification

Social stratification in the rest of the city is complex. The middle-income group is predominant in Santiago proper and in Nuñoa. The lower income group is crowded into the peripheral northern, western, and southern communities.

Transportation. Santiago's urban interests have largely conditioned the development of Chile's transportation system. The city is the focus of the nation's internal communications. Because of the configuration of the country, most transportation routes are established to the north and south of Santiago, where the northern and southern sections of the Pan-American Highway meet. The state railroads also run north and south from Santiago. There are eight city railroad stations, the most important of which are Alameda and Mapocho. Highways and roads connect the city with the ports of San Antonio to the west and Valparaíso to the northwest, thus providing an outlet to the Pacific Ocean. To the east, there are only short roads leading to winter resorts.

Air communications are provided by the international airport at Pudahuel and the airport at Los Cerrillos, which handles domestic flights. There are also two smaller civil airports—Lo Castillo and Tobalaba—as well as El Bosque, a military airport.

The internal road system in Greater Santiago does not meet the increasing traffic needs, especially during the rush hour. Construction of a north-south highway through the city and an avenue encircling it are scheduled for the early 1970s. A subway is to be completed by 1976.

Demography. In 1970 the population of Greater Santiago was approximately 2,780,000. Its rapid growth, as mentioned, is due mainly to an influx of migrants from rural areas and small towns. The Santiago metropolitan area contains 29 percent of the nation's inhabitants.

There is a noticeable movement from the old city to the suburbs. Between 1960 and 1970, the population of Santiago proper dropped from more than 646,000 to about 510,000. Each of the suburbs, however, has gained in population. Some areas have densities of over 52,000 inhabitants per square mile, especially in low-income districts. The upper-income suburbs in the east have much lower densities.

Housing. Houses are built in a wide variety of architectural styles. The one-floor family house prevails, although large apartment buildings for workmen and other employees have been built. A large percentage of the population is inadequately housed in the central slum tenements, called *conventillos*, as well as in the marginal shanty towns, or *callampas*. The inevitable social pressures have been accumulating in these districts.

Building types. Architectural remnants of the colonial era include the Palace of the Governors, the Metropolitan Cathedral, the Mint, the Consulate Tribunal, and the churches of San Francisco, Santo Domingo, the Recoleta Franciscana, and the Church of Mercy. The Cousiio Palace is an example of 19th-century architecture, while early-20th-century styles are expressed in the Fine Arts Palace, the National Library, and the Union Club. Modern architectural achievements are represented by residences at Vitacura, San Luis Hill, and Lo Curro.

Industry. Greater Santiago contains Chile's greatest concentration of industry and produces about 50 percent of the nation's total industrial output. There are over 13,000 industries, employing more than 227,000 people—almost half the nation's industrial work force. The main products are foodstuffs, textiles, shoes, and clothes; metallurgy is also important. The preferred industrial locations are in Santiago proper and in the southern suburbs of San Miguel, Nuñoa, and Maipú. Important copper deposits are mined in Las Barrancas and Las Condes.

Commerce and services. Most of the labour force is engaged in providing services, but commercial activities are also of great importance. The city has an active financial sector, as well, including a stock exchange, 20 major banks with hundreds of branches, and many insurance companies. These activities were traditionally concentrated downtown, but, by the 1970s, other centres were forming, such as those in Nuñoa and Providencia.

Political institutions. Most of the governmental and public institutions are located near the Mint, near the residence of the president of the republic, and along Bulnes Avenue, an area known as the Civic District. Santiago, as noted, is the seat of the National Congress and the Supreme Court of Justice.

Public utilities. Santiago's accelerated growth has outstripped the effective capacity of public services. The provision of drinking water, sewage disposal, lighting, gas, telephones, and sanitation is reliable in the downtown area and the high-income district, while such services have deteriorated in the less wealthy neighbourhoods. Drinking water is supplied from Laguna Negra (Black Lagoon), situated approximately 30 miles east-southeast of Santiago, the Yeso Dam in the Andes, and the Vizcachas and Vizcachitas filtration plants east of Puente Alto. Electricity is provided by the Chilean Electricity Company from hydroelectric stations in the Andes, a coal-powered thermal plant in Renca, and the facilities of the National Electricity Enterprise.

Health and safety. There are over two dozen public hospitals and several first-aid stations. Public medical assistance is available for private homes, and there are also about 30 private clinics.

Police services are provided by a force of *carabineros*, or armed policemen, who are organized into precincts and subprecincts; there are also radio-patrol services. Fire protection is efficient and is provided by a nonprofit institution called the Firemen of Chile, consisting of about 50 units.

Education. Public education facilities include primary schools, vocational schools, and private high schools. Advanced educational institutions include the University of Chile, the Catholic University, and the State Technical University.

Cultural life. The city's cultural life is cosmopolitan, its native institutions exhibiting European and North American influences. There is a strong resurgence of mestizo artisanship, especially in the fields of music, theatre, painting, and literature.

The city contains about nine libraries and the National Archives. Museums include the National Museum of Natural History, which contains objects from Easter Island; the Museum of Maipú, containing colonial furniture and religious art; the National Historical Museum; the San Francisco Museum, with exhibits of colonial art; the Contemporary Art Museum; the Fine Arts Museum; and the Popular Arts Museum housing pieces of Chilean folk art.

There are almost a dozen newspapers, with a combined daily circulation of 400,000 copies. There are also 20 radio stations and three television channels that broadcast in Spanish.

The most prominent recreation areas are the public parks of Santa Lucía Hill; San Cristóbal Hill, with its zoo and camping grounds; Forestal; Cousiio; Quinta Normal; and La Quintrala. There are also more than 60 swimming pools, almost all of which belong to private institutions, and two circuses.

The National Stadium has a seating capacity of 80,000 people and is used for soccer games and gymnastic events. Many private and public sports clubs, as well as stadiums, offer varied facilities. There are ski slopes in Farellones and excellent transportation to the nearby seaside resorts spread along the coast between Algarrobo and Santo Domingo.

The popularity of drama and motion pictures is evidenced by Santiago's eight legitimate theatres and 90 movie houses.

(P.C.I.)

Santo Domingo

Santo Domingo, the capital of the Dominican Republic and the oldest surviving city established by Europeans in the Western Hemisphere, is situated on the southeast coast of the island of Hispaniola, on the west bank of the Ozama River. It was founded in 1496 by Bartolomeo Columbus, brother of Christopher, as the capital of the first Spanish colony in the New World. The Distrito Nacional (federal district) of the Dominican Republic includes the capital city and bears the same name. Its area is 570 square miles, with a population of about 800,000, of which about 670,000 live in the city proper.

History. From its beginnings in 1496, Santo Domingo was the seat of many of the New World's earliest important institutions: the first bishopric, 1504; the first Spanish viceroys, 1509; the first Royal High Court of Justice, 1511; the first cathedral, 1521; and the first university (the Royal and Pontifical University of Saint Thomas Aquinas, now Santo Domingo University), 1538.

Some scholars believe that the city was named after Domenico (or Domingo) Columbus, father of Bartolomeo and Christopher, whereas others think it was named in honour of the Spanish Saint Dominic (Domingo de Guzman).

The original city was located on the left (east) bank of the Ozama River and was called Nueva Isabela in honour of Queen Isabella. It was destroyed by a hurricane, however, and was rebuilt in 1502 at its present location on the right bank of the river. It became the starting point of most of the expeditions of exploration and conquest of the other West Indian islands and the adjacent mainland. The colony prospered as the seat of government of the Spanish possessions in the Americas until the conquest of Mexico and Peru, after which its importance declined.

In 1586, Sir Francis Drake, the famous English buccaneer, sacked the city and even cannonaded the cathedral, retiring only after he had been paid a ransom of 25,000 gold ducats. In 1655 its inhabitants defeated a British force that had been sent to seize the city.

For a few years, from 1795 to 1809, Santo Domingo was under French domination, and then, after a brief Spanish period, it was conquered by invaders from Haiti. Independence was proclaimed in 1844, and Santo Domingo became the capital of the new Dominican Republic until the republic's annexation to Spain in 1861-1865. It has been the Dominican capital since the restoration of independence in 1865. The city's name, officially changed to Ciudad Trujillo in honour of the dictator Rafael L. Trujillo Molina, who governed the republic from 1930 to 1961, was restored after his assassination in 1961.

The contemporary city. *Districts and landmarks.* Like many other Hispano-American cities, Santo Domingo was built on a geometric pattern. After a period of rapid growth since World War II, there are now two distinct districts: the old colonial city and the modern new city, or garden city. In addition there are some colourless, styleless buildings that are remnants of the 19th and early 20th centuries and some dilapidated slum areas that are being replaced by apartment complexes. These belong neither to the old city nor to the new.

The Distrito Nacional, as distinguished from the capital city, includes rural areas as well as suburbs, such as Boca Chica, San Lorenzo de los Minas, Guerra, La Victoria, and Los Alcarizos, all of which are within an average of about 12 miles of the capital's centre.

Much of the colonial city has been painstakingly reconstructed. The old section near the Ozama River continues south along the coast of the Caribbean and rises to the west and north until it reaches what is called the barrio (quarter or district) of San Carlos de Tenerife, where at one time the city fortifications ended. Within this area are almost all the buildings in the colonial style, including

churches, convents, palaces, civic buildings, and forts. The two most prominent colonial monuments are the cathedral, containing the reputed remains of Christopher Columbus, and the palace (or alcazar) of Diego Columbus. Other edifices of the colonial period include the San Diego Gate; the impressive ruins of the church of San Francisco; the church of the Society of Jesus, now the National Pantheon; the Count's Gate; and the Gate of Mercy, three Carmelite churches, and the church and fort of Santa Barbara, part of the old city's defense system. Among the secular remains are the Ozama Fortress, with what is called the Tower of Homage; the Sun Clock in front of the old Palace of the Generals; the House of the Cordon; the Arsenal; and the House of the Roasting (Casa del Tostado).

To the west of the old city the new city stretches along the coast and inland. Growing continuously toward the west, it includes thousands of middle-class and well-to-do homes. Broad front gardens and flowering interior patios present an orgy of colours and tropical plants, with geraniums, carnations, poinsettias, rose bushes, gladiolas, climbing plants, and trees such as the almond, mahogany, and palm in abundance. The homes are of many different styles, including colonial, modern, Bermudian, and Mediterranean. The government has built well-designed duplex and multifamily dwellings for working families. The architecture of privately owned suburban development is also attractive. This building boom, however, is resulting in the overexpansion of the city.

Climate. Santo Domingo enjoys a tropical climate. Tropical cyclones and hurricanes have usually missed the urban area, except for the one that destroyed the original city in 1502 and a hurricane that devastated the city of wooden houses in 1930. The average annual temperature has been 78° F (about 26° C), with a maximum of 91° F (33° C) in the summer and a minimum of 66° F (19° C) in the winter. The annual average rainfall is about 50 inches.

Transportation. Three principal roads connect the capital with the rest of the republic: the Duarte expressway to the north, the Mella road to the east, and the Sanchez road to the west. There are no railway lines from the capital, except those of the nearby sugar refineries. The port of Santo Domingo handles heavy passenger and freight traffic between Santo Domingo and the United States, Japan, and Europe. The Airport of the Americas, 18 miles from the city, is one of the most modern in the Americas. In 1969 a new air-conditioned terminal and a 270,000-square-foot airplane park were built.

Economic activity. Santo Domingo is the industrial and commercial centre of the country and is the location of a central bank for issuing currency and of the Dominican State Reserve Bank, as well as of branches of the most important United States and Canadian banks. The government has enacted an industrial-incentive law, exempting businesses in the city from heavy duties, and has ceded 2,000 acres for the Herrera industrial zone, which is four and a half miles from the capital and is supplied with all the basic urban services. Santo Domingo's progress, especially its industrial development, has been greatly influenced by the construction of two hydroelectric dams. The country's most important industries, such as metallurgy, refrigerators, automobile batteries, petrochemicals and plastics, cement, construction, furniture, textiles, shoes, perfumes, brewing, and food processing, are located in Santo Domingo.

The city's health services are advanced, and malaria, which had been a serious problem throughout the republic, has been eliminated. In early 1969 there were about 90 public and private health establishments of all types in the capital, with a total of about 5,000 beds.

Education, cultural life, and recreation. There are two universities, one public—the autonomous University of Santo Domingo—and the other private—the Pedro Henriquez Ureña National University—founded in 1966. In addition to primary schools, there are numerous private lycées and secondary schools (*colegios*) with religious affiliations, both Roman Catholic and other.

Santo Domingo's cultural institutions include the Na-

Industrial development

The Armed Forces building in Santo Domingo. A statue to Trujillo Molina stands at right foreground.

Photo Research International

tional Institute of Dominican Culture, the Higher Education Institute, the Higher School of Fine Arts, the National Theatre-School of Art, the Music Conservatory and the National Symphony Orchestra, the National Museum—important for its pre-Columbian collection—and various public and private libraries, especially the great National Library.

In the early 1970s three daily newspapers were published—two in the morning and one in the evening—plus several weeklies and magazines. There are 22 radio transmitters and two television stations; one, Dominican Radiotelevision, is the government station, and the other, Rahintel, is privately owned.

In addition to its zoo, Santo Domingo has also a beautiful green area, Mirador Sur Avenue, featuring small parks, illuminated fountains, and statues. There are also numerous plazas and parks.

For sports there are numerous volleyball fields and basketball courts in the schools and barrios, a magnificent baseball stadium capable of holding 16,000 spectators for the professional championship, and the Juan Pablo Duarte Olympic Centre for track and field events. Work has begun on the stadium in which the Central American Olympic Games will be held in 1974. There are five first-class international hotels, one of which has a polo field and golf course.

BIBLIOGRAPHY. For a general picture, HOWARD J. WARD, *The Dominican Republic (1969)*, has much material on Santo Domingo. For the historical and political background, see V.T. ROJAS, *This Is the Dominican Republic (1954)*; and the *Santo Domingo Year Book, 1950–54 (1954)*.

(M.G.A.)

São Francisco River

One of the greatest rivers in South America, the São Francisco is the third largest river system of Brazil and the largest river wholly within the country. It is regarded as "the river of national unity" because it has long served as a 1,800-mile (2,900-kilometre) line of communication between Brazil's maritime and western regions and between the north and the south. The river is named for the 16th-century Jesuit leader, St. Francis Borgia (São Francisco de Borja). It is an important source of hydroelectric power for northeastern Brazil and is a potential source of irrigation water for the country's dry interior plain. (For related articles, see BRAZIL and articles on the states of ALAGOAS; BAHIA; MINAS GERAIS; PERNAMBUCO; and SERGIPE.)

The river's course. The São Francisco rises at about 2,400 feet above sea level on the eastern slope of the Serra da Canastra (Canastra Mountains) in southwestern Minas Gerais state (estado), some distance south of the Brazilian capital of Brasília (*q.v.*). It flows for more than

1,000 miles northward across the State of Bahia to the twin cities of Juhzeiro and Petrolina. In this stretch the river receives the main left-bank tributaries—the paracatu, Umcuia, Corrente, and Grande rivers—and the right-bank tributaries—the Verde-Grande, Paramirim, and Jacaré.

About 100 miles above Petrolina, the river begins a great curve to the northeast and enters a 300-mile-long stretch of rapids and falls. In this section the São Francisco forms the border between the states of Bahia to the south and Pernambuco to the north. The upper rapids are navigable during periods of high water, but below Petrolina the river is impassable. The broken course—during which the São Francisco receives the San Pedro, Cocheira, and Pajehú rivers—culminates in the great Paulo Afonso Cachoeira (Paulo Affonso Falls). At the top of the falls, the river divides suddenly and violently and cuts three successive falls through the granite rocks for a total drop of about 250 feet. Below the falls, the river flows about 150 miles to its one mile-wide mouth on the Atlantic Ocean, about 60 miles north of Aracaju. In its lower section it is joined by the Rio Moxotó and forms the border between the states of Sergipe to the south and Alagoas to the north.

The environment. The São Francisco Valley includes a total area of 243,681 square miles (631,133 square kilometres). The upper river valley is an area of *caatinga*, or thorny forest, vegetation. Important plants include the caroá, used for its fibres, and the mamona, which yields castor oil. There are trees, such as the oil, carnauba, and date palms; the cajú (cashew), which yields edible fruits; the palma, a spineless cactus with a high water content; and rubber trees. The upper middle valley, extending to the falls zone, is less dry and is covered with grassland (*campos cerrados*) and forests of semi-deciduous trees. Hardwoods include the jacaranda, Brazilian cedar (cedro), and vinhatico, and cochineal cactus, aloes, and vanilla plants also grow here.

The falls zone passes through the dry Brazilian interior, known as the *sertão*. The small amount of rainfall in the area permits the growth of only drought-resistant brush and grasses. The dry forests of the hilly uplands support carnauba and babassu palms and such plants as the cactus, the rock rose, and the rhododendron. Underground water in the region is too saline for irrigation or drinking.

The Lower São Francisco flows through a floodplain of fine silt soils. Most of the original tropical semi-deciduous forest that grew along the river has been cleared for agriculture.

The river's fish are an important source of food. They include robalo, sardines, pocomó, and sarapó. The river mouth supports meru (squalas), manatees (sea cows), and sharks.

The climate of most of the river basin is hot and dry. The average maximum temperature for the region is 97° F (36° C) and the average minimum 66° F (19° C). The highest temperature recorded is 107° F (42° C). The prevailing winds are from the southeast, east, and northeast. Rainfall is deficient over most of the area and drought is frequent. Average annual precipitation measures 20 to 40 inches in the middle basin and 40 to 80 inches at the river mouth; about 8 percent of the basin receives only ten inches of rain annually. Precipitation occurs during the summer months, from December to March, while the rest of the year—the winter season—is dry.

Human ecology. Except for the blacks who live along the coast, the people of the São Francisco Basin are of mixed Portuguese and Indian descent. The upper middle valley is an agricultural region in which cotton, rice, and maize (corn) are grown. The region also produces pineapples, barley, potatoes, rye, maté (tea), melons, sugarcane, beans, coffee, castor and cottonseed oils, and rum. Its major urban centre is Pirapora.

Pastoral-
ism and
vazante
agriculture

The dry *sertão* is used largely for the grazing of cattle, goats, sheep, and donkeys. Along the river banks *vazante* agriculture is practiced: during the rainy season, shallow waterbeds (*vassantes*) are enclosed by bars of river sediment, and support the cultivation of manioc (cassava), water beans, and melons. Truck crops are grown on the river banks, and carnauba, caroá, and rubber are collected. The major town is the market centre of Salvador. Most of the lower river valley is dry and suitable to pastoral activities. Along the coast, wetland rice is grown.

Hydrology, navigation, and river crossings. Because the river flows through the driest region of Brazil, it is subject to seasonal changes in water level of up to 30 feet (ten metres). All of its tributaries run dry during the winter; above Jukzeiro, the riverbed varies from a narrow channel during drought periods to several miles in width during the rainy season.

The river is navigable for small steamers for more than 1,000 miles from Pirapora, Minas Gerais, to *Várzea Redonda*, Bahia, upstream of Petrolina. Sandbars at the river's mouth prevent the entry of deep-draft ocean vessels. There is a railway bridge across the river at Pirapora, and another bridge connects the cities of Petrolina and Jukzeiro. Although river transport is slow and difficult, the São Francisco is an important link between the mining district of Minas Gerais and roads that radiate north and east from Jukzeiro.

The
river's
hydro-
electric
potential

Resources and their development. The river's hydroelectric potential is its most important resource. The main centre of power for northeastern Brazil is the Paulo Afonso Cachoeira, where the Três Marias Dam, completed in 1960, has a total installed capacity of 520,000 kilowatts. Further construction will provide another 900,000 kilowatts by the mid-1970s. There are also hydroelectric possibilities of providing electricity to the coastal cities of Salvador, Aracaju, and Recife with dams on the upper and lower stretches of the river, the total hydroelectric power potential of the river is estimated at 520,000,000 kilowatts.

The river basin is also important as a source of irrigation water. The largest storage dam is at Quixadá, Ceará state. There are large reservoirs at Cachoeira and Pedra d'água, and there are plans for a reservoir on the Jaguaribe and a 300-mile-long irrigation canal to join the São Francisco at Petrolina to branches in eastern Pernambuco, Paraíba, and eastern Ceará states.

The river basin contains deposits of agate, gold, iron, diamonds, opals, antimony, galena (the principal ore of lead), mercury, copper, arsenic, manganese, cobalt, and pyrites. There are also deposits of salt, sulfur, alum, marble, limestone, and clay. (C.E.Ca.)

São Paulo (State)

One of the 22 states of Brazil, São Paulo comprises the richest and most populous region of the country. With a total area of 95,714 square miles (247,898 square kilo-

metres) and a population that in 1970 numbered about 18,000,000, it produces nearly two-thirds of the nation's manufactures and about a third of its leading crop—coffee.

São Paulo is bordered by the states of Paraná to the south and Mato Grosso to the west and north, by Minas Gerais to the north and east, by Rio de Janeiro to the east, and by a 386-mile Atlantic coastline to the south-east. About 80 percent of its population is urban and suburban. The state capital, São Paulo, is the largest city in Brazil. (See city article SAO PAULO; for an associated physical feature, see PARANA RIVER.)

History. The area that was to become São Paulo was settled in 1532 by the Portuguese under the explorer Martim Afonso de Souza, who established a flourishing settlement at São Vicente, now a resort town near Santos, as well as the village of Piratininga on the plateau. When Brazil was divided into captaincies, or hereditary fiefs, the captaincy of São Vicente, comprising the whole of Brazil south of Rio de Janeiro, was granted to Souza (1534). By the middle of the 16th century, the captaincy had a population of about 5,000, including the growing port of Santos and the town of São Paulo (founded 1554). The Vicentinos (inhabitants of São Vicente) had begun to explore the hinterlands, and new villages began to appear on the coastline (Iguape, Cananéia) and on the plateau (Paraíba, Mogi das Cruzes, Taubaté, and others), which became the main region of inland settlement. In 1681 the captaincy was renamed São Paulo, and the town of that name was designated the capital.

Throughout the 17th century, roaming bands of armed pioneers (*bandeirantes*) explored the interior in search of Indian slaves and precious metals. Their enslavement of the Indians brought the settlers into conflict with the Jesuit mission—a conflict that continued intermittently until after the introduction of slaves from Africa.

In the 18th century the Portuguese inhabitants of the captaincy (called Paulistas or Paulistanos) continued to penetrate the west, north, and south. But before the end of the century the regions conquered and peopled by the pioneers—Minas Gerais, Mato Grosso, Goiás, Santa Catarina, and Rio Grande do Sul—were separated from the captaincy, leaving it impoverished and in decline. São Paulo existed on its commerce, sugar growing, and diversified agriculture until the introduction of coffee planting in the 19th century opened a new economic era.

The national independence of Brazil was proclaimed in São Paulo in 1822, at which time the captaincy became a province of the Brazilian Empire. São Paulo became a state when the republic was formed in 1889. Political importance grew with the economy. The nation's first three civilian presidents after the downfall of the empire in 1889 were Paulistas. The state provided leadership for the frustrated military uprising against Pres. Arthur Benardes in 1924 and for the abortive revolution against Pres. Getúlio Vargas in 1932. Paulistas, who first served as mayors of the capital city, as governors, or as local political or industrial leaders, have occupied the presidency, cabinet, and other federal positions with significant regularity in the 20th century.

The natural environment. São Paulo's narrow coastal zone is broken by lagoons, tidal channels, and mountain spurs. It is bordered by the well-wooded slopes of the Serra do Mar (Mountains of the Sea), which lead up to the Great Escarpment, behind which is an extensive plateau with wide grassy plains, about 1,500 to 3,000 feet above sea level. The most productive land occurs in streaks of *terra roxa* ("red-purple earth"), a deep, porous soil containing humus. Isolated ranges of low elevation break the surface in places, but in general the undulating tableland slopes toward the Rio Parana (Parana River), the state's western boundary.

The Paraná—and its tributaries, the Paranapanema, Tieté (which traverses the whole state), Pardo, Canoas, Inferno, Anhanguera, Turvo, and Dourados—flows westward into the estuary of the Rio de la Plata. The extreme eastern part of the tableland, however, slopes to the east, and, from a little east of the city of São Paulo, the Rio Paraíba do Sul turns northeastward and flows parallel to

Early
Portu-
guese
settlement

The rivers

the coast, meandering across a wide floodplain used for the production of rice. The state has no lakes of importance, but has several sizeable artificial weirs (such as Cjuarapiranga, and Billings). On the coast the average temperature is about 68° F (20° C), and the annual rainfall is about 79 inches; on the plateau the average temperature varies between about 64° and 68° F (18° and 20° C), and in the mountainous areas annual rainfall reaches 59 inches.

The lower third of the state is crossed by the Tropic of Capricorn. The weather in general is mild and healthy and in some places—such as Campos do Jordão and Cunha—comparable to southern Europe. The coastal zone has a hot climate and heavy rainfall. On the plateau rainfall is ample, but the air is drier and more bracing, daytime temperatures being high and the nights cool.

The evergreen forests are reminiscent of the wealth of vegetation in Brazil in days gone by. The vegetation is greatly diversified and includes several kinds of hardwoods, wild fruits, and plants that are used for medicinal and ornamental purposes or for making textiles. The hardwoods have furnished the rosewood and other cabinet woods for which Brazil is famous.

The Paulista animal life is rich and diverse. Mammals include the jaguar, cougar, tapir, capybara (an edible rodent related to the guinea pig), squirrel, and howling monkey. Birds range from the parrot and macaw to such songbirds as the sabia and red grackle. Reptiles include the alligator, the rattlesnake, freshwater turtles, and lizards. The rivers abound with fish and there are many kinds of insects.

Population. Before the arrival of the Portuguese, the region was inhabited by Indians of various tongues and cultures. The two principal tribes were the Tupi-Guarani, who lived on the coast and on the plateau, and the Tapuia, who lived farther inland. Remnants of these tribes either escaped to other regions, were killed off by disease or war, or were enslaved by the conquerors. Portuguese men, however, formed unions with some of the women, which resulted in the creation of a new ethnic group called *mamelucos* ("Mamelukes," since they were thought to resemble the Mamlûks of Egypt, a military class originally consisting of a group of Caucasian slaves) or *mestiços* (mestizos). With the introduction of black Africans during the 17th century and after, a new element was added to the population. Further ethnic intermixing between Portuguese and Africans resulted in the appearance of mulattos, while intermixing between Africans and *mamelucos* resulted in a group called *cabures*. Those descended from all three stocks were called mestizos.

With the absorption of the Indian element and with further European immigration, from the end of the 19th century onward, the population of the state was reduced to three elements—white, black, and mulatto. Subsequently, however, a small number of Japanese immigrants arrived. In the early 1970s the population of the state was composed of 62 percent white, 11 percent black, 26 percent mulatto, and about 1 percent of either Asian or unidentified origin. Of the 3,000,000 immigrants who have been admitted to São Paulo since 1885, more than 1,000,000 have been Italian, about 600,000 Portuguese, 500,000 Spanish, and almost 300,000 Japanese.

The population of São Paulo, as mentioned, is predominantly urban. In addition to the capital, other principal cities of more than 200,000 population are Santo André, Campinas, Santos, Osasco and Guarulhos. Ribeirão Preto, São Bernardo do Campo, Sorocaba and Jundiaí have populations of about 150,000 and several other cities have more than 100,000 inhabitants.

While Portuguese is the language in general use, the idiom has some semantic differences from the Portuguese spoken in Portugal. English is also relatively widely spoken and is more in use than such other European languages as French, Spanish, Italian, and German.

São Paulo is predominantly Roman Catholic, though other Christian religions are relatively widely practiced by various Protestant and Orthodox sects.

Administration and education. The state administration consists of independent executive, legislative, and

judiciary branches. The executive function is carried out by a governor (who serves for a term of four years), with the assistance of 13 undersecretaries of state. The legislature consists of the Assembly of Deputies, composed of men and women, all aged over 21, elected in secret ballot by men and women voters who must be more than 18 years old and literate. The judiciary power is exercised by tribunals and judge advocates, with the members chosen by the governor.

Under federal law all citizens are entitled to primary education, which is free and compulsory. The cities have the best educational facilities, but more primary as well as secondary schools have been built outside the cities, and the numbers of pupils have increased.

Institutions of higher learning include the Universidade de São Paulo (University of São Paulo, with its constituent colleges and affiliated institutes), Mackenzie University, Pontifícia Universidade Católica de São Paulo (Pontifical Catholic University), and the Polytechnic School of Engineering—all of which are in the city of São Paulo—and Luis de Queiroz' Higher School of Agriculture in Piracicaba.

Economy and transport. The economy of the state is based on agriculture and industry. Agriculture is largely mechanized; it owes its modernization largely to the Luis de Queiroz school and to the Instituto Agrônomo de Campinas (Institute of Agronomy of Campinas).

Coffee was formerly the main source of wealth of the state and still accounts for a considerable portion of the total value of its products, although industry is surpassing it in importance. Besides coffee, other crops are sugarcane, cotton, corn (maize), rice, beans, Indian or Paraguayan tea (maté), potatoes, and such fruits as bananas and oranges.

Cattle raising has begun to transform the old coffee lands into stock-raising areas and pastures. The local horses are renowned, and there are vast herds of cattle. Hog, sheep, and goat raising are actively pursued. Most of the industry is centred in the city of São Paulo and its environs.

The state has an extensive network of highways and of federal, state, and private railroads of varying gauges. Santos is the nation's busiest port and the largest coffee-shipping port in the world. The ports of São Sebastião, Iguape, Ubatuba, and Cananéia, which are considerably smaller, serve the coastal trade; Iguape and Cananéia are known especially for the rice grown in their vicinity. In addition to a large international airport at São Paulo, there are about 50 other airports in the state.

Cultural life. The most important cultural institutions are concentrated in the capital. Many of the other cities and towns, however, have their own press, literary associations, public libraries, cinemas, theatres, and sports and recreation clubs and associations. Among the more important institutions in São Paulo (in addition to those named in the São Paulo city article) are the Academia Paulista de Letras (São Paulo Academy of Letters), Museu do Ipiranga (Museum of Ipiranga), the Biblioteca Municipal Mário de Andrade (Mário de Andrade Municipal Library), the Museum of Sacred Art, the Brazilian Union of Writers, the Museum of Archaeology, and the Association of Medical History.

(1925–28), a study by an author who does not agree with the methods of the *bandeirantes* concerning the Indians, but praises them in matters of war.

(A.Lc.)

São Paulo (City)

The largest city of Brazil and the dynamic capital of the state of the same name, São Paulo is the foremost industrial centre in Latin America. With a metropolitan area population of about 6,000,000, it is one of the five most populous cities in the Western Hemisphere. Located in the hills of the Serra do Mar (Mountains of the Sea) on the edge of Brazil's Great Escarpment 30 miles inland from its port of Santos, it is 220 miles southwest along the Atlantic coast from Rio de Janeiro. The city obtained its name from a religious settlement founded by the Jesuits in 1554, on the anniversary of the conversion of St. Paul.

History. São Paulo began as a small Indian settlement founded on January 25, 1554, around a modest house that was at the same time a school, church, and residence for Portuguese Jesuits under Manuel da Nóbrega, assisted, among others, by the saintly José de Anchieta, to whom is attributed the prophecy that the little village would become the metropolis of Brazil.

São Paulo became a township in 1560, at which time it had a city council that could enact and enforce laws. In 1683 it succeeded São Vicente as capital of the captaincy, or hereditary fief; the inhabitants thereafter became known as Paulistanos or Paulistas. Throughout the 17th century São Paulo was a base for expeditions (*bandeiras*) of armed pioneers (*bandeirantes*) who penetrated the remote hinterlands in search of Indian slaves, gold, silver, and diamonds. It was raised to the status of a city in 1711.

During the 18th century the importance of the captaincy, and thus of its capital city, declined as successive parts of its vast territory were cut off to form other captaincies in southern Brazil. In the early 19th century, São Paulo—for a time without its own government—remained an agrarian town.

In 1822 Emperor Pedro I proclaimed Brazil's independence in São Paulo at a site marked by the museum and monument of Ipiranga. Nevertheless, São Paulo continued to retain its colonial aspect until the latter part of the 19th century. The spread of coffee planting to the province opened a new source of wealth that, after 1880, stimulated the city's sudden growth. Immigrants arrived in large numbers, including Italians (who for a time outnumbered native Brazilians), Portuguese, Spaniards, Germans, east Europeans, Syrians, Lebanese, and Japanese. An era that was to transform São Paulo into a modern city had begun.

The contemporary city. Located at an altitude of 2,400 feet, the terrain on which the city stands consists of open country, valleys, and foothills. The higher parts, as in the district of Sumaré (2,600 feet), constitute the preferred residential areas; the lower parts are on alluvial land on the banks of three rivers—the Tietê, the Pinheiros, and the Tamanduatei. The area of the city proper is 627 square miles (1,624 square kilometres), while Greater São Paulo covers an area of about 884 square miles. Suburban communities include São Bernardo do Campo, Santo André, São Caetano do Sul, Osasco, Guarulhos, Mairiporã, Barueri, Santana de Parnaíba, and Franco da Rocha. Open spaces nearby, which are clayey with sandy deposits, are extensively used for market gardening. The nearby Jaraguá Hills, the Serra da Cantareira (maximum altitude 3,900 feet)—where there is a forest reserve of about 39 square miles—and the beaches at Santos and Guarujá provide pleasant resort areas.

Climate. Although just within the tropics, the city enjoys a temperate climate because of its elevation; the temperature occasionally reaches freezing point in winter and on rare occasions rises to 86° F (30° C) in summer. The air, brought by the gentle wind that blows from the Serra da Cantareira, would be excellent if it were not for pollution by automobile exhaust fumes and dust from the demolition and reconstruction of buildings.

City plan. São Paulo had no city plan until 1889; it was only with the astonishingly rapid development of the metropolis that thought was given to the matter. Formerly a capital city of colonial aspect—its narrow streets unpaved, and its buildings shabby, with here and there old churches and convents in Jesuit and Franciscan styles—its urban growth in general was swift and uncontrolled.

Successive city administrations since then have attempted to stimulate more rational urban growth and to modernize the city's transportation system. Projects have included the straightening and rechanneling of the Tietê and Tamanduatei rivers, the widening and relocation of streets and avenues, and the construction of bridges, overhead roads, subterranean passages, and new parks and lakes, as well as the beginning of construction of a 40-mile subway network, due for completion in the mid-1970s.

The residential districts of the well-to-do are attractively laid out, the more recent—influenced by English town planning—contrasting sharply with the crowded sections of the industrial districts.

Transportation. In addition to improved transport within the city, São Paulo is served by good highways connecting it with the inland cities and with Rio de Janeiro, Minas Gerais, and almost all the other states of Brazil. The city is also a key junction for three of the country's important railroads. It is connected with the Atlantic at Santos by a cable railway and a four-lane highway, both of which cross the steep escarpment. Its airport is one of the busiest in the world.

Population. The city is divided into three regions—urban, suburban, and rural. The population of the metropolitan area is 5,921,796, that of the city proper 5,186,752 and that of Greater São Paulo approximately 8,000,000. The proportions of the various racial, religious, and ethnic groups in the population approximate those of the state as a whole—that is to say, about 62 percent white, 11 percent black, 26 percent mulatto, and 1 percent miscellaneous.

Economic life. Industrial development, beginning in the late 19th century, transformed São Paulo with its neighbouring municipalities—notably Santo André—into the foremost industrial centre of Latin America. (It has been called the "Chicago of South America.") Leading industries produce textiles, mechanical and electrical appliances, building and furniture, foodstuffs, and chemical and pharmaceutical products. There are also heavy metallurgical plants at Taubaté and oil refineries at Cubatão (which has the largest refinery in Brazil) and Capuaçu; there are also plants manufacturing motor vehicles and farm machinery at various places. Altogether, about 3,000 industrial establishments employ almost 2,000,000 workmen. Power for the industries is supplied by hydroelectric stations. The demand for electricity outstrips local hydroelectric resources, however, so that extra power is brought from the gigantic complex at Salto do Urubupungá, nearly 400 miles to the northwest.

Both wholesale and retail commerce are strongly developed, being spread over the city in zones, each according to its own speciality. The banks, although centralized in the old part of the city (the Triângulo), maintain agencies and branches in almost every district. In addition to important local, state, and national banks, there are banking institutions representing interests in North and South America, Europe, Asia, and Africa. Savings banks are operated by the federal government and by the state.

Government and services. The city is governed by a mayor and council. It is also the seat of the state government, the headquarters of which is at the Palácio dos Bandeirantes (Bandeirantes Palace) in the district of Mo-

Develop-
ment in the

century

Industrial
develop-
ment

Downtown São Paulo.
Manchete — Pictorial Parade

rumbi. In addition to the state offices and departments that have headquarters in the capital, there are more than 50 consulates representing the countries of all the Americas excepting Cuba and many of the countries of Europe, Asia, and Africa.

The city has a plentiful piped supply of drinking water of good quality. In order to ensure a sufficient supply for a population of 12,000,000 projected by the year 2000, the government has undertaken to divert the flow of some rivers toward the city by tunnelling through hills for many miles. The drainage system, as well as the water supply service, are both entrusted to the Sanesp (from Saneamento do Estado de São Paulo—literally, sanitation of São Paulo state). Municipal electricity services have been provided since 1900 by an enterprise of Canadian origin, the Brazilian Traction, Light, and Power Company.

No epidemics have been registered in the city since extensive sanitation measures were undertaken at the beginning of the 20th century. Public and private hospitals and nursing homes are plentiful; hospitals include the Santa Casa de Misericórdia, the General Clinics Hospital, and the Beneficência Portuguesa, as well as hospitals for civil servants, maternity hospitals, and hospitals specializing in cancer, tuberculosis, and other diseases.

Education. São Paulo has a well-developed system of primary and secondary schools and a variety of vocational schools. Under Brazilian law, primary education for all up to the age of 14 is free and compulsory.

Among the institutions of higher learning the most esteemed is the state-supported Universidade de São Paulo (University of São Paulo), established in 1934, which incorporated the historic Faculdade de Direito (College of Law) in the old São Francisco Square and pre-existing polytechnical schools, as well as schools of pharmacy and dentistry, agriculture, and medicine; faculties of economics, architecture, and engineering were added later. Affiliated institutions include the School of Sociology and Politics, founded in 1933, and the Instituto Butantã (Butantã Institute), a world-famous research centre for the study of snakes and the production of antitoxins and antivenoms. The Pontifícia Universidade Católica de São Paulo (Pontifical Catholic University of São Paulo) was established in 1946, and Universidade Mackenzie (Mackenzie University) in 1952.

Cultural life and institutions. São Paulo early became a prominent cultural and intellectual centre, largely be-

cause of the opening in 1827 of the College of Law—one of the first two in Brazil—where many of the nation's most eminent men were educated. Its Instituto Histórico e Geográfico de São Paulo (São Paulo Historical and Geographical Institute), founded in 1894, is one of the oldest cultural associations in the state. It is also a leading centre for libraries (which include a skyscraper municipal library), publishing houses, and theatres. In 1922, São Paulo's Modern Art Week—celebrated by a group of young writers, artists, and musicians in the Teatro Municipal (Municipal Theatre)—introduced modernism in the arts of Brazil, and in 1951 the city's Museu de Arte Moderna (Museum of Modern Art) organized the first biennial exhibition in the Americas.

The city is also a focal point for news media and is the location for several of the largest and most important newspapers, television stations, and radio networks in Latin America. Its great dailies, *O Estado de São Paulo* and *Diário Popular*, are both nearly 100 years old.

The Paulistas are enthusiastic followers of sports, particularly soccer, and its association football clubs, especially Santos, are world renowned. Facilities include a stadium seating 10,000 spectators, the Jockey Club, and one of the world's largest car-racing tracks. The permanent fairgrounds, erected for the city's fourth centennial (1954), are distinguished for their modern architecture.

Sapindales

The plant order Sapindales consists of perhaps 2,300 species in 168 genera and nine families. Although not a very large group compared to many other natural orders of flowering plants, the Sapindales attract much attention because most species are trees or shrubs, many of which

Health
facilities

Sports
facilities

are favoured ornamental, shade, or timber trees of both tropical and temperate regions. Several of the tropical trees produce fruits with distinctive flavours. Some of the widely disjunct distribution patterns possessed by several genera are of interest to biogeographers.

GENERAL FEATURES

Growth habit and size range. Centred around the largest family, Sapindaceae, the order is basically a tropical to warm-temperate group, relatively nonspecialized in habit of growth. Most members of the order are small to moderate sized trees, large shrubs, or woody climbers.

tion, is occasionally found as far north as Missouri, Illinois, and New Jersey.

Other warm, temperate areas of the world also have a few representatives of the family Sapindaceae. China, for example, has, among others, the decorative *Koeleruteria paniculata* (goldenrain tree) and *Xanthoceras sorbifolium*. Chile has several shrubs or small trees, as does the Republic of South Africa. Temperate Australia has numerous shrubby species of *Dodonaea* (varnish leaf), subshrubs or even prostrate herbs of *Diplopeltis*, and small trees of such genera as *Atalaya* and *Heterodendron*.

The order Sapindales presents many examples of the widely discontinuous patterns of distribution that are of interest to biogeographers. Among the more striking disjunctions are the following: (1) the essentially temperate North American–Eurasian (represented by the genera *Acer*, *Aesculus*, and *Staphylea*); (2) the largely tropical Asiatic–American (*Meliosma*, *Sapindus*, and *Turpinia*); (3) the tropical American–Madagascan (*Paullinia*); (4) the Mascarene Islands–Fiji–New Caledonia (*Cossinia*); (5) the African–Asian–Malesian region (*Aphania*, *Filicium*, and *Ganophyllum*); and (6) the tropical African–Asian–Australian–American (*Allophylus*, *Cardiospermum*, and *Dodonaea*). On the other hand, many genera are restricted to single continents or portions thereof, archipelagos, or single islands.

Economic importance. Because of the large number of trees, the **principal** economic importance of the order is for wood products. Undoubtedly the best known timber tree is *Acer saccharum* (sugar, hard, rock, or black maple), which has been described as the most valuable hardwood tree of North America. The figured wood (curly and bird's-eye maple) is valued for cabinet work; the plain wood for construction, flooring, interior finish, and furniture. The species also provides choice firewood and abundant maple syrup and sugar from the sap. The hard, strong, heavy, close-grained wood is often beautifully patterned. The sugar maple, too, is a splendid ornamental, shade, and street tree because of its thick, shapely crown and the bright yellows and reds of its autumnal coloration. Other American maples are of lesser importance as timber, paper-pulp, sugar, and ornamental trees.

Next to the maples, the buckeyes probably have the most economic significance in temperate areas. The Balkan *Aesculus hippocastanum* (horse-chestnut), the American *A. glabra* (Ohio buckeye), and *A. octandra* (yellow, or sweet, buckeye) have light, soft, tough, fine-grained wood; although once used for artificial limbs, splints, and various kinds of woodenware, the wood is now more important as a source of paper pulp. Selected varieties and hybrids of these species are frequently cultivated as ornamentals or as shade or street trees.

Economically valuable species of the order in the tropics belong mostly to the family Sapindaceae. Some of the larger tree species, such as *Pometia pinnata* of the Malesian region and *Blighia sapida* of tropical Africa, are useful for their timber. *Pometia pinnata* has been described as one of the most important timber trees in New Guinea, where its wood is useful for general construction, furniture, mouldings, veneer, floors, interior finish, and boats. *Blighia sapida* (akee) wood in tropical West Africa is used for furniture, boxes, oars, punting poles, and charcoal. It is light, hard, close-grained, durable, and apparently resistant to termites. In tropical America, none of the family is of more than local importance for timber or fuel because of scarcity or low resistance to decay. Some woods of this order are not durable if exposed to weather; they are not resistant to termites or borers, are somewhat saponiferous (*i.e.*, they produce a soapy lather), are cross-grained and hard to work, require very careful seasoning, and have heartwood difficult to impregnate with preservatives.

As with the temperate maples, some species of the family Sapindaceae are much esteemed as ornamentals or shade trees. Among the more desirable of these are *Koeleruteria paniculata* (goldenrain tree), *Ungnadia speciosa* (Mexican-buckeye), *Blighia sapida* (akee), various species of *Sapindus* (soapberries), and *Dodonaea viscosa* (hobpash, varnish leaf).

Discontinuous distribution patterns

Ornamental and shade trees

Figure 1: Representative plants from the family Sapindaceae, the largest family of the order Sapindales.

There are no small annual herbs, desert succulents, or aquatic species. Even in the forests none has evolved into an epiphyte (plant that grows upon tree branches), a saprophyte (nongreen plant that absorbs nutrients from dead organic matter), or a parasite. The most specialized growth forms are rather strange, unbranched, palm-like trees (such as *Pseudima* and *Talisia*), woody climbers (*Paullinia*, *Serjania*, *Urvillea*, and *Sabia*), subshrubs or perennial herbs with woody basal parts (*Diplopeltis* and *Melianthus*), and one annual vine (*Cardiospermum halicacabum*, balloon vine).

The largest trees of the order are in the family Sapindaceae; they include *Schleichera oleosa* (to 60 metres, or 200 feet, in Burma), *Pometia pinnata* (to 40–50 metres, or 130–160 feet, in the Malesian region), and *Tristiropsis canarioides* (to 45 metres, or 145 feet, in New Guinea).

Distribution. Although the family Sapindaceae is mostly distributed in the tropics and subtropics, it does have some temperate representatives. In temperate North America these include, among others: *Sapindus* (soapberries) with two species that extend north as far as Georgia, Missouri, Kansas, and Colorado; *Ungnadia speciosa* (Mexican-buckeye) of Texas, New Mexico, and Mexico; the circumtropical *Dodonaea viscosa* (hobpash) reaching into Arizona and temperate Florida; and several members of the climbing, tropical genera *Cardiospermum*, *Serjania*, and *Urvillea*, all represented in Texas. The herbaceous vine *Cardiospermum halicacabum* (balloon vine), which presumably has escaped from cultiva-

The plants of the family Sapindaceae are better known in the tropics for their fruit than for their wood. Most popular for the fleshy pulp or succulent seed coats are *Litchi chinensis* (lychee), *Nephelium lappaceum* (rambutan), *Euphoria longana* (longan), *Blighia sapida* (akee), *Melicoccus bijugus* (Spanish lime), and *Aphania senegalensis* (Senegal cherry).

Saponins—chemical substances that produce soapy lathers—are present in the fruits, seeds, and other tissues of many members of the family Sapindaceae; genera such as *Sapindus*, *Aphania*, and *Paullinia* are used in tropical countries as soap substitutes. Crushed materials from some species of *Paullinia*, *Serjania*, and related genera stupefy fish when thrown into pools or small streams. The seeds of the Brazilian *Paullinia cupana* (guarana) contain much caffeine, and the roasted seeds are used to prepare a stimulating beverage. The bark of *P. yoco* (yoco) is similarly used as a caffeine source.

NATURAL HISTORY

Pollination agents. Although little is known about pollination in the Sapindales, most species are thought to be pollinated by insects. This assumption is based on the usual presence of petals, the strong tendency toward bilateral symmetry in the flowers, and the presence in the flowers of a glandular nectar-secreting disc. The small size of the flowers of the families Sapindaceae, Aceraceae, and Sabiaceae indicates small flies or bees as the pollinating insects. The larger flowers of *Aesculus*, often supplied with coloured honey guides, which are patterns on the flowers that indicate the location of nectar glands, are visited extensively by bumblebees. The white-flowered *A. parviflora* (bottlebrush buckeye) is probably pollinated by moths. The brilliant red flowers of *A. pavia* (firecracker plant; red, or scarlet, buckeye) and *Billia hippocastanum* closely match the colour and shape of known hummingbird flowers, and in the South African *Melanthus* (honey bush) the sturdy, dark purplish flowers with their abundance of nectar probably attract the nectar-eating sugarbirds and sunbirds.

The maples (*Acer*) demonstrate marked evolution toward wind pollination. Some species, which retain both petals and well-developed, ring-shaped, nectar-producing discs, are mainly visited by bees. Others, particularly the hard maples, retain the disc but have lost the petals. *Acer saccharinum* (silver maple) has lost both petals and disc, and its flowers form headlike yellow or reddish clusters; pollination may occur by both insects and wind. *Acer negundo* (box-elder) has lost both petals and disc and is functionally and anatomically dioecious—the male and female flowers occur on separate plants. The male flowers produce an abundance of pollen in large anthers from densely clustered and pendulous flowers. The female flowers are in drooping clusters and have long, narrow stigmas. This is a characteristic group of features that points to complete reliance on wind pollination and to the highly specialized position of the species.

Dispersal. The wide variety of fruit types in the Sapindales indicates adaptations to an equally wide variety of dispersing agents. Among the kinds of fruits are capsules (in *Aesculus*, *Cupania*, *Dodonaea*, and *Melanthus*); drupes, which are fleshy fruits with a single-seeded, stony pit (*Exothea*, *Melicoccus*, and *Meliosma*); berries (*Allophylus*, *Aphania*, and *Hypelate*); and samaroid schizocarps, fruits that break up into winged segments (*Acer*, *Dipteronia*, and *Thouinia*). Possibly the most primitive fruit type is the simple, readily opening capsule containing seeds with fleshy outer seed coats (sarcotesta). During the evolution of the order this became reduced to the arillode, or partial sarcotesta. Later, through transference of function, the fleshiness of the seed was replaced by the fleshy pulp of the fruit, the fleshy, outer fruit wall (drupe), or the entirely fleshy fruit (berry). All these fruit types are especially attractive to birds, and some also attract small mammals. The fruits of several genera, including *Sapindus*, *Melicocca*, *Nephelium*, and *Xerospermum*, are thought to be dispersed by fruit-eating bats.

Throughout the order there is a rather marked evolution toward bladdery or winged fruits designed for transporta-

tion by wind. Because of their wide occurrence on oceanic islands and tropical shores, the polymorphic *Dodonaea viscosa* (hopbush) and some *Sapindus* (soapberry) species are thought to be transported by ocean currents.

Ecology. Most species in the order are found in tropical or subtropical rain forests, mostly below elevations of 2,000 metres (6,600 feet). A few of the larger tree species, as *Pometia pinnata* in the Malesian regions, are important constituents of the canopy layer of lowland rain forest. Most members of the order, however, are smaller trees and thus are common members of the lower rain-forest strata. In tropical Australia and in New Caledonia, they are frequent components of drier, more seasonal types of tropical forest and woodland. *Dodonaea viscosa* (hopbush) is a common pioneer species not only on beaches and lava flows but also on landslides and other disturbed areas inland. *Jagera* also has rather weedy tendencies. *Meliosma*, *Billia*, and *Turpinia* are, in Mexico, frequent components of high-elevation oak forests. *Acer* and *Aesculus* are important components of the temperate deciduous forests, with *Acer saccharum* and *Aesculus octandra* often among the dominant trees of the richest deciduous forests of eastern North America.

FORM AND FUNCTION

Distinguishing vegetative characteristics. The order of Sapindales is overwhelmingly composed of woody plants, mostly trees, large shrubs, or woody climbers. Small shrubs and herbaceous vines are rare. Most species have compound leaves, usually pinnately divided (*i.e.*, with the leaflets of each compound leaf arranged along both sides of a central axis). The leaves are alternate on the branches and are without stipules, the small leaflike appendages at the base of leaf stalks. Some genera, however, have

Leaves

Drawing by R. Findahl based on G.H.M. Lawrence, *Taxonomy of Vascular Plants* (1951); The Macmillan Company.

Figure 2: Representative plants from three of the smaller families of the order Sapindales.

simple or palmately divided leaves (compound leaves with leaflets radiating from one point) that are either alternate or opposite in arrangement on the branches and may have very small or large stipules attached to the leaf stalks. Stomates, microscopic pores in the leaf surfaces, are mostly restricted to the lower surfaces of the leaves and are anomocytic (surrounded by ordinary epidermal cells). Most leaves have mucilage cells or secretory cells or sacs or both. The vascularization of the petiole (leaf

Wind
pollination
in maples

stalk) appears in cross section either as a circular strand or as a ring, sometimes dorsally flattened, of separate vascular bundles.

Flower and fruit characteristics. Throughout the order there is a strong tendency toward obligate crossbreeding through progressive decrease in bisexuality, culminating in dioecism, a condition in which there are species with male and female flowers borne on separate plants. Most species in the order appear to be **polygamous**—having bisexual and unisexual flowers on the same plant—thus presumably combining the advantages of maximum fertility through inbreeding with increased variability through outcrossing. Some species are **polygamomonocious**—i.e., with bisexual flowers and both male and female flowers on the same plant. Most are apparently polygamodioecious, with male and female plants each bearing a few bisexual flowers. Many structurally bisexual flowers, however, as in many maples, are functionally unisexual, for either the stamens (male organs) produce no fertile pollen or the stigmas (sticky pollen-receiving areas of the female flower parts) are not receptive. Even in species with functionally bisexual flowers, cross-pollination is assured through protogyny or proterandry; i.e., the female or the male organs, respectively, mature before the structures of the other sex in the same flower. Some species—e.g., *Acer platanoides*, *A. spicatum*, and *A. saccharinum*—are self-sterile. Most unisexual flowers in the order have become that way through abortion, in which either the male or the female structures fail to develop, for the flowers often retain rudimentary structures of the nonfunctional sex. Only a few species, such as *Acer negundo* (box-elder), have unisexual flowers with usually no vestige at all of the organs of the other sex. Thus, though most species of the Sapindales have insured outbreeding by one technique or another, most have not achieved complete anatomical dioecism.

The anatomically bisexual flower is either radially or bilaterally symmetrical and is typically small, except in a few genera. The male flowers often have a nonfunctional pistil (the female structure consisting of stigma, style, and ovary), called a pistillode, and female flowers similarly have sterile stamens.

The fruit is basically a capsule that splits open between the partitions but is often **modified** into many other types, such as fleshy, berrylike, stony-pitted, or dry and bladderlike or winged. In the seed, endosperm (the starchy nutrient tissue for the developing embryo) is usually absent or scanty, and the embryo is often curved, folded, or contorted.

EVOLUTION

Fossil record. The fossil record, the many present-day relict endemics (species of restricted range that are remnants of an earlier widespread flora), and the widely disjunct distribution patterns, often relict, attest to the ancientness of this group. Because of the easily preserved and recognizable leaves, flowers, and fruits, the fossil record is rather good for *Acer*, *Dipteronia*, *Aesculus*, *Cupania-Cupaniopsis*, *Dodonaea*, and *Sapindus*, among other genera. Fossil evidence indicates that the distributions of these genera in former times exceeded their present ranges, especially in North Temperate areas.

The earliest fossils attributed to this order, believed to represent early ancestors of the genus *Sapindus* (soapberries), are two species of the fossil genus *Sapindopsis* from late Lower Cretaceous time (the Cretaceous Period extended from 136,000,000 to 65,000,000 years ago) of Crook County, Wyoming. *Sapindophyllum* is also from Cretaceous deposits. *Sapindus oregonianus*, one of several early Tertiary Period (beginning 65,000,000 years ago) fossils of the modern genus, is known from the Miocene Epoch (26,000,000 to 7,000,000 years ago) of Idaho, Oregon, and Nevada and approaches most closely still living Asiatic species. Two fossil *Cupania* species, resembling living South American species, are known from the Goshen and Chalk Bluff floras of the upper Eocene–lower Oligocene boundary (about 38,000,000 years ago) of central Oregon. Several species of the fossil *Cupanites* are represented by leaves and fruits in Europe-

an Tertiary deposits and by leaves in the Eocene (54,000,000 to 38,000,000 years ago) of the southeastern United States. Tertiary leaves and fruits have been described from 15 fossil species of *Dodonaea* from western Europe, the southeastern United States, Colorado, California, Bolivia, and Brazil. *Dipteronia*, now restricted to China, was represented in western North America during the Tertiary by *D. insignis*.

The genus *Acer* has the most extensive Tertiary fossil record, consisting of fruits, inflorescences, and leaves, throughout the North Temperate and Boreal zones north to Iceland and Spitsbergen. The red maples, now restricted to Japan and eastern North America, were once found in Eurasia and North America north to Greenland. As late as Miocene time they were represented in Oregon by *A. chaneyi*; in northern Italy they were present until the Pliocene (7,000,000 to 2,500,000 years ago) and Quaternary Period (beginning 2,500,000 years ago). Other groups of maples, now absent from Europe, were present there in the Tertiary. Fossil species of *Aesculus* ranged farther north in the Tertiary in Europe, eastern Asia, and North America than they do today.

Phylogeny. Most authorities are convinced that the two groups of families here called the orders Sapindales and Rutales are closely related (see also RUTALES). Within the Sapindales, the family Sapindaceae is the large, varied, and central group. Very closely related to the Sapindaceae are the families Aceraceae, Hippocastanaceae, and the monotypic (single-species) relicts *Akania* and *Bretschneidera*. Less closely but still rather obviously related to this family complex are the Asiatic–American family Sabiaceae (at least the *Meliosma* group) and the African family Melianthaceae.

CLASSIFICATION

Distinguishing taxonomic features. Within the order the families are usually distinguished from one another by combinations of characteristics or by the level or degree of advance along certain evolutionary trends. Regarded as especially critical in the group's classification have been placement and division of the leaves; presence, size, and position of stipules; kind of inflorescence; symmetry, size, and sexuality of the flowers; number and position of stamens; presence, shape, and position of the nectar-producing disc; number of locules (chambers) in the ovary; kind of fruit; abundance or absence of endosperm; and the alignment of the embryo.

Within the larger families, classification depends largely upon such characteristics as the number and position of ovules in each locule, habit of growth, presence of a terminal leaflet in compound leaves, shape and position of the disc, and number of fertile stamens.

Annotated classification. The classification, as outlined below, is generally accepted for the first seven families, both in relationship to one another and in family content. The last two families, Greyiaceae and Staphyleaceae, however, are no longer widely accepted as members of the Sapindales. Totality of evidence indicates that they really belong with the order Saxifragales (Rosales, suborders Saxifragineae and Cunoniineae of traditional classifications). They are retained here because of long association with the true members of the order.

ORDER SAPINDALES

Trees, shrubs, or lianas, rarely herbs. Leaves mostly alternate, pinnately compound, and without stipules. Inflorescences mostly thyrses (compact panicles like clusters of grapes), panicles (many-branched loose clusters), racemes (clusters with flowers on short stalks arising from a central axis, the lower flowers maturing first), or corymbs (flat-topped flower clusters maturing from edge to centre). Species mostly polygamous (bisexual and unisexual flowers both present) but functionally monoecious (male and female flowers on the same plant) or dioecious (separatelysexed flowers on different plants). Flowers mostly small, with sepals, petals, and stamens attached at the base of the ovary (hypogynous), radially or bilaterally symmetrical, usually unisexual but with rudimentary organs of the opposite sex retained. Sepals 3 to 5, overlapping in the bud (imbricate), separate or basally joined (connate). Petals 3 to 5, imbricate, usually clawed, separate, rarely absent. Nectar-producing disc present. Stamens mostly 8 but sometimes 10, in

Fruit characteristics

Criteria used to determine classification

2 whorls, distinct or connate at the base; anthers 2-chambered, opening longitudinally. Pollen mostly with 3 germination furrows, subspheroidal in shape with a reticulate (net-patterned) or striate surface. Ovary of 2 to 5 but mostly 3 fused carpels (simple ovaries or segments of compound ovaries) with a similar number of locules (chambers). One or 2 ovules in each locule, attached along central axis of ovary (axile placentation), variously oriented, with 2 integuments (outer tissue layers). Fruits various but basically capsules; seeds mostly with no or scanty endosperm and a well-developed, curved, plicate (pleated, fanlike) or contorted embryo, less commonly with abundant endosperm and a straight embryo. Nine families, 168 genera, and about 2,300 species, primarily of tropical to warm-temperate forests of the world.

Family Sapindaceae (soapberry family)

Trees, shrubs, or tendril-climbing lianas, rarely perennial herbs. Tissues often rich in saponines. Leaves mostly alternate, even-pinnate (compound, without a terminal leaflet) to decompound (with many leaflets), rarely simple. Stipules absent or rarely present. Flowers mostly in thyrses or panicles, small, hypogynous, radially or more commonly bilaterally symmetrical, usually unisexual by abortion but sometimes also bisexual. Sepals mostly 5 or 4, distinct, unequal, and imbricate. Petals mostly 5 to 3, distinct, imbricate, clawed, with a petal-like appendage above the claw inside, rarely absent. Nectar-producing disc mostly extrastaminal (positioned outside the whorl of stamens), annular or unilateral. Stamens mostly 8 or 7 (but from 6 to 12 occasionally), distinct. Gynoecium (ovary) 2- to 6- but mostly 3-locular; stigmas simple, lobed, or 3 on single style. Fruit a capsule, often inflated or winged, or a drupe, berry, or schizocarp (a fruit that breaks into 1-seeded pieces). Seed with fleshy to bony coat; endosperm scanty or absent; embryo usually curved. About 150 genera and 1,500 to 2,000 species in all tropical areas of the world, especially tropical America. A few genera extend into warm-temperate regions, and a few are wholly extratropical.

Family Akaniaceae (akania family)

Small trees with alternate, leathery, odd-pinnate (with a terminal leaflet) leaves without stipules. Flowers in panicles, bisexual, radially symmetrical. Sepals 5, imbricate, separate. Petals 5, separate, contorted. Disc lacking. Stamens usually 8, separate, with outer 5 opposite the sepals. Gynoecium 3-locular with 2 anatropous (inverted and straight), pendulous ovules in each locule; style simple and stigma 3-lobed. Fruit a loculicidal (splitting dorsally into cavity of locules) capsule. Seed with straight embryo in abundant, fleshy endosperm. One genus and species (*Akania lucens*) of the eastern Australian subtropical rain forests in southeastern Queensland and adjacent New South Wales.

Family Bretschneideraceae (bretschneidera family)

Trees with alternate, compound leaves with terminal leaflets and without stipules; with myrosin cells (secretory cells producing the enzyme myrosin) in bark of branches and in inflorescences. Flowers in terminal racemes, large, pale rose, bilaterally symmetrical; calyx (the whorl of sepals) 5-lobed, open bell-shaped. Petals 5, clawed, somewhat unequal, imbricate, arising from a position on the inner surface of the calyx tube; disc lacking. Stamens 8 in 2 whorls. Gynoecium 3-locular with 2 pendulous ovules in each locule; style long and curved with small capitate stigma. Fruit an obovate (approximately oval but more swollen at end opposite stem), thick-walled, 3-valved capsule; seeds red, lacking endosperm. One genus and species (*Bretschneidera sinensis*) in the low mountain forests of southwestern China.

Family Hippocastanaceae (horse-chestnut family)

Trees and shrubs with stout twigs and opposite, 3- to 11-parted, palmately compound (divided into leaflets that attach at a single point and radiate like fingers on a hand) leaves. Flowers large, showy, bilaterally symmetrical, in terminal thyrses. Calyx of 5 sepals, separate or fused to half or more of their length. Petals 5 or 4, unequal, clawed, often slightly crested at top of claw inside. Stamens separate, 8 to 5, in 2 whorls. Nectar-producing disc extrastaminal, eccentric, one-sided or, rarely, annular. Gynoecium 3- (rarely 2- or 4-) locular; style and stigma 1; ovules 2 in each locule, amphitropous (half-inverted and straight). Fruit a loculicidal, leathery capsule with smooth to spiny surface. Seeds 1 to 3 (rarely 4 to 6), large, with smooth, shining, dark testa with pale hilum (scar where developing seed attached to ovary wall), endosperm lacking and embryo large with thick, unequal, incurved cotyledons (seed leaves). Two genera, *Billia*, with 2 polymorphic species in tropical forests from southern Mexico to northern South America, and *Aesculus*, with 13 species in the temperate, deciduous forests of North America, southeastern Europe, and southeastern Asia from India to Japan.

Family Aceraceae (maple family)

Trees or shrubs with opposite, simple, entire (smooth mar-

gined) or palmately lobed or pinnately compound, 3- to 7-foliate leaves mostly without stipules, often with milky sap. Inflorescences mostly terminal corymbs, racemes, thyrses, or umbellate fascicles (clusters radiating from one point). Flowers small, radially symmetrical, bisexual to usually unisexual. Sepals 5 or 4, distinct or basally connate, imbricate. Petals 5 or 4, distinct, imbricate, rarely lacking. Disc thick, annular, lobed, exterior to or interior to stamens, rarely lacking. Stamens 4 to 10 but mostly 8, distinct. Stigmas 2, spreading on a single style. Ovary mostly 2- (rarely 3- to 8-) locular, much compressed at right angle to partition; ovules 2 in each locule. Fruit a schizocarp, separating at maturity into 2 samara-like mericarps (segments), winged on one side or all around. Seeds with no endosperm and embryo conduplicate or coiled. Two genera, *Dipteronia*, with two species in central and western China, and *Acer*, with about 150 species throughout the North Temperate Zone.

Family Sabiaceae (sabia family)

Trees, shrubs, or lianas; leaves alternate, pinnately compound with a terminal leaflet or simple, without stipules. Flowers in panicles, racemes, or cymes (similar to racemes but with flowers maturing from the top down), small, usually bisexual, bilaterally symmetrical. Sepals 3 to 5, distinct or basally connate, open or overlapping. Petals sometimes 6, usually 4 or 5, distinct or basally connate. Disc small, annular, cup-shaped, with serrations. Stamens sometimes 6, usually 3 to 5, distinct, opposite the petals, free from or attached to them, all but 2 sometimes reduced to staminodes (sterile stamens); anthers with thick connective. Gynoecium 3- or 2-locular; ovules 2 or 1 in each locule, horizontal or pendulous. Stigmas 2 on joined or separate styles. Fruit of 2 1-seeded drupes or dry; seed with scanty or no endosperm and large, plicate cotyledons and bent or folded hypocotyl (the part of the embryo below the cotyledons—the root-end). Four genera (*Sabia*, *Meliosma*, *Phoxanthus*, and *Ophiocaryon*) with about 90 species in tropical and subtropical continental and island regions of the world.

Family Melianthaceae (honey bush family)

Trees, shrubs, or, rarely, suffrutescent (woody at the base) herbs. Leaves alternate, pinnately compound with a terminal leaflet, with large, intrapetiolar stipules. Flowers in racemes, bisexual or unisexual (species then polygamodioecious); bilaterally symmetrical, twisted on pedicels (stalks) 180°. Sepals 4 or 5, distinct or basally connate, unequal, imbricate. Petals 4 or 5, distinct, unequal, clawed, imbricate. Disc extrastaminal, unilateral, crescent-shaped. Stamens 4 or 5, separate or united at base, often bent or curved downward. Gynoecium 4- or 5-locular with 1 to 4 basal or axile ovules in each locule; ovules erect or pendulous, anatropous; stigma 4- or 5-lobed on a single style. Fruit a woody or papery capsule, seed with straight embryo in abundant endosperm. Two genera, *Bersama* with 2 polymorphic species of tropical and southern Africa, and *Melanthus* with 6 species of South Africa.

Family Greyiaceae (greyia family)

Small trees or shrubs with soft wood. Leaves alternate, simple, with shallow marginal lobes bearing smaller rounded teeth, without stipules but with base of petiole (leaf stalk) sheathing the stem, deciduous. Flowers in a terminal raceme, bisexual, slightly bilaterally symmetrical, showy, with stamens maturing before pistil of the same flower. Sepals 5, small, imbricate, shortly connate at base. Petals 5, scarlet, imbricate. Disc fleshy, extrastaminal, cupular, crowned with 10 glands. Stamens 10 in 2 whorls, extending beyond petals. Gynoecium deeply 5-lobed, 5-locular; ovules numerous; style simple, slender with small, mostly 5-lobed stigma. Fruit a septicidal (opening through the partitions and between the locules) capsule; seeds with straight small embryo in abundant endosperm. One genus *Greyia* with 3 species in South Africa.

Family Staphyleaceae (bladdernut family)

Trees or shrubs. Leaves alternate or opposite, pinnately compound with a terminal leaflet, trifoliate (with 3 leaflets), or rarely with a single leaf blade. Flowers in panicles or racemes, bisexual or unisexual, radially symmetrical. Sepals 3 to 5, imbricate, distinct or connate. Petals 3 to 5, imbricate, distinct. Stamens 5, distinct, inserted outside the large, cup-shaped disc, or disc small or absent. Gynoecium with 2 to 4 carpels, separate or connate; ovules few to 1 in each locule, anatropous, mostly ascending; styles as many as carpels and mostly distinct, some connate. Fruit free follicles (single carpels that split open by a ventral suture), membranous, inflated capsules, berries, or drupes; seeds few, with straight embryo in abundant, fleshy or horny endosperm. Five genera (*Euscaphis*, *Tapisia*, *Huertia*, *Turpinia*, and *Staphylea*) and about 60 species of the North Temperate Zone but reaching into tropical southeastern Asia and tropical America.

Critical appraisal. The major problems related to the classification of the Sapindales are how to circumscribe

the order and whether the order is distinct from or better treated as a suborder of the Rutales. The families included here are those of a recent classification system. Other recent attempts at phylogenetic classification treat the order differently. One treatment, for example, includes eight of the above families along with ten others, primarily from the Rutales, and a few from the Rosales and Geraniales. The family Sabiaceae is placed in the order Ranunculales. Another recent treatment includes seven of the above families in the suborder Sapindineae, coordinate with the suborders Rutineae and Juglandineae, in the order Rutales. The families Greyiaceae and Staphyleaceae are transferred to the order Rosales of that system. Several other classification systems also exist and if any consensus can be drawn from recent classifications, it might be that seven of the families are indeed closely related, *Bretschneidera* perhaps too close to the family Sapindaceae for independent recognition as a family; that the sapindalean group is too close to the rutalean group to treat the two as separate orders; and that the families Greyiaceae and Staphyleaceae do not belong with the Sapindales but probably in the vicinity of the Saxifragaceae and Cunoniaceae.

General agreement in the treatment of the families described here must await more research and accumulation of data. Especially profitable areas of research not yet sufficiently investigated are paleobotany, leaf and stem anatomy, comparative biochemistry, embryology, palynological (pollen) fine structure, and the natural history of sexuality, pollination, and seed dispersal. Such important living relicts as *Akania* and *Bretschneidera* need definitive study; *Sabia*, *Greyia*, and some of the little-known genera of the family Staphyleaceae require monographic treatment. Whether the families Aceraceae and Hippocastanaceae are truly distinct on the family level from the Sapindaceae also needs careful examination.

(R.F.Th.)

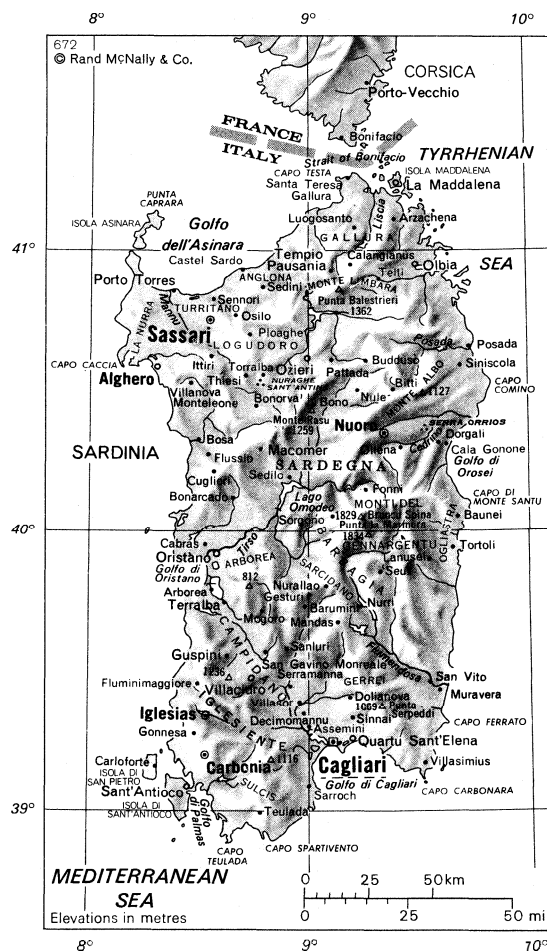

Sardinia

One of the largest islands in the western Mediterranean, second only in size to Sicily, Sardinia (Italian Sardegna) was for centuries ravaged by invaders, malaria ridden, backward, and poverty stricken. Almost ignored by the modern world until the 1950s, this autonomous region within the Italian republic was, by the early 1970s, included in one of the most ambitious industrial development schemes in Europe. It was also rapidly becoming an important tourist centre.

Ichnusar or *Sandaliotis*, the names given to the island by

the Greeks, derived from its shape, which resembles a sandal or foot, the later name, Sardinia, stemming from Latin.

Divided into the three provinces of Sassari (in the north), Nuoro (covering most of the centre), and Cagliari (in the south), Sardinia measures some 150 miles (240 kilometres) from north to south and about 75 miles (120 kilometres) at its widest point, with a surface area of 9,194 square miles (23,813 square kilometres). It lies 112 sea miles from the Italian mainland and 120 from Africa, which is just visible on a clear winter's day from Sardinia's most southerly point, Capo Teulada. Its island neighbour, Corsica, lies 7½ miles to the north, across the Strait of Bonifacio. By the early 1970s, Sardinia was the home of about 1,500,000 people. For related information see ITALY AND SICILY, HISTORY OF; MEDITERRANEAN FOLK CULTURES, WESTERN.

SARDINIA

History. *Ancient origins and the classical period.* The dominating feature of the island (7,000 examples are said to exist) is the nuraghi: strange, truncated cone structures of huge blocks of basalt taken from extinct volcanoes, built without any bonding. Most are quite small, a few obviously fortresses, with wells and other defensive measures; two of these latter, Sant'Antine at Torralba and Su Nuraxi at Barumini, are three stories, and about 50 feet, high. One nuraghe is always within sight of another, the greatest concentrations being in the northwest and south centre. There is also an important nuraghic village at Serra Orrios, near Dorgali, with traces of nearly 80 buildings identified, including temples, wells, and a theatre. The rock-cut tombs of Anghelu Ruju, the Dolmen, Thombe dei Giganti (Tombs of the Giants, for mass burial), and Domus de Janas (Witches' Homes) are also yielding much interesting information to archeologists.

But though modern science has helped to identify and approximately date weapons, jewelry, utensils, and votive

objects of metal, pottery, obsidian, and other stones, almost nothing is known of the nuraghic people themselves. The expression "*il vero Sardo*" (the true Sard), referring to a certain type of man or woman, rarely met with, obviously different, may hint at an ethnic survival, and there are a few place names that have no origin in Greek, Punic, or Latin tongues. Expert opinion now gives the dates of the nuraghi from about 1500 to 400 BC, but the mystery remains how such a people, well organized, with remarkable engineering skill and an equal talent in the creation of the beautiful and often witty bronzes to be seen in the Cagliari and Sassari museums, apparently left no trace of a written word.

Phoenicians were the island's first recorded settlers, at about 800 BC. They traded in metals and founded colonies in the south at Nora, Sulcis, Bithia, Tharros, and Karalis (or Cagliari). The Greeks soon raided the north and sacked the town of Olbia, to be followed in turn by the Carthaginians, against whom the Sardis revolted repeatedly. In 238 BC the long and brutal Roman occupation began. It was to last nearly 700 years, with Sardinia becoming the first Roman province and Cagliari a port for the Roman fleet in AD 46.

The medieval and modern period. After the Romans there were the Vandals, about AD 477, followed briefly by the Romans again, then Byzantines, and later still the Saracens, who in 711 sacked and occupied Cagliari, forcing the luckless Sardis to pay heavy ransom.

Ninth-century records mention the *giudice* (governing judge) for the first time, and at the beginning of the 11th century the four divisions of the island are described: that of Cagliari (for the south), Arborea (the centre), Logudoro (Torres), and Gallura (northeast), each with its own *giudice*. By this time the Italian cities of Pisa and Genoa, with papal support, were struggling against each other and the Sardis for domination of the islands. Vatican influence shifted, however, to Alfonso IV of Aragon, who in 1326 defeated the Pisans, taking Cagliari by force. Later in the same century, the famous warrior queen Eleanor of Arborea unsuccessfully rallied the island against the invaders. Her outstanding work, the codifying of the laws begun by her father, was nevertheless completed, and in 1421, after her death, her Carta de Logu was accepted by the Sard Parliament as valid for the whole island and remained so until the Treaty of Utrecht in 1713. In the 15th century, meanwhile, under Spanish occupation, Sardinia was raised to the status of a dominion, with its own viceroy. In 1720 Victor Amadeus II of Savoy was proclaimed first king of all Sardinia, and in 1861 the accession of Victor Emmanuel II finally united Sardinia with Italy, although it was not until 1948 that Sardinia was given a degree of autonomous government.

The land. Among the natural features of the island, the mountains are outstanding, particularly the Gennargentu in Nuoro, the Limbara heights in Gallura, and the famous *macchia*, the grasslands mingled with scrub of cistus, lentisk, myrtle, prickly pear, and dwarf oaks, which covers most of the uncultivated countryside. Yet man, too, has left an impressive imprint: among a notable range of architectural monuments, generally Romanesque or Pisan in style, the Paleo-Christian Church of San Gavino at Porto Torres is exemplary. Rising, like many of its kind, among solitary, rolling hills, the beautiful Pisan Saccargia di Santa Trinità (located near Sassari), of alternate limestone and basalt, lends its own character to the landscape, as do the ancient citadel walls rising high above the modern city of Cagliari.

Topographically, a pattern of rolling uplands predominates. It leads in the eastern centre to the Gennargentu, with La Marmora (6,017 feet [1,834 metres]), the highest point in Sardinia, just above Bruncu Spina (6,001 feet). The Punta Balestieri (4,468 feet) tops the granite range of the Limbara, surrounded by ancient cork forests. Only in the extreme northwest and in the west coast near Oristano are there large areas of low-lying land. The plain of the Campidano, 60 miles long, running diagonally from Cagliari to Oristano, is an exception. Today, its fertile soil produces much of the island's corn, as well as fruit and vegetables.

With some nine months each year of sunshine, Sardinia has a predominantly mild climate; there are only slight variations of temperature — between 43° and 55° F (6° and 13° C) in winter and from 61° to 79° F (16° to 26° C) in summer, except in the mountains, where snow may lie on the topmost peaks for as long as six months. The name Gennargentu—"the silver gate"—refers to the spectacular effect of the sun on the gleaming snow crystals. There is generally a breeze, the prevailing wind being the *maestrale*, from the northwest; the *greco* is from the east, and only when the *sirocco* blows from the southeast is the air damp and oppressive.

Rainfall is low, the mean in Cagliari being only 18.9 inches (480 millimetres), in Sassari, 23.1 inches (587 millimetres), though this increases in the higher lands. The longest rivers, the Tirso (93 miles) and the Flumendosa (79 miles), both rise in Nuoro, fed by innumerable mountain streams that dry up in summer, but for months from the end of January onward the island is a paradise of fruit blossoms and of wild flowers that yield their fragrance and colour to the thyme and other herbs mingling in the *macchia*. Oleander blooms abound in every shade from white to vivid reds. In addition to cork oaks, ilex, chestnuts, and pines throng the forests.

Cattle, goats, and pigs are allowed to wander freely in the uplands, with only sheep being herded as protection against foxes and other predators. In early summer the shepherds lead their flocks to the highlands, the men taking only a little wine and their *carta da musica* (wafers-thin bread), finding meat and water as they need it, milking their ewes and making *peccorino* cheese.

Donkeys abound; the only albinos in the world are found in Asinara, and at Castel Sardo there is a diminutive breed hardly larger than a big dog. The Sard's horse is prized above all, and its well-being was protected by laws in medieval times. In the heart of the island, in the plain of Gesturi, there is still a breed of wild horse, swift and beautiful, of unknown origin, also protected by law. Conservation measures also apply to the mufloon (horned sheep), the rare red and fallow deer, and, in the marshes of Cagliari, a species of heron and also the fleeting spring flocks of flamingos. Other wild birds include eagles, quail, and woodcock. Wild-boar hunting is allowed only at certain seasons, and there are no poisonous snakes.

The 500 miles of coastline, fringed with small bays and endless white sands lapped by translucent seas, are riddled with deep caves, many unexplored. The two most famous are the Grotto di Nettuno (Cave of Neptune), among the coral beds of Alghero, and the Grotta del Bue Marino (the Grotto of the Sea Ox), stretching more than two miles long at Cala Gonone on the east coast. Here, stalactites and stalagmites of unbelievable hue and texture, of metal as well as quartz and other stone, share hidden beauty with white-fronted seals, the only ones left in the Mediterranean.

Sardinia has also three first-class natural harbours: at Cagliari; at Asinara on the northwest; and, on the extreme northeast, among an archipelago of seven small islands, the harbour of La Maddalena, where Lord Nelson held his fleet for nine months before setting out on the voyage that led to Trafalgar. He declared it to be the finest harbour in the Mediterranean and—unavailing—besought his country to take it.

The people. A people whose origin remained unknown in the early 1970s, the Sardis (and their similarly mysterious language) have inevitably been influenced by the successive nations that occupied the island. Some of the linguistic results are not without humour: at Alghero, half the people speak Catalan but the others Sardo, so communication has to be in Italian. Similarly, the islanders of San Pietro still speak Genoese, inherited from refugees from Tabarca who settled there in the 18th century; on the adjacent San'Antioco, Sardo is the language, so once more Italian must be used. In general, Tuscan has a definite sphere of influence north of a line from Olbia, through Tempio, to Castel Sardo; Genoese predominates around Sassari, with the exception of Alghero, Spanish, and Arab in the south; and the purest native strains, both of people and of language, are found in the isolated

mountains of the Gennargentu. The strongest foreign associations are Spanish, contacts with the Iberian Peninsula having been dated from as early as the 2nd millennium BC. The legendary foundation of Nora by an Iberian chief, Norax, from Tartessus, before the Phoenician arrival, is perhaps associated with this link. Certainly, modern Sardo includes many Spanish words.

The Sardinians are a devout Catholic people. The population has increased in recent years, in spite of considerable migration, and reached about 1,500,000 by the early 1970s. Distribution was uneven, the only considerable concentrations being in Cagliari and Sassari, and then, much further down the scale, at Nuoro, Iglesias, and Oristano. By the early 1970s annual death and live-birth rates were given as 8.1 and 19.2 per thousand population, respectively.

Profound material and psychological changes are besetting contemporary Sardinia. All serious observers agree that the Sards are a dignified, brave, and loyal people, whose backward, almost tribal way of life, especially in isolated villages and mountain areas, is suddenly being catapulted, as it were, from the flint to the jet age, without the centuries of gradual transformation experienced on the mainland of Europe.

In the past, robbery or violence among the Sards arose generally from either hunger or vendetta, the former often tempered by generosity from others hardly better off and from which stems, in part, the fiercely held tradition of hospitality to the stranger. Loyalty to friend or family has, for centuries, facilitated survival in the face of savage butchery. It is a natural habit as ingrained as sleeping and eating, the results of failure to observe it in the past often being so dire that only blood could wash away the stain. It is said, with pride, that if a Sardinian is your friend he is your friend for life and that no Sardinian will ever betray another to a "foreigner." That includes Italians, who, after all, were invaders, too.

The economy. The two most important developments in the economy in recent years have been the inclusion of Sardinia in the Italian government-sponsored scheme of aid for the developing areas of southern Italy, Sardinia, and Sicily and the extermination of the malaria mosquito. Known as the Cassa per il Mezzogiorno (Fund for the South), the former project involves giving financial help and technical advice toward the establishment of new businesses, assistance in the training of workers, remission of taxes for ten years, and other incentives. The plan is based on the idea that in the scheduled areas lies a potentially enormous supply of untapped labour that could help to give Italy an important lead in export markets and increase its value within the European Economic Community. Petrochemical plants in Sardinia at Porto Torres and at Sarroch near Cagliari are being extended, and other far-reaching plans involve foreign as well as Italian investors.

The extermination of the malaria mosquito, begun in 1943 by the United Nations Relief and Rehabilitation Administration, UNRRA, with a pilot scheme at Oristano, was followed in 1947 by a campaign that covered the whole island and that was financed by the Rockefeller Foundation of the U.S. For centuries the ubiquitous disease, known as *intemperie*, was thought to be caused by the climate, and its elimination, apart from the obvious improvement in health of the people, helped to treble the number of foreign tourists over the 1950s and 1960s. An outstanding example of tourist development was the construction, over a short period in the 1960s, of a luxury resort, the Costa Smeralda, at Arzachena, by an international consortium headed by the Agha Khan.

Sardinian mining for gold, silver, lead, copper, and other ores has been known since ancient times, and the island is the most important source of fluorspar in Europe. Poor-quality coal is mined at Carbonia and is mainland Italy's only source of natural supply, as is the sea salt from the lagoons of Carloforte and Cagliari. The centuries-old cork forests of Gallura produce 80 percent of Italy's total output. Other industries include the making of *peccorino* cheese, and the processing of such wines as

the *vernaccia* and *Malvasia*, from the Ogliastra, and the celebrated red wine of Olbia.

At Stintino, on the Golfo dell' Asinara (Gulf of Asinara), and also at Carloforte, fishing for *tonno* (tunny) is skilled, well organized, and profitable for all. It is financed by Genoese. The only difficulty with this industry is that the course of these great fish, storming their way through to spawning grounds in the Black Sea, remains uncertain until the last moment.

The building of good motor roads linking the main centres of Sardinia and improvements of lesser routes, in conjunction with considerable government concessions to tourists bringing cars to the island, probably doubled motor traffic over the 1960s. Rail communications between the main centres are now fairly good, but other services are slow and limited. The two international airports at Cagliari and Alghero were joined in the early 1970s by a third, at Olbia. A private airline connects the Costa Smeralda with the mainland. In the peak season there are scheduled daily flights to main Italian and Sicilian cities and to Nice and twice weekly a direct service to London. In 1970 alone, there were 300 charter flights bringing passengers from all over Europe. Maritime services are good and include car ferries. Connections are frequent between the Sardinian towns of Cagliari, Olbia, Golfo degli Aranci, and Porto Torres and the mainland towns of Civitavecchia, Genoa, Naples, Palermo, Toulon, and Tunis.

Administration and social conditions. Article 1 of the special statute for Sardinia, dated February 26, 1948, states: "Sardinia and its islands shall be considered an autonomous region with its own legal status, within a united Republic of Italy." Government is administered by a small executive body, the *giunta*, appointed from among members of the Regional Council, themselves elected on the basis of proportional representation in the ratio of one councillor for every 20,000 inhabitants. Members of the Council elect a president from among themselves; he has the right to be present at Cabinet meetings in Rome when matters concerning Sardinia are involved. Only in rare cases—usually where expert knowledge is required—are other than regional councillors appointed to administrative posts within the *giunta*.

Elections are held every four years. Every citizen reaching the age of 21 has the right to vote but cannot become a councillor until the age of 25. There are no postal votes; although, in theory, absentee voters abroad can claim free second-class transport "to the border," this privilege is not much exercised.

The wide legislative powers held by the *giunta* affect nearly all spheres of life: social services, labour, industrial conditions, hotel and tourist trade, and public works, including building and urban planning. The region retains 90 percent of the income collected from the many tax sources, as well as from a state tobacco monopoly. The central government nevertheless retains control of customs and excise, the armed forces, the *carabinieri* and the finance police (who watch the entry of goods and may examine corporate records in tax matters), the urban and rural police having only 'limited functions. The railways are also state property, but other means of transport within the island, as well as local sea and air traffic, are the responsibility of the *giunta*. Two years of military service are compulsory, as on the mainland.

Under Italian law every citizen has the right to free education, and in Sardinia "subscription" is available to assist talented children from poor families to attend universities. Taxes include contributions toward medical care and pensions, the latter being payable at the age of 55 for women and 65 for men.

Within the framework of the Regional Council the three provinces have considerable administrative powers over their domestic affairs, all of which are jealously guarded. Isolation of small villages is one of the problems but is, to a growing extent, being overcome by the organization of communes (numbering about 300), whereby two or more communities join for mutual benefit and protection. Each commune has at least one policeman, while in other, solitary villages, the local mayor has authority to

The constitutional background

The campaign against the mosquito

enlist up to 15 volunteers, known as *baracelli*, whose powers are limited but who perform a useful function. The origin of this force goes back to the days of the Spanish vigilantes.

Cultural life and institutions. As might be expected in an island with so long and varied a history, folklore and craftwork abound in Sardinia, in many cases the origins and inspiration for both going back to forgotten centuries and pagan beginnings. Witchcraft and both black and white magic are still part of life. No one realized this better than the Nuorese authoress Grazia Deledda, who was given the Nobel Prize for literature in 1926 for her understanding portrayal of the power and passions of life in the primitive communities around her.

Every town and village has its own festival, but the most important is the Sagra di Sant'Efisio at Cagliari in early May, which commemorates the martyrdom of a Roman general who was converted to Christianity. All Sardinia flocks to the capital for this spectacle, which affords an opportunity to witness the exquisitely embroidered (and often valuable) costumes of the women. The men's national costume includes, together with the stocking cap seen on the nuraghic bronzes, a tunic said to be similar to that worn under their armour by Roman soldiers.

Most of the festivals involve feats of horsemanship, as at the Sartiglia of Oristano, the dangerous Ardia at Sedilo, and the Cavalcata at Sassari, where there is also a Feast of the Candles. At Mamoiada, in Nuoro, a remarkable feature is the Feast of the Mamuthones, where men, wearing masks and sheepskins on their backs loaded with bells, perform a ritual dance, ending with a symbolic "killing" of the scapegoat. The variety of songs, and dances is endless; they are often performed to the accompaniment of the *launeddas*, ancient triple pipes.

Much of the craftwork, still unspoiled by the intrusion of modernity, is skilled and beautifully made, some being decorated with designs based on Punic and even earlier symbolic patterns. Gold filigree, often allied to coral, is always worn on special occasions. Woodcarving exhibits a great variety and includes the making and decorating of the cassapanca, the bridal chest. Other examples include leatherwork from Dorgali, basket making of palm or asphodel from Castel Sardo or Flussio, as well as finely woven carpets from Nule and Ploaghe, filet lace from Bosa, ceramics and terra-cotta from, among other places, Tortoli, Assemini, and Oristano, and the finely woven *arazzi*, or wall hangings, made in Mogoro, some of which show Arab influence.

The outlook. The success of the development of Sardinia is likely to hinge on the skill and understanding with which new ideas, new standards of living, and new industries are welded on to the existing strata of life and how well the tourist trade is extended. Experienced observers who both know and appreciate the basic qualities of the Sards do not expect the transition to be an easy one. Much will depend on access to education and on the manner whereby a man is enabled to earn a better living for his family, yet still call his soul his own.

BIBLIOGRAPHY. MARGARET GUIDO, *Sardinia* (1963), is a scholarly book on Sardinian prehistory, with important illustrations. The section on Sardinia by the ECONOMIST INTELLIGENCE UNIT in *The Mezzogiorno: Investment Prospects for the Seventies* (1971), deals with economics but is rather technical. T. and B. HOLME and B. GHIRADELLI, *Travellers' Guide to Sardinia* (1967), is a short guide for the interested tourist covering a wide range of subjects; MARY DELANE, *Sardinia: The Undefeated Island* (1968), an account of a journey, includes descriptions of terrain, as well as history and folklore. JOHN WARRE TYNDALE, *The Island of Sardinia*, 3 vol. (1849), is a survey by a barrister dealing in great detail with the history and customs of Sardinians at that time, as does LA MARMORA, *Voyage en Sardaigne*, 3 pt. (1839-60), DH. LAWRENCE, *Sea and Sardinia* (1921), is a highly personalized report of people encountered on a brief visit. MARCELLO SERRA, *Mal di Sardegna* (1955), is considered as something of a classic in its analysis of the effects of history and the conditions of life on the island. G.M. TREVELYAN, *Garibaldi and the Thousand* (1909), is of special note for the description of the island of Caprera where Garibaldi lived and is buried, his tomb guarded always by a sailor. GRAZIA DELEDDA, *Canne al Vento* (1958), is a novel demonstrating the continuing belief

in witchcraft, as well as a remarkable understanding of the attitudes of the Sards to each other; the author received the Nobel Prize for Literature in 1926 for her descriptions of Sardinian life.

(M.De.)

Sargon of Akkad

One of the great rulers of the ancient Near East, Sargon of Akkad (c. 2334-2279 BC) wrested the hegemony of the Mesopotamian city-states from the Sumerians and established a Semitic dynasty in the area. That dynasty, though it lasted little more than a century, left a permanent imprint on Mesopotamian society and culture.

Sargon is known almost entirely from the legends and tales that followed his reputation through 2,000 years of cuneiform Mesopotamian history, and not from documents that were written during his lifetime. The lack of contemporary record is explained by the fact that the capital city of Agade, which he built, has never been located and excavated. It was destroyed at the end of the dynasty that Sargon founded and was never again inhabited, at least under the name of Agade.

Hirmer Fotoarchiv, Munchen

Bronze head from Nineveh believed to be Sargon of Akkad, 2nd half of the 3rd millennium BC. In the Iraq Museum, Baghdad.

According to a folktale, Sargon was a self-made man of humble origins; a gardener, having found him as a baby floating in a basket on the river, brought him up in his own calling. His father is unknown; his own name during his childhood is also unknown; his mother is said to have been a priestess in a town on the middle Euphrates. Rising, therefore, without the help of influential relations, he attained the post of cupbearer to the ruler of the city Kish, in the north of the ancient land of Sumer. The event that brought him to supremacy was the defeat of Lugalzaggisi of Uruk (biblical Erech, in central Sumer). Lugalzaggisi had already united the city-states of Sumer by defeating each in turn and claimed to rule the lands not only of the Sumerian city-states but also those as far west as the Mediterranean. Thus Sargon became king over all of southern Mesopotamia, the first great ruler for whom, rather than Sumerian, the Semitic tongue known as Akkadian was natural from birth, although some earlier kings with Semitic names are recorded in the Sumerian king list. Victory was ensured, however, only by numerous battles, since each city hoped to regain its independence from Lugalzaggisi without submitting to the new overlord. It may have been before these exploits, when he was gathering followers and an army, that Sargon named himself Sharru-kin (Rightful King) in support of an accession not achieved in an old-established city through

Legendary origins

hereditary succession. Historical records are still so meagre, however, that there is a complete gap in information relating to this period.

Military campaigns

Not content with dominating this area, his wish to secure favourable trade with Agade throughout the known world, together with an energetic temperament, led Sargon to defeat cities along the middle Euphrates to northern Syria and the silver-rich mountains of southern Anatolia. He also dominated Susa, capital city of the Elamites, in the Zagros Mountains of western Iran, where the only truly contemporary record of his reign has been uncovered. Such was his fame that some merchants in an Anatolian city, probably in central Turkey, begged him to intervene in a local trouble and, according to the legend, Sargon, with a band of warriors, made a fabulous journey to the still-unlocated city of **Burushanda** (Purshahanda), at the end of which little more than his appearance was needed to settle the dispute.

As the result of Sargon's military prowess and ability to organize, as well as of the legacy of the Sumerian city-states that he had inherited by conquest, and also of previously existing trade of the old Sumerian city-states with other countries, commercial connections flourished with the Indus Valley, with the coast of Oman, with the islands and shores of the Persian Gulf, with the lapis lazuli mines of **Badakhshān**, with the cedars of Lebanon, with the silver-rich Taurus Mountains, with Cappadocia, with Crete, and perhaps even with Greece.

During Sargon's rule Akkadian became adapted to the script that previously had been used in the Sumerian language, and the new spirit of calligraphy that is visible upon the clay tablets of this dynasty is also clearly seen on contemporary cylinder seals, with their beautifully arranged and executed scenes of mythology and festive life. Even if this new artistic feeling is not necessarily to be attributed directly to the personal influence of Sargon, it shows that, in his new capital, military and economic values alone were not important.

Because contemporary record is lacking, no sequence can be given for the events of his reign. Neither the number of years during which he lived nor the point in time at which he ruled can be fixed exactly; **2334 BC** is now given as a date on which to hang the beginning of the dynasty of Agade, and, according to the Sumerian king list, he was king for 56 years.

Difficulties in his last years

The latter part of his reign was troubled with rebellions, which later literature ascribes, predictably enough, to sacrilegious acts that he is supposed to have committed; but this can be discounted as the standard cause assigned to all disasters by Sumerians and Akkadians alike. The troubles, in fact, were probably caused by the inability of one man, however energetic, to control so vast an empire without a developed and well-tried administration. There is no evidence to suggest that he was particularly harsh, nor that the Sumerians disliked him for being a Semite. The empire did not collapse totally, for Sargon's successors were able to control their legacy, and later generations thought of him as being perhaps the greatest name in their history.

Attributing his success to the patronage of the goddess Ishtar, in whose honour Agade was erected, Sargon of Akkad became the first great empire builder. Two later Assyrian kings were named in his honour. Although the briefly recorded information of his predecessor **Lugal-zaggisi** shows that expansion beyond the Sumerian homeland had already begun, later Mesopotamians looked to Sargon as the founder of the military tradition that runs through the history of their people.

Sargon II of Assyria

Sargon II, one of the most outstanding rulers of Assyria, during his reign (721–705 BC) consolidated Assyrian predominance over an area that was to remain the mainstay of the Assyrian empire for a century.

Sargon II, detail of a relief from the palace at Khorsabad. In the Louvre, Paris.

By courtesy of the Musée du Louvre, Paris; photograph. Maurice Chazelle

Sargon is the Hebrew rendering (Isaiah **20:1**) of Assyrian Sharru-kin, a throne name meaning the King is Legitimate. The name was undoubtedly chosen in reminiscence of two former kings of Assyria, particularly in commemoration of Sargon of Akkad (flourished **2300 BC**).

Although Sargon's ancestry is partly veiled in mystery, he was probably a younger son of Tiglath-pileser III and consequently a brother of his predecessor Shalmaneser V, who may have died ignominiously or may have been deposed. It was for Sargon to resume the conquests and to improve the administration of the empire his father had begun to assemble.

Early career

Upon his accession to the throne, he was faced immediately with three major problems: dealing with the Chaldean and Aramaean chieftainships in the southern parts of Babylonia, with the kingdom of Urartu and the peoples to the north in the Armenian highlands, and with Syria and Palestine. By and large, these were the conquests made by Tiglath-pileser III. Sargon's problem was not only to maintain the *status quo* but to make further conquests to prove the might of the god Ashur, the national god of the Assyrian empire.

When Sargon succeeded to the Assyrian throne, **Marduk-apal-iddina II** (Merodach-Baladan of the Old Testament), a dissident chieftain of the Chaldean tribes in the marshes of southern Babylonia, committed the description of his victory over the invading Assyrian armies (**720 BC**) to writing on a clay cylinder, which he deposited in the city of Uruk (biblical Erech; modern Tall al-Warkā). The presence of this record obviously did not suit Sargon. After having discharged other commitments, he uncovered Marduk-apal-iddina's record and removed it to his own residence, then at **Kalakh** (modern **Nimrūd**), substituting what has been described as an "improved" version that was more to his liking.

At the beginning of his reign, Sargon had limited time to concentrate his efforts on the building of his palace at Khorsabad, and indeed the palace was not dedicated until the year **706 BC**, less than a year before he met his death.

The extant texts reveal little about Sargon himself. With few exceptions, ancient Mesopotamian rulers have left no documents from which to write an actual biography. No personal documents have survived from Sargon's reign; but it seems fair to assume that phraseologies uncommon in the inscriptions of other Assyrian kings, found in his texts, must have met with his approval, even though it is uncertain whether such phrases—sometimes turning into what is obviously poetry—were in fact conceived by Sargon himself or ascribed to him by his historiographers. The discovery, at **Nimrūd**, of series of texts of omens written in cuneiform on beeswax encased in ivory and walnut boards and marked as being the property of the palace of Sargon perhaps also throws some light on Sargon the man. Although he may not have been the one to introduce cuneiform texts written on wax, this novel

The Letter
to Ashur

method of committing texts to writing apparently took his fancy. This assumption tallies well with the interest he took in the engineering projects undertaken in cities he conquered. Sargon's palace at Khorsabad was dedicated in 706 BC, less than a year before he died.

An unparalleled record of Sargon's eighth campaign (714 BC)—in the form of a letter to the god Ashur—has been recovered. According to this letter, Sargon, in 714, led the Assyrian armies from Kalakh, which at the time was still his residence, into the areas around modern as-Sulaimānīyah in Iraqi Kurdistan and into the highlands of the Zagros Range beyond. His purpose was to come to the aid of allies of the Assyrian realm who were threatened by Rusa I, a king of Urartu and a bitter enemy of Assyria. During the progress of this campaign, the author of the account visualized, or anticipated, the reactions of his adversary as, from a mountain, he watched the approach of the Assyrian armies. The passage, like many others in this unique text, constitutes an ingenious stylistic device unparalleled in Assyrian historical literature. The phraseology employed by the author is original by Mesopotamian standards as they are known today: inventive, resourceful, testifying to a fertile mind, and clearly deviating from the commonplace platitudes that mostly characterize the standard accounts of Assyrian kings. Whether or not Sargon himself is responsible for the wording of this narrative, it is to his credit that an account of this nature emerged from his chancery, with his approval and endorsement. Sargon is assumed to have died in battle in 705.

BIBLIOGRAPHY. A.G. LIE, *The Inscriptions of Sargon II, King of Assyria* (1929), is still the only acceptable edition of Sargon's various inscriptions other than his account of the eighth campaign. FRANÇOIS THUREAU-DANGIN, *Une Relation de la huitième campagne de Sargon (714 avant Jésus-Christ)* (1912), remains a standard edition of a unique document. It was left for A. LEO OPPENHEIM, in his article "The City of Assur in 714 B.C.," *Journal of Near Eastern Studies*, 19: 133–147 (1960), to expound ingenious and stylistically sophisticated analyses of this unparalleled example of a first account of an Assyrian campaign into a foreign territory. A rendering, in translation, of the entirety of this text may be found in D.D. LUCKENBILL, *Ancient Records of Assyria and Babylonia*, 2 vol. (1927, reprinted 1969), as well as translations of various texts laid down by Assyrian monarchs. With its small shortcomings, owing to subsequent research and corrections of some readings of cuneiform configurations, Luckenbill's two volumes remain a standard work of reference. A.T. OLMSTEAD, *History of Assyria* (1923, reprinted 1960), although old, seems to be the only comprehensive history of Assyria so far available. SIR MAX MALLOWAN, *Nimrud and Its Remains*, 2 vol. (1966), contains a full account of the excavations of Nimrūd (ancient Kalakh) that were continued from 1949 for more than a decade.

(Jo.La.)

Sarmatians

The Sarmatians were a people who, during the 4th century BC–4th century AD, occupied much of southern European Russia and penetrated into the eastern Balkans beyond.

Sarmatian studies were in their infancy in the early 20th century; but excavations conducted in the U.S.S.R. since the 1920s have provided much information. The earliest accounts of the Sarmatians are those of Herodotus and other ancient Greek historians who stated that the Sarmatians, or Sauromatians, were an association of tribes. As with the Scythians and the Cimmerians before them, the most vital element in their political group came from central Asia. Its members were of Iranian stock and language; their tongue closely resembled that of the Scythians (Herodotus, Book IV, 117). Like the Scythians they were nomadic, excelling in horsemanship and displaying the same skill in warfare. They also had a keen political sense and administrative ability and followed their conquest of the western Eurasian plain by obtaining full political control over what is now southern European Russia. In consequence their name acquired generic significance; it quickly came to represent a large group of kindred and allied tribes that remained thenceforth attached to the smaller Sarmatian core. The Alani and Roxolani were the

most important of these secondary tribes, yet, even when acting independently, all retained their place in the Sarmatian community. All of them accepted the culture favoured by the Sarmatians, practicing and disseminating it with such vigour and enthusiasm that Sarmatian taste and influence were felt even on the shores of the Black Sea and in the west.

History. It is evident now that the Sarmatians advanced from central Asia to invade and conquer the Scythians (q.v.) and did not, as stated by Diodorus Siculus (Book II, 43), rise against them from within their own territory. It has become possible to divide Sarmatian history into four periods. The first extends from the 6th to the 4th century BC, during which the Sarmatians migrated from Asia and penetrated to the western foothills of the Urals. Toward the end of this period the Roxolani pushed on toward the Volga River and the Alani settled in the Kuban Valley. For the most part they remained till they were dislodged in the period of the great migration, when some of the latter infiltrated into Ossetia, surviving there as a community till about the 9th century AD.

The Sarmatians followed closely in the steps of these tribes, and by the 5th century BC they had already made themselves masters of the plain that stretches between the Urals and the Don River. This success encouraged them to intensify their pressure on the Scythians, and in the 4th century BC they crossed the Don and entered Scythia proper. This rapid advance may well have coincided with a decline in Scythian might, resulting from the death of their aged king, Ateas, in battle against Philip II of Macedon in 339 BC; if so, this would help to account for its speed.

The incursion serves to herald the second (Early Sarmatian) period in Sarmatian history, from the 4th to the 2nd century BC, often called the Prokhorov Period after the important burials of that name with which it is associated. During this period the Sarmatians partially overcame the Scythians and gradually succeeded them as rulers over most of southern Russia. The Roxolani had begun by joining with the Sarmatians in attacking the Scythians, advancing upon them from the south. Toward the end of this period, when the Sarmatians had strengthened their hold over the territory of the Royal Scyths, the Roxolani changed their allegiance, joining forces with the Scythians to attack the Greek Black Sea cities.

In the third (Middle Sarmatian) period, between the 1st century BC and the 1st century AD, the Sarmatians conquered all but the Crimean Scythians, bringing the assaults on the Greek cities to an end. Having consolidated their hold over the captured areas, the Sarmatians did not attempt to annex any of these cities; instead, early in Nero's reign, they invaded the Roman province of Lower Moesia (Bulgaria). Although the Roman general Plautius Silvanus Aelianus ejected them in AD 62–63, the Sarmatians and some Germanic tribes they had joined were thenceforth a menace to the Romans in the west, as were the Alani in the Caucasian area. Vespasian, Trajan, and Marcus Aurelius were forced to adopt such defensive measures as to attempt to transform the vassal Bosporan kingdom into a buffer state. Hadrian had to build a network of fortresses manned with Roman troops along the borders of Lower Moesia and Cappadocia.

In the last phase of their history, spanning the 2nd to 4th centuries AD, the Sarmatians and their Germanic allies entered Dacia (Romania) and began raiding the lower reaches of the Danube, but in the 3rd century the Gothic invasion put an end to their independence. Many Sarmatians nevertheless retained their position and influence under the Goths; others joined them to sweep into western Europe, fighting at their sides. Soon after AD 370, however, waves of migrating Huns effectively ended the very existence of Sarmatia; the majority of the Sarmatians who remained in southern Russia perished at the hands of these Asian invaders. Some of the survivors were assimilated by their new masters and others by the Slavs of the lower Dnieper, but most fled westward to join their neighbours in harassing the Huns and the remaining Goths. Their descendants continued to do so until the 6th century, when they finally disappeared from history.

Invasion
of Scythia

Social structure and way of life. Very little was known till the 1960s about the social structure or way of life developed by the Sarmatians. Basically both at first followed closely those established by the Scythians, largely as the result of a common Central Asian origin and heritage. Nevertheless, several fundamental differences serve to distinguish the two peoples. Scythians venerated nature deities, while the Sarmatians were fire worshippers who sacrificed horses to their god. Scythian women were relegated to a life of semiseclusion; Sarmatian women, at least in the earlier periods, however, were expected to fight in time of war, and could not marry until they had killed an enemy in battle. After marriage, however, women were obliged to abandon warfare and to devote themselves entirely to their homes and families. Greek tales about Amazons may have been based on exploits of early Sarmatian women, many of whom were buried with their weapons.

Amazons

When the Sarmatians penetrated into southeastern Europe, they were already accomplished horsemen. They followed a nomadic way of life, devoting themselves to hunting and to pastoral occupations; most of them adhered to this form of existence to the end. There is evidence that some of them practiced an elementary form of husbandry, but few settlements of Sarmatian origin have as yet been studied. In the earlier periods their customs, clothes, and many other possessions resembled those of the Scythians, but their society was matriarchal in character. Gradually, as a prosperous class began to form, the tribe entered a transitional phase during which tribal chieftains tended to replace women as rulers; eventually, kings seem to have predominated.

The rise of a male monarchy may have been stimulated by the formation of a male corps of heavy cavalry, facilitated by the probably Sarmatian invention of a metal stirrup, soon followed by that of the spur. The methods of warfare thus made possible were largely responsible for Sarmatia's military supremacy. The Romans noted and gradually adopted certain of their tactics. During the 3rd century they went so far as to incorporate Sarmatian units in some Roman regiments, equipping them with their traditional weapons and encouraging them to fight in their own manner. From early times onward Sarmatian military accoutrements included conically shaped helmets worn with scale, ring, or plate armour of iron that often protected horses as well as riders. Unlike the Scythians, the Sarmatians did not excel at archery; they relied on long lances or spears and long, sharply pointed swords.

The Sarmatians were excellent craftsmen. Perhaps artistically less inventive than the Scythians, they were nevertheless equally proficient metalworkers, better potters, and no less adept at curing hides; they were thus able to maintain the important trade in furs, grain (levied from local settlers), honey, fish, and metal that the Scythians had established with the Greek cities on the northern shores of the Black Sea. The Sarmatians also developed commercial contact with the Syr-Darya region, the borderlands of China, and the kingdom of *Khwarezm* (Chorasmia).

Until disrupted by the Huns, Sarmatian culture presented a uniform and all-embracing character, even though it altered with each period in its history. Its evolution is reflected in burials that distinguish each of the four periods. Thus, no large mounds are associated with the earliest phase when objects were seldom included in the graves, though the occasional presence of articles points to the beginnings of a class society. Burials of the second period often display considerable wealth; those of the third phase also reflect the growth of a more complex way of life, stemming in part from the Sarmatian subjugation of alien tribes and assimilation of many of their customs. It also was a result of the flourishing trade the Sarmatians had established. During these periods the truly typical Sarmatian culture evolved and was imposed on the entire region. In the last phase Germanic influence led to the introduction of fibulae (brooches or clasps like safety pins), with resulting changes in costume.

Tombs and their contents. The richest Sarmatian burials have been found in the Kuban area, and on the edges

of the great riverbeds of the southern Russian S.F.S.R. and the Ukraine, where many have been subjected to regular seasonal flooding. Hundreds of other graves are to be found throughout the area the Sarmatians once occupied. Many of these were excavated in the second half of the 19th and in the first half of the 20th centuries, and sufficient material has become available to permit an overall picture to be outlined.

Except in the Kuban, where they are generally oval in shape, the mounds the Sarmatians constructed are similar to those of the Scythians; but the tombs beneath them are different from the elaborate Scythian mortuary chambers. For the most part Sarmatian graves consist of simple square, circular, or oval holes (sometimes pocketed trenches); very occasionally, tombs are found lined with rushes. No coffins were used; the body was usually wrapped in a leather or fur rug and laid on the bare earth, though sometimes on a rush mat. In the vicinity of Kerch, paintings survive on the walls of some graves of late date, some showing Sarmatians wearing cloaks held in place by fibulae; some contain traces of what may be the beginnings of an alphabet.

Diagonal and crouched burials and cremations occur side by side; thus although Sarmatian culture prevailed, local habits evidently persisted. In the last phase the influence of the Huns is reflected in the practice of cranial deformation. In the graves of earlier periods Scythian influence is often apparent throughout; horses are associated with most burials, their trappings being generally placed in the graves. In richer burials, such as those of Starobelsk and Yanchokarski, their hooves and skulls were often included, but not, as was customary in Scythian times, the rest of their bodies. Most of the tombs also contained caldrons of the Scythian type as well as utensils for inhaling hemp, bronze vessels, and mirrors of Oriental form in silver alloy. Tiny gold plaques designed as trimmings for clothes are also common but, in contrast to similar gold plaques of Scythian date, which were generally decorated with an animal design, these are usually geometric in character. Among articles of personal adornment, fibulae make their first appearance in graves of Sarmatian date; little gold bottles set with jewels are especially characteristic of the period, and various types of glass are numerous. The locally made pottery is of a higher quality than the pottery that is typical of the Scythian age.

Sarmatian horse trappings differ from those used by the Scythians, as do some of their arms. The iron Sarmatian bits had rings to hold the leather and had fewer animal terminals and decorations than those of Scythian date; hard saddles with a high frontal arch were also new to the Black Sea region. The saddles were often covered with gold leaf, studded with bosses and adorned with coloured glass or precious stones; trappings tended to be less ornate than those of the Scythians, although often of silver or silver gilt. The long swords peculiar to the Sarmatians were set into wooden hilts surmounted by a knob of precious stone (*e.g.*, agate or onyx) or in wood laced with gold; the handguards were generally cut from a single large stone. Spears were longer and sharper than the Scythian, but the variety of knives and daggers was equally great.

Metalwork and the polychrome style. Whereas the Scythian was an animal art, the Sarmatian, though it retained many animal forms, was primarily geometric and was largely in polychrome (many colours). The Sarmatians apparently delighted in glass inlay, gold-wire granulations, and embossed effects achieved by *repoussé* or inset stones and jewels; the taste was basically Asian, the designs primarily geometric and floral, though frequently also of an animal character. Jewellers produced diadems, torques, bracelets, rings, fibulae, gold plaques, buckles, buttons, and mounts of various sorts. Hoards that have been found and objects acquired from the more important tombs form an important collection of jewelry and fine metalwork. The Pashkov group of burials in the Kuban, excavated during 1929–37 and 1946–49, are among the earliest known. They are associated with a *Meteo-Sarmatian* tribe and date in the main from the 5th to the 3rd

Burial rites

Jewelry

century BC, though one mound contained jewelry and vessels assigned to the 3rd century AD. In the earlier instances the men were buried with spears, swords, and arrows; the women were adorned with beads and with bronze bracelets of local manufacture. The Prokhorov burials lie near Sharlyk in Orenburg *oblast* (province), Russian S.F.S.R., and were excavated by the Russian archaeologist S.I. Rudenko in 1916. The largest belonged to a chieftain who had been buried in an iron chain-mail coat with gold torque and bronze bracelets; a sword and gold-handled knives were placed within easy reach of his hands, and two magnificent silver vessels of Persian workmanship stood close to him. One of these was inscribed in Aramaic with the words "the cup of Atromitra." The richest burial so far known belonged to the Novochoerkassk group and is to be dated to the 2nd century BC. Discovered in 1864, it produced objects of such value that it seems probable the tomb was for a queen. In addition to a magnificent crown the woman wore a gold necklace and gold bracelets. A small agate bottle mounted in gold and adorned with animal designs and several gold cups and silver vessels lay beside her. All these were of Sarmatian workmanship but placed with them was a terra-cotta statuette of Eros, of Greek origin, and two Greek-inscribed silver d'shes; these testify to the links that the Sarmatians maintained with their Greek neighbours. Another burial in the same region produced a gold vessel, dating from between the 2nd century BC and the 1st century AD, signed in Greek letters with the name of its Sarmatian maker, Tarulla.

BIBLIOGRAPHY. M.I. ROSTOVTSSEV, *Iranians and Greeks in South Russia* (1922), remains essential reading for all serious study in this field, although much new information has come to light since its publication. T. SULIMIRSKI, "The Forgotten Sarmatians," in E. BACON (ed.), *Vanished Civilisations* (1963), is a convenient introduction to the subject; the same author's *The Sarmatians* (1970), a careful and detailed summary of all available archaeological evidence and analysis of the tribes and their movements.

(T.T.R.)

Sarpi, Paolo

Paolo Sarpi, Venetian patriot, polemicist, and scholar, was the theological adviser to the Republic of Venice during its struggle in the 17th century with Pope Paul V, author of an influential work attacking papal absolutism, and, among Italians, a pioneer advocate of the separation of church and state.

Thomas-Photos, Oxford

Sarpi, portrait by an unknown artist. In the Bodleian Library, Oxford, Eng. (The black spot on his face covers the scar from an unsuccessful attempt on his life in 1607.)

Sarpi was born in Venice on August 14, 1552, the son of Francesco Sarpi, an unsuccessful businessman, and Isabella Morelli, of a prominent but not noble Venetian family. His father died when Sarpi was a child and he was brought up in poor circumstances by his pious mother and his maternal uncle Ambrogio, a priest. Delicate, studious, and clever, at 14 Sarpi joined the Servite Order and

at 20 became court theologian to the Duke of Mantua, a post which gave him leisure to study Greek, Hebrew, mathematics, anatomy, and botany. Young Sarpi was known as *La Sposa*—"the bride"—because of his modesty and moral seriousness. Of medium height, with a large brow, long nose, black eyes, and thin beard, he lived simply and suffered from poor health. He is reported to have possessed a photographic memory and to have been a most persistent scholar.

At 27 Sarpi was appointed provincial of his order and won a reputation as a firm but sensible ruler. He visited Rome several times and became friendly with Pope Sixtus V and the great theologian Robert Bellarmine. Continuing his anatomical studies, he discovered the valves of the veins that facilitate the circulation of the blood, and he was the first to demonstrate that the pupil of the eye dilates under the action of light. His many friends included Galileo, who thought no one in Europe could surpass Sarpi in mathematics, while Sarpi said of the astronomer's condemnation by Rome, "The day will come, I am almost sure, when men, better versed in these matters, will deplore the disgrace of Galileo and the injustice dealt so great a man."

Venice, with its cosmopolitan population, had long followed a liberal religious policy, resisting any intrusion by Rome into its internal affairs. In 1606 Paul V demanded that Venice repeal a law restricting church building and hand over to him two priests, one charged with murder, whom the Venetian government intended to try before civil courts. When Venice refused, Paul excommunicated the senate and the doge (the Venetian head of state) and put the republic under an interdict, meaning that all priests were debarred from their functions.

Sarpi, having been appointed consultor to the government, wrote powerfully in support of the Venetian case. He argued that the Pope was infallible only in matters of faith and that his interdict was invalid. Sarpi's basic tenet was that "princes have their authority from God, and are accountable to none but him for the government of their people." It was in the public interest, he said, to fix limits on church building in a small city like Venice, for ecclesiastical property—already extensive—paid no taxes to the state. As for the two priests, while the church had every right to try them for crimes committed as priests, for crimes such as murder and adultery the state courts must be responsible. Sarpi concluded that Venetians were not bound to observe the interdict, and his advice was followed.

Sarpi's works were influential because he wrote in a clear, witty style and argued not from legal textbooks but from the evident facts of history. He constantly argued, for example, that the pope's power should not exceed that of St. Peter. Sarpi's writings played an important part in sustaining Venetian morale and in winning sympathy abroad. Paul V had a powerful ally in Spain, then dominant in Italy, and when he threatened recourse to arms, Venice secured the support of France and even threatened to call on Protestant countries. Finally the Pope, fearing Venice would become Protestant, agreed to a settlement. The interdict was ended, and Venice handed over the two priests, reserving, however, her right to try churchmen before civil courts. "The Republic," said Sarpi, "has given a shake to papal claims. For whoever heard till now of a papal interdict, published with all solemnity, ending in smoke?"

Sarpi refused to answer a summons to appear before the Roman Inquisition. On October 5, 1607, he was stabbed during an attack on him in the street. He blamed the Roman Curia but the charge has never been proved.

Between 1610 and 1618 Sarpi wrote the first full history of the Council of Trent (1545–63), using Venetian archives and private papers, notably those of **Arnauld du Ferrier**, French ambassador to the council. Sarpi strongly criticized the council for not giving bishops more autonomy, for hardening differences with the Protestants, and for increasing the Curia's absolutism. The only one of Sarpi's writings to be printed in his lifetime, the *History of the Council of Trent*, appeared in London in 1619, under the pseudonym Pietro Soave Polano. Though put

Personal characteristics

Defense of Venice against the papacy

Writings

on Rome's *Index* of prohibited books, it went through several editions and five translations in ten years.

The *History*, like most of Sarpi's writings, is a partisan work, written with one eye on the Protestants whom Sarpi saw as Venice's potential allies against Rome and Spain. Similarly, in his extensive correspondence, Sarpi sought the friendship of all who took an independent line toward Rome, including French Huguenots and German Protestants; but there is no evidence to suggest that he himself was, in doctrine, anything but an orthodox Roman Catholic. Sarpi's quarrel was never with the Roman Church but—as he saw it—with an interfering Roman Curia.

In his later life Sarpi was something of a hero to the Venetians and was sought out by foreign visitors. He continued to live frugally and, though excommunicated, he celebrated mass to the end. He died on January 14, 1623, and his last words—"Esto perpetua" ("May she endure")—were, characteristically, a reference to Venice.

BIBLIOGRAPHY. PAOLO SARPI, *Opere* (1761–68), is the first collected, and still the most complete, edition of Sarpi's writings, though it will eventually be superseded by the critical edition of individual works in course of publication by LATERZA OF BARI. The *Lettere* (1863), throw light on Sarpi's character and his relations with a wide variety of Italian and foreign thinkers. *Istoria del Concilio Tridentino* (1935), is a critical edition by G. GAMBARINI of Sarpi's largest and most influential work, based on the manuscript by one of Sarpi's copyists in the Biblioteca Marciana, Venice. There is still no adequate balanced biography of Sarpi; the best existing biography is the uncritical and laudatory *Vita del padre Paolo dell'ordine de' servi*, by FULGENZIO MICANZIO (1646).

(V.C.)

Sarraceniales

The Sarraceniales, or pitcher-plant order, consists of the single family Sarraceniaceae, a small group of low perennial herbs of bogs and wet savannas with pitcher-like leaves specialized for trapping insects and other tiny animals. The Sarraceniaceae is confined to the New World, where it ranges from the tropics to the southern rim of the Arctic; but it has a counterpart in the Old World pitcher-plant family, Nepenthaceae (see NEPENTHALES). The approximately 15 species, despite their relative homogeneity, constitute three distinct genera, which are endemic (native) to three widely separated regions.

Sarracenia, the largest genus (eight or nine species), occurs in the Atlantic coastal regions of North America. The South American pitcher plants, genus *Heliamphora*, number four to six species and are known only from isolated mountains of the Guiana Highlands of northern South America. The genus *Darlingtonia* includes only *D. californica*. This distinctive pitcher plant is endemic to Pacific North America, where it is highly localized in montane (mountain) meadows in northern California and adjacent Oregon.

FEATURES OF THE ORDER

General description. The pitcher plants are totally unlike any other plants in the Western Hemisphere. As a group, they take their common name from their hollow tubular leaves, which are shaped like urns, trumpets, or small pitchers. Some species have hooded pitchers. In *Darlingtonia californica*, for example, the overarching hood gives to the tall, upright, tubular leaf the appearance of a cobra raised in striking position, hence its local name, cobra lily, or cobra plant. The curious landing ramp protruding from the mouth even suggests a snake's tongue.

The hollow leaves of pitcher plants are carefully constructed pitfalls that entrap insects or other tiny prey lured to the mouth of the leaf by glistening surfaces or unusual light-transmitting patches. Downward-pointing (retrorse) hairs in the throat of the pitcher and other devices prevent escape, and the exhausted prey fall into the digestive liquor at the bottom. The liquor is a mixture of digestive enzymes (biological catalysts) and other secretions involved in digestion, rainwater (in hoodless species), and decomposing bacteria. In all species the trapping mechanism is of this passive, pitfall type.

Representative plants from each of the three genera in the family Sarraceniaceae.

Drawing by M. Pahl based on (*Darlingtonia californica* section of fruit; androecium and gynoecium; *Sarracenia purpurea* section of flower; *Heliamphora nutans* seed, section of fruit, entire leaf) Wunschmann, Warburg, and Heal in A. Engler, *Syllabus der Pflanzenfamilien* vol. II (1964); Gebiuder Borntraeger

Distribution and abundance. Excepting *Sarracenia purpurea*, species of the genus *Sarracenia* are confined to the southeastern part of the United States, where they occur mainly on the Coastal Plain and adjacent Piedmont from southern Virginia to eastern Texas. The green pitcher plant, *S. oreophila*, the only species whose geographic distribution is completely isolated from the other species, occurs in the Appalachian Mountains of northeastern Alabama and extreme west central Georgia. The greatest concentration of species, populations, and individuals is in the region from southern Georgia and northern Florida to the southern half of Alabama.

Sarracenia purpurea is the most widespread species, ranging from the sub-Arctic to the subtropics, from Labrador to Great Bear Lake, near the Arctic Circle in northwest Canada, southeastward over central and eastern North America to Georgia, Florida, Alabama, Mississippi, and possibly Louisiana on the Coastal Plain. The yellow pitcher plant, *S. flava*, probably the most common species of the genus in terms of numbers of individuals, ranges from southern Virginia to northern Florida and southern Alabama on the Coastal Plain and Piedmont. The hooded pitcher plant, *S. minor*, is relatively common on the Coastal Plain from South Carolina to southern Florida (east coast). The other species of *Sarracenia* all have very restricted distributions.

Darlingtonia occurs from the central Oregon coast through the southwest Oregon mountains southward to Nevada County in the Sierra Nevada Range of northern California. It is abundant in the Mt. Shasta region, where it may be found in at least 30 to 40 localities within a 15- to 20-mile (25- to 30-kilometre) radius. Thus, despite its localized distribution, the California pitcher plant is by no means rare. Distribution of South American pitcher plants is still poorly known, but they exist in Guyana and Venezuela.

Economic importance. The pitcher-plant order is of minor economic importance, even though species of *Sarracenia* have been cultivated as curiosities for many years. The species most commonly cultivated are *Sarra-*

Entrap-
ment of
insects

cenia *flava*, *S. purpurea*, and *S. rubra*. The common pitcher plant was introduced into culture in England at least as early as 1640. Since their discovery, both *Darlingtonia* and *Heliamphora* have been grown in cultivation but on a much more limited basis; the latter is grown only rarely, however, because of the inaccessibility of its native habitats. *Darlingtonia* is extremely difficult to grow and seldom survives long under artificial conditions, although it has done well when transplanted to New England bogs.

It is not unusual that such bizarre plants as the sarracenias would draw the attention of the American Indians and early explorers and settlers in North America as possible sources of medicines and drugs. For a time the roots were reputed to have various medicinal properties, including efficacy in treating smallpox. Indians in Newfoundland used the root to treat smallpox, and the treatment enjoyed a short-lived popularity in England, beginning about 1865. Neither the root nor any other part of the plant has ever been proved to have real medicinal value.

Common names and lore. Pitcher plants have received many fanciful vernacular names through the years, some of which allude to a specific feature of the plant. The first English settlers in North America called the common pitcher plant (*S. purpurea*) the sidesaddle flower, apparently in reference to the peculiar umbrella-like expansion of the style (a portion of the female structure). This wide-ranging species has been called by a host of other interesting names: huntsman's-cup, Adam's cup, whip-poorwill's-boots, devil's boots, flytrap, northern pitcher plant, forefather's-cup; and, in Quebec, *petits cochons* and *herbe-crapaud*. Some of the common names given to other species are huntsman's-horn, flycatchers, trumpets, trumpet-leaf, biscuit flower, fiddler's trumpet, white-top pitcher plant, sweet pitcher plant, parrot pitcher plant, and calf's head.

Fantastic claims have often been made about pitcher plants—for example, that they will catch all the flies in a house—and the layman may find it difficult to separate fact from fiction. Carnivorous plants have excited the imagination of many popular writers; most stories involving so-called man-eating plants seem to be inspired by a vague knowledge of the tiny, harmless Venus's-flytrap (*Dionaea*; see NEPENTHALES) or of some other carnivorous species with an active trapping mechanism. There is no scientific fact to substantiate such stories.

NATURAL HISTORY

Life cycle. The pitcher plants are herbaceous perennials (*i.e.*, nonwoody plants that live several years) with a round, horizontal, underground stem (rhizome or root-stock). An upright, above-ground stem is lacking, with the occasional exception of *Heliamphora*. The mature rhizome, which is three to 12 inches (eight to 30 centimetres) long and of a typical form for each species, grows for 10 to 15 years (*Darlingtonia*) or as many as 20 to 30 years (*Sarracenia*). It forms new nodes (stem regions that give rise to leaves or other structures) at intervals. The nodes usually remain compacted and give rise to adventitious roots, rosettes of leaves, and flowering stalks. The interior of the rhizome is white from the abundant store of starch. During the life of the plant, the older end of the rhizome slowly decays; the middle part is covered with leaf scars and decaying roots; and the growing end (perhaps half of total length of rhizome) has functional roots and leaves, as well as older leaves in various stages of decay. A new set of roots forms and develops to maturity every season; the older roots continue to function as storage organs for six or seven years. During the years of rhizome growth, lateral underground buds may occasionally form; the buds develop into separate plants by forming new roots and leaf rosettes, after which the parent rhizome decays. In *Darlingtonia* but rarely in *Sarracenia*, the internodes (stem regions between nodes) elongate slightly, spacing out the new plants that are formed. This gives rise to gradual vegetative spreading in pitcher-plant colonies, particularly of *D. californica*. Thus, once established, pitcher-plant species slowly propagate themselves vegetatively.

Leaf forms. Two and sometimes three types of leaves are formed each year in *Sarracenia*. A crop of pitched, insect-catching leaves is produced in the spring, and a second crop, differing markedly in shape, may be produced in the fall. Half or all of the autumn leaves, depending on the species, may be swordlike and tubeless (phyllodia); phyllodia overwinter in the green condition. They may also develop in the summer in cool, shady places. The pitched leaves are evergreen in species in which they lie close to the ground (*S. psittacina* and *S. purpurea*) but tend to die back in the fall in the upright species (*e.g.*, *S. flava*). In addition, all species produce small, scalelike leaves.

The pitched leaves clearly seem to be adapted to function like flowers in attracting the insects they trap. The leaves are flower-like in their striking colour patterns and shapes, which are distinctive for each species, and may be easily mistaken for true flowers. During May and June, the active period of the leaves, glands over the surfaces of the flower-like leaves exude nectar drops containing fruit sugar, which permeates the air with a fruity or honey-like fragrance. By early June the entire outer surface of the pitcher below the mouth in some species may glisten with almost continuous secretion. Heavy feeding activity by ants, wasps, bees, butterflies, moths, and other insects indicates the great attraction of the nectar and its sweet scent.

Flowering and seed germination. The flowers of all pitcher-plant species are showy and have a more or less agreeable scent. Most of the sarracenias produce their flowering scapes (leafless stalks) in the spring before the new leaves appear, but the common pitcher plant flowers after new leaves have begun to mature. Only a minority of the plants in a given population seem to produce flowers in any one year. Flower buds form the previous year in August and September and remain concealed in the leaf bases until March or April. In the southern states the sarracenias begin to bloom in March or April, continuing for a month or two or throughout the summer until August or September, depending on the species. *Sarracenia purpurea*, which has a wide latitudinal distribution, begins flowering during the first week of April in Florida but not until about the second week of August in Labrador. The petals of a sarracenia flower wither after two or three weeks; the rest of the flower remains green until the capsule and seeds mature in four to five months.

The flowers, at first pendulous, may in some species become erect after pollination. The anthers (male reproductive organs) begin to shed pollen copiously as soon as the flower opens, and in *Sarracenia* the inverted umbrella-like style (a portion of the female structure) catches the pollen and holds it where insect visitors can find it readily. The nectar-scented flowers attract ants, bees, pollen-eating beetles, and other insects but especially bees, which seem to be the primary pollinators and tend, in the course of their nectar-feeding activities, to carry the pollen of younger flowers to the stigmas (female pollen-receiving areas) of older flowers. Glands on the ovary, sepals, or accessory leaves (*Heliamphora*) secrete the nectar that attracts insects, and the scent is more or less specific to each species. Cross pollination seems to be essential in *Darlingtonia* and *Sarracenia*, both of which have protandrous flowers—*i.e.*, flowers in which the pollen is ripe before the stigmas are receptive.

Heliamphora pollination is poorly known. The floral structure suggests that insects, which are attracted by the nectar secreted by the sepals and ovary walls, effect pollination.

Seeds are shed from July to September, and in the warmer southern states germination may take place in three to five weeks; a recognizable seedling may form before winter dormancy sets in. Germination may be delayed until the following spring in the colder latitudes. The wide and sporadic distribution of some species suggests that migrating birds, by picking up seeds on their feet, may play a role in dispersing the seeds.

Hybridization and chromosome number. Species of the *Sarracenia* have been known to hybridize freely, both in cultivation and in nature. Perhaps the most com-

Seasonal
variation
of leaves

Pollina-
tion

Medicinal
properties

mon natural hybrid is the cross between *Sarracenia purpurea* and *S. flava*, two species with overlapping ranges.

The chromosomes, which carry the hereditary material, have been counted in all species of *Sarracenia*, and the number has been found to be the same (26) throughout the genus. It is not surprising, therefore, that the species hybridize freely. The reproductive barriers between species are weak. Geographic separation and separation of flowering time seem to be the chief means by which a species are isolated. Bees, the most common pollinators, visit different plants or species indiscriminately. Four to seven years are required for a *Sarracenia* hybrid to reach flowering stage.

The chromosome number of *Darlingtonia* is 30. There are no known reports of attempts to hybridize this genus with *Sarracenia*.

Carnivorous adaptations. Trapping mechanism. Insects are trapped in basically the same way by the various species of *Sarracenia*. They are attracted to the mouth of the pitcher by a trail of nectar-secreting glands on the leaf extending downward from the lip along the outside. The lip is provided with stiff, downward-pointing (retrorse) hairs; below the lip, in the steepest part of the throat, is the highly polished area without hairs, from which digestive enzymes are secreted. Insects attempting to garner nectar around the lip almost invariably fall into the pitcher. Like a greased slide, the polished zone sends them tumbling into the liquor below, where they quickly become submersed and drown. Escape is prevented by the retrorse hairs at the mouth, which are too dense for the insects to crawl between and too stiff and downward directed for them to climb over.

Several species of *Sarracenia* have specialized luring devices that resemble those of the cobra lily, *Darlingtonia*. The cobra lily has a landing ramp from which insects can enter the pitcher. Because of the domelike hood, insects must enter from the side. The presence of the hood darkens the pitcher; this would discourage insects from entering if numerous translucent "windows" that permit light to penetrate were not present. The windows also serve to attract insects that have already entered the pitcher toward a point other than the true opening; they waste their energy trying to crawl through or fly against the translucent tissue, eventually tire, and drop into the liquid below. Retrorse hairs and a polished secretory zone are also present in this species.

The trapping mechanism of *Heliamphora* differs only in details from that of *Sarracenia*.

The quantity of debris—the undigested remains of the plant's victims—in any mature pitcher, especially in the fall, when the pitcher of some species may be half full of remains, illustrates the effectiveness of the pitcher-plant leaf as an insect-trapping mechanism. Ants are especially common prey, but flies, wasps, spiders, crickets, and other tiny animals often fall victim.

Digestive mechanism. *Sarracenia* species secrete digestive enzymes that accumulate in the bottom of the pitcher, where they become diluted with rainwater in species in which the leaves are not entirely closed off at the mouth by a hood or lid (e.g., *S. purpurea*). The liquid in the pitchers usually includes bacteria, and digestion is accomplished by the combined action of enzymes and bacteria. The insect that falls into this digestive broth is attacked almost immediately, and odours of decay are often evident. The end products, including nitrogen compounds, are absorbed by the leaves; the indigestible outer skeletons of the insects accumulate at the bottom of the leaf until it dies.

In *Darlingtonia* and *Heliamphora*, enzymatic glands are lacking, and apparently only bacterial digestion occurs.

Evidence suggests that the carnivorous habit is not essential to the survival of the pitcher plants but that they grow better and probably flower more profusely when provided with an animal diet. In the long run, young plants benefit more directly from an animal diet than mature ones, but carnivory helps the latter to produce more leaves and flowers.

Animals that exploit pitcher plants. Some animals, apart from the pollinators, have evolved methods of elud-

ing the trap and using the pitcher plant for food, for shelter, or as a host for part of their life cycle. Certain insects parasitize the plant tissue; others rob the pitchers by parasitizing insects trapped there. In fact, some of these insects have lost the ability to survive under any other conditions. Birds often slit the pitchers to get at the insects inside, and tree frogs—which sometimes take shelter by day in the mouth of the pitcher by clinging to the inside walls with the suction pads of their feet—probably eat some of the insects visiting the traps.

Several moth species lay eggs in the pitchers, in which the caterpillars hatch and feed before they spin a cocoon and overwinter. The pitcher-plant moth (*Exyra* species) even passes its adult phase sitting inside the pitcher by day. Other moths parasitize the flowers and seed capsules and then spin a cocoon or tunnel into the stem to pupate; one moth larva is a root borer in *sarracenias*.

Flies of the genus *Sarcophaga* deposit larvae (maggots) within the pitcher's mouth; the larvae prey on flies captured by the plant and then bore through the pitcher wall to pupate in the soil. These larvae apparently do not have any structural adaptation for this dangerous habitat, but they do secrete an anti-enzyme that protects them from the otherwise destructive digestive enzymes produced by the plant. Like the pitcher-plant moth, the flies are able to go in and out of the pitcher without falling victim to it. Wrigglers (larvae and pupae) of the pitcher-plant mosquito, *Wyeomyia smithii*, thrive in the pitchers of *Sarracenia purpurea* and overwinter in them, emerging as adults in the spring. This northern species of mosquito, which belongs to an otherwise tropical group of mosquitoes, is rarely absent from a colony of the common pitcher plant, even at its northern limits of distribution in Canada.

Larvae of the minute gnat, *Metriocnemus edwardsi*, are found in the pitchers of *Darlingtonia*, where they hatch and feed in great numbers.

Ecology. The pitcher plants are hydrophytes—water plants—that commonly inhabit bogs, swamps, wet, sandy meadows, or savannas where the soils are water saturated, moderately to intensely acidic, and deficient in nitrates and phosphates. Some species can tolerate standing water, and a few may even thrive underwater for a time (e.g., *S. psittacina*). The montane species, *S. oreophila*, occurs in sands and gravels on stream banks rather than in bogs or swamps, and other pitcher plants may be able to tolerate moderately well-drained acidic soils. On the Atlantic coastal plain, the pitcher plants characteristically inhabit wet, sandy areas in the pinelands, often over extensive areas. Frequently, several species occur together, and there may also be other carnivorous plants (e.g., sundews and flytraps—see *NEPENTHALES*). The most common plant associated with pitcher plants is sphagnum or peat moss. In Alabama, in both the bogs of the uplands and the boggy marshes of the coastal plain, *sarracenias* form characteristic hydrophytic associations with sundews, pipeworts, orchids, and dichromenas. In the pine barrens of New Jersey, the common pitcher plant, sunken in the peat moss, helps to make the bogs and white-cedar swamps attractive. The *sarracenias* usually demand full or partial sunlight, but at least one species (*S. rubra*) can grow in dense shade.

Grass fires often burn *Sarracenia* colonies to the ground during the summer months, but these plants are remarkably fire-resistant and usually can survive underground and make a comeback.

The California pitcher plant occurs in marshy or boggy habitats from near sea level to 6,000 feet (2,000 metres), ranging from the redwood forest zone to the red-fir forest zone. The soils in these regions are very acid, and the temperature never goes above about 65° F (18° C).

Heliamphora grows under extremely humid and wet conditions; it occurs from the lower slopes to the exposed crests and cliffs of Mt. Roraima (British Guyana, now Guyana) and Cerro Duida (Venezuela), two mountains about 400 miles (600 kilometres) apart at the eastern and western ends of the Pakaraima Mountains of the Guiana Highlands, which constitutes the known distributional range of the genus. On Mt. Roraima it reaches its full size and best development on the ledges of the cliff of Rorai-

Charac-
teristic
habitats
of
pitcher
plants

ma. On Cerro Duida it occurs in association with various other plants, as part of the dense undergrowth in the forested valleys of the plateau, and as a cushiony growth in patches on practically all the adjoining ridge crests. In swampy depressions it mingles with sphagnum.

FORM AND STRUCTURE
