High quartz (p-quartz). High quartz, or β -quartz, is the more symmetrical form quartz takes at sufficiently high temperatures (about 573° C [1,063° F] at one atmosphere of pressure), but the relationship is pressure-sensitive (see Figure 3). High quartz may be either left- or right-handed, and its *c* axis is one of sixfold symmetry rather than threefold symmetry; thus, many of the twin laws of ordinary quartz cannot occur. High quartz twins typically involve inclined sets of axes, for example. High quartz can form directly from silicate magma or from high-temperature gases or solutions. It invariably undergoes the transition to ordinary quartz (low quartz) on cooling, and all ordinary quartz, when heated above the transition temperature, is transformed into high quartz. The transformation involves only displacement of the linkage between the tetrahedra, and no bonds are broken. Much quartz that formed originally as high quartz in volcanic rocks has lost all morphological or twinning evidence of its origin and is virtually indistinguishable from ordinary quartz on any other basis.

Tridymite. Tridymite, an uncommon silica mineral, may occur as a primary magmatic phase (*i.e.*, as a direct result of crystallization from a silicate melt) in siliceous rocks but is most abundant in voids in volcanic rocks where it probably was deposited metastably (*i.e.*, formed instead of the form more stable at existing conditions of temperature and pressure) from hydrous gases. Tridymite also forms in contact-metamorphosed rocks; *e.g.*, those that were close to very hot basic intrusions. It has

Transition from high quartz to low quartz

Colours of quartz varieties

been found in meteorites and is common in lunar basalts. It occurs in quantity in firebricks and other siliceous refractories. Natural tridymite has no specific commercial use.

The
tridymite
structure

Tridymite characteristically forms thin plates made up of three crystals in twin relationships; hence the name, which means triplet. The tridymite structure can be considered as cross-linked hexagonal sheets of tetrahedra perpendicular to the *c*-axis that approximate hexagonal closest packing of the oxygen atoms. (This is one of the two ways in which spheres can be packed together in space with the greatest possible density and still have a periodic arrangement, the other way being cubic closest packing.) These sheets may be stacked in regular, random, or irregular sequences, and the stacking can be different in parts of the same crystal. So much crystallographic complexity results that confusion exists as to the precise stacking arrangements. The stacking sequence and tetrahedral linkage within a sheet can change easily with temperature change, the transition temperatures being sensitive to the original stacking sequence and the composition. The high tridymite that is stable at one atmosphere pressure, from about 867° C (1,593° F) to 1,470° C (2,678° F), contains two sheets and has orthorhombic symmetry (related to three mutually perpendicular crystallographic axes of unequal length), though it is dimensionally hexagonal. Tridymite retains an orthorhombic cell as a subcell at lower temperatures but may contain as many as 20 sheets. Such tridymite also has pseudohexagonal symmetry (*i.e.*, appears to have sixfold symmetry but does not), but most carefully studied samples are actually monoclinic at room temperature. Terrestrial low tridymite does not show the characteristic monoclinic supercell of extraterrestrial samples. This probably is related to the influence of conditions of formation on stacking sequences. Tridymite transforms sluggishly to quartz because the transformation requires tetrahedra to be disrupted and relinked.

Tridymite can be synthesized with high purity, but natural material commonly contains as much as 2 percent by weight of sodium and aluminum oxides substituting for silica, as well as fractions of 1 percent of titania, ferric iron, magnesia, calcium oxide, or potassium oxide.

Cristobalite. Cristobalite is probably more abundant in nature than tridymite, although it seldom forms as distinctive crystals. The devitrification (transformation from the glassy to the crystalline state) of siliceous volcanic glasses yields abundant tiny crystallites of cristobalite, and the mineral is also deposited metastably from hot hydrous gases in cavities and cracks of many volcanic rocks. It has been found in lunar basalts and in meteorites and is common in silica refractories exposed to very high temperatures.

Cristobalite is made up of sheets of silica tetrahedra that can be considered to be stacked in sequences of three sheets normal to a threefold axis; this approximates cubic closest packing of the oxygen atoms. Isometric high cristobalite is the stable phase at one atmosphere of pressure from about 1,470° C (2,678° F) to melting, and this form can be supercooled to the range 270°–175° C (520°–350° F) before it transforms reversibly to a metastable tetragonal form. The latter is called low cristobalite and shows complex polysynthetic twinning (twins of three or more individual crystals conforming to the same twin law). As might be expected from its open structure and high temperature of origin, substitution of small alkali and aluminum atoms for silicon atoms may amount to several percent in cristobalite, and minor amounts of other coupled substitutions are known.

Opal. Opal is poorly crystalline or amorphous hydrous silica that is compact and vitreous and most commonly is translucent white to colourless. Precious opal reflects light with a strong play of brilliant colours across the visible spectrum, red being the most valued colour. Opal forms by precipitation from silica-bearing solutions near the Earth's surface. Electron microscopy has shown that many opals are composed of spheres of tens to a few thousand angstrom units in size (one angstrom unit equals 10⁻⁸ centimetres) that are arranged in either hex-

agonal or cubic close packing. The spheres are composed of hydrous silica that may be either almost cristobalite-like, tridymite-like, mixtures of both, or random and non-diffracting. The specific gravity and refractive index are lower than those of pure silica minerals and tend to fall along lines extending from cristobalite, tridymite, and vitreous silica (see Figure 1) toward the point for water (the index of refraction of water is 1.33, and the specific gravity is 1). The play of colours in precious opal arises from domains of regularly oriented spheres that satisfy Bragg's law (relating the angle of reflection of X-rays from a crystal to the spacing of crystallographic planes and the wavelength of the incident radiation) for the wavelength of visible light observed. When heated, opal may lose as much as 20 percent of its weight of water, fracture, and then crystallize to any one of the silica minerals described above.

Opal usually contains 4 to 9 percent water, but lower and much higher values have been observed. The contents of alumina, ferric oxide, and alkalis are variable but may amount to several percent in light coloured opals and more if pigmenting minerals are also present. Precious opal has been synthesized. Opaline silica is a friable hydrous silica found near hot springs and geysers.

Vitreous silica. Vitreous silica is supercooled liquid silica. It has been observed in nature as the result of fusion of quartz by lightning strikes or by shock associated with large meteorite impacts and may approach artificial, very pure silica glass in composition and physical properties.

Melanophlogite. Melanophlogite is a cubic silica mineral with a gas-hydrate structure containing many large voids. In nature these are filled with 6 to 12 percent by weight of compounds of hydrogen, carbon, and sulfur, which may be necessary for mineral growth. If these compounds are destroyed by heating, they do not cause the crystal to collapse, but the free carbon formed does darken it. Melanophlogite occurs with bitumen and forms at temperatures below 112° C (234° F) on native sulfur crystals in Sicily.

Kratite. Keatite is a tetragonal form of silica known only from the laboratory, where it can be synthesized metastably over the range of temperatures from about 300° to 600° C (600°–1,200° F) and 400 to 4,000 bars (standard atmospheric pressure at sea level is 1,013.3 millibars, or slightly more than one bar, which equals 760 millimetres of mercury) in the presence of steam. It has negative thermal expansion along the *a* axes and positive thermal expansion along the *c* axis, so that the overall expansion is very low or negative.

Coesite and stishovite. Coesite and stishovite are rare dense forms of silica observed in nature only where quartz-bearing rocks have been severely shocked by a large meteorite impact, such as Meteor Crater, Arizona. Coesite is made up of tetrahedra arranged like those in feldspars (*q.v.*). Stishovite is the most dense form of silica and consists of silicon that is octahedrally coordinated with oxygen. Both coesite and stishovite have been synthesized and found to be stable only at high pressures (Figure 3).

Occurrence in magmas and solutions. Silicon and oxygen are the two most abundant elements in the Earth's crust, in which they largely occur in combination with other elements as silicate minerals. Free silica, SiO₂, appears as a mineral in crystallizing magma only when the relative abundance of SiO₂ exceeds that of all other cations available to form silicates. Silica minerals thus occur only in magmas containing more than about 47 percent by weight of SiO₂ and are incompatible with minerals with low cation/silica ratios—such as olivine, nepheline, or leucite. Basaltic and alkalic igneous magmas therefore can crystallize only minor amounts of silica minerals, and sometimes none are produced. The gas released from such rocks can dissolve the silica component, however, and later precipitate it as silica minerals upon cooling. The amount of silica minerals crystallized from magma increases with increasing silica content of magma, reaching 40 percent in some granites and rhyolite. In granitic pegmatite, where a hydrous gas was

Arrange-
ment of
spheres in
opal

Figure 3: Silica phase diagram.

From F.R. Boyd and J.L. England, *Journal of Geophysical Research* vol. 65, p. 752 (1960)

present in addition to magma, igneous-appearing rocks composed largely or almost completely of quartz can occur because of transport of silica through the hydrous gas.

The solubility of silica minerals in natural solutions and gases is of great importance. The solubility of all silica minerals increases regularly with increasing temperature and pressure (Figure 4) except in the region of 340°–550° C (640°–1,020° F) and 0–600 bars, where retrograde solubility occurs because of changes in the physical state of water. The solubility of quartz in steam reaches at least 22 percent by weight at 10,000 bars and 1,055° C (1,931° F). The solubility of silica increases in the presence of anions such as OH⁻ and CO₃²⁻, which form chemical complexes with it.

Quartz is the least soluble of the forms of silica at room temperature. In pure water its solubility at 25° C (77° F) is about 6 parts per million, that of vitreous silica being at least 10 times greater. The amount of dissolved silica in hot springs has been utilized to measure the temperature at the depth from which the water emanates, because the major control of silica solubility appears to be with quartz. Typical temperate climate river water contains 14 parts per million of silica, and enormous tonnages of silica are carried away in solution annually from weathering rocks and soils. The amount so removed may be equivalent to that transported mechanically in many climates. In tropical climates, waters enriched in organic acids may leach silica completely to form lateritic residual soils enriched in hydrous iron and aluminum oxides. Silica dissolved in moving groundwater may form hollow spheroids lined with crystals called geodes, or it may cement loose sand grains together to form concretions and nodules or even entire sedimentary beds into sand-

stone, which, when all pore space is eliminated by selective solution and nearby deposition during metamorphism, form tough, pore-free quartzite.

The silica content of seawater is highly variable because it is removed by plankton (floating organisms). An estimate for average upper ocean waters is 4.3 parts per million, but values of 0.1 part per million can occur at the surface. Deep sea sediments are highly siliceous from the accumulation of the siliceous skeletons of single-celled plants and animals (diatoms and radiolaria), sponges, and other organisms.

Gases or solutions escaping from cooling rocks, especially volcanic or intrusive igneous rocks, commonly are saturated with silica and other compounds that, as they cool, precipitate quartz along their channelways to form veins. The quartz may be fine-grained (as chalcedony), massive granular, or in coarse crystals as large as tens of tons. Most of the natural colourless quartz crystals—the "rock crystal" found in collections or used in jewelry and electronic and optical apparatus—were formed in this way. Famous localities for rock crystal are the Swiss Alps; Herkimer County, New York; Minas Gerais, Brazil; Hot Springs, Arkansas; and the Malagasy Republic.

The emergence of heated silica-bearing solutions onto the surface results in rapid cooling and the loss of complexing anions. Rapid precipitation of fine-grained silica results in formation of siliceous sinter or geyserite, as at Mammoth Hot Springs in Yellowstone National Park.

Quartz is mechanically resistant and relatively inert chemically during rock weathering in temperate and cold climates. Thus, it becomes enriched in river, lake, and beach sediments, which commonly contain more than one-half quartz by weight. Some strata consist almost entirely of quartz over large lateral distances and tens or hundreds of feet in thickness. Known as glass sands, these strata are important economic sources of silica for glass and chemical industries. Quartz-bearing strata are abundant in metamorphic terrains. The reincorporation of

Rock crystal, spring deposits, and glass sands

Solubility of silica minerals

free silica into complex silicates and the solution and redeposition of silica into veins is characteristic of such terrains.

The silica phase diagram. The pressure-temperature fields of stability of silica minerals as presently understood are shown in Figure 3. The experimentally determined boundaries are drawn with heavy lines. No data have been obtained for certain boundaries because of slow reaction rates or difficulties in obtaining the required conditions. Traces of water, for example, are necessary for reactions to take place over much of the diagram. Stability fields are not shown for keatite, melanophlogite, opal, or the low forms of tridymite and cristobalite because they have not been demonstrated. Quartz is the stable phase of silica under the physical conditions that prevail over most of the Earth's crust. Coesite is possible at depths of about 100 kilometres (60 miles) in the Earth's mantle, but free silica is not thought to be abundant there. Stishovite would require even greater depths of burial, and no rocks that occur on the Earth's surface have been buried so deeply.

Silicate Minerals

Silicate minerals are compounds of silicon (Si) and oxygen (O) that occur as the major constituents of the rocks that form the Earth's crust. Although more than 1,000 minerals have been recognized, the igneous rocks, born from molten silicate material deep below the Earth's crust, of which they comprise about 95 percent, are made up of only a few—all silicates. Sedimentary rocks, which are made of pre-existing rocks for the most part, contain large amounts of silicate minerals, and metamorphic rocks, formed by the alteration of igneous or sedimentary rocks, also consist largely of silicates. Furthermore, silicate minerals are important constituents of meteorites and lunar samples. Spectral analysis of the outer regions of the Sun shows silicon to be the sixth most abundant element, following hydrogen, helium, oxygen, carbon, and nitrogen. Chemical analyses of meteorites reveal silicon to be third in abundance, after oxygen and iron, and estimates of its cosmic abundance rank it seventh, following hydrogen, helium, oxygen, neon, nitrogen, and carbon. Thus it is clear that silicon is an important element in the Earth-Moon system, the solar system, and the cosmos; and it follows, then, the minerals that contain silicon—the silicate minerals—are of like importance.

Silicate minerals have great economic importance as well. Some fibrous amphiboles (asbestos) are used in the textile industry, for manufacturing rope, brake linings, nonflammable cements, and shingles. Tremolite and anthophyllite have been used for filtering fruit juices and chemicals. Montmorillonite (sometimes called bentonite) is used in drilling muds. Igneous and metamorphic silicate rocks are used for building and monumental materials. The very abundant feldspar minerals are used as additives in paint and as a mild abrasive as well as in the manufacture of glass and in ceramics. Some silicates are prized as gems; among these are emerald, aquamarine, and morganite, all varieties of beryl; peridot; moonstone, amazonstone, peristerite, and labradorite, all

feldspars; garnet; jadeite and nephrite, the two forms of jade; opal, onyx, chalcedony; agate, bloodstone, and quartz, all forms of silica; staurolite; tourmaline; and zircon. Spodumene and lepidolite are ore minerals of lithium. Muscovite and phlogopite are used in radio tubes, in capacitors, and in insulating of heating elements. Pyrophyllite is used in ceramics, paints, soap, textiles, cosmetics, and rubbers. Quartz is sometimes used as an abrasive, and high-quality quartz crystals are used for precision electronic control components and for optical lenses. Andalusite, kyanite, and sillimanite are used in the preparation of mullite, a high-temperature refractory. Vermiculite is used for home insulation, concrete aggregate, agricultural chemicals, and fertilizers. Wollastonite is used in ceramics, especially for single-fired wall tile. Zircon is an ore mineral of zirconium and also of hafnium.

This article treats the chemical composition and crystal structure of the silicate minerals, their classification, and their occurrence and distribution in the Earth's crust and mantle and in meteorites and the moon. For further detail on any of the specific groups of silicate minerals that are here covered in overview fashion, see FELDSPARS; FELDSPATHOIDS; OLIVINES; PYROXENES; AMPHIBOLES; CLAY MINERALS; MICAS; SILICA MINERALS; and ZEOLITES. Additional information on crystal structure and chemical bonding in general is given in the articles CRYSTALLOGRAPHY; CHEMICAL BONDING. See also EARTH, STRUCTURE AND COMPOSITION OF; MOON; METEORITE; and METEORITE CRATERS for details on the several principal environments of silicate minerals.

CRYSTAL STRUCTURE AND CHEMICAL COMPOSITION

The SiO_4 tetrahedra and SiO_6 octahedra. The fundamental unit of all silicates formed at low to moderate pressures is the silicate tetrahedron, an SiO_4 group in which one silicon atom (Si) is surrounded by and bonded to (coordinated with) four oxygen atoms (O_4), each at the corner of a regular tetrahedron (a solid that has four triangular faces). Although this tetrahedron does show various distortions from regular shape in different minerals, it is not broken down until extremely high pressures, where silicon assumes a new coordination, forming SiO_6 groups, in which one silicon atom is surrounded by six oxygen atoms, each at the corner of an octahedron (a solid with eight triangular faces that looks like two pyramids joined at the bases). This increased coordination (four to six) results in the higher density minerals that would be expected at high pressure.

Silicate minerals can be thought of as three-dimensional arrays of oxygen atoms that contain void spaces (crystallographic sites) where various cations (positively charged atoms) can enter. Other than the tetrahedral and octahedral sites, the positions of the silicon atoms in 4-fold and 6-fold coordination, respectively, 8-fold and 12-fold sites, are also quite common. A correlation exists between the size of a cation and the type of a site it can occupy: the larger the cation, the greater the coordination, because large cations have more surface area for oxygen atoms to make contact with than small cations. The most common cations that occur in silicate minerals include, from smallest to largest, silicon (Si^{4+}), aluminum (Al^{3+}), ferric iron (Fe^{3+}), titanium (Ti^{4+}), magnesium (Mg^{2+}), ferrous iron (Fe^{2+}), lithium (Li^+), manganese (Mn^{2+}), sodium (Na^+), calcium (Ca^{2+}), and potassium (K^+). Tetrahedral (4-fold coordination) sites commonly are occupied by silicon and aluminum; octahedral (6-fold) sites by aluminum, iron, titanium, magnesium, lithium, manganese, and sodium; 8-fold sites by sodium, calcium, and potassium; and 12-fold sites by potassium.

Chemical substitution. Elements with similar ionic radii often can substitute for one another in a mineral. In such cases, a complete substitutional series may be found, as between magnesium silicate, Mg_2SiO_4 , and iron silicate, $\text{Fe}_2^{2+}\text{SiO}_4$ (olivine minerals), for example. Between these pure magnesium and pure iron compounds, called end-members, substitution of one for the other can occur in any amount, and thus any magnesium-

to-iron ratio may be observed in natural minerals. If the discrepancy in the size or charge, or both, of cations is large, only limited substitution, also called solid solution because one end-member can be thought of as being "dissolved" in the other, will be observed, and a miscibility gap may occur between compositional end-members.

Silicates as geothermometers and geobarometers

Silicate minerals act as tiny probes that record the detailed evolutionary history of the rocks that contain them. For example, the composition or crystal structure of a mineral (its detailed arrangement of atoms) may give clues to its temperature history (geothermometry) or pressure history (geobarometry). The amount of substitution (solid solution) between compositional end-members commonly increases with temperature, and thus the miscibility gaps usually decrease in size with increasing temperature. In addition, the way that cations are distributed between the different crystallographic sites in the oxygen three-dimensional network is commonly a function of temperature. For example, if a mineral contains two different cations and two different crystallographic sites, the distribution of the cations among the sites usually becomes more random with increasing temperature. Thus, when calibrated, the degree of substitution (solid solution) between compositional end-members and the degree of randomness (disordering) of cation distributions in a mineral structure is useful in deducing the thermal history of rocks.

The element aluminum plays an interesting role in silicate structures because it can enter both octahedral and tetrahedral sites. As pressure is increased, however, aluminum prefers octahedral coordination (6-fold) rather than tetrahedral (4-fold). This increased coordination of aluminum in silicates results in minerals with higher density, as would be expected from a high pressure of formation. Thus, in some silicates, it is possible to correlate the amount of aluminum in octahedral coordination with the pressure history of a rock (geobarometry).

CLASSIFICATION OF SILICATES

Because the basic building block of a silicate structure is the SiO_4 tetrahedron, most of the important rock-forming silicate minerals can be divided into groups based on the degree to which the SiO_4 tetrahedra are linked together (degree of polymerization).

A common structure is one that contains isolated SiO_4 groups (Figure 1A). If the charge on the silicon atom is considered as $+4$ and that on the oxygen as -2 , a SiO_4 group has a total charge of $[1(+4) + 4(-2)]$, or -4 . To achieve electrical neutrality in a silicate structure, therefore, cations must be present in addition to silicon; their charges must total $+4$ for each SiO_4 group.

Another common silicate structure type has double tetrahedron groups (Figure 1B) in which one oxygen atom is shared by two tetrahedra. The formula for this structural group is Si_2O_7 , and the charge on the group is $[2(+4) + 7(-2)]$, or -6 . Thus, cations must be added with charges totalling $+6$ for each Si_2O_7 group for an electrically neutral structure.

Further polymerization may result in a third structure type—infinite single chains (Figure 1C) in which each tetrahedron shares two oxygen atoms. The formula for these chains is $(\text{SiO}_3)_n$, with a charge of -2 on each SiO_3 group. Another type of chain, a double chain (Figure 1D), occurs when two single chains are linked by the sharing of one oxygen atom between every second tetrahedron on each chain. The formula can be derived by counting the silicon and oxygen atoms in a portion of the double chain and can be expressed as $(\text{Si}_4\text{O}_{11})_n$, in which each Si_4O_{11} group has a -6 charge. In both the single and double chain structures, the negative charges on the groups require additional cations in the structure.

A fourth basic structure type contains infinite sheets of tetrahedra, in which each tetrahedron shares one oxygen atom with each of three other tetrahedra (Figure 1E); the basic unit in these sheets has the formula $(\text{Si}_4\text{O}_{10})^{4-}$. The tetrahedra are linked to form interconnected six-member rings.

Figure 1: important silicate structure types. (A) Isolated tetrahedra, with the formula $[\text{SiO}_4]^{4-}$. (B) Double tetrahedra, with the formula $[\text{Si}_2\text{O}_7]^{6-}$. (C) Single tetrahedral chain, in which the basic structural unit has the formula $[\text{SiO}_3]^{2-}$. (D) Double tetrahedral chain, in which the basic unit has the formula $[\text{Si}_4\text{O}_{11}]^{6-}$. (E) Sheet, in which the basic unit has the formula $[\text{Si}_4\text{O}_{10}]^{4-}$.

From *Crystallography and Crystal Chemistry: An introduction* by F. Donald Bloss. Copyright © 1971 by Holt, Rinehart and Winston, Inc. Reprinted by permission of Holt, Rinehart and Winston, Inc.

The last structure type to be considered is an infinite three-dimensional network of tetrahedra, in which each tetrahedron shares all of its oxygen atoms. This structure has no residual negative charge; because it is electrically neutral, it does not contain appreciable amounts of any other cations.

Substitution of aluminum (charge $+3$) for silicon (charge $+4$) will change the negative residual charge on a silicate group; for example, if an aluminum atom is substituted for one silicon atom in the basic formula for a sheet structure, the formula $(\text{Si}_4\text{O}_{10})^{4-}$ becomes $(\text{Si}_3\text{AlO}_{10})^{5-}$. Thus, in the three-dimensional network structures (framework structures), substitution of aluminum for silicon leaves a residual charge on the framework, as in the feldspars; the feldspar mineral albite has the formula $\text{NaAlSi}_3\text{O}_8$, in which the substitution of the aluminum atom is balanced by the addition of a sodium atom with a charge of $+1$.

Isolated or double tetrahedral group silicates. The olivine mineral group has two important end-members, forsterite, or magnesium silicate (Mg_2SiO_4), and fayalite, or iron silicate (Fe_2SiO_4). The solid-solution series

Olivines

between these two end-members is complete and involves the substitution of magnesium for ferrous iron, $\text{Mg}^{2+} \rightleftharpoons \text{Fe}^{2+}$. The crystal structure consists of an array of SiO_4 groups between which octahedral sites exist. These octahedral positions are occupied by Mg^{2+} , or Fe^{2+} , or both. The magnesium end-member (forsterite) melts at approximately 1,900° C (3,450° F), while the iron end-member (fayalite) melts at 1,200° C (2,190° F), and thus in a crystallizing basaltic silicate melt (molten rock) the magnesium-rich olivines will precipitate first, and the olivine crystals that precipitate later with falling temperature will be richer in iron. Therefore, by means of chemical analysis of olivine minerals, it is possible to make some estimates of the temperature at which they crystallized. Olivines are important constituents of terrestrial and lunar basalts. In addition they are components of other rocks that occur in the lower crust of the Earth or the upper mantle. Olivines also commonly occur in meteorites.

Humites

The humite group is comprised of four minerals: norbergite, chondrodite, humite, and clinohumite. The structures of the humite minerals are related to those of the olivine minerals and consist essentially of layers of forsterite intergrown with layers with the composition of brucite, or magnesium hydroxide $[\text{Mg}(\text{OH})_2]$, which is composed of magnesium-containing octahedra. The two main substitutions in these minerals are ferrous iron for magnesium, $\text{Fe}^{2+} \rightleftharpoons \text{Mg}$, and fluorine for hydroxide, $\text{F} \rightleftharpoons (\text{OH})$. The humite minerals occur in metamorphosed carbonate rocks.

Garnets

The garnet minerals are usually divided into two groups, each composed of a solid-solution series with three end-members. Pyrope, almandine, and spessartine form the pyrope group of aluminum silicates in which divalent cations (atoms with a charge of +2) of magnesium, ferrous iron, and manganese substitute for one another in the R position in the general formula $\text{R}_3\text{Al}_2\text{Si}_3\text{O}_{12}$. Uvarovite, grossularite, and andradite are included in the ugrandite group of calcium silicates in which trivalent cations (atoms with a charge of +3) of chromium, aluminum, and ferric iron substitute for one another in the R position in the general formula $\text{Ca}_3\text{R}_2\text{Si}_3\text{O}_{12}$. There is far less solid solution between the two groups because this would involve substitution of atoms of significantly different atomic radii. The crystal structure of garnet is comprised of silicate tetrahedra arranged to provide octahedral and 8-fold sites; the octahedral sites are occupied by the trivalent cations Cr^{3+} , Al^{3+} , or Fe^{3+} , and the 8-fold sites can be occupied by Ca^{2+} , Mn^{2+} , Fe^{2+} , and Mg^{2+} . The pyrope end-member is stabilized at high pressures, and thus the amount of this end-member in a garnet specimen gives an indication of the pressure at which it formed.

Alumino-silicates

The aluminosilicate mineral group contains three important members: andalusite, kyanite, and sillimanite—all with the chemical formula Al_2SiO_5 . The difference between the members of this group does not involve chemical composition but involves instead the way the atoms are arranged in their crystal structures; these minerals are therefore polymorphs.

The structure of sillimanite is comprised of AlO_6 octahedra, SiO_4 tetrahedra, and AlO_4 tetrahedra; it has half of its aluminum in octahedral coordination and half in tetrahedral coordination. To express this concisely, the formula can be written as $\text{Al}^{\text{VI}}\text{Al}^{\text{IV}}\text{Si}^{\text{IV}}\text{O}_5$. The crystal structure of andalusite is comprised of AlO_6 octahedra, SiO_4 tetrahedra, and irregular AlO_5 groups in which the aluminum atom is surrounded (coordinated) by five oxygen atoms. Its formula can be written as $\text{Al}^{\text{VI}}\text{Al}^{\text{IV}}\text{Si}^{\text{IV}}\text{O}_5$. The last member of the aluminosilicate group, kyanite, has a structure comprised of only AlO_6 octahedra and SiO_4 tetrahedra. Thus, both Al atoms are in octahedral coordination, and the formula for kyanite can be written $\text{Al}^{\text{VI}}\text{Al}^{\text{VI}}\text{Si}^{\text{IV}}\text{O}_5$.

The aluminosilicate minerals offer an unusually good opportunity to relate mineral crystal structures, temperature–pressure conditions, and natural occurrence. Figure 2, which illustrates some of these relations in a diagrammatic form, indicates which polymorph will occur at

Figure 2: Temperature–pressure stability of the various forms of aluminosilicate.

From M.J. Holdaway, *American Journal of Science*, vol. 271 (1971); Yale University

specific temperature and pressure combinations. At low temperatures and pressures, andalusite (region 1 on Figure 2) forms; with increasing temperature, sillimanite (2) becomes the stable mineral, whereas increasing pressure results in kyanite (3). At high pressures all of the aluminum is in octahedral coordination, and the densest polymorph, kyanite, forms, whereas at high temperatures the least dense mineral, sillimanite, forms, with half the aluminum in tetrahedral coordination. Along any of the lines on the diagram (4,5,6) two polymorphs can coexist; along line 4 andalusite and sillimanite coexist, along line 5 andalusite and kyanite coexist, and along line 6 kyanite and sillimanite coexist. When two forms are coexistent, the temperature and pressure conditions of their formation falls along these lines; either temperature or pressure, but not both, can be varied independently to achieve a new set of conditions where this is possible. At point 7 on the diagram, andalusite, kyanite, and sillimanite coexist; this point is fixed, and neither temperature nor pressure can be varied to achieve another set of conditions.

These relationships can be used in geobarometry and geothermometry of natural rock systems because, depending on the number of polymorphs existing in a rock, it is possible to make estimates of temperature and pressure conditions with various degrees of certainty. If a rock contains only one aluminosilicate, then only broad temperature–pressure estimates can be made corresponding to regions 1, 2, or 3 on the diagram. If two polymorphs coexist in a rock, then the possible combinations are limited to the univariant lines 4, 5, and 6, and, if all three polymorphs are present, then the conditions are uniquely defined, within the certainty of the experimental determination.

Mullite, a related compound, can be formed from the aluminosilicate polymorphs by heating them to extremely high temperatures. The following reaction may occur:

($3\text{Al}_2\text{O}_3 \cdot 3\text{SiO}_2$ is just a convenient way of writing the formula of the aluminosilicates instead of $3\text{Al}_2\text{SiO}_5$.) Thus, the reaction involves liberation of some silica, and mullite contains proportionally more aluminum than the aluminosilicate polymorphs. Mullite is of commercial value as a high-temperature refractory material.

In minerals of the epidote group, silicon occurs both in isolated tetrahedra and double tetrahedral groups. Important members of this group are epidote, a calcium and ferric iron silicate $[\text{Ca}_2\text{Fe}_3^{3+}\text{Si}_3\text{O}_{12}(\text{OH})]$, and the polymorphs zoisite and clinozoisite, calcium and aluminum silicates $[\text{Ca}_2\text{Al}_3\text{Si}_3\text{O}_{12}(\text{OH})]$. Extensive substitution occurs in the group, which may be given the general formula $\text{X}_2\text{Y}_3\text{Z}_3(\text{O},\text{OH})_{13}$. The X position can be occupied by calcium (Ca^{2+}), cerium (Ce^{3+}), lanthanum

Epidotes

(La^{3+}), yttrium (Y^{3+}), thorium (Th^{4+}), ferrous iron (Fe^{2+}), and both divalent and trivalent manganese (Mn^{2+} and Mn^{3+}); the Y position can be occupied by aluminum (Al^{3+}), ferrous and ferric iron (Fe^{2+} and Fe^{3+}), divalent and trivalent manganese (Mn^{2+} and Mn^{3+}), and titanium (Ti^{4+}); and the Z position can be filled by either silicon (Si^{4+}) or beryllium (Be^{2+}) ions. Zoisite has the restricted composition expressed above, but clinozoisite (which has a different crystal structure) shows extensive substitution of ferric iron for aluminum to give a composition nearer that of epidote. In zoisite, clinozoisite, and epidote, the calcium ions occupy irregular 7-fold or 8-fold sites, whereas the aluminum or the ferric iron ions occupy octahedral (6-fold) sites. The epidotes are common in metamorphic rocks, those derived from pre-existing igneous or sedimentary rocks by changes in pressure and temperature.

Melilites

The melilite group consists essentially of a solid-solution series between Ikermanite, or calcium magnesium silicate ($\text{Ca}_2\text{MgSi}_2\text{O}_7$), and gehlenite, or calcium aluminum silicate ($\text{Ca}_2\text{Al}_2\text{Si}_2\text{O}_7$). The crystal structure contains double groups of SiO_4 tetrahedra. In addition to a large 8-fold site occupied by the calcium ions, an additional tetrahedral (4-fold) site exists that is occupied by aluminum in gehlenite and magnesium in Ikermanite; this tetrahedral coordination of magnesium is rare in silicates. The melilite minerals are characteristic of high-temperature metamorphic rocks formed from impure carbonates.

Pyroxenes

Chain silicates. Pyroxenes comprise undoubtedly the most important group of ferromagnesian minerals—those containing ferrous iron (Fe^{2+}) and magnesium (Mg^{2+})—in the Earth–Moon system and, in addition, are important in meteorites; they almost certainly will prove to be an important silicate type on other planets as well. Pyroxenes are important not only because of their abundance but also because they are capable of revealing their detailed evolutionary history. The most important pyroxene minerals are part of a threefold solid-solution series, in which substitution takes place between wollastonite, a calcium silicate ($\text{Ca}_2\text{Si}_2\text{O}_6$) abbreviated as wo; enstatite, a magnesium silicate ($\text{Mg}_2\text{Si}_2\text{O}_6$) abbreviated as en; and ferrosilite, a ferrous iron silicate ($\text{Fe}_2\text{Si}_2\text{O}_6$) abbreviated fs. A convenient way to represent the pyroxene solid-solution series is as a triangular diagram that represents the composition of the pyroxenes as percentages of the three end-members. Triangular compositional diagrams such as these are rather easy to read: if a mineral composition plots on a corner of the triangle, only one end-member is present (in this case, either wo, en, or fs); if the composition plots on one of the bounding lines, the mineral is a solid solution between two of the end-members (en–fs, fs–wo or wo–en); if the composition plots within the triangle, all three end-members are present in solid solution. The actual position of a mineral's chemical analysis on the diagram gives the proportions of the three end-members: the closer the analysis plots to an end-member, the more of it in solid solution.

Figure 3A represents such a diagram and gives a generally accepted nomenclature for intermediate members. The apex of the triangle represents pure wollastonite ($\text{Ca}_2\text{Si}_2\text{O}_6$); a point on the base directly below the apex represents a composition of $\text{MgFeSi}_2\text{O}_6$, or species that contain equal numbers of enstatite ($\text{Mg}_2\text{Si}_2\text{O}_6$) and ferrosilite ($\text{Fe}_2\text{Si}_2\text{O}_6$) formula units. In like manner a point on the side of the triangle directly opposite the right-hand corner represents a composition of $\text{CaMgSi}_2\text{O}_6$, or that of pure diopside, abbreviated di. A point opposite the left-hand corner represents a composition of $\text{CaFeSi}_2\text{O}_6$, or that of pure hedenbergite, abbreviated hed. The compositional region bounded by the diopside, hedenbergite, enstatite, and ferrosilite is known as the pyroxene quadrilateral; minerals with compositions that fall above the di–hed line no longer possess a pyroxene crystal structure.

The crystal structure of the pyroxenes contains infinite chains of linked silicate tetrahedra (see Figure 1C). Each tetrahedron contains a tetrahedral (4-fold coordi-

Figure 3: (A) Nomenclature of clinopyroxenes in the system $\text{CaMgSi}_2\text{O}_6$ – $\text{CaFeSi}_2\text{O}_6$ – $\text{Mg}_2\text{Si}_2\text{O}_6$ – $\text{Fe}_2\text{Si}_2\text{O}_6$; (B) one important type of pyroxene crystallization trend (see text). Modified from A. Poidervart and H.H. Hess, "Pyroxenes in the Crystallization of Basaltic Magma," *Journal of Geology*, vol. 59 (1951); University of Chicago Press

nation) site. In addition, there are octahedral (regular 6-fold) sites, called $M(1)$ sites, and irregular 6-fold to 8-fold sites, called $M(2)$ sites. The tetrahedral sites may be filled with silicon as well as aluminum ions; the $M(1)$, or octahedral, sites can be occupied by aluminum (Al^{3+}), magnesium (Mg^{2+}), ferrous or ferric iron (Fe^{2+} or Fe^{3+}), trivalent chromium (Cr^{3+}), divalent manganese (Mn^{2+}), or titanium (Ti^{4+}) ions. The $M(2)$ sites can be occupied by calcium (Ca^{2+}), sodium (Na^+), manganese (Mn^{2+}), ferrous iron (Fe^{2+}), lithium (Li^+), or magnesium (Mg^{2+}) ions; when such a site is occupied by a large cation (*i.e.*, calcium or sodium), it essentially has an 8-fold coordination, but when it is occupied by one of the smaller ions it has a 6-fold coordination. Within the pyroxene crystal structure, the tetrahedral chains are arranged in layers that alternate with layers containing the $M(2)$ and $M(1)$ sites. Various stacking possibilities for these tetrahedral and octahedral layers result in three different crystal structure types: orthopyroxenes, which crystallize in the orthorhombic system, and have a unit cell (the basic crystal building block) with three mutually perpendicular cell edges of unequal lengths; primitive clinopyroxenes, which crystallize in the monoclinic system and have a unit cell with three unequal cell edges, two of which are perpendicular and the third of which is inclined to the plane of the other two; and the C-centred clinopyroxenes, which also crystallize in the monoclinic system and have a unit cell like that of the primitive clinopyroxenes, except that the arrangement of atoms in the unit cell is slightly more symmetrical.

The orthopyroxenes and primitive clinopyroxenes have chemical compositions that plot close to the line in the pyroxene quadrilateral connecting enstatite and ferrosilite, called the enstatite–ferrosilite join. Therefore, these pyroxenes have the rather small magnesium and iron atoms in the $M(2)$ site, which thus has a 6-fold coordination. C-centred clinopyroxenes have compositions that plot near the diopside–hedenbergite join. It follows that they are enriched in calcium, and thus the $M(2)$ site has an 8-fold coordination.

At low temperatures, there is incomplete solid solution between the calcium-poor orthopyroxenes and primitive

clinopyroxenes and the calcium-rich 6-centred clinopyroxenes; in other words, a miscibility gap exists. As temperature is increased, however, the miscibility gap decreases in size, and increased solid solution takes place between the low-calcium and high-calcium pyroxene groups. The degree of solid solution between these pyroxene groups is thus an indication of the temperature history and serves as a powerful geothermometer.

Close to the join at which orthopyroxenes and primitive clinopyroxenes, the pigeonites, exist, the M(2) and M(1) crystallographic sites are largely occupied by magnesium and ferrous iron. At low temperatures the iron prefers the M(2) site and magnesium the M(1) site, which gives a highly ordered distribution of atoms. As temperature is increased, however, a more random distribution of atoms occurs between these sites, which gives increased disorder; the degree of disorder is, therefore, another temperature indicator.

Natural basaltic rocks contain pyroxenes the compositions of which can be expressed rather well within the pyroxene quadrilateral. In addition, these pyroxenes show orderly crystallization trends which can be represented within the quadrilateral. Figure 3B illustrates one important pyroxene crystallization sequence. With falling temperature and degree of crystallization of the basaltic melt, the pyroxene compositions move in the progression 1, 2, and 3. The two point 1s on the diagram are joined by a line; this line, called a tie line, indicates that the two pyroxenes (one calcium rich and the other calcium poor) crystallize together at the same temperature. Progressing through the sequence 1, 2, and 3, the pyroxenes are becoming richer in iron, because they contain more of the fs (ferrosilite) end-member. Thus, the iron-to-magnesium ratio in naturally occurring pyroxenes provides information about the rock's place in the crystallization sequence: those rocks rich in magnesium crystallized early, and those rich in iron crystallized late.

In addition to having use as geothermometers and as indicators of their place in a crystallization sequence, pyroxenes have potential as geobarometers. One example of the usefulness of pyroxenes as geobarometers, but certainly not the only one, concerns the pyroxene jadeite, sodium aluminum silicate ($\text{NaAlSi}_2\text{O}_6$). In terrestrial crustal rocks the feldspar mineral albite, a different sodium aluminum silicate ($\text{NaAlSi}_3\text{O}_8$) that will be discussed in detail below, is an important constituent. In this mineral all of the aluminum is in tetrahedral (4-fold) coordination. When pressure is increased, however, as in the lower crust, upper mantle, or in a meteorite-impact-induced shock event, albite becomes unstable and breaks down to jadeite ($\text{NaAlSi}_2\text{O}_6$) and quartz (SiO_2). In jadeite all of the aluminum is in octahedral (6-fold) coordination, and the mineral assemblage jadeite + quartz is denser than albite. The reaction can be written:

in which the superscripts indicate the coordination of al. Thus, the amount of jadeite in a pyroxene gives some indication of the pressure history.

The pyroxenoids, an interesting group of minerals somewhat similar to but not as abundant or important as the pyroxenes, have structures that contain chains of SiO_4 tetrahedra. The pyroxene chain (Figure 1C) has a repeating two-tetrahedra unit along it. This means that, on a line drawn from any point on a tetrahedron parallel to the chain direction, that point will be repeated at a distance of two tetrahedra along the chain. In pyroxenoids, however, the repeat distance varies from one mineral to another. In wollastonite, calcium silicate (CaSiO_3), the repeat distance is three tetrahedra; in rhodonite, manganese and calcium silicate $[(\text{Mn}, \text{Ca})\text{SiO}_3]$, it is five; in pyroxmangite, a manganese, calcium, iron, and magnesium silicate $[(\text{Mn}, \text{Ca}, \text{Fe}^{2+}, \text{Mg})\text{SiO}_3]$, it is seven; and in ferrosilite III, an iron silicate, it is nine. In general, the repeat distance increases as the mean radius of the cation decreases. A new lunar mineral, pyroxferroite, has essentially the same structure as pyroxmangite. Wollastonite is

a common mineral in metamorphosed limestone that has been subjected to high temperatures.

Among the important rock-forming minerals the amphiboles are perhaps the most complicated. Their crystal structures are capable of accommodating cations of diverse size and charge. A general chemical formula for amphiboles can be written as $\text{A}X_2Y_5Z_8\text{O}_{22}(\text{OH}, \text{F})$, in which the A position can be potassium or sodium; the X position can be calcium, sodium, manganese, ferrous iron, lithium, or magnesium; the Y position can be filled with manganese, ferrous or ferric iron, magnesium, chromium, titanium, or aluminum; and the Z position can be filled with silicon or aluminum. Important species include anthophyllite, grunerite, tremolite, ferrotremolite, edenite, ischermakite, ferrotschermakite, pargasite, ferrohastingsite, glaucophane, magnesioriebeckite, riebeckite, and richterite, all of which are end-members in the various solid-solution series exhibited by the amphiboles. In addition to these end-members, important intermediate members include hornblende (calcium and aluminum rich), cummingtonite (a solid solution between anthophyllite and grunerite), and gedrite (aluminum- and sodium-rich anthophyllite).

An amphibole quadrilateral can be constructed that is directly analogous to the pyroxene quadrilateral. The four end-members are tremolite, calcium magnesium silicate $[\text{Ca}_2\text{Mg}_5\text{Si}_8\text{O}_{22}(\text{OH})_2]$; ferrotremolite, calcium iron silicate $[\text{Ca}_2\text{Fe}_2^{2+}\text{Si}_8\text{O}_{22}(\text{OH})_2]$; anthophyllite, magnesium silicate $[\text{Mg}_7\text{Si}_8\text{O}_{22}(\text{OH})_2]$; and grunerite, ferrous iron silicate $[\text{Fe}_7^{2+}\text{Si}_8\text{O}_{22}(\text{OH})_2]$. The calcium-rich join includes tremolite and ferrotremolite, whereas the calcium-poor join includes anthophyllite and grunerite.

Amphibole structures contain double chains of silicate tetrahedra (Figure 1D). In addition, there are sites with three types of coordination: the A site, a large site with up to a 12-fold coordination; the M(4) site, an irregular site with 6-fold to 8-fold coordination; and the M(1, 2, 3) sites, regular octahedral (6-fold) sites. The A site is occupied by those cations that can be in the A position in the general chemical formula, but sometimes it is vacant; similarly, the M(4) site is occupied by the cations in the X position and the M(1, 2, 3) sites by those in the Y position. Amphibole structures, like pyroxene structures, can be considered in terms of alternating tetrahedral and octahedral layers. Different structural arrangements of these layers and certain distortions result in three important structure types that correspond to the three different pyroxene structures: orthoamphiboles, primitive clinoamphiboles, and C-centred clinoamphiboles.

Orthoamphiboles and primitive clinoamphiboles have compositions near the anthophyllite-grunerite join and thus are calcium poor. In these structures, the M(4) site is occupied by ferrous iron and magnesium and has a 6-fold coordination. C-centred clinoamphiboles have compositions near the tremolite-ferrotremolite join and are therefore calcium rich. In these amphiboles, the M(4) site is largely occupied by calcium and has an 8-fold coordination. At low temperatures there is limited miscibility (solid solution) between the calcium-poor group (orthoamphiboles and primitive clinoamphiboles) and the calcium-rich group (C-centred clinoamphiboles). The amount of mixing between these groups increases with temperature; although this relation has potential in geothermometry, as with the pyroxenes, the amphibole geothermometer has not been properly calibrated.

In orthoamphiboles and primitive clinoamphiboles the M(4) and M(1, 2, 3) sites are largely occupied by ferrous iron and magnesium. At low temperatures the ferrous iron is concentrated largely in the M(4) site, whereas the magnesium is concentrated in M(1, 2, 3); at higher temperatures a more disordered distribution obtains. Again as in the pyroxenes, a second type of geothermometer is available, which involves the degree of disorder of the ferrous iron and magnesium ions between two kinds of sites.

A third striking analogy between the pyroxenes and the amphiboles concerns the aluminum-rich end-members. In the pyroxenes, the aluminous pyroxene jadeite forms at the expense of the sodium feldspar albite under high-

Amphiboles

Pyroxenoids

pressure conditions. Similarly, in amphiboles the aluminous end-member glaucophane, a sodium magnesium aluminosilicate $[\text{Na}_2\text{Mg}_3\text{Al}_2\text{Si}_8\text{O}_{22}(\text{OH})_2]$, forms at the expense of albite at high pressures. Glaucophane forms preferentially over jadeite in rocks formed under high pressures when hydrous conditions prevail.

Thus, as in pyroxenes, amphiboles offer potential as geothermometers and geobarometers. Pyroxenes and amphiboles are not redundant in this application, however, because the two groups of minerals commonly form in different pressure and temperature regimes, with the amphiboles commonly forming at lower temperatures and under more hydrous conditions.

Sheet silicates. Sheet silicate structures are characterized by silicate tetrahedral layers (Figure 1E), octahedral layers, and, in some instances, interlayer cations. The tetrahedral (4-fold) sites can be occupied by silicon or aluminum; the octahedral (6-fold) sites commonly are occupied by magnesium, ferrous and ferric iron, aluminum, and titanium; and the interlayer sites (up to 12-fold coordination) are occupied by sodium or potassium ions or by water molecules or hydronium ions (water with an added proton, H_3O^+). Two groups of structures are defined: in the dioctahedral structures, two-thirds of the octahedral sites are occupied by cations and one-third are vacant; in the trioctahedral structures, all the octahedral sites are filled.

Trioctahe-
dral micas

Trioctahedral mica minerals have an octahedral layer, designated TRI, that is usually occupied by magnesium (Mg^{+2}) and ferrous iron (Fe^{+2}) ions with a $+2$ charge. It is possible to develop the various trioctahedral minerals by combining silicate tetrahedral layers (T) with trioctahedral layers (TRI) in various combinations. A simple member of this series is obtained by forming composite layers containing one tetrahedral layer (T) and one trioctahedral layer (TRI); these composite layers are designated concisely as T-TRI. A structure can be built by stacking T-TRI layers—i.e., T-TRI, T-TRI, T-TRI, etc. The bonding between T and TRI is rather strong, but that between one T-TRI layer and the next is very weak. Thus, these structures have excellent cleavage; that is, they can be broken readily between the composite layers. Antigorite, a mineral with this structure, has the chemical formula $\text{Mg}_3(\text{Si}_2\text{O}_5)(\text{OH})_4$.

Another trioctahedral structure can be derived by constructing a tightly bonded composite layer of two T layers and one TRI layer—i.e., T-TRI-T. When stacked, the structure would thus consist of the sequence T-TRI-T, T-TRI-T, T-TRI-T, etc. Again, good cleavage exists between the composite layers. Talc is such a mineral, with the formula $\text{Mg}_3(\text{Si}_4\text{O}_{10})(\text{OH})_2$.

A third member of the trioctahedral group can be derived if one-fourth of the silicon atoms in the tetrahedral (4-fold) sites are replaced by aluminum atoms. Because of the charge difference (silicon has a $+4$ charge, aluminum only a $+3$), this leaves a residual charge on the T-TRI-T layers; interlayer cations enter the structure to achieve electrical neutrality. An example of such a structure has potassium (K) as the interlayer cation; its structure can be represented as (T-TRI-T)K(T-TRI-T)-K(T-TRI-T)K(T-TRI-T), etc. In these structures the bonding between adjacent T-TRI-T layers is stronger than before because of the presence of an interlayer cation; however, the cleavage is still good. Biotite micas are examples of this type: the group is a solid-solution series with two important compositional end-members: annite $[\text{KFe}_3^{2+}(\text{Si}_3\text{Al})\text{O}_{10}(\text{OH})_2]$ and phlogopite $[\text{KMg}_3(\text{Si}_3\text{Al})\text{O}_{10}(\text{OH})_2]$.

Still another trioctahedral structure can be derived by filling half of the tetrahedral sites by aluminum and half by silicon. The negative residual charge is thus increased, and calcium, which has a $+2$ charge, can enter the structure. The structure can be represented as (T-TRI-T)Ca(T-TRI-T)Ca(T-TRI-T), etc. A mineral representative is the brittle mica xanthophyllite, with the formula $\text{CaMg}_3(\text{Al}_2\text{Si}_2)\text{O}_{10}(\text{OH})_2$. The bonding between T-TRI-T layers is stronger because of calcium's greater charge, and thus the cleavage is not as pronounced.

An additional member of the trioctahedral group can be

formed by adding interlayer water molecules to the structure of talc. Such a structure can be represented as (T-TRI-T) H_2O (T-TRI-T) H_2O (T-TRI-T), etc. The addition of water between the layers causes the structure to expand, which gives such minerals the name swelling micas. A mineral example is vermiculite, with the formula $\text{Mg}_3(\text{Si}_4\text{O}_{10})(\text{OH})_2 \cdot \text{H}_2\text{O}$.

A parallel development can be made for dioctahedral micas. Addition of one T layer to one dioctahedral layer (DI) yields a structure T-DI, T-DI, T-DI, etc. As expected, there is weak bonding between individual T-DI layers. A mineral representative is kaolinite, with the formula $\text{Al}_2(\text{Si}_2\text{O}_5)(\text{OH})_2$.

Dioctahe-
dral micas

Another member can be derived from T-DI-T layers; it has the structure T-DI-T, T-DI-T, T-DI-T, etc. Again, the bonding is weak between composite layers, and the cleavage is good. Pyrophyllite, $\text{Al}_2(\text{Si}_4\text{O}_{10})(\text{OH})_2$, represents this group.

Addition of aluminum to one-fourth of the sites previously occupied by silicon allows the addition of a monovalent interlayer cation (charge of $+1$), either sodium or potassium; the structure can be represented as (T-DI-T)(Na, K)(T-DI-T)(Na, K)(T-DI-T). The cleavage is not as good as in the dioctahedral micas without interlayer cations. Muscovite is the potassium end-member of this group $[\text{KAl}_2(\text{Si}_3\text{Al})\text{O}_{10}(\text{OH})_2]$, and paragonite is the sodium end-member $[\text{NaAl}_2(\text{Si}_3\text{Al})\text{O}_{10}(\text{OH})_2]$.

When half of the tetrahedral sites are occupied by silicon and half by aluminum, the structure of the mineral margarite $[\text{CaAl}_2(\text{Si}_2\text{Al}_2)\text{O}_{10}(\text{OH})_2]$ can be derived and represented as (T-DI-T)Ca(T-DI-T)Ca(T-DI-T). This brittle mica does not have as good cleavage as do the other dioctahedral micas.

Addition of water to pyrophyllite results in montmorillonite, a dioctahedral swelling mica with the formula $\text{Al}_2(\text{Si}_4\text{O}_{10})(\text{OH})_2 \cdot \text{H}_2\text{O}$.

The micas can be used as geobarometers as well as geothermometers. Solid solution between the potassium-rich dioctahedral mica, muscovite, and the sodium-rich dioctahedral mica, paragonite, is not complete at low temperatures but increases with increasing temperature; this relationship has been calibrated rather well by experimental studies. Thus, the chemical compositions of coexisting muscovite and paragonite solid solutions in natural rocks can yield information about the thermal history of the rock. Furthermore, as with the pyroxenes and the amphiboles, the amount of aluminum in octahedral coordination in a mica may be indicative of its pressure history. For example, under high pressures phlogopite, which has its aluminum in tetrahedral (4-fold) coordination, is converted at the expense of potassium-feldspar into the mica phengite, which has its aluminum in octahedral (6-fold) coordination and is thus denser. The reaction proceeds as follows:

Framework silicates. There are six important polymorphs of silica, silicon dioxide (SiO_2); these include low quartz, high quartz, tridymite, cristobalite, coesite, and stishovite, all of which have the silica composition but have different crystal structures. The structures of all except stishovite are made up of SiO_4 tetrahedra with all four corners linked to other tetrahedra, but even though they are made up of three-dimensional frameworks, their densities vary significantly because the arrangements of the tetrahedra differ.

Silica
minerals

At low temperatures and pressures, low quartz is the stable form. If the pressure is held at one atmosphere and the temperature is raised, high quartz becomes the stable form in the temperature range $573^\circ\text{--}870^\circ\text{C}$ ($1,063^\circ\text{--}1,600^\circ\text{F}$), tridymite in the range $870^\circ\text{--}1,470^\circ\text{C}$ ($1,600^\circ\text{--}2,680^\circ\text{F}$), and cristobalite above $1,470^\circ\text{C}$ until it melts at $1,720^\circ\text{C}$ ($3,130^\circ\text{F}$). The high-temperature polymorphs have lower densities than the low-temperature polymorphs. If pressure is increased, all will transform to coesite; this transition takes place at approximately 20

kilobars (one bar = 29.5 inches of mercury) at room temperature and approximately 40 kilobars at 1,900° C (3,450° F). Although coesite is denser than most of the silica polymorphs, it still has silicon in tetrahedral coordination. The high density results from tight packing of the SiO₄ tetrahedral groups. At extremely high pressures (near 160 kilobars), silica has the very dense stishovite structure. In this structure silicon is in octahedral coordination; octahedral coordination of silicon may well be the important silicon coordination in the lower mantle of the Earth.

Feldspars The feldspar minerals are the most abundant mineral group in the Earth's crust, where they make up 60 percent of the rocks and, thus, are an extremely important group of silicates. They, like the forms of silica discussed above, have framework structures, but, unlike the silica polymorphs, they have some of the tetrahedral (4-fold coordination) silicon atoms replaced by aluminum. The substitution results in a residual negative charge on the framework structure caused by the charge difference between aluminum and silicon, and other cations can be accommodated—*e.g.*, sodium, calcium, or potassium. Feldspars are less important in the mantle of the Earth. Their relatively low-density crystal structures give way to denser structures under high-pressure conditions.

The three most important end-members are potassic feldspar (KAlSi₃O₈), the sodic feldspar albite (NaAlSi₃O₈), and the calcic feldspar anorthite (CaAl₂Si₂O₈). There is limited solid solution between potassic feldspar and albite (mutual substitution between potassium and sodium ions) at low temperatures because of the great disparity in ionic radii between the potassium ion, with a radius of about 1.5 angstrom units (symbolized Å; 1 Å = 10⁻⁸ centimetre), and the sodium ion, with a radius of about one angstrom. At high temperatures the amount of solid solution increases, which makes this relationship useful in tracing the temperature history of feldspar-bearing rocks.

There is little solid solution between anorthite and potassic feldspar at any temperature. This is perhaps due not only to the size discrepancy of cations (about the same as between sodium and potassium because the ionic radius of calcium is very similar to that of sodium) but also to the difference in charge, because calcium ions have a +2 charge, whereas potassium ions only have a +1 charge.

Because the ionic radii of calcium and sodium are similar, there is complete solid solution between albite and anorthite at high temperatures, but the substitution involves four cations (coupled substitution) instead of the usual two, Na⁺Si⁴⁺ ⇌ Ca²⁺Al³⁺ (sodium and silicon reversibly replacing calcium and aluminum), and this results in some small miscibility gaps in this series at low temperature.

The crystal structure of anorthite (CaAl₂Si₂O₈) is a framework of linked SiO₄ and AlO₄ tetrahedra with large void spaces that are occupied by calcium. There is the same number of aluminum and silicon atoms in the crystal structure, and the tetrahedra are arranged so that every SiO₄ tetrahedron is linked to four AlO₄ tetrahedra, and every AlO₄ tetrahedron is linked to four SiO₄ tetrahedra. This relationship is a general rule in silicate mineralogy—*i.e.*, that AlO₄ tetrahedra tend not to share corners with other AlO₄ tetrahedra. This perfectly ordered distribution remains essentially intact even at high temperatures and so offers little in the way of geothermometry for anorthite-bearing rocks.

In albite (NaAlSi₃O₈) the aluminum-to-silicon ratio is 1 to 3 rather than 1 to 1 as in anorthite; this offers more freedom in the arrangement of the silicon and aluminum atoms in the albite structure. Although all of the silicon and aluminum occupy tetrahedral (4-fold) sites in the albite structure, these tetrahedra sites differ in detail; the four types have slightly different distortions and are referred to as T1(0), T1(m), T2(0) and T2(m). At low temperatures most of the aluminum occupies the T1(0) site, and the silicon atoms occupy T1(m), T2(0), and T2(m), which gives a highly ordered distribution. At high temperatures (about 1,000° C, or 1,800° F) the alumi-

num and silicon atoms have a much more random distribution. Thus, order-disorder relationships between silicon and aluminum are very useful in determining the temperature history of albite-bearing rocks.

In potassic feldspar, as in albite, the aluminum-to-silicon ratio is 1 to 3, and again the possibility of order and disorder of aluminum exists. In the low-temperature form, called microcline, the potassic feldspar has four distinct tetrahedral sites, referred to as T1(0), T1(m), T2(0), and T2(m), just as in albite. At low temperatures the aluminum-silicon distribution is highly ordered, with aluminum in T1(0) and silicon in T1(m), T2(0), and T2(m). As temperature is increased, microcline changes to orthoclase, which has only two distinct tetrahedral sites—T1 and T2 sites. In the orthoclase structure, aluminum preferentially occupies the T1 sites, but the overall aluminum-silicon distribution is more disordered than in microcline. As the temperature is increased further, orthoclase becomes sanidine, with a very disordered distribution of the aluminum and silicon atoms. Thus, as in albite, the aluminum-silicon distribution in potassic feldspar provides a powerful geothermometer.

The feldspathoid minerals take the place of feldspars when igneous rocks are deficient in silica; important species include leucite, kalsilite, nepheline, sodalite, noselite, and cancrinite.

Leucite, potassium aluminum silicate (KAlSi₂O₆), is the commonest potassium-containing feldspathoid; it occurs frequently in potassic rocks that are poor in silica.

Nepheline, sodium aluminum silicate (NaAlSi₃O₄), and kalsilite, a potassium aluminum silicate (KAlSiO₄), form a solid solution series; both end-members (*i.e.*, nepheline and kalsilite) have a framework structure with half the silicon atoms replaced by aluminum. Electrical neutrality is achieved by the addition of sodium or potassium ions (Na⁺ or K⁺) into structural cavities in the framework. Extensive substitution exists between sodium and potassium at elevated temperatures, but at low temperatures a large miscibility gap exists because of the significant difference between the ionic radii of sodium and potassium. Again, as with the feldspar minerals, the amount of solid solution between these two end-members serves as a geothermometer. Nepheline and kalsilite are found in igneous and metamorphic rocks in which the silica content is low; in these rocks nepheline commonly is present instead of the feldspar albite, which is richer in silica.

In sodalite, noselite, and cancrinite, the tetrahedral framework units have a negative residual charge of -6. In this case, however, electrical neutrality is not achieved by the addition of positively charged metal ions alone; anions or anionic groups—ions or ion groups with a negative charge such as chloride (Cl⁻), sulfate (SO₄²⁻), or bicarbonate (HCO₃⁻)—are added to these structures as well. Charge balance is achieved as follows: in sodalite, (8 Na⁺)⁸⁺ + (framework)⁶⁻ + (2Cl⁻)²⁻ = 0 residual charge; in noselite, (8 Na⁺)⁸⁺ + (framework)⁶⁻ + (SO₄²⁻)²⁻ = 0; and in cancrinite, (8 Na⁺)⁸⁺ + (framework)⁶⁻ + (2HCO₃⁻)²⁻ = 0.

Although not considered feldspathoid minerals, the scapolites bear resemblances to both the feldspathoids and the feldspars. The scapolites are a solid-solution series between two important end-members: marialite, a chloride-containing sodium aluminum silicate [Na₄Al₃(Si₉O₂₄)Cl] that can be said to be made up of three albite (NaAlSi₃O₈) formula units and one sodium chloride (NaCl) formula unit; and meionite, a carbonate containing calcium aluminum silicate (Ca₄Al₆Si₆O₂₄CO₃) that can be said to be made up of three anorthite (CaAl₂Si₂O₈) formula units and one calcium carbonate (CaCO₃) formula unit. These minerals have framework structures with aluminum-to-silicon ratios ranging from 1 to 3 in marialite to 1 to 1 in meionite. Large central cavities in the structures accommodate the anionic chloride (Cl⁻) and sulfate (SO₄²⁻) group, whereas smaller cavities accommodate the sodium and calcium ions. Other anionic groups can substitute into the scapolite structure, including fluoride, bisulfate, and hydroxide ions. Scapolites can form over a wide range of temperatures and pressures and are found both in metamorphic and igneous rocks.

Feldspathoids

Scapolites

Another mineral that bears a strong resemblance to the feldspathoids and also to the zeolites is the mineral analcime $[\text{Na}(\text{AlSi}_3\text{O}_6) \cdot \text{H}_2\text{O}]$. Analcime has a framework structure that contains large cavities capable of accommodating both sodium ions and water molecules. It is a primary constituent of some igneous rocks that are rich in sodium and poor in silica.

Zeolites

The zeolite minerals are hydrated aluminosilicates that have very open three-dimensional framework structures and form at low temperatures. As in the case of the feldspars, aluminum atoms in the tetrahedral framework result in a negative residual charge, which is compensated by the entrance of additional cations (*e.g.*, lithium, sodium, potassium, magnesium, calcium, strontium, and barium) into the large holes. Because these holes can also be occupied by water molecules, zeolites have the property of reversible hydration and dehydration. Compared to the feldspars, zeolites have the cations loosely bonded in their structures, and these cations essentially rattle around in the large structural cavities. The randomness of cations and water molecules make it difficult to determine the crystal structures of many members of this very complex silicate group. The large cavities in zeolite structures allow a second type of coupled substitution—*i.e.*, two cations for one cation, as two sodium ions for one calcium ion: $2\text{Na}^{1+} \rightleftharpoons \text{Ca}^{2+}$.

Zeolites are commonly divided into three main groups, but recent work has shown that this is not rigorously correct; the three groups are the natrolite group, the heulandite group, and the chabazite group. In considering these groups, account is taken of the bonding strength in various directions in the structures. Therefore, although all zeolites are three-dimensional frameworks, the strong bonding linkages may be considered as being linear in one group of zeolites, two-dimensional (planar) in a second, and three-dimensional in another. The natrolite group of zeolites has strong linear bonding linkages, which gives members of this group a fibrous appearance; members of the group include natrolite, mesolite, scolecite, thomsonite, gonnardite, and edingtonite. The heulandite group has strong two-dimensional linkages, and thus members of the group commonly have a platy appearance; members of this group include heulandite, stilbite, and epistilbite. The chabazite group of zeolites has bond linkages of approximately the same strength in all three dimensions; members of this group include harmotome, phillipsite, chabazite, gmelinite, levyne, and faujasite.

A general correlation exists between the number of tetrahedra in various rings or loops in the tetrahedral framework and the minimum diameter of the widest channel (MDWC). Harmotome and phillipsite have four- and eight-membered rings and an MDWC of 3.2 Å; levyne has four-, six-, and eight-membered rings and an MDWC of 2.7 Å; erionite has four-, six-, and eight-membered rings and an MDWC of 3.6 Å; chabazite has four-, six-, and eight-membered rings and an MDWC of 3.9 Å; gmelinite has four-, six-, eight-, and 12-membered rings and an MDWC of 6.4 Å; fanjasite has four-, six-, and 12-membered rings and an MDWC of 9 Å. It is apparent that the degree of openness of zeolite structures varies considerably from one to the next.

Zeolites are useful as crystalline ion exchangers, drying agents, and molecular sieves. The cation exchange property means that if a zeolite with a certain cation content is put into an aqueous solution with a different cation content, an exchange of cations will take place, resulting in a more similar cation content of both solid and solution. Zeolites are useful as drying agents, but they must first be dehydrated. Because zeolites have the property of reversible hydration, they will take up water molecules again, and thus containers of dehydrated zeolites may be placed in areas to remove moisture from the air, as for example in areas for precise weighing of materials. A third use of zeolites is as molecular sieves. This property results because of the range of structural channel sizes discussed above. Molecules with diameters larger than the channelways are excluded, whereas molecules with smaller diameters can enter. Because of this, zeolites

provide an effective way of separating (sieving) materials on a molecular scale.

Zeolites typically occur in low-temperature environments in the Earth's crust. They fill small openings (vesicles or fissures) in late-stage igneous rocks, can form in sedimentary rocks, and occur in very low-grade metamorphic rocks (those formed at low temperatures).

OCCURRENCE OF SILICATES

In the Earth's crust. Igneous rocks are composed largely of a few silicate minerals, namely feldspars, (about 60 percent), amphiboles and pyroxenes (about 17 percent), quartz (12 percent), micas (about 4 percent), and olivine. The igneous rocks are classified according to their mineral content: for example, syenites are rocks containing potassic feldspar, micas, and amphiboles; granites contain potassic feldspar, sodium-calcium feldspars, micas, and amphiboles; gabbros contain sodium-calcium feldspars and pyroxene; peridotites contain pyroxene and olivine; dunites are pure olivine rocks.

Sedimentary rocks result largely from the breakdown of pre-existing rocks, mainly igneous rocks, by the action of air and water. The minerals formed in igneous rocks are stable at high temperatures, but, after the rocks have cooled and hydrous conditions prevail, many are broken down to other low-temperature, usually hydrous minerals, which may be carried and redeposited by water.

The silicate minerals that form sedimentary rocks fall into two genetic groups: first, those resistant minerals that have not been altered from their composition in the parent igneous rock and, second, those that have been newly formed. The first silicate minerals that are broken down from igneous rock parents are usually those that formed at the highest temperatures; thus, olivine and anorthite-rich feldspars are broken down readily. The later stage (lower temperature) silicate minerals, such as albite-rich feldspar, potassic feldspar, muscovite mica, and quartz, are more resistant and may occur as unchanged constituents in sedimentary rocks. Silicates that form from the breakdown of pre-existing high-temperature silicate minerals usually have layer structures, such as the kaolinites, montmorillonites, and some zeolites.

Metamorphic rocks can be formed from pre-existing igneous, sedimentary, or other metamorphic rocks. They are formed within a temperature range between the low-temperature conditions under which sedimentary rocks are formed to the high temperatures (about 700° C, or 1,300° F) at which igneous rocks may be generated. Metamorphic silicates include the aluminosilicate minerals, andalusite, kyanite, sillimanite; cordierite, a framework silicate containing magnesium and ferrous iron; garnets; chlorite, a sheet silicate rich in magnesium and ferrous iron; talc; staurolite and chloritoid, hydrous iron- and aluminum-rich silicates; amphiboles; pyroxenes; feldspars; and micas. Metamorphic rocks are commonly classified according to the pressure and temperature conditions under which they formed (metamorphic facies concept). The minerals present at the various pressure-temperature combinations are largely a function of rock composition. At low to moderate pressures the progression from low-temperature to high-temperature facies is as follows: the greenschist facies, which include quartz, muscovite, microcline, albite, zoisite-epidote, tremolite, chlorite, and chloritoid; the epidote-amphibolite facies, which include quartz, kyanite, muscovite, microcline, albite, zoisite-epidote, cummingtonite, talc, anthophyllite, tremolite, hornblende, chlorite, chloritoid, almandite, and biotite; and amphibolite facies, which include quartz, kyanite-sillimanite, muscovite, microcline, plagioclase, zoisite-epidote, wollastonite, cummingtonite, anthophyllite, forsterite, tremolite, diopside, hornblende, cordierite, almandite, staurolite, and biotite; the granulite facies, which include quartz, kyanite, sillimanite, orthoclase, plagioclase, wollastonite, orthopyroxene, forsterite, diopside, augite, pyrope-almandite, and biotite. At low temperatures and high pressures (200°–300° C [400°–600° F], five to eight kilobars) the glaucophane schist facies is represented. It includes, in addition to many of the above, the high-pressure minerals glaucophane, jadeite, and phen-

The two genetic groups of sedimentary silicates

gite. The high pressure, high-temperature eclogite facies contain jadeite-rich pyroxene and pyrope-rich garnets.

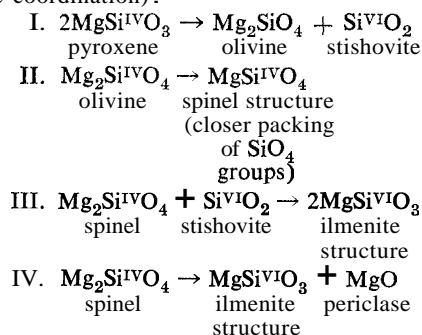

In the Earth's mantle. The Earth's mantle extends from depths of approximately 36 kilometres (22 miles) to 2,900 kilometres (1,800 miles), which represents a pressure range of 10–1,400 kilobars and a temperature range of roughly 600–6,000° C (1,100°–11,000° F). The mantle is sometimes divided into three parts: the upper mantle (36–400 kilometres, 10–160 kilobars), the transition zone (400–1,000 kilometres, 160–450 kilobars) and the lower mantle (1,000–2,900 kilometres, 450–1,400 kilobars).

Unlike the parts of the crust of the Earth that can be observed and sampled, the mineralogic nature of the mantle has to be deduced largely on theoretical grounds. The constraints on the theoretical mineralogic combination of the mantle include the temperature gradients, pressure gradients, mean density of the Earth, moment of inertia of the Earth (related to the distribution of mass in the Earth), and the velocity of seismic waves in the mantle. In addition, there are some samples of the upper mantle that have been delivered to Earth's surface: inclusions of rock carried up in deeply derived basalts; and inclusions in diamond pipes, which are thought to be derived with explosive violence from the Earth's mantle. Any model of the mantle, then, must be compatible with both the constraints and the actual samples. In addition, it must be able to account for the composition of igneous rocks derived from the mantle.

The problem of mantle mineralogy has been reviewed by S.P. Clark and Alfred E. Ringwood, and the ideas expressed here are largely theirs. The upper mantle may be represented by four important mineral assemblages (minerals occurring together) and include:

- I. olivine + amphibole
- II. olivine + aluminum-poor pyroxene + calcium-sodium feldspar (plagioclase)
- III. olivine + aluminum-rich pyroxene + spinel
- IV. olivine + aluminum-poor pyroxene + garnet.

The Clark–Ringwood model for the transition zone assumes a chemical composition comprised largely of magnesium oxide (MgO) and silica (SiO₂), corresponding to a mixture of the olivine mineral forsterite (Mg₂SiO₄) and the pyroxene mineral enstatite (MgSiO₃). These minerals would be stable to a depth of about 400 kilometres (approximately 160 kilobars). With increasing depth into the transition zone, Clark and Ringwood propose the following reactions (the Roman superscripts indicate coordination):

This series of transformations should be complete at about 1,000 kilometres (approximately 450 kilobars) and result in a density increase from 3.2 to 3.9 grams per cubic centimetre. It is apparent that the general sequence from crust to upper mantle through the transition zone involves an increase in coordination of aluminum atoms from 4-fold to 6-fold, an increase in packing density of SiO₄ groups, and an increased coordination of silicon from 4-fold to 6-fold.

The lower mantle appears to be more homogeneous and may be made up largely of magnesium silicate (MgSiO₃) with the ilmenite structure and magnesium oxide (MgO) with the periclase structure.

In meteorites and in the Moon. Silicate minerals are important in meteorites and lunar samples, which pro-

vide solid extraterrestrial material for mineralogic study. The silicate minerals occurring in meteorites include the silica polymorphs quartz, tridymite, and cristobalite, as well as olivine, pyroxenes, and plagioclase. Thus, for those meteorites studied, the range of silicates observed is far more limited than on Earth. This may reflect a much more extensive study of terrestrial silicates, a smaller compositional range for silicate meteorites, and a more limited temperature and pressure range for many meteorites.

The Apollo 11, 12, 14, 15, 16, and Luna-16 missions have provided a wealth of lunar samples. Apollo missions 11, 12, 15, and Luna-16 sampled mare regions (low, dark, relatively smooth areas), and the samples returned were largely basalts. The silicates found in these rocks included the pyroxenes augite and pigeonite, anorthite-rich feldspar, olivine, and the silica polymorphs (cristobalite and tridymite); pyroxenes are the most abundant and important constituents of these basaltic rocks. In addition to these common silicate minerals, a new silicate mineral was discovered, pyroxferroite Ca_{1/7}(Fe,Mg)_{6/7}SiO₃. This mineral has a structure that contains chains of SiO₄ tetrahedra and octahedral (6-fold) and 8-fold sites, which accommodate the calcium, ferrous iron, and magnesium. It is one of the last minerals to crystallize from the basaltic melt. Detailed study of these rocks demonstrated that they crystallized rapidly at or near the lunar surface under extremely anhydrous and reducing conditions.

The Apollo 14, 15, and 16 missions sampled the lunar highlands (lighter in colour, older, and displaying rough surface areas heavily pockmarked by meteorite impact craters) and provided samples different from the mare areas. These samples contained far more feldspar (anorthite-rich) and also contained orthopyroxene. Most of these rocks are breccias (rocks formed by breaking up of previously existing rock largely by meteorite impact) the most abundant constituent mineral of which is feldspar.

Although the samples provided information about the distribution of silicate minerals in lunar mare and highlands regions, far less is known about the interior of the moon. Because samples of the lunar interior are lacking, information on it is based largely on theoretical ground. Based on such reasoning, it appears that a pyroxene-olivine lunar interior is likely.

Siliceous Rocks

The siliceous rocks are those sedimentary rocks that consist largely or almost entirely of free silica (SiO_2), in the form either of quartz or varieties of amorphous silica and cristobalite. By custom the term includes rocks that have formed as chemical precipitates of one type or another but exclude rocks high in free silica content that are of detrital or fragmental origin, such as the quartz arenites, those sandstones composed almost entirely of quartz grains. Though many of the siliceous sediments are relatively pure silica, the same rock types may be mixed with clays, carbonates, or detrital grains of sand and silt so that they are impure. By far the most abundant type of siliceous rock is chert, a common constituent of strata of every age and character.

This article deals with the general characteristics and occurrence of siliceous rocks and their origins within the framework of the biogeochemistry of silica. For further information on diagenesis, the alteration of sediments to solid rocks, see **SEDIMENTARY ROCKS**; see also **SHALES**; **SANDSTONES**; and **LIMESTONES AND DOLOMITES** for specific rock types involved. For an expanded treatment of the role of organisms, see **ELEMENTS, PHYSIOLOGICAL CONCENTRATION OF**; and **MARINE SEDIMENTS**. The formation of siliceous crusts is treated in the article **DURICRUSTS**.

OCCURRENCE AND CHARACTERISTICS

Chert is a dense, more or less microcrystalline rock, composed of chalcedony and quartz, that occurs in beds and nodules. Flint, a term that is used synonymously with chert, tends to be used more for references to artifacts such as arrowheads. Various other names have been used for chert, including silicite, hornstone, and phthanite. Porcellanite is a variety of chert, equally dense and hard, that breaks in the manner of unglazed porcelain. Jasper is a coloured chert; the most abundant variety is mixed with iron oxide that makes it red and brown in colour. Such rocks contain much nonsiliceous material, chiefly clay and calcium or magnesium carbonate (calcite or dolomite). Novaculite is a bedded chert (deposits exhibit stratification); the name has been applied mainly to formations of Paleozoic age in the Ouachita Mountains of Arkansas and Oklahoma and, to some extent, to rocks of the same age in the Marathon Mountains of Texas.

Marine and hot spring deposits. Many siliceous rocks called chert are composed almost entirely of siliceous fossils. Thus, diatoms (one-celled marine plants) sink to form diatomaceous oozes on the sea floor, which ultimately may become diatomaceous earths or, if well indurated, diatomite, a hard rock. In the same way, radiolaria (one-celled marine animals) form oozes, earths, and radiolarites. The radiolarians or radiolarian cherts of the Alpine chain are the most famous representatives in the geologic column (the strata that represent all of geological time). Other names used for siliceous fossil earths are infusorial earth, or kieselguhr, and tripoli.

Yet another mode of occurrence of siliceous deposits is as sinters and encrustations formed by evaporation in and around hot springs. There are many names applied to these kinds of deposits; most frequent are siliceous sinter, geyserite (if associated with geysers), and fiorite. The areal extent and total volume of the deposits associated with hot springs and geysers are relatively small, but it is not known how much silica is deposited under the sea or in the interstices of rocks by rising hydrothermal solutions. In contrast, the areal extent and volume of cherts, both bedded and nodular, is large. Some formations containing abundant chert are known to have covered many tens of thousands of square miles in their former extent. Cherts also may be a prominent constituent of many stratigraphic sections (the sequence of strata in a given locale); and though quantitatively small compared to the total amount of clastic rocks (those consisting of aggregates of individual grains) and limestone, they are probably the most abundant chemically precipitated rock type after limestone. Much of their total volume is distributed in small beds and nodules, mainly in carbonate rock sections, and tends to be underestimated.

Various forms of siliceous rocks have found a wide vari-

ety of uses from prehistoric times on. The earliest important use was that of chert or flint for the making of weapons in early prehistoric cultures. Another former use for flint was its use in firearms. In modern times chert pebbles have been found useful as grinding agents in ball mills. Diatomaceous earths are used for fine abrasives (as are crushed cherts of various kinds), for molded refractories, and for some fluid filtering purposes. As a major source of silica, the siliceous rocks can be used as the raw material for the making of portland cement, as crushed rock for secondary roads, and as raw material for the making of chemical compounds of silicon. In some localities they are used for building stone.

Physical properties. The diverse origins of siliceous rocks are reflected in the variety of their physical characteristics. Cherts range from almost pure white through tones of cream and buff to dark grays and blues and black. The colours come from impurities, the most common of which are iron impurities, usually finely disseminated ferric oxide (hematite), that colour the rock yellow, brown, and red. The jaspers may represent various mixtures of hematite and silica. Included clay gives a gray or gray-blue colour, whereas finely dispersed organic matter produces a dark blue or black colour. Diatomaceous and radiolarian oozes and earths are white to cream coloured unless they are mixed with large amounts of clay. The sinters and geyserites are white to varying shades of gray.

The porosity of cherts is very low, usually less than a few percent; and electron micrographs have shown that this porosity is distributed as very tiny cavities and holes. Thus, the permeability is immeasurably small. In contrast, the diatomaceous earths may be very porous and permeable; the pore space between the fossil skeletons may be as high as 50 percent if the rock is not cemented at all. The bulk specific gravity (density of a bulk specimen) of the rock, therefore, may range from a value near that of quartz (2.65) to very low values, depending on its porosity. The cherts tend to have relatively high specific gravities and will be particularly high if much iron is included. Almost all cherts are hard, and some particularly dense varieties may approach seven (the value of quartz) on the Mohs scale of hardness. The siliceous earths are softer because of the friability of the skeletal remains of diatoms and radiolaria, although the silica substance itself is hard. Chert is brittle and breaks with a conchoidal fracture, two properties that made it so suitable for prehistoric arrows, spears, and axes.

The composition of cherts, in terms of free silica present, ranges from opaline silica, a type of amorphous silica, through a form of disordered cristobalite similar in some respects to amorphous silica, to a chalcedonic silica that consists largely of microcrystalline quartz, perhaps with an admixture of cristobalite or amorphous silica. Composition varies with age; the oldest cherts are entirely microcrystalline quartz, whereas younger rocks have more amorphous silica or cristobalite. The siliceous oozes and earths are composed entirely of the untransmuted skeletons of diatoms and radiolaria, which are amorphous silica. The common nonsilica components of siliceous rocks—carbonate (calcite and dolomite), clay minerals, and iron oxides—contribute calcium, magnesium, sodium, potassium, aluminum, and iron, the presence of which is shown by chemical analyses. There is usually a fine-grained fraction of detrital quartz in cherts. The texture of cherts under the microscope is that of a fine-grained microgranular rock composed of interlocking and intergrown tiny crystals of quartz. Chalcedonic quartz, commonly present in many cherts, is composed of radiating sheaves and fibres of material whose index of refraction (ratio of velocity of light in air to the velocity in the substance) is slightly lower than that of quartz (1.54; 1.55), a property that may be the result of occluded water in tiny holes in the structure. Opaline silica is isotropic (its properties of light transmission are the same in all directions) with an index of refraction from 1.41 to 1.46. Electron microscopy of cherts has revealed a great range of textures, ranging from equigranular to those exhibiting complex intergrowths of different size crystals with vary-

Types of
siliceous
rocks

compo-
sition

ing morphology. The oldest fossils known, those of cells of primitive algae, have been noted by microscopic and electron microscopic studies of Precambrian cherts.

Bedding and sedimentary structures. The bed-thickness characteristics of siliceous rocks are linked to their composition and origin. The bedded cherts are those that show continuous beds of wide areal extent, with more or less uniform thickness. Such beds usually range in thickness from less than an inch to a foot and are most commonly several inches thick. A succession of these layers makes up a thicker unit of chert, varying from one foot to hundreds of feet in thickness. The beds may alternate with beds of siliceous clay or shale or with limestones and dolomites. In contrast, the nodular cherts have a much more uneven bedding development. The chert beds may be stratigraphic horizons (zones that represent a given time interval) along which many chert nodules occur, or they may be continuous beds that pinch and swell, composed of coalesced nodules. Some formations have been traced laterally from a zone in which a few nodules are present, through one in which nodules are abundant, to one in which the nodules are completely coalesced to make a continuous bed. The siliceous earths tend to be more or less evenly bedded.

The common sedimentary structures of cherts are the nodules. A nodular character, however, is entirely missing from the bedded cherts. In some bedded cherts one can sometimes see faint traces of current bedding and ripples. Bands of reddish or brownish colour are common in many cherts; they may cut across the bedding and thus indicate their postdepositional origin. Cherts are in some places deformed by contemporaneous or postdepositional movements that give rise to contorted bedding, intrusions of a chert layer into overlying or underlying beds, and brecciation, the breakage and reconsolidation of angular chert fragments. One variety of siliceous rock is actually a silicified limestone; some of these limestones were originally oolitic, that is, they were composed of rounded carbonate grains that had formed by precipitation about various nuclei. Thus, in a few instances, a siliceous oolite rock results. None of the primary siliceous rocks, the bedded cherts, contains such oolites, and the nodular cherts are oolitic only when the nodules have replaced sections of oolitic limestone.

ORIGIN OF THE SILICEOUS ROCKS

The origin of chert and the siliceous rocks has been the subject of controversy for as long as the rocks have been studied (Figure 1). There is little doubt as to the origin

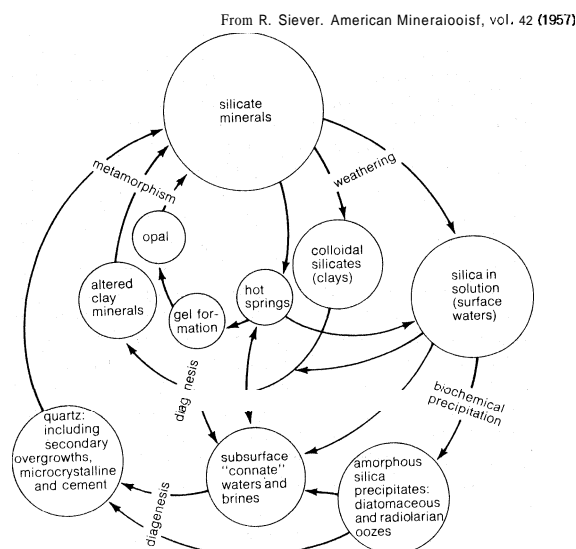

Figure 1: Silica cycle.

of the diatomaceous and radiolarian oozes and earths. Sediments in all stages of development have been found. It is clear that they form by the sedimentation of the shells and other hard parts of siliceous organisms that live in surface waters, such as diatoms, radiolaria, and

silicoflagellates, together with the spicules of siliceous sponges. It is probable that portions of such shells, or the entire shells of the most fragile species, dissolve as they fall through the lower part of a seawater column that is undersaturated with respect to silica. Freshwater diatomaceous earths form in lakes as they do in the oceans. The transformation of such unindurated (relatively soft) siliceous sediments into hard cherts has been partly traced by studies of Tertiary cherts that show all intermediate stages. The hardness and denseness of the cherts comes from the precipitation of silica in the void spaces between skeletal fragments, the source of the silica being the more soluble parts of the skeletons themselves. The net result of the dissolution and reprecipitation process is the making of a hard rock out of soft sediment, with an accompanying loss of many identifiable fossils and an increase in bulk density of the rock. Although the fossils in older cherts, those of the Paleozoic, are harder to see, they contain siliceous sponge spicules and radiolarians. The Precambrian cherts, however, contain no recognizable fossil remains other than the organic remains of algae; and it is doubtful that such algae secreted silica at that early evolutionary stage.

The interrelation of siliceous organisms, sedimentary deposits, and the geochemistry of oceans or lakes is fairly well understood. Most of the silica-secreting organisms require silica as an essential nutrient, usually coupled with phosphate. As a result, abundant populations of these organisms are found in those surface waters of the oceans overlying upwellings that supply sufficient quantities of nutrients from deep water, or in nearshore areas where nutrients are supplied from the land. Important locales for the supply of dissolved silica are regions surrounding active volcanoes or submarine extrusive volcanics, where the seawater becomes enriched in silica by the continuous alteration and hydrolysis of volcanic glass. In such regions the silica-secreting population more or less maintains a balance with the supply of dissolved silica; the solid biogenic amorphous silica sediments sink to the bottom of the sea. These organisms, then, are the vital link between volcanism and siliceous sediment formation. Such an association has been known for many years from work on bedded cherts in volcanic geosynclinal terranes, which are sites of ancient and modern mountain building.

The formation of siliceous sediments in some freshwater lakes is the result of much the same process, the abundance of dissolved silica promoting extensive growth of diatoms. In some alkaline lakes, however, the dissolved solids in the water inhibit or prevent much biological growth, and inorganic precipitates of silica may form. This process apparently occurs through an intermediate mechanism precipitating first a variety of sodium silicate (named magadiite for Lake Magadi in Africa) that later converts to free silica by the leaching of sodium. Such alkaline lakes are almost all restricted to volcanic-rich terrains, where the source of dissolved silica and alkalis comes from alteration of volcanic material, demonstrating again a clear relationship between volcanism and chert formation.

Origin of nodular chert. The origin of the nodular cherts is tied to a much different kind of environment. Where the bedded cherts show little or no evidence of postdepositional origin other than cementation and have every appearance of a primary sedimentary deposit, the nodular cherts in limestones appear to be almost entirely the product of diagenesis, whereby the rock is extensively altered after deposition. The evidence for this is the commonly seen replacement texture, in which primary sedimentary features, such as fossils, bedding, and oolites, are partially or completely replaced by secondarily precipitated silica. A key observation in such rocks is the presence of the remains of siliceous organisms in the chert nodule—usually sponge spicules and radiolaria in Paleozoic formations—and the absence of such fossils in the limestone bed between nodules. Because it is most unlikely that the original fossil distribution bore any relation to the nodules, which follow somewhat braided paths and cut across bedding, it must be concluded that

Role of organisms and their remains

Volcanism and the supply of silica in oceans and lakes

Chert nodules and horizons

the fossils were originally distributed more or less evenly through the largely limy sediment and that subsequently silica through much of the rock dissolved and reprecipitated as inorganic silica in the form of nodules. Such redistribution of silica in an early stage of diagenesis may have been caused by localized clumpings of decaying organic matter in the sediment. These could give rise to a lateral variation in pH (acidity-alkalinity index) and dissolved organic matter, both of which are known to affect the solubility of silica.

The nodules are typically distributed along some bedding planes but are absent in others, even though there seem to have been no obvious differences in permeability between the beds. This suggests that the beds that contain nodules were laid down during times in which the silica-secreting organisms were particularly abundant. The lateral variation between the occurrence of occasional nodules and their coalescence to form lumpy beds of continuous nodular chert suggests that the population of organisms increased toward the source of dissolved silica. Because there seems to be no association with volcanic activity for most of these formations, the source was probably solid and dissolved land-derived material from a nearby shoreline.

Siliceous
shales and
sandstones
and
nonbiogen-
ic silica

Mixed siliceous sediments. The mixed siliceous sediments, those intermediate between chert and shale or chert and limestone, are the products of varying amounts of dilution of the chemically precipitated silica by solid terrigenous detritus or by biogenically formed carbonate. Some highly siliceous shales have been shown to have formed by diagenetic redistribution of siliceous organisms; others show no identifiable fossil remains and may be the result of redistribution and cementation by non-biogenic silica. The source of the nonbiogenic silica may have been groundwaters that were enriched with silica by passing through volcanic rocks in some stage of weathering and alteration. By convention, siliceous shales do not include very silty shales, which contain large amounts of fine-grained detrital quartz and thus show high proportions of SiO_2 in a chemical analysis.

Many types of both clastic and chemical sediments may become impregnated with secondarily precipitated silica; sandstones that have become completely cemented by silica are the most common. If the original sandstone were composed chiefly of quartz grains, the cemented rock, which may have the appearance of a true quartzite in which the rock splits across the grains of sand, is practically a monomineralic rock. It is less common to find sandstones with smaller quantities of quartz completely cemented by silica. The silica may be the result of pressure solution, a process by which quartz grains dissolve at points of grain-to-grain contact and the whole rock loses pore space and becomes more compact. Other sources of silica are clay minerals, which under appropriate chemical conditions may transform to a less siliceous clay, releasing silica into solution in the process.

Modern siliceous analogues. Though contemporaneous siliceous oozes and freshwater silica deposits are clearly the modern analogues of the process that formed many of the ancient siliceous rocks, until recently there have been few observations in modern sediments of opaline silica forming as an early diagenetic product. Small amounts of opaline silica have been found in the Coorong Swamp, an intermittently hypersaline and desiccated inlet of the sea in South Australia. A program of deep drilling in the bottom sediments of the oceans of the world, initiated in 1968 by the U.S. National Science Foundation, has resulted in knowledge of the commonplace and relatively abundant occurrence of chert and other siliceous sediments in the stratigraphic columns beneath the deep sea. Such cherts appear to be similar to their ancient continental analogues and to have formed in the same way, that is, by diagenetic reorganization of a biogenic silica deposit. The evidence of these deep-sea cherts is proof that siliceous deposits need not be uplifted or subject to any special conditions to become cemented; the norm is an isochemical redistribution of silica, in which there is no addition or subtraction of material from outside the bed.

CHERTS IN THE GEOLOGICAL RECORD

Although cherts are widespread in the geologic columns of the continents, they are most prominent in two associations. These are nodular cherts occurring with shallow-water platform limestones (miogeosynclinal) and bedded cherts occurring with graywacke and volcanic rocks (eugeosynclinal). Both associations are known from all parts of the geological record. Most of the famous cherts come from the eugeosynclinal suite. The Arkansas novaculite comes from the eugeosynclinal sections of the Ouachita Geosyncline, the Alpine radiolarian cherts from the Tethyan eugeosynclinal facies, and the Franciscan and Monterey cherts (Figure 2) from the far western parts of the Cordilleran Eugeosyncline. Nodular cherts, less well known by formation name, are similarly distributed in the stable continental interior and shallow-water deposits of the major geosynclines of the world.

Figure 2 Lenticular chert beds along the Californian coast two miles northwest of Pismo Beach. The scale is five inches long.

Precambrian cherts are noted for a third association, that with bedded iron formations. The taconites of the Lake Superior region of North America are bedded cherts associated with some of the most famous iron ores of the world, an association which stimulated much speculation on its origin. No remains of possible silica-secreting organisms have ever been found in such Precambrian cherts; and there seems little basis for speculation that siliceous sponges and radiolaria had evolved that early but that all traces of them have been lost in subsequent diagenesis. It seems probable, rather, that these cherts are the product of chemical sedimentation in large lakes or arms of the sea, where the seasonal overturn of the water column (known in many modern lakes) would have given rise to seasonal alternations of silica and iron bands. There would have been no biogenic silica deposits and, in their absence, the solubility of amorphous silica could have been exceeded in such water bodies. Thus, the silica would have precipitated as a finely particulate gel that would quickly have dewatered and compacted.

Silurian Period

The time interval of 430,000,000 to 395,000,000 years ago is termed the Silurian Period. As indicated on the geological time scale (*q.v.*), the Silurian is a division of the Paleozoic Era. The rocks deposited during Silurian time comprise the Silurian System, which was named in 1835

Establish-
ment of
the Silurian
System

Table 1: General Subdivisions and Local Rock Sequences of the Silurian Period

Lower Silurian										Upper Silurian										series
Llandoveryan										Wenlockian		Ludlovian				Pridolian		stage

by Sir Roderick Impey Murchison after the warlike Silures. The latter were inhabitants at the time of the Roman occupation of the Welsh borderland where Murchison and his successors studied the complicated rock system of the type Silurian, subdividing it and establishing its graptolitic and shelly faunas as independent worldwide standards for correlation. In most of the rest of the world, however, the Silurian has, until recently, been one of the most neglected and thus most poorly known sequences—an ironic contrast to the wide attention given to the lower part of Murchison's original Silurian, the Ordovician, which was not split off as an independent system until 1879.

Rocks are identified as Silurian (or a specific part of it) from comparison of their contained fossils with those of the type marine sequence in Wales and Shropshire or in relationship to or correlation with other rocks so dated. By definition, therefore, the Silurian includes all deposits formed during the same time as those in the type sequence, regardless of origin, location, or local relationships. The principal Silurian subdivisions for selected regions are outlined in the accompanying correlation table, emphasizing marine sequences as the basic local standards (see Table 1).

Silurian deposits contain some of the earliest good fossils of various fishes, although fish originated tens of millions of years earlier. An aberrant possible vertebrate relative, *Monograptus*, the last surviving bladelike graptolite, burst into a flowering of short-lived species whose flexible external skeletons are used to divide the Silurian marine deposits of the world into time-equivalent zones. Also important in subdividing the Silurian marine deposits of the world into time-equivalent zones are the brachiopods and conodonts. The evidence of widespread Silurian marine shallow-water invertebrates and the sediments is interpreted to signify mild climates, not markedly zoned latitudinally.

The responses of Silurian rocks to local conditions of erosion and weathering account for some of the world's distinctive landscapes. Undercutting of weak sedimentary layers beneath massive Late Silurian dolomites at the outlet of Lake Erie created and maintains Niagara Falls. The picturesque glade country of Tennessee consists of isolated grassy areas on infertile shales surrounded by wooded areas on more calcareous shales or limestones of Late Silurian age. Beautiful Wenlock Edge in Shropshire is an east dipping Silurian limestone ridge, and much of Wales, the Lake District of England, and the Southern Uplands of Scotland are underlain by Silurian rocks. The Swedish island of Gotland is the type site of the Gotlandian; picturesque Visby, its capital and ancient Hanseatic harbour, is built around a Silurian reef limestone. In the U.S., Early Silurian sandstones crest many of the ridges in the central Appalachians.

Mountain-building deformation older than the oldest local Silurian deposits is indicated by Silurian overlap across folded Ordovician rocks in portions of the Acadian region of east central North America (Taconic folding or orogeny), the Angara Shield region of Central Asia (from the southeastern Altai, Sayan, and Tuva to the Amur River's middle reaches), a few restricted areas in northwestern Europe, and eastern Australia (Benambran orogeny). Similar relationships indicate later deformation between Silurian and overlying Devonian in eastern Victoria and New South Wales, Australia (Bowning orogeny), and in a few minor regions of northwestern Europe (Caledonian orogeny). Strong evidences of volcanism throughout the Silurian of portions of eastern Australia, a few localities within the Pacific border of North America, the Acadian region, the eastern Urals, and Kazakhstan and the thick sequences of coarse detrital sediments in eastern Australia, south Scotland, Ireland (except for the northern portions), western Scandinavia, and the eastern Appalachian trough, however, seem to imply continued crustal instability in the borderlands and the Ural-Kazakhstan region during the Silurian. Broadly speaking, however, the bulk of the Silurian sediments (platform carbonates, platform mudstones, and nonmarine platform sediments together with platform regions subject to subaerial erosion) indicate widespread shallow seas over the present

land masses of the Northern Hemisphere, both widespread shallow seas and low-lying land areas in Australia and South America, and land only in most of Africa below the Equator, as well as in Antarctica.

Silurian rocks have yielded about 10 percent of U.S. iron, 20 percent of its salt, and a little oil and gas. They also serve, especially where mainly limestone and dolomite, as host for many metallic mineral deposits, including important gold and tin ores in eastern Australia. And they are exploited industrially for cement, agricultural lime, and building stone. Petroleum from Algeria and Libya as well as the central Sahara is mostly from the Silurian.

This article treats the rocks, life, and environments of Silurian time. For additional relevant information, see also the articles EARTH, GEOLOGICAL HISTORY OF; ORDOVICIAN PERIOD; DEVONIAN PERIOD; SEDIMENTARY FACIES; STRATIGRAPHIC BOUNDARIES; PALEOZOIC ERA, LOWER; and FOSSIL RECORD.

SILURIAN ROCKS

Sedimentary rocks. Silurian rocks formed under differing local physical or chemical conditions, with differing sources of sediment supply, and various biologic migration routes. For this reason, they have a characteristic stamp, or facies, that may tell a great deal about their origin and ecology. Facies variations of rocks and accompanying fossil assemblages may be lateral (in space), vertical (in time), or both. Similar sedimentary facies that do not differ drastically in age, and some that do, are likely to contain similar fossils, and different facies of the same age ordinarily contain different assemblages of fossils (see also FOSSIL RECORD).

The stratigraphic correlation of unusual facies to deposits of known age is determined from field relations or is based on ubiquitous fossils of restricted time span. Species of graptolites, brachiopods, and conodonts, so characteristic of Silurian as well as of Ordovician beds, have proved especially useful in indicating the probable contemporaneity of contrasting sedimentary facies. Graptolites are generally excellent guide fossils that are interpreted as animals that floated at the surface of the water all or much of their lives instead of living somewhere below the surface like most planktonic species or floating only temporarily like the larval stages of so many aquatic organisms. This would explain their being buried, not only with the open-sea sediments of their normal living environment but also in many different shallow-water deposits, together with bottom-living shelly fossils.

Silurian stratified rocks may best be divided into the following broad categories: (1) platform carbonates (including both limestone and dolomite suite rocks), (2) platform mudstone, (3) terrigenous and volcanic (geosynclinal rocks), and (4) nonmarine. The usage of the term platform is here defined for the Silurian, as well as for the rest of the Early Paleozoic, as a large (minimum dimension in thousands of kilometres), relatively planar, vertically stable portion of a continent. The platform carbonate rocks are characterized by a relatively small thickness (seldom exceeding 300 metres but in a few minor instances reaching 1,200 or 1,500 metres) of either limestone and calcareous shale (limestone suite) or dolomite (dolomite suite) predominating over each other by a large factor except at major facies boundaries and including relatively minor amounts of clean-washed, well-sorted quartz sand, light-coloured nodular chert, glauconite, and nonmarine strata. The platform mudstones are characterized by a relatively small thickness (seldom exceeding 300 metres, except in central China where 1,200 to 1,500 metres is not unusual) of mudstone, shale, and siltstone, often highly carbonaceous and containing limestone nodules or concretions with less abundant interbeds of very argillaceous limestone. The terrigenous and volcanic rocks are restricted to the so-called geosynclinal regions, which, where present, border the Silurian platforms. The terrigenous and volcanic rocks are characterized by overall thicknesses of 3,100 to 4,600 or even 6,100 metres. Limestone is uncommon, never making up more than 5 percent of the total volume; dolomite is almost unknown. The predominant rock types in this category are sandstone containing much

Sedimentary facies and their distribution

silt and mud, graywacke, together with bedded chert and minor amounts of conglomerate made up chiefly of pre-Silurian rocks, plus large amounts of both light- and dark-coloured volcanic rocks in certain regions of certain geosynclines. Nonmarine rocks may occur on platforms, as broad, thin sheets of mudstone, siltstone, and sandstone or as restricted occurrences in the geosynclines.

The platforms of the Silurian include the following: (1) North American, (2) South American, (3) Old World, and (4) Australian. The North American Platform is characterized by a broad platform carbonate sheet extending from the Arctic islands to Mexico and from Anticosti Island to Nevada. Limestone suite rocks are peripheral to dolomite suite rocks. Terrigenous and volcanic geosynclinal rocks occur in the northern Appalachians from Newfoundland to Long Island Sound. These geosynclinal strata are bounded to the west by a linear island, Appalachia, which extended from the northern Gaspé region southwest along the Sutton Mountain, Green Mountains, Jersey Highland, and eastern valley and ridge regions to at least central Tennessee. Terrigenous rocks occur farther to the south in northern Alabama and Georgia as well as in the subsurface of northern Florida. On the southern border of the North American Platform occur the terrigenous rocks of the Ouachita Geosyncline in Oklahoma and Arkansas, as well as in the subsurface of adjoining states. On the west, the North American Platform is bordered by the poorly known terrigenous rocks (volcanic rocks are present in only a very minor amount) of central Nevada and Idaho, northern California, northeast Washington, southeast Alaska, western British Columbia, and the western Yukon Territory. The Silurian of the bulk of Alaska to the west of the Yukon Territory is too poorly known to be added to this picture. To the north of the North American Platform occur the widespread terrigenous sediments present in the northern Arctic islands of Canada and portions of northwestern Greenland.

The South American Platform is very poorly known but appears to consist of a northern and western half covered by platform mudstone and a southeastern portion possibly covered in part by nonmarine strata. Silurian geosynclinal rocks have not been recognized in South America.

The Old World Platform consists of a number of subdivisions. On the northwest it is bounded by the Caledonian Geosyncline, which is present in the western and northwestern portions of the British Isles and is concluded to extend into and through western Scandinavia (Norway west of the Oslo region and the mountainous border region of central Norway and Sweden), from where its northern limits are very uncertain. In the north central region the Old World Platform is partially divided by a geosyncline extending from the northern three-fourths of the north island of Novaya Zemlya down through the northeastern portion of the south island, northeastern Vaigach Island, eastern Pai-Hoi, the eastern Urals, and the entire southern Urals, plus Kazakhstan. This Ural-Kazakhstan Geosyncline, chiefly volcanic in character, appears to terminate in the middle of the Old World Platform against the west side of the Angara Shield. A third geosyncline, characterized by volcanics, may be present along the southeastern side of the Japanese islands. The western portions of the Old World Platform may be divided into an eastern half characterized by platform carbonates (this includes the Russian Platform plus its extension into portions of the Near East and Central Asia) and a western to southwestern half characterized by platform mudstones up to the Caledonian Geosyncline and bounding islands on the west and a shoreline region on the south extending from Sierra Leone to eastern Libya, southeastern Turkey, and then southeast into the Persian Gulf region. This shoreline region gradually prograded during the Silurian until by the end of the period it was situated as far north as central Algeria. South of this shoreline region in both Africa and Arabia was an area above sea level—with the possible exception of southernmost Africa, which may have been briefly subject to shallow-water sedimentation. It is possible that peninsular India was a part of this same great land area during the Silurian. In northeastern Asia the Siberian Platform seg-

ment of this Old World Platform extended from the Altai-Sayan-Tuva-Lake Baikal-Amur region on the south to the lower Yenisei through Kolyma region on the east, bearing a cover of platform carbonate rocks, which grades to the south into the nonmarine beds on the northern border of the Angara Shield. The precise eastern and southeastern as well as northern boundaries of the Siberian Platform carbonate rocks are unknown but may have extended well beyond the limits discussed here. The bulk of China, including the vast Yangtze River region, is characterized by thick platform mudstone in the lower half of the Silurian, succeeded by shelly sandstone on the north and shelly limestone on the south, which suggests that the Angara Shield to the north was rising during the latter half of the Silurian and shedding debris to both north and south. Southeastern Asia is characterized by the presence of both platform mudstone and platform carbonate rocks, with a common boundary extending southerly from the Shan states of Burma through the Isthmus of Kra into the vicinity of Kuala Lumpur.

Silurian rocks of the Australian Platform are virtually unknown except for a borehole penetrating carbonate rocks on Dirk Hartogs Island, the westernmost part of the continent; but it is concluded that most of this platform was subject to subaerial conditions—except for the easternmost fringe, which graded laterally into the Tasman Geosyncline, and possibly to the north in the Papua region.

Volcanic deposits. Volcanism is relatively subordinate during the Silurian as contrasted with some other periods. The most important site of Silurian volcanism is to be found within the Ural-Kazakhstan Geosyncline, where important centres of volcanism, chiefly andesitic and basaltic, extend along the east slope of the Urals from the polar through the central Urals, both east and west slopes of the southern Urals, and in Kazakhstan. Very minor dark-coloured volcanics of Late Silurian age exist in the Prague region, where they raised the sea bottom high enough locally to support a rich shelly fauna whose skeletal debris forms the fringing limestones of this area, which grade laterally into the typical deeper water platform mudstones so characteristic of North Africa and central and western Europe, as well as the Balkans and Turkey. Volcanics are also known from the southeastern Silurian deposits of Japan. Within the Caledonian Geosyncline, volcanics are very rare, known from only a few minor, scattered occurrences. Within the Appalachian Geosyncline, volcanics are abundant in a narrow belt extending from eastern Massachusetts through coastal Maine, adjacent New Brunswick, western Nova Scotia (westernmost portions of the Cobequid Mountains), Gaspé (central and southern), northern New Brunswick, northern Maine, and northern New Hampshire. In the Cordilleran Geosyncline, minor volcanics are known in the Klamath Mountains and southeastern Alaska. Within the Tasman Geosyncline of eastern Australia, minor occurrences of volcanics are known in eastern Victoria, eastern New South Wales, and possibly in Queensland.

SILURIAN LIFE

Characteristics and evolution. The record of Silurian invertebrate life shows an elaboration of Ordovician lineages. It has, however, novel and distinctive features of its own, such as expansion of the corals and echinoderms and a general evolutionary development of the dominant groups of brachiopods, graptolites, and conodonts. And it differs from the Devonian record in the types of corals and brachiopods present and in many less striking features. The faunal changes at both the Ordovician and Devonian boundaries may best be regarded as transitional, reflecting the slow progress of evolution.

Silurian fishes are the oldest preserved, except for isolated occurrences of fragments in the Middle and Upper Ordovician of the North American Rocky Mountains. Silurian plants also are the oldest preserved, except for questionable Cambrian plants reported from eastern Siberia, Estonia, and northern India and less doubtful Middle Ordovician plants recently described from near Prague. This distribution pattern is attributable to the rarity of preserved pre-Silurian terrestrial deposits.

The characteristics and evolution of Silurian or any other fossil life are of interest not only from an aesthetic and scholarly point of view but also because they provide us with a practicable means of consistently telling fossil time. Radiogenic methods of absolute age determination do not yet suffice for general dating or correlation of the Paleozoic rocks, even though a very few apparently reliable dates are used to set, approximately, the hands of the paleontological clock in terms of years. From the fossils also can be deduced much of the history, ecology, and geography of ancient times, always in connection with the characteristics and positions of the rocks. Ecologic deductions are greatly aided by the tracks, trails, and burrows of different organisms; these are almost the only traces of life in some deposits, such as the Silurian of the eastern Appalachian trough.

Invertebrates and associated fossils. In the Silurian, as with other fossiliferous rocks, the invertebrate and non-cellular (or unicellular) organisms are the true indices of time, on the basis of which nearly all meaningful stratigraphic correlation with the standard marine sequence is founded. The form sequence of the monograptid graptolites illustrates well how such correlation may be accomplished either by relating stage of evolution to time or by the empirical knowledge of the ranges of specific mor-

phologic types. Correlation, or paleoecological analysis, in practice, however, is also made by analysis of the total biotal characteristics of the problem sample, considered in relation to lithology and sequence of the enclosing sediments. Ranges of representative genera (shown in Table 2) illustrate how Silurian fossiliferous sediments can be dated, using apparent terminal ranges of a variety of fossils. (In Table 2 the symbols e, d, c, and f stand for *Microcardinalia triplesiana*, *M. raberensis*, *Plicostrophia castellana*, and *P. inultilata*, respectively.)

The graptolites, despite their suggested close alliance to the vertebrates, are at best invertebrate chordates and, in this sense, are among the most conspicuous and distinctive Silurian invertebrates. The monograptids are the evolutionary culmination of the simply saw-blade-like forms of graptolites and appear to be exclusively Silurian and Early Devonian.

Moreover, only a few species of two genera (*Diplograptus* and *Climacograptus*) of their Ordovician ancestors carried over into the Silurian, and these only into the lower part. The Silurian graptolite assemblage thus consists almost entirely of *Monograptus*, of short-lived derivative genera from it or older forms, and of occasional reticulate colonies such as persisted into the Devonian. The time subdivision of Silurian rocks is based largely on

short-ranged species of *Monograptus*, and many of the same species are present around the world.

Corals,
bryozoa,
brachio-
pods,
and
pelecypods

Corals and stromatoporoids are subordinate to the graptolites as Silurian time indicators but far ahead of them in range of evolutionary diversification. Compound corals particularly flourished, including the tabulates, which reached their greatest expansion, and fasciculate tetracorals, which did not attain their acme until the Devonian. Horn corals of simple types were more abundant and more complicated than Ordovician, less so than Devonian relatives. Stromatoporoids had also to await the Devonian for their climax, and no Silurian or other common Paleozoic coelenterate is anything like its modern relatives. Presumably, however, they did have the same alternation of sessile and free-floating generations as typifies the living representatives of the phylum, which would account for wide distribution of identical species in favourable environments. Unlike the graptolites, which apparently could drift even after death, they are not found far from their place of life except as a result of unusual events.

Bryozoa are about as common as they were in the Ordovician, with a slight dwindling of stony types and an increase of the more delicately ornamented twiglike cryptostomes. Locally they made small mounds at the bottom of the Silurian seas, as represented by the ball reefs of the Rochester Shale in western New York State.

Among Silurian brachiopods, the globular, short-hinged, and commonly large pentamerids were the most distinctive forms. Short-hinged, spire-bearing brachiopods were essentially new, although there are common Ordovician forms. The wide-hinged spiriferoids began the expansion that was to flower in Devonian and Lower Carboniferous time. A number of new genera and families make their first appearance near the base of the late Llandovery, the most marked faunal break occurring within the Silurian or even at its boundaries.

The pelecypods continued to expand slowly from Ordovician beginnings, and the prosobranch gastropods became important fossils in continuance of a long progressive expansion to modern times. Among the cephalopods, ammonitoid progenitors appeared and nautiloids dwindled. Some distinctive Ordovician groups of nautiloids were missing completely (e.g., Endoceratidae), and others died out during the Silurian (e.g., Ascoceratida). As if to emphasize their decline, no important new nautiloid groups appeared.

Trilobites
and
ostracods

Among the arthropods, trilobites continued their slow decline from a Cambrian maximum, and ostracods and merostomes both expanded slightly. Among the latter, eurypterids became much more common, while the aglaspids were missing, but xiphosurans ancestral to living *Limulus* are recorded. Ostracods are locally abundant and are useful Silurian index arthropods, particularly within the Appalachian region for the late Llandovery through Pridoli and in the Baltic region, coastal Maine, adjacent New Brunswick, and Nova Scotia for the Ludlow and Pridoli. Trilobites, despite their general decline showed an expansion of bizarre spiny types, perhaps as an adaptation to floating or camouflage, forced by increasing competition for the nutrient-rich bottom niches or predation. Allied developments may have caused the eurypterids to enter freshwater in later Silurian time, from which, according to one theory, they eventually chased the fishes.

Crinoids were the most successful Silurian echinoderms, enjoying their greatest recorded expansion of numbers and kinds. Unlike their commoner living relatives, these lilies of the sea were stalked forms; if they were equally colourful, their colonies must have been the showy marine gardens of Silurian time. Cystoids also were common and, although much more primitive, were similar in living habits and appearance to the crinoids.

Noncellular invertebrates, or the Protista (Protophyta and Protozoa), are abundant in some Silurian deposits. Chitinous and agglutinated Foraminifera have been described from North America, the Baltic, and England, and Radiolaria are occasionally reported, but little is known in detail of these Silurian records.

An important, but problematical, Silurian group is the Chitinozoa, consisting of minute, black, chitinous, vase-

shaped to club- or ball-shaped organisms. Equally important are the enigmatic, minute acritarchs. Revelation of such tiny organisms by chemical treatment of apparently unfossiliferous rocks sometimes permits the correlation of deposits whose position cannot be closely established by other methods.

Of growing importance are the conodonts, a group of toothlike objects of unknown affinity, and only recently intensively studied.

Fishes, land plants, and associated fossils. Silurian occurrences of fish and plant fossils are more numerous and complete than in older rocks. They are, however, mostly, though not entirely, restricted to the upper part of the system, and the fossils are not demonstrably more advanced than their predecessors. Conversely, they are greatly surpassed in number and variety by Devonian records. In the Late Silurian, in fact, the arthropods appeared to be making more headway than the vertebrates in colonizing the lands. The arachnids were represented by the scorpionid *Paleophonus*, from the Upper Silurian of both sides of the Atlantic. Millipedes are reported to occur in association with eurypterids (water-dwelling, scorpion-like creatures) in Wales. Neither scorpion nor millipede was surely air breathing, but both were at least evolving in that direction. In the estuarine to questionably marine or freshwater deposits, where the early fishes are most commonly found, is also an abundance of eurypterid remains. Indeed, the Silurian and Devonian saw the climax of this group, which comprised the greatest arthropod predators of all time, perhaps including principal foes of the early fishes and possible ancestors of the arachnids.

The simple, externally armoured, mainly backboneless, earliest fishes and the primitive early plant assemblages are discussed in a separate article on the DEVONIAN PERIOD.

SILURIAN PALEOGEOGRAPHY

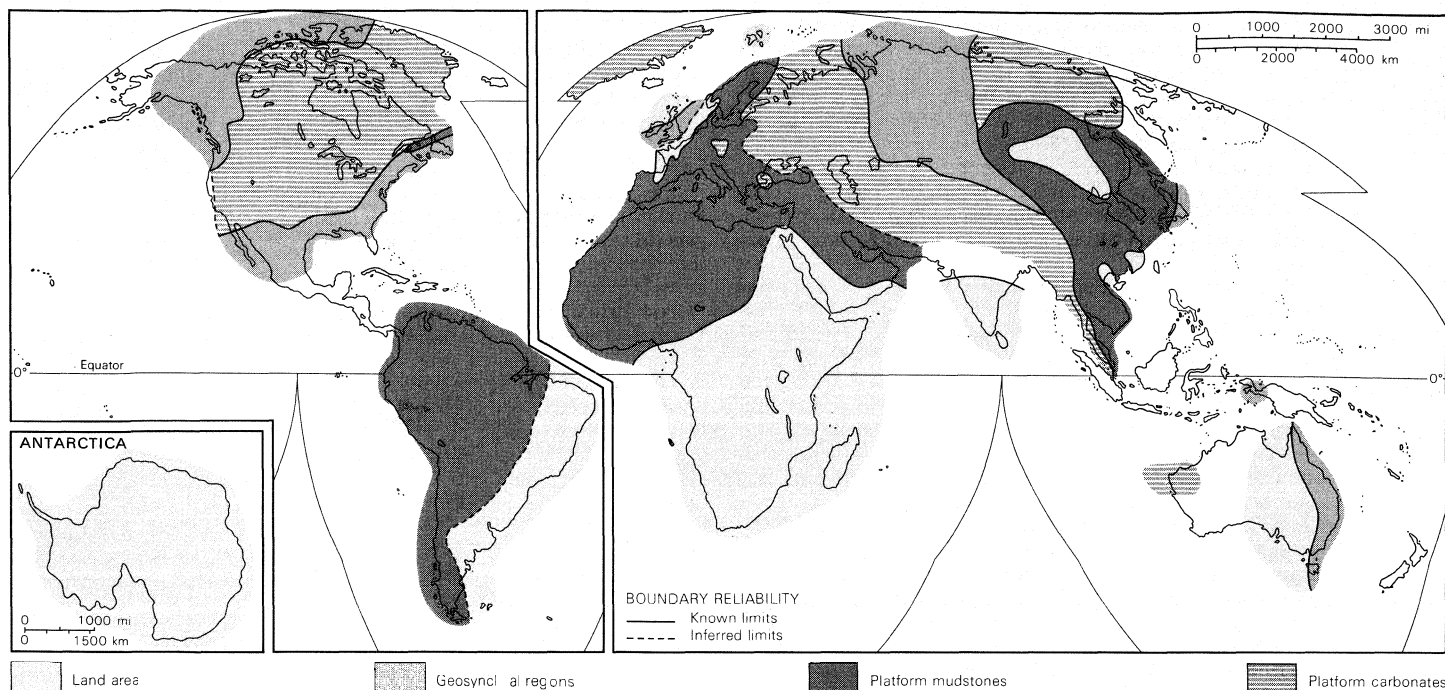

Continental stability. The vast continental platforms of the Silurian (Old World, Australian, North American, and South American) appear to have been very stable in a vertical sense, as shown by their relatively uniform veneer of platform carbonate, platform mudstone, and nonmarine sediments, considered together with the position of the strandlines and community boundaries. The strandlines and community boundaries provide third-order level lines of a sort. Evidences of intra-Silurian tectonism are almost wholly lacking except for the very minor Salinic Disturbance of the northern Appalachians. Minor disconformities upon the continental platforms record, at best, relatively trivial vertical movements.

Colonizers
of land
areas

Vertical
move-
ments
and
strandlines

Northwestward strandline migration from the central Sahara to Morocco and Algeria during the Silurian indicates a steady rising of that continent, but the total change in elevation is no more than a few hundred metres as indicated by the sediment thicknesses. Gradual sinking of a series of islands off the eastern coast of the U.S. and extending from north central Spain through northwestern France, south central England, and west central Scandinavia, occurred during the Silurian. Gradual shoreline migration to the south occurred during the Llandovery and early Wenlock Stages on the northern margins of the Angara Shield, followed by similar migration to both the south and north as the shield slowly rose again during the latter half of the Silurian. Shorelines gradually encroached upon the Russian platform during the Llandovery until by late Llandovery time it must have been completely covered. Geosynclinal records of marine sedimentation are in some regions quite complete, in others fragmentary. Where adequate information is available it is obvious that a complex geography—an alternation of islands (both volcanic and basement complex in type), shallow waters, and deeper waters—was present within the geosynclines.

Subsequent to the Silurian, large areas of the former platforms have been incorporated with younger geosynclines and orogenic belts, viz., Rocky Mountains, Atlas, Tíman, Hercynian chains of the Old World, Great Basin, Carpathians, Alpine chains of Europe and the Near East, Pyrenees, Cantabrians, Himalayan chains, Tien Shan, Sette-Daban, Altai-Sayan, Andean chains, and Southeast

Depositional regions during the Silurian Period.

Asian chains. It is obvious that the Silurian, as well as the preceding Cambro-Ordovician, was an interval of relative orogenic and geosynclinal quiescence, with the presence of vast, stable platforms, contrasting markedly with the smaller platforms and greater degree of orogenic and geosynclinal activity characterizing many subsequent time intervals (see also PALEOGEOGRAPHY).

Relative continental positions and sediment sources. The relatively uniform sheet of platform mudstone covering North Africa, Turkey, and the bulk of Europe west of the U.S.S.R., considered together with the shoreline extending across Africa from Sierra Leone to the Kufra Basin, coupled with similar relations in southeast Turkey and other portions of the Near East, indicates that this region formed one continental block during the Early Paleozoic (Cambro-Ordovician relationships are not far different). Relations between Asia and Eurafica plus the Near East are less certain, because of the paucity of data for the West Siberian Lowlands, Tibet, Afghanistan, Iran, and the Himalayan region, but there are no compelling reasons why Asia should have been dissociated from Eurafica during the Silurian. From a Silurian point of view, the modern Mediterranean Sea and its Tethyan predecessor are merely a more complicated Red Sea; *i.e.*, a portion of a shield (Arabian and Nubian in the case of the Red Sea) sundered subsequent to the Silurian.

The relative position of Australia is enigmatic, particularly in view of the total absence of information between Malaya and New Guinea. Possibly Australia has always been isolated.

The position of South America relative to Africa is equivocal: Silurian data are consistent with either continental drift (*q.v.*) away from Africa or for its present position having obtained during the Silurian. The position of North America vis-à-vis Europe is similarly equivocal from a Silurian point of view. Data for the Silurian on opposite sides of Bering Strait are too scanty to provide an adequate basis for speculation.

The source of terrigenous sediment poses serious questions about continental relationships. The platform mudstones of Africa, Europe, and the Near East may be easily accounted for by postulating Africa south of the central Sahara, plus portions of Arabia, and possibly peninsular India plus the western Indian Ocean as sources. The platform mudstones of South America are too poorly known, relative to possible sources upon that continent, to prove a problem at present. The platform mudstones of China and Southeast Asia may call upon the Angara Shield and

potential sources in the Yellow and South China seas. The Tasman Geosyncline may call upon the Australian Platform as a source. The Caledonian and Appalachian Geosynclines require exterior sources, but the available continental shelves may be adequate. The Franklinian Geosyncline as well as the terrigenous Silurian abutting the Kara Sea (chiefly in Novaya Zemlya and the Taimyr Peninsula) may require a source within the confines of the present Arctic Ocean. Too little is known of either the Cordilleran or Ouachita Geosynclines to make them worthy of consideration.

The presence of Silurian platforms adjacent to or near modern ocean shorelines raises questions about the permanence and relative position in time of the continents. Such problem areas include the abrupt termination of the North American Platform against the San Andreas-Gulf of California lineament, the termination of the Russian Platform carbonates against the White and Barents seas, of the Siberian Platform carbonates against the Laptev and East Siberian seas, of the Eurafican Platform mudstones against the Atlantic, of the South American Platform mudstones against the Atlantic and Pacific, of Africa south of the central Sahara against the Atlantic and Indian oceans, of southern Australia against the Southern (Antarctic) Ocean, and of the platform carbonates of Southeast Asia against the Bay of Bengal. There are at present no satisfactory solutions, although continental drift and oceanization have been offered. Continental drift would, in some cases, bring together regions of widely contrasting geology, *viz.*, Australia and Africa or southern Asia, or require the removal of large segments of present continents (the bulk of Central America) or open up vast chasms for which no geological evidence exists (a wide separation between southern Turkey and Syria). Oceanization, on the other hand, requires such vast transfers of material within the mantle and deeper crust of the earth as to beggar the imagination of the geochemist and geophysicist (see SEA-FLOOR SPREADING; ISLAND ARCS; and EARTH, STRUCTURE AND COMPOSITION OF).

Climate and general ecology. Widespread reef formation by Silurian corals and stromatoporoids (hydrozoan relatives) couples with the evidence for high calcium metabolism furnished by laterally equivalent limestones and dolomites to imply extensive warm, shallow seas in present continental areas and little latitudinal or seasonal temperature variation. Interference of mountainous tracts with prevailing winds or other special meteorologic cir-

Silurian evidence of continental drift

cumstances created local conditions in the middle latitudes such as those under which the Late Silurian salt and gypsum deposits of New York State and the Michigan Basin originated. If deposits, interpreted as glacial, in Bolivia, northern Argentina, and Africa prove to be basal Silurian, they would suggest conditions adequate to support basal Silurian continental glaciation (see also CLIMATIC CHANGE). Silurian animal community distributions are consistent with this glacial hypothesis, but the absence of proved tillite in intervening Brazil is still puzzling.

The relatively cosmopolitan shallow-water Silurian invertebrates of the Northern Hemisphere suggest the presence of widespread, uniform conditions under which migration from one region to another was unhindered. This situation contrasts strongly with that existing during the preceding Late Ordovician interval and the succeeding Early Devonian interval, both times of high provincialism relative to the Silurian. (Low-level provincialism does, however, exist during the Silurian.) Combined ecologic, lithologic, and biogeographic data suggest that South America south of Venezuela, Europe (south from Brittany and the Caucasus), the Near East, and Africa may have possessed a climate cooler than that existing in such places as North America, northern Europe (including the Urals), Central Asia, Siberia, eastern Asia and Australia.

Ecological
variation
and
environ-
mental
factors

Principal ecologic variations appear to have been connected with physical, chemical, and biologic factors. Faunas best interpreted as marine and indicative of hypersaline conditions are known in the Late Silurian of the Michigan Basin and adjacent areas and are characterized by an abundance of ostracods (chiefly smooth), eurypterids, and a few other invertebrates, including mollusks and brachiopods. Faunas best interpreted as brackish occur in a few regions, including parts of the central Appalachians, the Welsh Borderland, Midland Valley of Scotland, Tuva, and the Siberian platform, for which a mixture of lingulid and rhynchonellid brachiopods, homolanotid trilobites, fish, eurypterids, and the bellerophonitid gastropod *Plectonotus* are characteristic. Nonmarine deposits are characterized chiefly by an association of fish together with certain types of eurypterids. The reef environments, which have been little investigated ecologically, appear to have provided a multitude of niches controlled in all probability by both biologic and physicochemical factors. The ecologic influence of depth and temperature, or more probably temperature varying directly with depth, has been considered for the Silurian shallow-water marine animal communities. In those portions of the Northern Hemisphere inferred to have been relatively warm, there is a definite sequence, proceeding away from the shoreline toward deep water, of shallow-water animal communities. At the shoreline is found a *Lingula* community, followed away from the shoreline successively by an *Eocoelia* community, a *Pentamerus* community, a *Stricklandia* community, a *Clorinda* community, and finally a pelagic community characterized by graptolites to the exclusion of most shelly organisms. The depth control of these communities is confirmed by a few occurrences of interbedded lava flows, which when thin do not alter the sequence of communities but when thick result in nearer shore; *i.e.*, shallower water communities occurring on top of the flows and farther from shore; *i.e.*, deeper water communities below. The occurrence of the pelagic community next to the *Lingula* community in those portions of the Northern Hemisphere concluded to have been relatively cool suggests that water temperature is ecologically the most important variable controlling the distribution of Northern Hemisphere and Australian shallow-water marine invertebrates. Otherwise the absence in this vast region of the *Eocoelia* through *Clorinda* communities is difficult to explain. The sole exception to these generalizations is in the Istanbul region, where late Llandovery *Stricklandia* and Llandovery through Pridoli age shells occur. Recent studies are developing a depth zonation for Paleozoic graptolites, including Silurian plankton, by comparing Paleozoic plankton faunas with benthic faunas whose depth values are known.

WORLD DISTRIBUTION OF SILURIAN DEPOSITS

The paleogeographic map (see the Figure) shows where Silurian marine deposits and nonmarine regions of different ages might have been in existence on the present continental areas. Naturally a map for any instant of the 30,000,000 years or so of Silurian time would look different in detail from this highly generalized scheme, particularly if the Paleozoic condition of the ocean basins were known. This map and the correlation table together give a general view of Silurian stratigraphy and paleogeography that supplements the condensed discussion of outcrop regions below.

Great Britain. Silurian sediments of the type region in Wales and western England and extending into southern Scotland were deposited in a northeast-southwest-trending subsiding area (the Caledonian Geosyncline) and bordering shelf seas to the east. The basin or geosynclinal facies is characterized by graptolite-bearing slates and shales, flaggy and shaly siltstones, sandstones, and mixed, coarse detritus about 5,000 to 10,000 feet thick. This facies is typically developed in Wales, the Lake District of northwestern England, the Southern Uplands of Scotland, and much of Ireland. The shelf facies consists of shales (including mudstones), limestones, and siltstones with a shelly fauna and a maximum thickness of perhaps 1,000 metres in typical development. It thins eastward to disappear toward the inferred Silurian seashore in the subsurface of central England. Complete gradation in sedimentary facies, thickness, and fauna occur from shelf to basin along the margins of the subsiding trough, with some persistent zones of graptolitic shale that correlate between facies and record the history of downwarping. The type area of south Wales and the Welsh borderland is intermediate between extreme developments of either shelf or basin facies. Northward in the Midland Valley of Scotland, the sediments suggest approach toward the northwest side of the geosyncline as is also true in portions of northwestern Ireland.

At many places in the Welsh borderland the oldest Silurian deposits in Britain are separated from underlying rocks by unconformity. Preceding crustal movements, of which the profuse Ordovician volcanicity is one indication, may have brought the southeastern part of the British subsiding area generally above water in the waning stages of the Ordovician. Subsidence, with sharply waning volcanism, was almost immediately renewed, however, and continued intermittently to near the end of the Silurian. Onset of the Caledonian orogeny, chiefly at the end of the Early Devonian, forever reversed the process and made mountains where the sea had been from Wales to Scandinavia.

Subdivisions of the British sequence are shown on the correlation table. The oldest interval, the Llandoveryan (or Valentian), saw the beginning of a sharp distinction between basin graptolitic shale facies and calcareous and, in part, sandy shelf facies. This distinction was well marked in the Wenlockian or middle division, when the importance of the calcareous facies was increased by growth of coral-stromatoporoid reefs and colonies on the shelf. In Ludlovian time the same distinction continued. It finally disappeared in Pridoli time with the cessation of marine conditions coincident with the lower half of the Downtonian.

European continent. The same Caledonian Geosyncline, in and along which were deposited the Silurian sediments of Britain (except for eastern England), continued northeastward to western Scandinavia, with a bordering shelf sea that extended eastward. Best known Scandinavian sequences are in southern Norway, southern Sweden, and Gotland. That of south Sweden (Skåne) is a somewhat deformed but essentially complete platform succession of graptolitic shales with limestone interbeds increasing toward the top. This grades northwestward to the fine-textured and richly fossiliferous, but also structurally disturbed, intermediate to platform facies of limestones and shales north of Oslo. Southeastward it goes into the thin, calcareous, relatively flat-lying platform facies of Gotland and Estonia. Later Caledonian deformation from a northwest direction folded the Norwegian sequence and

Caledonian
Geo-
syncline
deposits

Scandi-
navian
sequences
and facies

that of south Sweden but did not noticeably affect Gotland or the eastern Baltic. The Silurian section of Gotland, important because it comprises the type Gotlandian (synonym of Silurian as here used), is a thin but richly fossiliferous succession of limestones and calcareous shales. Many of the hills (klintar) of Gotland are coral-stromatoporoid reefs, marvellously exposed for study.

Between the Baltic and Brittany, the Silurian is represented by shales and mudstones rich in graptolites and a few pelecypods, with small amounts of limestone, commonly strongly metamorphosed and discontinuous. Eastward in the Harz and Thuringian uplifts the section is similar. The Armorican Massif itself (Brittany) displays the same Silurian facies—500 metres or so of graptolitic, black shales with sandstone at the base.

In the Bohemian (or Czechoslovakian) Massif around Prague is the famous Silurian sequence of Joachim Barande and J. Perner, which is somewhat deformed by post-Middle Devonian movements. This is prevailingly of graptolitic shales with at first inconspicuous limestone bands. The calcareous fraction increases toward the top until the whole sequence goes over to gray and black limestones, with both bedded and reef facies and some volcanics. Total thickness is somewhat under 200 metres. This sequence represents a large span of Silurian time during which sediments presumably accumulated in a relatively shallow sea connected with Brittany and surrounding regions as far distant as North Africa. Similar well-known exposures are present in the Montagne Noire of south central France, Sardinia, Spain, the eastern Bavarian Alps, Austria, Romania, Poland, Denmark, Yugoslavia, Greece, Bulgaria, Portugal, and Andorra.

U.S.S.R. Platform carbonates rim the Russian Platform, including occurrences in the Baltic states, Volhynia, Podolia, Odessa, the west slope of the Urals from the central Urals north, Timan, Kanin Peninsula, western Pai-Hoi, southwestern Vaigach Island and south island of Novaya Zemlya, and the southern quarter of the north island of Novaya Zemlya. Similar carbonates occur in Russian Turkistan and may well have been continuous with those of the Russian platform as well as the Chinese Tien Shan. Geosynclinal accumulations of mudstone, siltstone, and related clastic rocks occur in northern and northeastern portions of Novaya Zemlya, Vaigach, and Pai-Hoi. The eastern slopes of the Urals, both slopes of the southern Urals, and Kazakhstan are occupied by geosynclinal deposits of volcanic type. The Altai–Sayan is occupied by interbedded carbonate and terrigenous sediments intermediate in character between those of the geosyncline and the adjacent Siberian Platform. The Siberian Platform (including the Kolyma Massif and the Sette–Daban Silurian) is covered by a thin veneer of carbonate rocks and subordinate shale. The Silurian carbonates of both Severnaya Zemlya and the New Siberian Islands are probably isolated portions of the Siberian Platform. On the northwest of the Siberian Platform, carbonates grade into the graptolitic clastic rocks of the northern Taimyr Peninsula. To the south the Siberian platform Silurian abuts the near-shore sediments of the southeastern Altai–Sayan, Tuva, and the Amur region, which flanked the emergent Angara Shield.

Near East. The Silurian of the Near East is merely an extension of that present in North Africa. Platform mudstone rich in graptolites occurs widespread in Turkey, grading to the southeast into near-shore sandstones. Similar sandstones with rare marine intercalations occur in Syria, Jordan, and Saudi Arabia. Graptolitic mudstones occur in southwestern Iran, and carbonates in central and northeastern Iran.

Asia. Silurian platform carbonates that were originally continuous with that of the Russian Platform occur in Afghanistan, Kashmir, Spiti, Nepal, the Shan states of Burma, and the western portions of Malaya bordering the Straits of Malacca. Platform mudstone is widespread in eastern, southeastern, and central China, extending south into northern Thailand, Indochina, and the eastern part of Malaya. Minor land areas are believed to have been present in southeastern China. During the upper half of the Silurian, the graptolitic platform mudstones of China

gave way to shelly limestone to the south and shelly, clastic rocks to the north. The Silurian of Japan contains carbonate rocks in the north and volcanic, clastic, and carbonate rocks elsewhere.

Australia. The known Silurian of Australia is limited to the eastern coast (Victoria, New South Wales, and Queensland) and Tasmania. Known Silurian sections consist dominantly of fine clastics. Interbedded with these locally are graptolitic shales and limestones or calcareous shales with a shelly fauna and volcanics. Northeast of Melbourne are clastic beds that represent the whole of the Silurian. In the Yass district of New South Wales the section is only about 1,000 metres thick but is famed for the rich and beautifully preserved fossils of its Yass Beds and Lower Hume Limestones and Shales. In eastern Victoria and New South Wales the Ordovician and Silurian are separated by an orogenic interval, the Benambran orogeny. Silurian crustal unrest culminated with compressive movements and deep-seated igneous intrusions locally (eastern Victoria and adjacent New South Wales) termed the Bowring orogeny and considered a phase of the more inclusive Caledonian orogeny. When the Devonian seas reinvaded eastern Australia their deposits came to rest on the folded and erosionally truncated edges of such eastern Silurian rocks.

On the west, Silurian carbonates, dated by conodonts, are known from a borehole on Dirk Hartogs Island, the westernmost point of the continent. To the north, graptolitic Llandovery shale and limestone containing corals are known from two areas in Papua. (Geologically New Guinea and the Sahul shelf form part of Australia.)

South America. The poorly known Silurian of South America may be divided into the marine-platform mudstones known in the north (Venezuela and the Amazon region of Brazil) and west (Bolivia, Argentina, and Paraguay) and the possibly Silurian nonmarine rocks known in portions of the continent from southeastern Brazil to the Falkland Islands and southern Argentina.

Africa. Platform mudstones rich in graptolites and certain pelecypods are widespread in North Africa from Sierra Leone on the southwest to the Kufra Basin on the Egyptian–Libyan frontier. To the southeast of this line they grade into nonmarine beds. This shoreline gradually migrates during the Silurian, until near the end of the period it comes to rest in Morocco and Algeria far to the northwest. This regional shift results from the Silurian marine beds to the southeast, representing only a fraction of early Llandovery time, whereas those to the northwest represent the entire period; *i.e.*, North Africa was gradually rising during the Silurian. Glacial tillites are known from the very base of the Silurian in parts of Africa. A single occurrence of shallow-water invertebrates in the Table Mountain Sandstone of South Africa of probable late Llandovery–Wenlock age represents the only marine Silurian south of the Sahara. The intervening region was above sea level during the Silurian.

North America. The widespread Silurian deposits of North America may for convenience be considered under the following categories: (1) platform carbonates of the continental interior and (2) terrigenous geosynclinal deposits: (a) Appalachian Geosyncline, (b) Ouachita Geosyncline, (c) Cordilleran Geosyncline, and (d) Franklinian Geosyncline. The platform carbonates are well known in both the surface and subsurface, as indicated in the following list of occurrences: Anticosti Island, northwestern Gaspé, western portions of the central and southern Appalachians, surface and subsurface of the midcontinent (including western Pennsylvania, New York, Ontario, Ohio, Michigan, Wisconsin, Illinois, Kentucky, Indiana, Iowa, Kansas, Nebraska, northwest Alabama, Missouri, Arkansas, and Oklahoma), Llano region of Texas, Permian Basin of Texas and New Mexico plus outcrops in southeastern New Mexico and western Texas, Hudson Bay region of Ontario and Quebec, Lake Timiskaming, Laramie Range of Wyoming, Great Basin (including western Utah, southeastern Idaho, eastern Nevada, southeastern California), Chihuahua, possibly southern Sonora, Williston Basin (including the Dakotas, Wyoming, Saskatchewan, and Manitoba), southern British Colum-

Australia

Deposits
of the
Russian
and
Siberian
platforms

Appalachian deposits of Silurian age

bia, northeastern British Columbia, central and eastern Yukon and Northwest territories, southern portion of the Canadian Arctic Archipelago, southern Baffin Island, Foxe Basin region, and portions of northwestern and northeastern Greenland.

The Appalachian geosynclinal deposits are widespread from northern Newfoundland southwest through Nova Scotia, New Brunswick, Quebec south of the St. Lawrence River, Maine, and New England from the Connecticut River region east and south to Long Island Sound. The Appalachian geosynclinal Silurian is separated from the platform carbonates by a linear island Appalachia, which shed clastic debris to both east and west to form dual aprons of both nonmarine and marine clastic rocks paralleling the shorelines. This island gradually submerged during the Silurian until, by Pridoli time, it formed only a small fraction of its early Llandovery extent. Sedimentary iron ores, Clinton Ores, are near-shore phenomena known on the west side of Appalachia intermittently and are of varying ages from New York to Alabama. Similar iron deposits related to land areas are also known in the Silurian of northern Maine and Nova Scotia.

Ouachita geosynclinal deposits are known from exposures in Arkansas, Oklahoma, and Tamaulipas, plus subsurface occurrences in Texas and Mississippi.

Cordilleran geosynclinal deposits are known in a north-south strip extending from near Bishop, Calif., through central Nevada to southeastern Idaho, in northern California (Klamath Mountains and Taylorsville district), northeast Washington (Metaline quadrangle), northern British Columbia, adjacent Yukon and Alaska (Road River Formation), and in southeastern Alaska.

Franklinian geosynclinal deposits are known from the northern parts of the Canadian Arctic Archipelago (Cape Phillipa Formation, Cape Rawson Formation, and their clastic equivalents) and portions of northwesternmost Greenland.

Isolated occurrences in central and western Alaska as well as in the subsurface of northern Florida are difficult to relate to the aforementioned units and may represent remnants of additional major platforms of platform carbonate (Alaska) and platform mudstone (Florida) character.

BIBLIOGRAPHY. RODERICK IMPEY MURCHISON, "On the Silurian System of Rocks," *Lond. Edinb. Dubl. Phil. Mag.*, 7:46 (1835); *The Silurian System*, 2 pt. (1839); and A. GEIKIE, *The Founders of Geology*, 2nd ed. (1905), are of historical interest. The basic sources today are the Silurian Correlation charts now being published by the Geological Society of America, edited and written by W.B.N. BERRY and A.J. BOUCOT, with many co-authors. These charts present the physical and biological bases for correlation in some detail and outline the rock types, paleogeography, fossil zonation, and paleoecology for the Silurian Period and System. W.B.N. BERRY and A.J. BOUCOT, "Pelecypod-Graptolite Association in the Old World Silurian," *Bull. Geol. Soc. Am.*, 78:1515-1522 (1967), gives the evidence for concluding that Silurian deposits of the Mediterranean region were deposited under a colder regime than that occurring to the North; "Continental Stability—A Silurian Point of View," *J. Geophys. Res.*, 72:2254-2256 (1967), presents additional evidence.

(A.J.Bo.)

Silver Products and Production

For thousands of years silver has been used for its aesthetic and monetary value. Today it is fundamentally an industrial commodity and will become even more so in the future. In the early 1970s the United States became the last large nation to eliminate silver from all coins, though some smaller nations retained it.

Silver is in the precious-metal group because of its scarcity and price. Although it is widely distributed in nature, the total amount in the Earth's crust is quite small compared with other metals. As a consequence it costs about 500 times more than iron and about 50 times more than copper. Among the noble metals, however, it is relatively abundant and costs about $\frac{1}{20}$ as much as gold and $\frac{1}{50}$ as much as platinum. Noble metals are not easily changed to an oxide form by air or oxygen and consequently can

be found in the elemental form or as an alloy in nature. They can be used for electrical contacts at which arcing (sparking) occurs, and they are excellent conductors of electricity. Silver is the best conductor of electricity and heat among all metals and is used as the electrical and heat-conductance standard against which other metals are measured in percentage terms. Copper, for example, has a relative electrical conductance of 95 percent and a thermal conductance of 73.7 percent.

Because of its resistance to atmospheric oxidation, as well as its beauty and value, silver has been used since antiquity for ornaments, jewelry, and coins. It is the whitest of all metals and has excellent ductility and malleability; pure silver, however, can be easily scratched and tarnishes quickly in the presence of certain sulfur compounds. Silver objects have been found in ancient tombs unaffected by air pollution but have tarnished rapidly in areas in which coal containing sulfur is burned. The reflectivity of silver, particularly to that part of the spectrum visible to the human eye, is one of the highest among metals. When properly polished and under favourable conditions, about 95 percent of the light striking the surface is reflected. Further information on physical and chemical properties of silver and its occurrence is contained in the articles TRANSITION ELEMENTS AND THEIR COMPOUNDS and NATIVE ELEMENTS.

History. The Latin name for silver is *argentum*, meaning white and shining, and from it the chemical symbol Ag was obtained. Silver ornaments, vessels for ceremonial services, and decorations have been found in royal tombs dating back to 4000 BC. The Egyptian Code of Menes, about 3000 BC, decreed that "one part of gold was equal to two and one-half parts of silver in value," perhaps the first gold standard. Records show that gold and copper were the first metals to be worked by man, with silver third. The Romans, who probably advanced the science of metallurgy further than any other people up to their time, had large plants to produce silver for ornaments and decoration. The Roman process, in which the silver was separated from the ore by heating in a furnace, was used throughout the Middle Ages, when silver-copper mines were worked in central Europe. In the 16th century the Spaniards discovered enormous silver deposits in South and Central America, and during the 19th century, a so-called patio process, involving grinding silver ore in the presence of salts, water, and mercury to make an amalgam (alloy), was developed in Mexico. The amalgam (mercury and silver and gold if present) was heated in a retort to drive off the mercury, leaving the silver and gold; the mercury was recovered by condensation. Spanish America supplied the world with silver until the Comstock Lode strike of 1859 in the Sierra Nevada area in the United States.

The cyanide process (*see* below), developed in the latter part of the 19th century, is still used today for ores containing only gold and silver values. About 1910 a froth flotation process was introduced. In this process, particles of sulfides of copper, lead, and zinc containing small amounts of silver and gold are made to adhere to rising air bubbles, which are skimmed off. The froth flotation process today accounts for about 75 percent of the world production of silver.

Occurrence. In the early 1970s, most of the silver produced from ores was associated with the sulfides of lead, copper, and zinc. These so-called argentiferous ores may contain from a trace to several thousand troy ounces of silver per ton of ore. Precious metals are generally sold by troy ounces, one troy ounce equalling 31.1 grams, or 1.097 avoirdupois ounces.

Unlike gold, silver is found in many naturally occurring minerals. The most important is galena (lead sulfide), followed by argentite (silver sulfide), cerargyrite (or chlorargyrite; silver chloride), polybasite (silver antimony sulfide), proustite (silver arsenic sulfide), pyrargyrite (or stephanite; silver antimony sulfides), and others. Deposits of native silver (generally an alloy) are commercially important and widespread. Sylvanite (gold and silver telluride) ores are of commercial value in some areas. Arizona, Utah, and Colorado in the United States are

Silver ore associations

Comparison with other noble metals

large producers of silver as a by-product from copper, lead, and zinc ores. Low grade porphyry copper ores mined in Arizona assay about 0.6 percent copper and about 0.1 ounce of silver per ton of ore. In Canada, silver is found in the Canadian Shield around Sudbury, Ontario, as part of the nickel-copper-cobalt ores, in British Columbia, and in the Yukon Territory. Large silver deposits at Cerro de Pasco, Peru, have been worked since the 17th century. Mt. Isa and North Broken Hill in Australia are becoming large producers.

Extraction and refining. Many methods are employed for the extraction of silver or silver and gold from ores, scrap, alloys, and used photographic materials. Most of the silver produced today is a by-product from the treatment of copper, lead, and zinc ores, and consequently any large increase in silver implies an increase in copper, lead, and zinc or vice versa. Silver occurring with copper ores is first extracted with the copper and recovered as a silver-gold anode mud after electrolysis. Silver occurring with lead ores is recovered from the lead bullion as a silver-gold dross (see LEAD PRODUCTS AND PRODUCTION). Silver occurring with zinc ores, which also contain lead, is recovered with the lead bullion as a by-product (see ZINC PRODUCTS AND PRODUCTION).

The cyanide process is generally used on ores that contain only silver or silver and gold as the valuable constituent. The ore is pulverized and leached with a dilute sodium cyanide water solution. The silver and gold form water-soluble sodium-silver-gold complexes. The resulting mixture is filtered and the solids discarded. The filtrate is generally treated with finely divided zinc dust that causes the silver and gold to precipitate from the solution. This precipitate is filtered off, melted, and cast into bullion bars.

Silver is recovered from used photographic film by burning the film and dissolving the silver in the ashes with nitric acid. The silver is precipitated with sodium chloride and the resulting precipitate filtered off and cast into bars. Silver is also recovered from photographic processing solutions by replacing the silver with another metal, such as zinc, by electrolysis or by chemical precipitation with chemicals such as sodium hydroxide or sodium sulfide.

The method used in refining the crude silver or silver-gold bullion obtained from these metallurgical processes depends upon its purity and the amount of bullion to be refined. For bullion containing a large amount of impurities, smelting in a small furnace with lead oxide, fluxes, and a reducing agent produces slag that is further processed in a lead smelter. The resulting lead bullion, containing the silver and gold, is melted in the presence of air. The oxidized lead (a liquid oxide) is evaporated or absorbed by a cupel (holding vessel), a process called cupellation. The end product is an alloy of silver and gold called doré, a high purity alloy. The cupel material (the liquid lead oxide absorber) can be cement or bone ash.

The two most important methods for separating silver and gold in silver-gold bullion are electrolysis and parting. In electrolysis, a silver nitrate water solution is employed, with silver, gold bullion, or doré serving as the anode (positive electrode). Pure silver is deposited at the cathode (negative pole), which can be a pure thin sheet of silver or stainless steel. The resulting cathode silver or silver stripped from the stainless steel cathode is melted and cast into bars assaying about 999.0+ fine of silver. Gold is recovered from the anode mud.

Silver and gold alloys are stated in terms of fineness, given by the parts of silver or gold per 1,000 of alloy. Sterling silver contains 92.5 percent silver and 7.5 percent of another metal, usually copper as a hardening agent; such silver is therefore 925 fine.

In the parting, or wet, method the doré or silver-gold bullion is placed in a bath of hot concentrated sulfuric acid or strong nitric acid, and the silver is allowed to dissolve. Gold is recovered from the residue. The clear solution contains a soluble silver sulfate or nitrate; it is treated with ferrous sulfate to precipitate the silver, which is filtered off and melted into bars assaying 995+ fine of silver. This method is applicable to doré or very high purity silver-gold bullion containing two or more

parts of silver to one part of gold. Additional silver may be added to achieve this ratio, as ratios of less than two to one will not dissolve in the acid.

Uses. *Pure metal applications.* In the 1970s coinage accounted for only about 8 percent of the world's silver production. The rest went to industrial production, with photography accounting for about 30 percent of this total, a proportion expected to increase in the future. Photographic silver is used in the form of halides, such as silver bromide. Television cassettes contain film using silver halides. Electrical and electronic equipment also accounts for a large percentage of silver consumption. Silver solders are used extensively in refrigeration units, air conditioners, automobiles, and electrical appliances. Brazing, soldering, and welding use substantial amounts of silver. Silver-copper alloys are used in welding and, in some cases, as contacts in relays for computers, tabulators, and other applications requiring high strength at elevated temperatures. Inexpensive though intricate electrical circuits for radios, television, computers, and other electronic devices may be made by stamping or printing a given circuit on insulating panels with silver ink. Silver is used in certain cold epoxy solders to bond microminiature electronic devices without heat and in some electronic adhesive applications. Silver-magnesium-nickel alloys are used for high thermal-conductivity applications and relay switches operating at high temperatures. Silver coatings on ceramics, glass, mica, and other insulators are widely used in electronic devices.

Silverware, plated and sterling, takes another large share of the production. An average sterling teaspoon contains about one ounce of silver. Electroplated ware also takes a considerable amount of silver. Thin plates of silver for bone replacement in the human body, silver wire to prevent movement of broken bones, and drainage tubes of silver are useful in medicine because the silver exhibits germicidal properties. These properties may result from the ability of silver to absorb oxygen. Liquid silver, for example, can absorb about 20 times its volume of oxygen. Silver water purifiers developed to make water bacteria free for space explorers are now also used by campers and sportsmen. High-silver batteries, requiring less space, maintaining higher voltages, and lasting longer than conventional batteries, are used for such applications as hearing aids. Because of the higher power per unit of weight, silver batteries are used in space travel, submarines, and portable television cameras.

Manufacturers of airplanes and diesel locomotives have been using a silver-base-alloy bearing containing 3 to 5 percent lead, which is much less subject to seizure (freezing) than Babbitt metal and has excellent oiliness under severe conditions. Because of its excellent reflectability, silver is used extensively as a coating on glass and other materials for making mirrors. Coatings may be applied in many ways, but generally the process uses an ammonium hydroxide-silver nitrate solution, which is applied to the surface, and a reducing agent, such as sugar, Rochelle salt, or formaldehyde, which is added to precipitate a layer of metallic silver. The process is hazardous because of the formation of ammonium nitrate; explosions may occur on the slightest disturbance.

Silver in colloidal form (very fine particles) is used as a catalyst in certain vapour-phase organic chemical reactions, such as the manufacture of various types of alcohols. Cesium-silver alloys are used in some types of photoelectric cells. Dental amalgams are alloys of silver-tin-mercury that can be molded at temperatures of the mouth and harden quickly to give a polished surface.

Silver is also used in the manufacture of jewelry and art objects. Jewelry silvers are alloys containing around 80 percent silver and 20 percent copper.

Applications of compounds. Silver is easily tarnished by sulfur, sulfur oxides, and hydrogen sulfide. The black tarnish can be removed by household silver polish, which generally contains fine abrasive material, or by an electrolysis kit that removes the tarnish with no loss of silver. An antitarnish dip of 1.5 percent tin chloride water solution, used for five to 30 seconds and followed by a water rinse, may prevent tarnishing. Silver dissolves rapidly in

Silver
coatings

Electrolysis and parting

strong or dilute nitric acid to form water-soluble silver nitrate. Silver nitrate solutions are used as fungicides in treating certain plants for disease control and as a starting point to make other materials, such as silver for photographic film and plates and for mirrors. The halogen compounds of silver are by far the most important; silver bromide makes possible the modern photographic industry. In photography the glass plate or film merely serves to hold the light-sensitive emulsion, generally silver bromide crystals, in suspension in some type of a gelatin. Silver chloride, a white crystal material practically insoluble in water, is made by adding hydrochloric acid to a silver nitrate solution. Silver iodide, a yellow crystal material, is made in a similar manner. In 1946, testing began on the use of finely divided silver iodide, which has a crystal structure similar to ice, for cloud seeding to produce rainfall, dissipate fog, and reduce the violence of hurricanes and hailstorms. Its effectiveness is open to some question, but one ounce of silver as silver iodide under the right conditions might produce as much as 3,000,000 gallons of water as rain.

Argentite fluoride (AgF_2), a dark brown solid formed when fluorine reacts with argentous fluoride (AgF), is a powerful oxidizing agent and a good fluorinating agent. Silver sulfadiazene is used in preventing infection resulting from burns because it combats bacteria by attacking the wall and not the nucleus of the cell.

Economic importance. Total world production of silver in 1980 was about 340,000,000 troy ounces, of which about 52 percent was derived from ores of the Western Hemisphere and about 9.1 percent (31,000,000 troy ounces) from the United States. Other major producers that year were Mexico (15.1 percent), the Soviet Union (13.5 percent; smelter and/or refinery production), Peru (11.9 percent), Canada (9.8 percent), and Australia (8.1 percent). India probably has the world's largest supply of refined silver, with about 4,000,000,000 ounces in the form of artifacts.

BIBLIOGRAPHY. A. BUTTS and C. COXE, *Silver: Economics, Metallurgy, and Use* (1967; repr, 1975), contains recent information on silver in general. J. NEWTON, *An Introduction to Metallurgy* (1938), is an excellent book for general fundamentals concerning extractive metallurgy. THE AMERICAN SOCIETY FOR METALS, *Metals Handbook*, 8th ed. (12 vol., 1961–), is a standard reference handbook for properties and selection of metals. UNITED STATES BUREAU OF MINES, *Minerals Yearbook* (annual), gives statistics on production, value, and location for all metals and nonmetals.

(S.L.Sm.)

Simpson, George Gaylord

Through his studies of the early history of mammals, George Gaylord Simpson established himself as one of the leading paleontologists of the 20th century. Among his important contributions were his studies of South American mammals, which shed much light on the subject of the intercontinental migration of animal species.

Simpson was born in Chicago on June 16, 1902, and received his doctorate from Yale University in 1926. He chose for his thesis the mammals of the Mesozoic Era, which are important for the understanding of mammalian evolution, but evidence of their existence consists mainly of tantalizing fragments of jaws and teeth. The materials were located chiefly in the Peabody Museum at Yale and the British Museum in London. Simpson produced substantial quarto monographs on the two collections, making his reputation as an able worker in mammalian paleontology.

In 1927 he joined the staff of the American Museum of Natural History, New York City, where he was to continue research in paleontology for three decades. The first 15 years were highly productive; he published about 150 scientific papers, many of considerable importance. A few dealt with lower vertebrates, but nearly all were on mammalian paleontology. In his first years in New York City he was interested in the fauna of the later Tertiary and Pleistocene of Florida, and he published a number of works on this topic. For the most part, however, his interests were in the early history of mammals, and most

of his publications in the 1930s were concerned with this field. He studied the Cretaceous mammals of Mongolia and North America, especially the Paleocene fauna of the latter continent. This resulted in a major work on the Paleocene fauna of the Fort Union Formation of Montana, in which about 50 mammals of a variety of primitive types were found. The breadth of his studies of mammalian evolution led to the writing of a detailed classification of mammals that is standard in the field.

In the Tertiary a series of mammalian fauna lived in South America that were quite unlike those of any other continent. Those of the late Tertiary and Pleistocene forms were fairly well known, but little was known of the earlier history of the peculiar South American groups. Hence, in the early 1930s, he made three expeditions to Patagonia to collect new material and re-study specimens already described; as a result of these efforts, the early history of the Tertiary mammals of South America became vastly better known. He published several dozen papers on these forms in the late 1930s and afterward two volumes summarizing their early history.

During World War II Simpson served the U.S. Army in staff work, principally in North Africa. On his return to the American Museum, he became curator in charge of the active department of paleontology, as well as a professor at Columbia University. This restricted the time available for research, but his scientific productivity remained undiminished. While his descriptive work in paleontology continued, his interests spread to other fields. The possibility of applying mathematical methods to paleontology had already led to his coauthorship of a work on quantitative zoology. A consideration of the successive faunas of the various continental areas led to studies of the problems of the intercontinental migrations of animal species. Problems of taxonomy and classification are intimately connected with evolutionary studies, and, in addition to giving a thorough consideration of principles of classification in his work on mammalian classification, he published in 1961 a volume on *The Principles of Animal Taxonomy*. In a series of lectures on *The Meaning of Evolution*, which appeared in book form in 1949, he discussed the philosophical implications of the acceptance of evolutionary theory, which attracted worldwide attention. In the postwar period there was a renewed study of evolutionary theory by geneticists, systematists, and paleontologists. Simpson took a major part in such studies; his principal publications in the area were his volumes *Tempo and Mode in Evolution* (1944) and *Major Features of Evolution* (1953).

In 1958 Simpson left New York City to spend a decade as an Alexander Agassiz Professor of Paleontology at the Harvard Museum of Comparative Zoology. After that he moved to Tucson, Arizona, where he was professor of geosciences at the University of Arizona. (A.S.R.)

Sinai Desert

The Sinai Desert forms a triangular peninsula linking Africa with Asia. It lies between the Gulf of Suez and the Suez Canal on the west and the Gulf of Aqaba and the Negev desert on the east, and it is bounded by the Mediterranean Sea on the north and the Red Sea to the south. It has an area of 23,500 square miles (61,000 square kilometres). Its greatest dimensions are about 130 miles from east to west and about 240 miles from north to south. Usually regarded as being geographically part of Asia, the Sinai Peninsula (Arabic: Shihb Jazirat Sinā') is the northeastern extremity of Egypt and adjoins Israel and the Gaza Strip on the east. The peninsula and the Gaza Strip were occupied by Israeli forces during the Arab-Israeli War of 1967. After the signing of a peace treaty between Egypt and Israel in 1979, Israeli forces began a withdrawal from the peninsula that was scheduled to be completed by 1982.

The earliest written information about Sinai dates from 3000 BC, when the ancient Egyptians recorded their exploration there in search of copper ores. But the name Sinai seems to have been known much earlier and may have been derived from the original name of one of the most

Evolutionary theory

Work in mammalian paleontology

ancient religious cults of the Near East, that of the moon god Sin. Mt. Sinai is famous as the scene of the giving of the Law to Moses, but there is doubt as to which of the mountains of Sinai is the actual site.

The landscape. *Relief.* Sinai occupies an ancient block, a portion of the African Precambrian Shield (more than 570,000,000 years old) that rose between two rifted areas and became tilted down in a northward direction and, between the Precambrian and the Quaternary Period (which began 2,500,000 years ago), was subject to both long and short transgressions of the Tethys Sea and, later, of the Mediterranean Sea. The Sinai Desert is separated by the Gulf of Suez and the Suez Canal from the Eastern Desert of Egypt, but continues eastward into the Negev desert without marked change of relief.

Two principal regions may be recognized in Sinai. The first region is the southern complex of high mountains, including such peaks as Mt. Catherine (Jabal Katrinah), which is 8,668 feet (2,642 metres) high; Umm Shawmar, 8,482 feet high; ath-Thabt, 7,997 feet high; and Jabal Mūsā, or Mt. Sinai, 7,497 feet high. The region is essentially comprised of igneous rocks and is sharply incised by deep, canyon-like wadis (seasonal watercourses) that drain toward the Gulf of Suez or the Gulf of Aqaba. This gaunt mountain mass is separated from the Gulf of Suez by a narrow coastal plain, but on its eastern side it rises precipitately from the Gulf of Aqaba. The second region, flanking this mass on the north and forming two-thirds of Sinai, is a great plateau sloping from heights of more than 3,000 feet downward to the Mediterranean. It is characterized by the extensive plain of Wadi al-'Arish, by a number of island-like massifs, and by broad western and northern coastal plains with extensive sand dunes.

Drainage. A conspicuous ridge runs from the south around Sinai in a great horseshoe curve, from which three main drainage basins have developed. The northern (or Mediterranean) drainage basin, in which Wādī al-'Arish acts as a master stream, empties into the Mediterranean near the town of al-'Arish. The eastern (Gulf of Aqaba and Dead Sea) basin and the western (Gulf of Suez) basin are both drained by a number of small streams.

The Sinai Desert receives more than 1,600,000 acre-feet (2,000,000,000 cubic metres) of water annually from local precipitation. About one-fourth of this water flows on the surface as runoff, and a similar amount percolates to groundwater reservoirs, thereby offering excellent opportunities for water conservation.

Soils. In Sinai, metamorphic rocks and igneous rocks predominate in the south, sedimentary rocks (mainly limestone) in the centre and north. Such rocks are either barren or covered with a mantle of young, unconsolidated deposits that are provisionally termed soils, although they lack organic matter and appear to be undeveloped. These soil deposits can be classified as rock debris (20 percent), desert detritus (50 percent), subdesert soils (25 percent), and hydromorphic soils (those formed by water; 5 percent). The rock debris is dominant in the south. The desert detritus occurs in the centre and north and includes the stretches of alluvial soils of Wādī al-'Arish and the dune complex of northwest Sinai. The subdesert soils include loesslike deposits and are found in the northeast and parts of the western coastal plain. The hydromorphic soils, which are localized in the northwest corner, are related to the soils of the Nile but have been subjected to strong salinization processes.

Climate. Sinai falls within the great arid belt crossing northern Africa and southern Asia. Aridity is manifested in Sinai by a degraded soil surface, sand-dune expanses, salinization, and dry watercourses (wadis). That less arid climatic conditions formerly prevailed is demonstrated by occasional terraces of thick alluvial and lacustrine deposits. In the northern, or Mediterranean, region of low relief, the climate in winter is unstable, with relatively high rainfall (five inches, or 125 millimetres); in summer it is dry and intensely hot, and in spring and autumn it is unstable again, with khamsin winds and occasional torrential rain. In the southern, or Red Sea, region, the climate differs because of the mountainous nature of the terrain. The prominent peaks are covered with clouds throughout

the year and with ice in winter. Again, in winter the rainfall is relatively high; in summer, rare monsoon winds from the southeast account for heavy rainfall. Nights are cold, even though the summer heat is intense.

In northern Sinai the average maximum winter temperature is 68° F (20° C), while the minimum is 45° F (7° C); the summer maximum averages 99° F (37° C) and the minimum 64° F (18° C). In southern Sinai the maximum winter average is 81° F (27° C), while the minimum is 55° F (13° C); the summer average maximum is 95° F (35° C), while the minimum is 77° F (25° C). In Sinai, prevailing light winds come mainly from the north. Storm winds, with velocities in excess of 34 knots, occur only once every three years in the north. Relative humidity is generally high on the coasts, reaching 74 percent along the Mediterranean and 60 percent along the Red Sea. Foggy intervals vary from four to six days a month in northern Sinai to one to three days a month in central Sinai.

Vegetation and animal life. Vegetation in the Sinai Desert is mostly ephemeral, but perennial scrub survives on the steep southern slopes and on the plateau to the north. Succulents and salt-tolerant plants are found on the subdesertic coastal plains, and medicinal and fodder plants are widely distributed. There are six ecological zones—the northern, the western, and the narrow eastern coastal plains; the central isolated domes; the south-central tablelands; and the southern mountain complex.

Animals are rare, but the species represented include ibex, gazelles, sand foxes, leopards, wildcats, jackals, hares, hedgehogs, and moles. Falcons and eagles are indigenous, and there are also seasonal migrants such as quail, partridge, and grouse.

The inhabitants. The scanty population of Sinai (170,000 in the late 1970s) is mostly concentrated in the northern fringe, where water supplies are adequate, as well as in the western fringe, where petroleum and manganese industries have been developed. About 80,000 are settled, and 90,000 are Bedouin. The limited number of Israeli settlements established in 1967–79 along the northern coast and along the Gulf of Aqaba were scheduled to be evacuated by 1982. The settled population is engaged in agriculture and land reclamation and in the petroleum, mining, and fishery industries.

The wandering Bedouin tribes migrate, seeking water and pasture—few are attracted to industry or agriculture. They comprise southern and northern groups. The southern group, known as Twara, inhabits all Sinai south of Darb al-Hāji; the principal tribes of this group are the Eleigat of northwest Sinai, the Sawallha of southwest Sinai, and the Umm Zeina of east Sinai, particularly along the Gulf of Aqaba. The northern group has no distinctive title and consists of a collection of tribes who have mostly migrated from Arabia. It includes principally the Tarabin (the largest tribe in Sinai), the Tiaha of east central Sinai, the Hueitat of west central Sinai, and the Aiada and the Eheiwat of northwest Sinai.

In the mountainous south, a community of Eastern Orthodox Christian monks lives in the Monastery of St. Catherine, which was founded by the emperor Justinian in AD 527. Construction of a prayer centre opposite the monastery for Muslims, Christians, and Jews was planned in the early 1980s.

Transport and communications. The banks of the Suez Canal are connected by the Ahmed Hamdi tunnel, located about 10 miles north of Suez. Opened in 1980, it was the first connection of the Nile Delta with the paved roads in Sinai. There is also a ferry crossing at Port Said.

Before 1936 the principal roads were desert tracks running from west to east. The northernmost of these was a track linking al-Qanṭarah on the Suez Canal with Rafah on the Mediterranean coast. There are two central tracks—the Syrian track, which runs between Ismailia on the canal and Abii 'Uwagilāh, and a track running from Suez to al-Quşaymah via al-Hasana (a route known since the 16th century BC). The southernmost track is the most important in Sinai and is variously known as Darb al-Hāji, al-Darb as-Sultany, or Darb al-Khuttalia; dating from the 13th century BC, it was the pilgrims' road running from Suez to Aqaba via an-Nakhl.

After 1936, paved roads and railway lines were constructed in Sinai for military purposes. Still more roads were constructed after World War II and, particularly in the west and southeast, after the war of 1967 for military purposes and to serve the petroleum industry and tourism. Paved roads in Sinai have a total length of more than 2,000 miles (3,200 kilometres).

The 250 miles of railway lines in Sinai were destroyed during and after the war of 1967, but three main railway lines (northern, central, and southern) with a length of about 500 miles are planned. The telephone network in Sinai was almost destroyed in 1967, and a new network was under construction in 1980. There are four civilian airports and landing strips in Sinai at al-'Arish, Abii Rudays, at-Ṭūr, and St. Catherine. Two other military airports were to be transferred to civilian use by 1982.

Three small harbours are located at Abii Zanimah and at-Tiir on the Gulf of Suez and at Sharm ash-Shaykh at the southern tip of the peninsula. In 1980, there were plans to construct a main harbour at al-'Arish and a fishery dock at al-Bardawil and to modernize the existing harbour at at-Ṭūr. At Abii Rudays, at-Ṭūr, al-Balā'im, and Sudr, crude oil is pumped into tankers through hoses.

Natural resources. *Water resources.* Surface water is supplied by the many usually dry watercourses, which become filled with water during rainy years (usually once every decade). The most important of these water supplies is that contributed by the Wādī al-'Arish Basin, which drains an area of about 7,700 square miles. Attempts to conserve the surface water in this wadi, as well as in many others, began in prehistoric times. A masonry dam was constructed across Wādī al-'Arish at ar-Ruāfa, some 30 miles south of al-'Arish, in 1946. The initial capacity of that dam was estimated at 100,000,000 cubic feet. Groundwater is provided by natural springs, shallow, hand-dug wells, and deep-drilled wells.

Water-bearing strata

Geological strata containing water consist of the Nubian Complex, fissured limestone, marly sandstone, and calcareous sandstone. In the Nubian Complex, water is stored under pressure; in some localities of lower altitude, it gushes strongly to the surface, and it will rise under pressure to a maximum height of 750 feet above sea level in central Sinai and 150 feet above sea level in west Sinai. The amount of potable water stored in the Nubian Complex has been estimated at 65,000,000 acre-feet (80,000,000,000 cubic metres). The fissured limestone occupies about 50 percent of Sinai's area; its potential as a groundwater carrier is little understood. Some natural springs in northeast Sinai receive their water supply from it. The amount of potable and brackish water stored in the fissured limestone has been estimated roughly at 24,000,000 acre-feet. Marly sandstone strata occur in west and north Sinai and form an aquifer of secondary importance, containing 2,400,000 acre-feet of brackish water.

Calcareous (chalky) sandstone strata, locally known as al-Kurkar, are found only in the coastal zone between al-'Arish and Rafah, but also extend farther eastward into the Gaza Plain. Al-Kurkar forms a basin within which water exists under pressure; it accumulates from both local and regional precipitation, as well as through upward leakage from underlying water-bearing layers.

In addition to all these strata, 1,200,000 acre-feet of water from recent wadis and sand-dune areas are the main source of water for shallow, hand-dug wells.

Mineral resources. Since the time of the ancient Egyptians, Sinai has attracted miners. Mineral ores considered feasible for exploitation include manganese (with reserves estimated at 3,800,000 tons), kaolin and fire clay (8,300,000 tons), gypsum and anhydrite (212,000,000 tons), glass sands, carbonaceous clay (75,000,000 tons), and coal (90,000,000 tons in two localities). Other deposits include copper ores, phosphates, iron ores, lead and zinc, sulfur, feldspar, quartz, black sands, bentonite, tungsten, and uranium. Building stones, dolomite, sands and gravels, marble, cement material, and pumice await future urban and industrial use. In 1980, there were plans to reconstruct the ferromanganese plant at Abii Zanimah.

Petroleum

Petroleum, first discovered in 1910 in Jabal Tanakah, in west Sinai, is the most important mineral exploited in

Sinai. Petroleum production was begun by large petroleum companies in 1935, especially in north central and west Sinai. Deep drilling operations begun in 1944 led to the discovery of oil fields at Sudr, 'Asal, Matārimah, Fayrān, al-Balā'im, and Abii Rudays. Further drilling, both on land and offshore, allowed for the discovery of more oil fields, some of which are among the largest known, in western Sinai and a gas field at al-'Arish. Plans for further oil exploration in Sinai in the 1980s were ambitious. Between 1921 and 1980, petroleum production in Sinai increased from about 200 to about 7,000,000 tons.

Agricultural resources. Although the agricultural potential of Sinai is high, its few inhabitants engaged in agriculture are predominantly concerned with the grazing of livestock and in the seasonal cultivation of such crops as barley, melons, and castor-oil plants. Date palm groves are widely distributed, and the total number of trees is about 1,000,000. Irrigation with water pumped from shallow groundwater sources is practiced in the deltaic portions of watercourses and along the coastal zone east of al-'Arish. Important sites of cultivation are al-'Arish, al-Kharruba, ash-Shaykh Zuweid, and Rafah along the Mediterranean; Qaṭia and Bir al-'Abd to the south of al-Bardawil; 'Uyūn Mūsā, Sudr, Abii Suwayrah, Gharandal, Abii Zanimah, and at-Ṭūr along the Gulf of Suez; and Wādī Fayrān, in south Sinai.

(Ab.A.S.)

Sind

Sind, or Sindh, is the southeastern province of Pakistan. Bounded by the neighbouring Pakistani provinces of Punjab and Baluchistan on the north and west and India on the east and southeast, it extends along 150 miles of the Arabian Sea coast on the southwest and covers an area of 54,407 square miles (140,913 square kilometres).

Sind is essentially part of the Indus River Delta and has derived its name from that river, which has been known to the people as the Sindhu. The province of Sind, which had a population of about 18,500,000 in 1978, was established in 1970, with the integration of Hyderābād and Khairpur Divisions and the District of Karachi. The city of Karachi, with a population in 1972 of 3,469,000 (metropolitan area), is the provincial capital. (For related physical features, see INDUS RIVER; THAR DESERT.)

History. The Indus civilization, represented by the archaeological findings at Mohenjo-daro, Amri, and Kot Diji, existed from 2300 to 1750 BC, after which there is a gap of more than a millennium before its earliest recorded history began, with Sind's annexation to the Persian Empire under Darius I (reigned 522–486 BC). Nearly two centuries later, Alexander the Great stormed through the region in 326 and 325 BC. After Alexander's death, Sind came under the domination of the empires of Seleucus Nicator, Candragupta Maurya (305 BC), the Indo-Greeks and Parthians (3rd–2nd century BC), and the Scythians and the Kushāns (100 BC–AD 200). Under the Kushān emperor Kaniška (c. AD 78–103), Sind embraced Buddhism. From the 3rd to the 7th century, the area remained under the Sāsānids, and Sind came to be ruled by the Samma chiefs of the local Rai Dynasty as feudatories of Persia. A Brahmin priest subverted Samma rule in 622 and brought Sind under Brahmin rule, which ended with the Arab invasion in 711.

The Indus Valley civilization

The Arab conquest of Sind heralded the entry of Islam into the subcontinent. As-Sind included the present Sind, Baluchistan, and southern Punjab; it became an administrative province of the Umayyad and 'Abbāsīd empires from 711 to c. 900, with its capital at al-Manṣūrah, 45 miles northeast of Hyderābād. With the weakening of central authority in Baghdad, the Arab governors in as-Sind established their own dynastic rule during the 10th century. The first Sindian dynasty of the Sūmrās was established between 1058 and 1348 and was followed by the Samma Chiefs of Sind from 1349 to 1520.

Over the next two centuries Sind came under the outside domination of the Arghūns (1520–56), the Tarhāns (1556–96) and the Mughals (1591–1700), followed by the independent Sindhian dynasties of the Kalhōrās (1700–82) and the Tālpur Baluch (1782–1843), who lost Sind to the British in 1843. Except for the princely state of Khairpur, all of Sind was annexed to the Bombay Presidency. In 1937 it was established as a separate province; but after Pakistan independence, it was integrated into the province of West Pakistan from 1955 to 1970, together with Khairpur state. Upon dismemberment of the province of West Pakistan in 1970, Sind was re-established as a separate province.

The landscape. Relief. From north to south, Sind assumes a pattern of three parallel belts—a central stretch of rich alluvial plain bisected by the long, winding, silvery line of the Indus, flanked on the west by the rocky range of the Khirthar Range and bounded on the east by a sandy desert belt.

The Khirthar Range consists of three parallel tiers of ridges. The easternmost section is steep on the west but has a long gradient to the east. The central ridge has flat tops and rounded sides broken by deep ravines and fissures, whereas the westernmost tier consists of a vast plateau or tableland with some peaks rising above 7,000 feet. This mountainous belt has little soil and is mostly dry and barren. The easterly desert region first appears in the north as low dunes and vast flats. Continuing southward, the Achhrro Thar (White Sand Desert) occurs in the middle of the belt and is followed by the Thar Desert (*q.v.*) in the southeast.

The central riverine belt—360 miles long and about 20,000 square miles in area—constitutes the Valley of the Indus. The fertile plain, gradually sloping down from north to south, in its long gradient forms the three flat regions known as *sirō* (the upper), *vichole* (the middle), and *larr* (the lower). The variety of soils includes *pakki*, or *patt*, the flat level land of old alluvium forming the northern strips of the Sukkur, Jacobābād, and Lārkanā districts; *reti-wari*, the soft reddish rocky soil of the belt skirting the northwesterly rocky range; *kacho*, the fertile silt alluvium in the narrow inundated belt of the Indus; *wariasi*, an admixture of soft clay and sand; *chiki*, the composite fine clay and soft sand on both sides of the inundated belt; and *kalar*, or alkaline soil, found mostly in the *larr* region.

Climate. A subtropical region, Sind is hot in summer and cold in winter. Temperatures frequently rise above 115° F (46° C) between May and August, and the minimum average temperature of 36° F (2° C) occurs during December and January. The annual rainfall averages about seven inches, falling mainly during July and August. The southwesterly monsoon wind begins to blow in mid-February and continues until the end of September, whereas the cool northerly wind blows during the winter months from October to January.

Vegetation and animal life. Except for the irrigated Indus Valley, the province is arid and has scant vegetation. The dwarf palm, *kher* (*Acacia rupestris*), and *lohirro* (*Tecoma undulata*) trees are typical of the western hill region. In the central valley, the babul tree is the most dominant and occurs in thick forests along the Indus banks. The *nim* (*Azadirachta indica*), *bēr* (*Zizyphus vulgaris*) or *jujuba*, *lai* (*Tamarix orientalis*), and *kirirr* (*Capparis aphylla*) are among the more common trees. Mango, date palms, and the more recently introduced banana, guava, orange, and *chiku* are the typical fruit-bearing trees. The coastal strip and the creeks abound in

semi-aquatic and aquatic plants, and the inshore Indus deltaic islands have forests of *timmer* (*Avicennia tomentosa*) and *chaunir* (*Ceriops candolleana*) trees. Water lilies grow in abundance in the numerous lakes and ponds, particularly in the lower Sind region.

Among the wild animals, the *sareh* (Sind ibex), *urial* or *gadh* (wild sheep), and black bear are found in the western rocky range, where the leopard is now rare. The *pirrang* (large tiger cat or fishing cat) of the eastern desert region is also disappearing. Deer occur in the lower rocky plains and in the eastern region, as do the *charakh* (striped hyena), jackal, fox, porcupine, common gray mongoose, and hedgehog. The Sindhi phekarī, red lynx or caracal cat, is encountered in some areas. *Phar-rho* (hog deer) and wild bear occur particularly in the central inundation belt. There is a variety of bats, lizards, and reptiles, including the cobra, *lundi* (viper), and the mysterious Sind krait of the Thar region, which is supposed to suck the victim's breath in his sleep. Crocodiles are rare and inhabit only the backwaters of the Indus and its eastern Nāra channel. Besides a large variety of marine fish, the plumbeous dolphin, the beaked dolphin, rorqual, or blue whale, and a variety of skates frequent the seas along the Sind coast. The *Pallo* (sable fish), though a marine fish, ascends the Indus annually from February to April to spawn.

The people. Population groups. Although the population is of mixed ethnic origins, the background of many groups remains visible. The Indus Valley of Sind has been the terminal for sizable migrations, particularly from the west. Of the more ancient groups of Panyas, Takkas, and Mēds, only the progeny of the Mēds has survived as the Mehs, or Muhannas—the professional fishermen living along the Indus and its channels, around the lakes, and in the southern deltaic region. Among the other ethnic groups who form the bulk of the indigenous population are Sammas and the related Lakhas, Lohānās, Nigamaras, Kahahs, and Channas; the Sahtas, Bhattis, and Thakurs (the present Sodhas of Thar Pārkar) of Rājput origin; and the Jāṭs and Lorrās, both admixtures of the ancient Scythian and the later Baluch peoples. The Jokhia, Burfat, and other sizable ethnic groups inhabiting the western rocky region also appear to be the remnants of early indigenous groups. With the advent of Islam (711), a number of groups of Arab, Persian, and Turkish origin settled in Sind, the most numerous of whom were the Baluch who, beginning from the 13th century, migrated to Sind and made it their second homeland after Baluchistan.

A great change occurred in the composition of the population with the influx of Muslim refugees from India after the partition of the subcontinent in 1947. As early as 1951, more than four persons in every 10 in Karachi and more than one in every 10 in the rest of Sind were refugees from India. Earlier, since the opening of irrigation barrages on the Indus in the 1930s, there had also been a regular flow of settlers from the other present-day Pakistani provinces. Thus, the ethnographic pattern of Sind continues to undergo a change that is marked and visible.

Sindhi, Seraiki, and Baluchi are the main indigenous languages spoken in Sind. Besides the standard Sindhi speech of the middle Sind region, Sindhi is spoken in five main dialects. Brahui is spoken in the northwestern districts by the migrating communities from Baluchistan; and Dhatki—a dialect of Rajasthani—is spoken in southeastern Thar Pārkar District. With the entry of numerous linguistic groups from India, varieties of languages have come to be spoken in the urban areas. Of these, the most numerous is Urdu, followed by Punjabi, Gujarati, Rajasthani, and Pashto. In schools, English is taught as a compulsory foreign language in upper grades and is spoken by all educated adults.

Most of the population is Muslim. The Hindus of Thar Pārkar District and the Christians and Parsis (Zoroastrians) of the city of Karachi constitute the province's minority religious groups.

Patterns of settlement. The ever-increasing population, large-scale immigration, and the process of agricultural development and industrialization have changed the

settlement pattern in both rural and urban areas. The population has doubled since 1947 and is concentrated in the cities and the irrigated central valley. With the extension of the irrigation system of the Indus, areas formerly barren have come under cultivation, and the semi-nomadic way of life has changed to that of permanent settlement. In 1947, some 15 percent of the population was urban; by the early 1970s the percentage had increased to 45. This trend towards urbanization is part of the historic process, but agricultural development since the 1930s and rapid industrial expansion since the 1950s have lent momentum to it.

Urban and industrial growth

The process of industrial growth has entailed alterations in the population's occupational structure, whereas large-scale movements have tended to accentuate local inequalities in the scope of social and economic development.

A number of urban areas have grown significantly, while a few rural areas have been consistently shrinking. By 1961 the total national urban population had increased 57 percent from 1951; two-thirds of that increase was accounted for by cities with a population of more than 100,000. Of the largest cities in Pakistan, Karachi and Hydrābād are in Sind, and Sukkur grew to more than 100,000 in 1961.

Administration and social conditions. The government. The head of the province is the governor, who is appointed by the president of Pakistan. The province has an elected legislature called the Sind Assembly. The majority party, with the chief minister as the leader, forms the government. Until the early 1970s, Sind province consisted administratively of the three divisions of Karachi, Hydrābād, and Khaipur, but was then divided into 11 districts, each of which is headed by a commissioner who is also a district magistrate. The districts are Kariichi (including the city of Kariichi), Hydrābād, Dādu, Sānghar, Thar Pārkar, Tatta (Thatta), Khaipur, Nawābshāh, Sukkur, Jacobābād, and Lārkanā. A district is divided into talukas, each headed by a *mukhtār-kār*; a taluka is further divided into *tappas* and a *tappa* into *dehs*, which are the smallest revenue units in the province. Law and order are maintained by an inspector general of police. For dispensation of justice and recruitment to government service, Sind and Baluchistan have a joint High Court and a joint Public Service Commission.

Health. The provincial government has a permanent department of health, which is responsible for the organization and expansion of health services administered through the Directorate of Health. Along with the modern allopathic system, which alone is public supported, the age-old indigenous *ṭibbī* (traditional) system is also widely practiced by private hakims (professional doctors of this system). Since 1947, medical facilities have been extended to all parts of the province. Besides a number of private hospitals and clinics, there are about 40 civil hospitals, more than 300 dispensaries, 75 rural health centres, two tuberculosis sanitariums, one epilepsy hospital, one mental hospital, and a dozen or so tuberculosis and dental clinics. In addition, there are child-health centres, midwifery and maternity services, mobile health units, and facilities for the training of nurses.

Health problems

Despite considerable progress, medical facilities remain inadequate, particularly in the rural areas. The problem of educating the general public to adopt preventive measures and seek timely medical advice needs to be tackled more effectively. The developmental health program of the early 1970s centred upon the provision of curative facilities, the prevention and control of epidemics, the checking of adulteration of food and drugs, the eradication of malaria, the control of smallpox, the strengthening of tuberculosis control projects, the extension of school health services, and the improvement of facilities for treatment in the medical colleges and their attached hospitals.

Education. The provincial department of education is responsible for policy and planning; except for the universities which are virtually autonomous, all educational institutions are under departmental control.

Primary school education is of five years duration, mid-

dle school of three years, and high school of two years. Primary schools have been extended to village areas, middle schools to bigger villages and small townships, high schools to the taluka towns, and colleges to the district headquarters. There are also teacher-training schools and technical, vocational, and commercial institutes. The institutions of higher education include colleges for secondary teacher training, for medicine, agriculture, and engineering, as well as the University of Karachi in Karachi, the University of Sind in Hydrābād, and an institute of education.

Welfare. Since the 1950s, welfare work has been organized and extended to a number of selected rural and urban areas through a system of community development projects. The program is administered by the provincial directorate of social welfare. Vocational training is one of the projects' significant activities, which are also designed to serve religious and recreational needs. Some special institutions, such as a socio-economic centre, a home for the destitute, and orphanages, have been established on a permanent basis.

The provincial Sind Family-Planning Board administers the family-planning program, which was started in six districts in 1965 and later expanded into all 11 districts. Some 600 clinics and 6,800 sales agents bring supplies and services within the reach of all, while family-planning workers, the lady health visitors, and other paramedical staff provide the necessary motivation and advice.

The Directorate of Labour Welfare maintains industrial relations conducive to higher productivity and promotes the welfare of all the workers employed in industrial establishments, factories, mines, docks, and other utilities by insuring their health and safety and improving their employment conditions. Employment exchange agencies and vocational guidance units render job-finding and job-placement services to the unemployed.

The Sind Employees' Social Security Institution, established in 1965, is an autonomous organization the governing body of which includes representatives of both employees and the government. It administers relief in the form of maternity, sickness, and injury benefits; total or partial disablement gratuities and pensions; and death grants and survivor's pensions. Nonmonetary benefits include medical care through social security dispensaries and polyclinics.

The economy. Agriculture, fishing, and forestry. The mainstay of Sind's economy is agriculture, and 38 percent of the provincial area is under cultivation. Production increased substantially after 1961 because of the advance in agricultural research and extension services, use of inorganic fertilizers, development of agricultural engineering, and construction of more than 1,000 miles of surface drains to counter the effects of waterlogging and salinity. Major crops include cotton, wheat, rice, sugarcane, corn (maize), millet, and oilseeds. Fruit orchards have been extended, and a substantial increase has been achieved in the production of mangoes and bananas. Fruit-bearing date palms are also important.

Livestock includes cattle, buffalo, sheep, goats, camels and poultry. The Red Sindhi and Tharee cows are the best dairy animals, and the Sakrai and Dia-ee are the best camel breeds for transport. The potential for animal husbandry for commercial production has not been fully exploited. The government maintains two livestock farms that are engaged primarily in experimentation and research. The Fourth Five-Year Plan for 1970-75 gives priority to the improvement of livestock, increased livestock products, and increased veterinary services.

With its 150 miles of coastline and hundreds of square miles of inshore backwaters, Sind has a high potential for marine fishing. The varieties found in abundance include prawns and shrimp, pomfrets, *palla* (shad), and khagga (catfish). The Indus and its deltaic branches, abandoned beds (*dhoras*) and irrigation canals, and the numerous freshwater lakes (*dhandhs*) constitute a rich reservoir for the breeding and production of freshwater fish, such as kurirro (*Cyprinus denticulatus*) and thelhi (*Catla buechanani*). About 1,700 acres have been developed on the Gudu Barrage for fish production.

The Sind family-planning program

Sind has more than 2,655,000 acres of forests managed by the Forest Department and the Agricultural Development Bank of Pakistan. The productive areas are exploited for both timber and firewood.

Mining and quarrying. The few known metallic minerals include celestite, laterite, and bauxite. Clays, gypsum, anhydrite (a mineral of calcium sulfate), limestone, chalk, dolomite (a mineral of calcium magnesium carbonate), silica sand, bentonite (a clay mineral), sulfur, flint, and lake salt all are available in large quantities. Coal, gas, and petroleum also occur. The resources exploited include coal, china clay, clay, chalk, fuller's earth, gravel, lake salt, limestone, and silica sand.

In 1970 about 89,000,000 tons of various petroleum products were produced in Sind, in excess of the provincial demand by about 2,000,000 tons. About 90 percent of the province's total energy was provided by oil and gas. In the early 1970s all of the transmission and distribution mains for the supply of gas were based on the Siii gas field of Baluchistan.

Water and power development. The West Pakistan Water and Power Development Authority (WAPDA) was established to unify and coordinate the development of resources in Pakistan. The WAPDA's main water-development schemes in Sind are the Gudu Barrage, which irrigates 2,900,000 acres and a forest area of 223,000 acres; the Karachi Irrigation Project to irrigate 84,000 acres and supply water for industrial and domestic use; the North Rohri Fresh Groundwater Project, involving the construction and electrification of almost 1,270 tube-wells; and the salinity control and reclamation projects in Khairpur, Lārkāna, and Shikārpur. The Gudu Barrage has been completed and handed over to the Irrigation Department and the Agricultural Development Bank.

The WAPDA power system, with a total installed capacity of 1,300,000 kilowatts, has four grids, two of which are in Sind. These are the Sukkur Thermal Grid Area, with a capacity of 25,000 kilowatts, which is to electrify Upper Sind, and the Hyderābād Thermal Grid Area in Lower Sind, with a capacity of 43,700 kilowatts.

The Kotri Gas Power Station, with an installed capacity of 42,250,000 kilowatts, has been linked with the Lower Sind Grid. The Gudu Steam Power Station was under construction in the early 1970s near Kashmor in Upper Sind; its plans called for two units of 110,000 kilowatts each for the first stage and one unit of 200,000 kilowatts for the second stage. The Water and Soil Investigation Division (WASID) of WAPDA also has four subprojects in Sind.

Industry. Sind is a highly industrialized area. It accounts for one-third of the entire cotton production of the country and contains almost half of the country's cotton textile mills. Four large cement factories turn out more than 60 percent of the country's cement production. The expanding sugar industry is expected to have a dozen large mills in operation by the mid-1970s.

Sind Industrial Trading Estates Ltd. has developed industrial Parks, or estates, at Karachi, Kotri, Hyderābād, and Tando Adam. Another project is planned at Sukkur. By 1970 the West Pakistan Industrial Development Corporation (WPIDC) had completed 15 industrial projects in Sind and was constructing four more. The corporation's Fourth Plan Program, for 1971 to 1975, called for investment in a machine tool factory, a chemicals and fertilizer complex, and a heavy electric complex.

The West Pakistan Small Industries Corporation (WPSIC) promotes cottage and other small industries. In Sind, WPSIC, established by the early 1970s, had 21 projects in the public sector, including two small-industry developments, or estates, four service centres, an artisans' workshop, a handicraft development centre, five handicraft sales centres, and an artisans' gallery.

Transport and communications. Communications are by road, rail, water, and, to a small extent, air. The network of roads of all types extends to more than 13,000 miles. Two highways traverse the province from south to north—the National Highway runs on the eastern bank of the Indus and leads to Multān and Lahore in the Punjab; and the Indus Highway, along the western bank

of the Indus, leads to Sibi and Quetta in Baluchistan. The 97-mile Karāchi–Hyderābād limited access highway was opened in 1970. Numerous feeder roads connect townships in the interior with the main roads.

The Pakistan Western Railway system starts at Karachi and bifurcates at Kotri on the Indus into two main lines. The Hyderābād–Nawābshāh–Rohri line leads to Lahore, and the Kotri–Sehwān–Lārkāna–Jacobābād line leads to Quetta. A main-line connection from Hyderābād runs eastward through Mirpur Khās to the Indian border at Khokhropār. There are also eight different link and loop sections extending to some 600 miles. In the city of Karāchi, the 19-mile Karachi Circular Railway was completed and opened to passenger traffic in 1970.

The Indus and some of its channels, particularly in the lower delta, have served as the main waterways since time immemorial. Country boats continue to ply the Indus, transporting grain, hay, timber, and firewood. Along the 150 miles of seacoast and the numerous creeks and abandoned mouths of the Indus, country boats and launches transport fish, grain, firewood, and other supplies.

Karāchi Airport maintains both domestic and international services. Within Sind, air services are in a preliminary stage of development. Hyderābād, 120 miles from Karachi, is connected by flights from Karāchi en route to Quetta and Lahore. Special weekly services operate from Karachi to Mohenjo-daro. The airstrip at Nawābshāh is subsidiary to Karachi Airport; eventually, it and airstrips at Jacobābād and Sukkur will prove important centres for travel and commercial transport from north to south.

Cultural life. Separated from the rest of the subcontinent by a vast desert belt on the east, by ocean on the south, mountain ranges on the west, and a bottleneck of the Indus on the north, Sind long remained an isolated and self-contained region. With comparatively less borrowing from the outside, Sind has therefore stamped its arts and crafts, games and sports, music, and folklore with a typical originality. The continuity of the ancient artistic tradition is manifest today in superb pottery; in work with glazed tile, lacquer, leather, and straw; and in carpetmaking, needlework, embroidery, quilt making, the making of hand prints, and the designing of textiles.

Melas (fairs) and *malakharas* (wrestling festivals) are the most popular recreation. *Malh* is the distinctive style of Sindhi wrestling, and the training of horses and camels to run in different styles is typical of Sindian riding and sport. Falconry is a time-honoured pastime. The method of catching the *palla* fish in the Indus by floating on an earthen pot is the distinctive technique of Sindhi fishermen. Bullock-cart racing and cockfighting are popular in some areas.

The music tradition in Sind goes back to early times. Its early professional minstrels, the *Loras*, carried Sindian music to ancient Iran, where it flourished as Luryan music; and the large variety of musical instruments confirms the existence of a long-standing musical tradition. The renowned poet Shāh 'Abd-ul-Laṭīf of Bhit (died 1752) founded a new music tradition of *Shah jō rāga* in which thematic music primarily based on popular themes was interpreted by folk melodies.

The literary tradition has been influenced by the region's history of disastrous floods and storms. The story of *Dodo-Chanēsar* is the theme of a great epic of the Sūmra period. *Mōmul-Rāno*, *Nūri-Jām tamachi*, *Suhni-Mekar*, *Līlan-Chanēsar*, and *Sassi Punnnān* are among the famous age-old romances of Sind. The story of *Umar-Mārui* represents the lofty character of a village girl who prefers the company of her own simple people to the comforts of a king's palace and resists the temptation to leave her poor family to become a queen. The story of *Siirath-Rai Daiāch* demonstrates the generosity of a munificent king and his love and appreciation of music, for which he lays down his life.

Traditional culture is greatly strained under the impact of modern development. It is mainly in the vast rural countryside and its more isolated areas where traditions have been perpetuated, although in a much diluted form. Unless sociocultural institutions attempt to preserve the traditional culture, it is likely to succumb to the growing

The railway system

Water-development projects

impact of such developments as modern education and Westernization, agricultural development, industrialization, the extension of transport and communications, the use of mass communication, continued immigration, and urbanization.

The Sindhi Adabi (literary) board, functioning at Hyderābād, has published more than 200 works in Sindhi, Persian, Arabic, Urdu, and English, covering Sindhi language, literature, folklore, history, and lexicography. The Shāh 'Abd-ul-Latīf Cultural Centre at Bhit Shāh, 35 miles north of Hyderābād, has conducted research and published works on the life, music, and poetry of Shāh 'Abd-ul-Latīf. The preliminary development of the Sind-Provincial Museum and Library, both located at Hyderābād, was completed by the early 1970s. The Mehran Arts Council at Hyderābād is concerned with the development of the fine arts, crafts, and general culture and has published useful monographs on the traditional arts and crafts, early musical tradition, and musical instruments of Sind.

Karāchi is the stronghold of the national press, publishing half a dozen widely circulated dailies in either English or Urdu. The interior of the province is served mainly by a local press, which includes four widely circulated dailies. Radio stations at Karāchi and Hyderābād broadcast national and provincial programs in Sindhi, Urdu, and English.

BIBLIOGRAPHY. SIR MORTIMER WHEELER, *The Indus Civilization*, 3rd ed. (1968); and F.A. KHAN, *The Indus Valley and Early Iran* (1964), are among the more recent works that deal with the beginning, development, and external relationships of the Indus Valley civilization. H.T. LAMBRICK, *Sind: A General Introduction* (1964), details the ancient history, though the more significant contribution lies in his delineation of the characteristic features of physical geography; MANECK PITHAWALLA, *A Physical and Economic Geography of Sind, the Lower Indus Basin* (1959), gives greater details of physiography, geology, hydrography of the Indus, climatic conditions, vegetation and animal life. H.M. ELLIOT and J. DOWSON, *The History of India As Told by Its Own Historians*, vol. 1 (1867), provides in English translation the more significant but copious extracts from the native histories in Persian and other sources. M.R. HAIG, *The Indus Delta Country* (1894), is a scholarly monograph that remains unsurpassed in its discussion of the changing courses of the Indus, particularly in the lower deltaic region. R.F. BURTON, *Sindh, and the Races That Inhabit the Valley of the Indus* (1851), contains general information on the ethnology and sociocultural conditions in Sind in the mid-19th century; while S.S. ANSARI, *Musalman Races Found in Sind* (1901), gives in alphabetical order a brief account (sometimes based on hearsay) of the different Muslim groups, communities, tribes, and racial stocks of Sind. H.T. SORELY, *Shah Abdul Latif of Bhit* (1940, reprinted 1966), in dealing with the poetry and biography of the renowned poet, Shāh 'Abd-ul-Latīf, presents a study of the literary, social and economic conditions in 18th-century Sind. *The Sindhi Folklore Project of the Sindhi Abadi Board, Hyderābād, Sind*, directed by N.A. BALOCH (1958-), is an extensive study and documentation of Sindhi folklore. N.A. BALOCH, *Traditional Arts and Crafts of Hyderabad Region* (1966); and *Musical Instruments of the Lower Indus Valley of Sind* (1966), are elementary brochures in English on these subjects. *The Census of Pakistan, 1961* (General Report, and the Sind District Volumes); H.T. SORELY, *The Gazetteer of West Pakistan: The Former Provinces of Sind, Including Khaifur State* (1968); and the *Sind Annual*, provide the latest information and statistical data on administrative and developmental aspects.

(N.A.B.)

Singapore

The Republic of Singapore is a city-state situated at the southern tip of the Malay Peninsula, about 85 miles (137 kilometres) north of the Equator. It consists of Singapore Island, which is diamond-shaped and 210 square miles (544 square kilometres) in extent, and 50 other islets, only half of which are inhabited, which make up another 16 square miles (42 square kilometres). To the north the main island is separated from West Malaysia by Johor Strait, a narrow channel crossed by a road and rail causeway more than half a mile long. The southern limits of the state run through Singapore Strait where outliers of the Riau-Lingga Archipelago, which forms a part of

Indonesia, extend to within ten miles (16 kilometres) of the main island. Singapore has a population of about 2,100,000, of which three-quarters are Chinese.

The largest port in Southeast Asia, and the fourth largest port in the world, Singapore owes its growth and prosperity to its focal position at the southern extremity of the Malay Peninsula, dominating the Strait of Malacca that leads from the Indian Ocean to the South China Sea. Once a British colony, and now a member of the Commonwealth of Nations, Singapore joined the federation of Malaysia on its formation in 1963. When friction subsequently developed between the Malay-dominated central government and the Chinese-dominated Singapore administration, Singapore accepted Malaysia's invitation to leave the federation and become an independent state, which it did on August 9, 1965.

Since 1965, despite a large and rapidly growing population concentrated on a minute geographical base, Singapore has reduced its birth rate, rehoused many of its people, initiated a program of industrial expansion, and raised national income to the highest per capita level of any Southeast Asian nation. Singapore was formerly the principal British naval and air base in Asia, but its strategic role lately has been eroded by developments in nuclear warfare, as well as by the withdrawal of British power from Asia (for coverage of an associated physical feature, see MALACCA, STRAIT OF; for coverage of historical aspects, see MALAYA, HISTORY OF).

The natural environment. Nearly two-thirds of the main island is less than 50 feet (15 metres) in altitude. Bukit Timah, the highest summit, is only 581 feet high (177 metres); with other peaks, such as Bukit Panjang and Bukit Mandai, it forms a block of rugged terrain in the centre of the island. To the west and south are lower scarps with marked northwest-southwest trends, such as Bukit Faber Ridge. The eastern part of the island is a low plateau cut by erosion into an intricate pattern of hills and valleys. These physical units reflect their geological foundations: the central hills are formed from granitic rocks, the scarplands from highly folded and faulted sedimentary rocks, and the eastern plateau from uncompacteds sands and gravels. A dense network of short streams drains the island, but floods are locally severe, owing to low gradients and to excessive runoff of water from cleared land. Many streams, especially those draining northwards, have broad, mangrove-fringed estuaries that extend far inland.

None of the soils is even reasonably fertile, but those derived from the granites tend to be better than most. Soils developed from the sedimentary rocks are variable, but many contain hard pans (compacted layers) that restrict plant roots and impede soil drainage. The soils of eastern Singapore are extremely infertile. All have suffered extensive degradation (loss of material through erosion) as a result of generations of careless exploitation.

Singapore, being in an equatorial region, experiences uniformly high temperatures throughout the year, with the mean monthly average varying from about 81° F (27° C) in June to 77° F (25° C) in January. The daily range is much greater, averaging 12° F (7° C), but the maritime location and constant humidity keep maximum temperatures relatively modest: the highest temperature ever recorded was only 95° F (35° C). As temperatures are so uniform, the incidence of rainfall defines the seasons; rainfall in turn depends on air-mass movements, which are affected by the presence of the Asian and Australian land masses. Between December and March, for example, the northeast trade winds that blow at that season are reinforced by outflows of surface air from Asia, bringing the strongest winds and heaviest precipitation of the year; rainfall averages over ten inches a month in both December and January. From May to September surface winds from the southern hemisphere are strengthened by the Australian high pressure belt and reach the Singapore-Malaya region. Winds are generally light during this season, however, and rainfall drops to around six inches in June and July. From April to May and from October to November sluggish air movements are common, and intense afternoon showers bring monthly rainfall averages

of from seven and ten inches. Altogether, the annual rainfall averages about 100 inches, and rain falls somewhere on the island every day of the year.

Little remains of the original vegetation or animal life, except for 4,000 acres of second growth rain forest preserved around catchment areas. Some mangrove vegetation survives in the Kranji estuary on the northwest side of the island, but elsewhere tracts of scrub, or of *Imperata* grass called lalang, are common. Many exotic plants have been introduced for ornamental use. The largest native animals are the long-tailed macaque (an Asian species of monkey), the slow loris (a large-eyed tailless nocturnal lemur), and the scaly anteater. Birds are numerous, especially those, such as the Indian mynah bird, the brahmī kite (a kite with reddish-brown plumage and a white head and breast), and the house swallow, which have adapted to a symbiotic relationship with man. Reptiles, such as cobras and lizards, are also common. Fringing coral reefs with their associated fish and wildlife occur around many parts of the coast.

Human settlement. The city of Singapore stands on the southern part of the main island. Urbanization has reduced differences between city and country. Today built-up areas cover 50 square miles (128 square kilometres), or 24 percent of the main island. In the older parts of the city (along Singapore River, in the Rochore-Kallang floodplain, and in the low hills behind the harbour), rows of narrow-fronted Chinese shops, with their upper floors subdivided into living cubicles, line the streets. Similar shops stand along the main roads that radiate from the city. Behind their facades lie extensive suburbs composed partly of bungalows, semi-detached residences, and apartments, and partly of rural types of dwellings, such as wooden huts roofed with atap (thatch made from the *Nypa* species of palm tree) or corrugated iron. Such huts are common in all the rural districts, and in squatter settlements in the city. The traditional Malay *kampongs* (villages built on stilts) are seldom seen, except in fishing villages on some of the smaller islands.

The port of Singapore occupies the southern coast of the main island south of the Singapore River. It consists of two partly sheltered areas of water—the Eastern Roads, which are subdivided by an offshore breakwater, and the Western Roads. The two roadsteads are connected by the deepwater channel of Keppel Harbour, with its miles of berths, docks, warehouses, and other facilities, which runs between the main island and islands to the south. A few miles further west is the new port, Jurong.

People and population. As a result of past immigration, the population is diverse. Chinese predominate, form-

ing 76 percent of the total. Malays form another 15 percent, and Indians 7 percent. None of these three major communities is homogeneous. Among the Chinese, 40 percent originate from Fukien province and speak the Amoy dialect; another 23 percent are Teochews from Swatow, and a further 19 percent are from Kwangtung. The Chinese community as a whole, therefore, uses mutually incomprehensible dialects. Linguistic differences are less pronounced among the Malays, but the group includes Indonesians speaking Javanese, Boyanese, and other dialects. The Indian group is most diverse, consisting of Tamils (60 percent), Malayalis, and Sikhs; it is also considered to include the Pakistani and Sinhalese communities.

Because of this diversity, no fewer than four official languages are recognized—English, Mandarin, Malay, and Tamil. English remains the main medium for administration, commerce, and industry; nearly 60 percent of all schoolchildren attend English-language schools. Mandarin, the national language of China, transcends dialect barriers; one-third of the school population is taught in that language. Malay, like English, is widely used for interracial communication and plays an especially useful role in view of the close ties between Singapore and Malaysia.

Religious affiliations reflect ethnic patterns. Over 70 percent of all Chinese profess some degree of attachment to Confucianism, Buddhism, or Taoism, or to some combination thereof. Virtually all Malays, and some Indians, adhere to Islām, which is the formal religion of about 16 percent of the population. The remaining population is either Christian or Hindu.

In 1970 there were 2,075,000 people in Singapore, and from immigration and natural increase combined, the population had been growing for many decades at the rapid rate of 3 percent a year. As a result, the proportion of young people to those of employable age is higher than it is among the advanced industrial nations. Since 1958 annual growth rates have, however, fallen dramatically. In 1970 the birthrate was 22 per 1,000, and the death rate was 5 per 1,000, resulting in a rate of natural increase of 17 per 1,000. With the ending of large-scale immigration after World War II, the sex ratio among the population has become more balanced, with 1,049 males per 1,000 females.

In the state as a whole, the density of population averages about 9,400 per square mile, but a more revealing statistic shows that 1,700,000 people, or 85 percent of the total population, live on 28 square miles. Of these, 750,000 occupy multistoried apartments that cover a mere 2.2 square miles. By contrast, rural areas of Singapore have

Official languages

densities of between only 1,900 and 2,700 per square mile. The most crowded areas are still the older parts of the city, where densities of more than 110,000 per square mile were recorded in 1966. In new housing developments, such as those at Queenstown and Toa Payoh, densities of 65,000 per square mile are normal.

Source: Official government figures.

The economy. With an urban population engaged largely in trade, finance, and industry, Singapore's economy differs markedly from that of most Southeast Asian countries, which are primarily based on the production of raw materials. In 1970 the per capita gross national product was about Sing\$2,682—more than twice that of Malaysia or the Philippines, but only about 60 percent of that of Japan. The monetary unit is the Singapore dollar (Sing\$3.06 equalled \$1.00 U.S.; Sing\$7.35 equalled £1 sterling on December 1, 1970).

Resources. The state has few natural resources, apart from small amounts of brick clays, rock aggregates, and building sand. The natural vegetation provides only firewood and a few poles. Local catchment areas are small, obliging Singapore to use water from Johor state in West Malaysia. The low-lying relief does not permit hydroelectric development, so that energy has to be generated from imported fuels.

Sources of national income. In 1970, about 55 square miles (140 square kilometres), or nearly a quarter of the total area, was devoted to agriculture. Although more than half the agricultural acreage is used for the cultivation of rubber and coconuts, most of the 20,000 registered farms produce vegetables, fruit, and livestock for local markets. Over 40,000 tons of fresh vegetables, representing half the total demand, were produced in 1970. Singapore is self-sufficient in pig, poultry, and egg production. Some 14,300 tons of marine fish were caught in local waters, and supplies are augmented by fish raised in freshwater ponds on farms. Total fish production nevertheless accounts for only one-quarter of total consumption. The joint contribution of agriculture and fishing to the gross domestic product fell from about 6 percent in 1961 to under 3 percent in 1970.

The manufacturing sector, on the other hand, has expanded rapidly and now forms nearly one-fifth of the total gross domestic product—a proportion nearly equal to that of the entrepôt trade. In 1971 there were nearly 1,880 industrial establishments with a combined work force of 148,587. Manufacturing plants produce transport equipment and petroleum products, and process food. The ship-repairing and ship-building industry is growing rapidly. In 1970 four power stations with a total generating capacity of 644 megawatts, producing a total of 2,220,000,000 kilowatt-hours, met industrial and domestic needs. The other major energy source was coal gas, of which about 1,600,000,000 cubic feet was used in 1969.

Financial services are available both from modern banks and insurance companies, and from traditional thrift societies and money lenders. In 1970 there were 37 commercial banks with combined assets of more than Sing\$5,000,000,000. Almost two-thirds of all bank credit

was advanced for general commerce and trade, but the proportion devoted to industry is growing, with encouragement from such official bodies as the Development Bank of Singapore. Other sources of finance include finance companies, building societies, insurance firms, and co-operatives. A stock exchange handled Sing\$1,100,000,000 worth of securities in 1969. Commodity markets, especially for rubber, pepper, and tin, form an important element in the economy.

The total value of foreign trade in 1971 was Sing\$14,000,000,000, representing one-third of the total gross domestic product. Singapore continues to perform its traditional entrepôt function of shipping raw materials from the region in exchange for finished products from the industrial nations. Malaysia, the U.S., the United Kingdom, China, and South Vietnam are—after Japan—Singapore's principal trading partners. Rubber and petroleum together account for 28 percent of the value of all trade. Crude rubber, imported from West Malaysia and Indonesia, is shipped to Japan, the U.S., China, the Soviet Union, and Britain. Petroleum from the Middle East is refined in Singapore, and the resulting fuel oils, diesel oils, gasoline, and other products are exported to South Vietnam, Thailand, Japan, and Hong Kong. Other significant items in foreign trade include timber, spices, and rice. The export of machinery, vehicles, and textiles is also increasing.

Management of the economy. The economy of Singapore is basically of the free-enterprise type. The private sector therefore has an essential role, and is expected to generate the increased productivity necessary for progress. At the same time the government is strongly committed to developmental goals, and its influence is pervasive.

In 1970 investment by the private sector amounted to Sing\$978,000,000, or about 70 percent of gross capital formation, while government development expenditure totalled Sing\$425,000,000, or about 30 percent.

The main sources of government revenue are excise duties (mainly on liquor, tobacco, motor vehicles, and petroleum products) and income tax (mostly from companies). Tax relief may be granted to new manufacturing and export enterprises; to encourage the entrepôt trade, free trade zones have been established. Revenue from all sources amounted to about Sing\$1,307,200,000 in 1971, while total expenditure amounted to about Sing\$1,942,800,000 resulting in a deficit. Overseas assets, however, totalled almost Sing\$4,400,000,000, of which government surpluses amounted to nearly Sing\$990,000,000.

About 25 percent of all workers are trade unionists. Most of those employed in the public sector and most employees of the larger, foreign-directed firms are unionized. There are 156 separate unions, led by the National Trades Union Congress, whose main objectives are to secure welfare benefits for workers by established procedures. The government regulates collective bargaining and compulsory arbitration, and it also provides a wide range of services, including training courses and a workers' superannuation scheme. Organized management is represented by two bodies, and there are, in addition to these, chambers of commerce representing different ethnic groups.

The country's limited area, a rapid population growth, and a weakening entrepôt role have virtually obliged Singapore to develop its manufacturing industries. Between 1961 and 1971, the number of manufacturing establishments rose by 235 percent from 560 to 1,880, the number of workers rose by 438 percent from 27,600 to 148,600, and the value of total manufacturing output rose in value by 832 percent from Sing\$518,000,000 to Sing\$4,310,000,000. Despite these advances, the economy still depends on external factors over which the state has no control, such as fluctuations in the price of rubber on the world market. The internal problem of providing full employment for an expanding population has yet to be solved; the work force of 444,000 in 1970 represented only 39 percent of the population of working age; i.e., those between the ages of 15 and 59. In the industrial sector productivity per worker has grown more slowly than total output, and the cost of capital investment in manu-

Sources
of
revenue

Employ-
ment

Agricul-
tural
production

facturing has risen from about Sing\$4,800 per worker in 1961 to Sing\$12,700 per worker in 1969.

Transportation. As the fourth largest port in the world, Singapore is a major transportation nucleus. In 1971, it handled nearly 38,000 vessels and 48,000,000 tons of cargo. Roughly one-half of all ships were engaged in the coastal and interisland trade conducted between Singapore and Indonesia, but the extent of this barter trade is poorly documented. Seaborne passenger movements declined in 1968 owing to competition from air transport and the continued closure of the Suez Canal. Railroads with a one-metre gauge connect Singapore with West Malaysia. There are over 1,200 miles of motorable roads used by more than 313,000 motor vehicles. More than 20 international and pan-Malaysian airlines use Paya Lebar Airport, which handled over 1,600,000 passengers and 25,700 metric tons of freight in 1971.

Administration and social conditions. Singapore is a parliamentary democracy based on the Westminster model. The government consists of a head of state, a president with nominal powers, and a fully elected, unicameral Parliament of 58 members. The electorate includes every adult citizen who is a registered voter, and voting is compulsory. The parliamentary majority selects the prime minister and cabinet from its own ranks. Since 1959 the government has been virtually synonymous with the Peoples' Action Party, led by Prime Minister Lee Kuan Yew. After three successive elections, the party now holds all the parliamentary seats. In each constituency there is a Citizens' Consultative Committee, designed to act as a link between government and people. Each committee explains official policies and transmits demands or grievances to the government. Similar exchanges are conducted with organized labour, which has six seats in Parliament.

Close liaison is maintained between the political and administrative arms of government. The administrative structure comprises various ministries and statutory boards. These are staffed by some 65,000 civil servants whose technical competence and integrity are monitored by a Public Service Commission, an independent body responsible for controlling standards, appointments, and discipline. A similar body maintains the status and assures the independence of the judiciary. Justice is administered by the Supreme Court and by courts of minor jurisdiction such as magistrates' and criminal district courts. Appeals can be made from the lower to the higher courts, with final appeal to the judicial committee of the Privy Council in London. Legal assistance in civil actions is available for the poor. The Shariah Court has jurisdiction in matters of Islamic law.

Defense. The armed forces of Singapore consist of six infantry battalions with supporting artillery, armour, engineer, and signal units. The training of fighter pilots and of personnel for local missile defenses began recently. There is also a flotilla of fast naval patrol boats. Military conscription for 18-year-olds was introduced in 1967. Those not selected for the statutory two-year period of service with the regular forces are obliged to serve on a part-time basis with either the Peoples' Defence Force, the Special Constabulary, or the Vigilante Corps (a paramilitary force largely made up of youths).

Social conditions. Primary education in any one of the four official languages is free for children of Singapore citizens, but the learning of a second language is compulsory. Secondary education is available in technical, commercial, and academic subjects; courses are combined to prevent premature specialization. In 1970 there were more than 500 schools at which more than 500,000 children were enrolled. Existing school facilities are sufficient to meet anticipated future demands. There are also three technical institutes with a combined enrollment of 4,000 students. The University of Singapore and Nanyang University provide academic and professional courses to postgraduate levels. There are separate institutes to train teachers, nurses, radiographers, and seamen; over 80 centres offer adult education. Total government expenditure on education in 1971 was more than Sing\$196,000,000, or roughly Sing\$392 per student.

The range and quality of medical services is notably high, with one doctor for every 1,500 persons, and one dentist for every 5,300 persons. Government and private hospitals provide a ratio of about four hospital beds for every 1,000 people; nonhospital care is dispensed from numerous out-patient clinics and mobile centres. Official campaigns to keep Singapore clean are conducted periodically. Singapore's most significant achievement is in family planning, a distinction that it shares with few other nations; it resulted in a drop in the birthrate from 32 per 1,000 in 1964 to 22 in 1970.

A housing and development board, established by the government, is responsible for building homes for families with low incomes. By the early 1970s it had completed nearly 144,000 home units, most of which are in high-rise apartment buildings, grouped into neighbourhood units, each with its own school, parking lot, community centre, and social facilities. All together, official programs housed over 650,000 people, or nearly one-third of the total population, in the 1960s alone. With more than 1,000 housing units being built each month, the severe housing shortages of the fifties have now been overcome. Nearly a quarter of all government apartments built have been sold to individual families. More than 16,000 residential units have been privately built since 1961, mostly in the suburbs.

The police force comprises 6,000 regulars and 9,000 members of the Special Constabulary. The force patrols the islands by land and water in order to maintain internal security. Traffic management, crime prevention, and political subversion are also matters under police jurisdiction. A police academy trains recruits and serving personnel.

The average weekly wage is about Sing\$46.00; male earnings are twice those of females. The working week ranges from about 45 hours for workers in commercial and service occupations, to 48 hours for construction workers. Since 1960 the consumer price index has risen by slightly more than 11 percent; food, which represents half of all consumer expenditure, has risen by 12 percent, as has the cost of housing.

Health conditions in Singapore compare favourably with those of the advanced nations. Life expectancy for all races and sexes is over 68 years; infant mortality is only 21 per 1,000 live births, and infectious diseases are of negligible significance. With the reduction in communicable diseases, cardiovascular diseases and malignant neoplasms account for an increased proportion of deaths. The government and voluntary associations, headed by the Council of Social Service, provide welfare services for the aged, sick, and unemployed. Welfare grants totalling Sing\$3,500,000 were paid in 1970.

Divided into ethnic groups, society is stratified by income and education. Income tax records show that there are only about 92,000 taxpayers, who form only 8 percent of the population of working age, or 23 percent of the work force. Of these, nearly half have assessable incomes below Sing\$6,000 a year, 32 percent have incomes of from Sing\$6,000 to Sing\$10,000, and 12 percent have incomes of from Sing\$10,000 to Sing\$12,000. In education, about one-quarter of all persons aged ten and above have had no education at all, and just over 30 percent have had only a primary education. Current educational levels, however, compare favourably with those of most other nations, with attendance rates of from 80 to 85 percent for children aged six to 14, 40 to 45 percent for those aged 15 to 19, and about 5 percent for those aged 20 to 24.

Cultural activities. As might be expected, cultural activities in Singapore are largely derivative, springing from one or another of the major civilizations of China, India, Indonesia, or the West. Traditional Chinese and Indian music, painting, and drama are actively practiced by numerous cultural societies and professional groups. Popular culture, based on modern mass media of communication, is far more widespread. Malay music, which has adopted the rhythms of Western orchestras, has a general appeal. Musical films that popularize Hindustani and Tamil songs have a considerable following. Films from Hong Kong, Taiwan, and the United States attract

Medical
services

Income
levels

Education

multiracial audiences, with attendances averaging 600,000 per week. Several Chinese, English, Indian, and Malay newspapers with a total daily circulation of over 400,000 copies serve a largely literate population. Magazines published in the West, Hong Kong, and Japan have wide appeal. Broadcasting is a government monopoly; radio programs in English, Chinese, Malay, and Tamil are transmitted daily on three separate channels. There are also two television channels.

Prospects for the future. Among developing nations, Singapore has an outstanding record of progress. The success it has so far achieved is largely due to the realism shown by government and people alike. Recognizing problems, yet capitalizing on advantages, they have initiated a determined program to make the small state more viable. While it is perhaps too early to judge whether Singapore can ultimately survive as an independent entity, its achievements in its first years of independence augur well for the future.

(Rt.H.)

Singing

In recitation and declamation, as in singing, the voice is sustained beyond the requirements of speech. But in song, the voice is sustained at greater length than in the others, and its sound distributed over a wider range of pitch.

Every individual normally has in his throat at birth a reed instrument, the two vocal cords in his larynx, which, with his breath, and assisted by the areas of the sinuses, mouth, and other areas of the throat, neck, and head that serve as resonance chambers (*i.e.*, vibrating with the voice's sound, enhancing it, and increasing its volume), produce rudimentary music when he speaks. Physiologically, what distinguishes singing from speaking is the manner in which the breath is expended to vibrate the vocal cords. Singing requires more breath, and ever more breath the louder, higher, and longer one sings. It also requires that the emission of breath be more firmly controlled. A pertinent analogy is the function of the instrumentalist's breath in playing a reed instrument—*e.g.*, a clarinet, an oboe, or a saxophone.

A further distinction between singing and speaking is the control required, in singing, of the movement and reflexes of the larynx. As one sings higher, the larynx tends to rise sympathetically and at a certain point becomes an interference causing the voice to break, or crack. Not much movement of the larynx occurs within a singer's normal range, usually about an octave and a third. Beyond that,

either above or below, an element of technical accomplishment sets the professional off from the unschooled amateur,

WESTERN ART SINGING

Western art singing is distinguished most strikingly by its volume. Singers of other cultures may have a wider range, particularly a greater upward extension; but it is doubtful that they have sung, or have been inclined or encouraged to sing, louder. And in Western singing, singers once sang even higher than they do today. Such ranges were acquired only at the expense of the large, ample, resonant tone which the requirements and conventions of opera have rendered fashionable, even indispensable, in Western music.

Related to concern for volume and range is a concern with pure sound, with the tone quality, or timbre, and with colour, with what is felt to be the sheer beauty or majesty of the voice itself. Both singers and their listeners, in Western music more than any other, have tended to lose sight of song's roots in language and to think of singing as a purely instrumental production. This has occurred at various critical junctures in the history of Western singing and has invariably precipitated a reaction in favour of a more linguistic approach to song and singing.

The bel canto era. *Aesthetic reorientation.* It is with one of these crises that the history of Western singing, in terms familiar to a contemporary audience, began in Italy, in the first decade of the 17th century, when the elaborate contrapuntal (based on interwoven melodies) vocal forms of the late Renaissance were felt to have reached such a peak of complexity that the words no longer mattered. A reaction was led by the Camerata, a circle of Florentine intellectuals who sought to recover the monodic technique (melody supported by expressive harmonies) they believed to have been employed in classical Greek drama, and the result was opera. Western singing ever since then, whether operatic or not, has reflected in its objectives, techniques, and criteria the trends and exigencies of operatic fashion and vocal production.

Little is known about Western singing prior to that time. Musicologists know what the troubadours and the German minnesingers (noble medieval poet-composers) sang, but they do not know exactly what kind of sound they made while singing. The same is true of singing in the medieval church. It may be said, however, that from multiple-voiced singing, cultivated in Europe as in no other civilization, both in church and out, evolved the devices of melodic ornamentation found in later monodic styles and the traditional voice categories of soprano, alto, tenor, and bass.

The most decisively influential figure in the crisis referred to above was the composer Giulio Caccini. Rebelling against the artificiality of the multiple-voiced music of his time and particularly against the want of any expressive relationship between text and melodic contour, he devised a style of solo singing, essentially recitative in character, over an instrumental accompaniment, in which the florid conventions of multiple-voiced song were harnessed to prosody and to the expression of the appropriate emotions. The style he inaugurated was brought to an early maturity in the operas of Claudio Monteverdi.

Caccini's objectives, laid down in a discourse, *Le nuove musiche*, in 1602, and refined and elaborated a century later by Pier Francesco Tosi in his *Observations on the Florid Song* (1723), may be summarized as a mellifluous kind of singing aimed at an agreeable, well-rounded tone, an even scale from bottom to top, a nicety of intonation, an eloquence of phrase and cadence, a purity of vowels, a mastery of the devices of ornamentation and embellishment, invention and taste in improvisation, and a disciplined avoidance of shouting, nasality, harsh or open sounds, disjointed registers, undue vehemence, and other evidence of vulgarity or negligent schooling. These became the precepts of a school of singing now referred to as *bel canto*, or "beautiful song."

Role of the castrati. The foremost early exponents of this kind of singing, and those whose example established

Early singing styles

The work of Giulio Caccini

Song and speech

the criteria of Western singing that have prevailed with some modifications to the present, were castrated males known as castrati, or *evirati* ("emasculated"). By fateful coincidence, castrati were introduced into the churches of Italy, and subsequently elsewhere, at about the same time that the reforms signalized by Caccini were beginning to take hold in the Italian musical theatre. The castrati, too, were a reflection of the excessive complexity of late Renaissance multiple-voiced song. Women's voices were barred from the Roman Catholic Church in obedience to St. Paul's injunction "Let your women keep silence in the churches." By the end of the 16th century, church music had become so exacting that a boy was approaching vocal mutation by the time he had developed the requisite skills. Male falsetto voices proved unsatisfactory, and castration, never condoned by church or civil authority, but accepted once performed, provided the solution.

Promi-
nence of
castrati
in opera

Women were also excluded from the theatre in many centres of Catholic Europe; and, by the middle of the 17th century, castrati, playing both male and female roles, were making notable careers in opera. The greatest of them dominated Italian opera throughout most of the 18th century, and a few survived in the theatre into the first three decades of the 19th. They survived in the church even longer, and the last of them, Alessandro Moreschi, who died in 1922, was director of music at the Sistine Chapel until his retirement in 1913 and made phonograph records shortly after the turn of the century.

The significant fact of a castrato's life was that it could have no satisfactory fulfillment other than singing. He would have begun his studies at the age of six or seven and would have proved to be an exceptional choirboy; otherwise, he would not have been castrated. His studies would be continued in the most rigorous manner for another four or five years. He would have developed an extraordinary chest expansion, an exemplary use of the diaphragm to support and control the emission of breath, an agile and supple throat, great virtuosity and imagination in vocal display and ornamentation, and, in a majority of cases, a notable degree of personal vanity.

And it was vanity, among prima donnas as well as castrati, that brought on the next crisis in Western singing. The virtues of textual expression so prized by Caccini and Tosi, gave way, toward the middle of the 18th century, to extravagant and competitive vocal athleticism. Words, and music, too, were lost in an orgy of exhibitionistic vocal self-indulgence. Gluck's opera *Orfeo ed Euridice* (1762) was an early symptom of reaction in favour of a simpler kind of singing and fidelity to music, drama, and text. In a manifesto accompanying his *Alceste*, in 1767, Gluck emphasized music's—and the singer's—subservience to the concerns of drama; and in the operas he composed for Paris between 1774 and 1779, he perfected the practice of his preaching.

Modification of the bel canto tradition. Vocal vainglory was not extinguished. But it began to be tempered both by the requirements and the character of opera as it evolved after Gluck in the late-18th- and early-19th-century masterpieces of Mozart, Beethoven, Rossini, Donizetti, and Vincenzo Bellini. The new operas tended to favour the exigencies of drama over the specialties and convenience of the singers; and the singers had to substitute real acting for the conventional posturing of earlier opera. The unmutated male, who had heretofore taken second place to castrati and prima donnas, now came into his own; and tenors and basses began to rival female sopranos and contraltos for top billing and top fees.

Promi-
nence of
the
orchestra
in the
19th
century

Theatres were becoming larger, and so was the opera orchestra, reflecting the evolution of symphonic forms in Austria and Germany, and assuming a dramatic function rather than serving merely as an accompanist. The size and assertiveness of the orchestra became critical—and decisive—toward the mid-19th century in the operas of Giacomo Meyerbeer, Verdi, and Wagner. Especially in the later music dramas of Wagner, sheer weight of orchestral sound forced the singer to unprecedented vocal exertions. With Verdi it was the vehemence of dramatic utterance rather than the presumptions of the orchestra that called for louder and more emphatic singing than

would have been thought seemly in the age of *bel canto*. But the orchestra, too, was a factor, mitigating against a perpetuation of the florid traditions of European singing. Singers found it difficult, if not impossible, to be at once forceful and elegant. Nor were they encouraged to try. A strong reaction had set in, especially in Germany, against vocal improvisation and embellishment of any kind. What had seemed the ultimate in vocal virtue and accomplishment from the 17th to well into the 19th century was now anathematized as presumptuous and impudent frippery.

Florid song did not die. It lived on in the surviving operas of the older repertoire. But it tended to become stereotyped and, even as a stereotype, the property of specialists. Whereas until about 1830 all singers were expected to be masters of the devices of *bel canto*, they were now categorized as dramatic, lyric, coloratura (specialist in florid song), and so on. The traditional range classifications of soprano, alto, tenor, and bass were also widened to admit the mezzo-soprano, the baritone, and the bass-baritone. A further departure from the canons of *bel canto* was implicit in the newer requirement of bringing more voice to the upper extremes of the vocal range. Western music had been growing louder since Haydn's time. Singers had to raise their voices in order to be heard. Their success was felt to be exciting, but a fundamental change of taste was involved. Even a Caruso's high C would have seemed vulgar to the vocal connoisseurs of the age of *bel canto*.

The art of the singer, as it had flourished in the 17th and 18th centuries, was inhibited throughout the 19th not only by the growth and burgeoning prestige of the orchestra but also by the new dominance of the composer. Whereas the composer formerly had worked for the singer, much as composers and arrangers work for the popular singer today, tailoring the music to his art and convenience, the singer was now seen as the servant of the composer. Improvisation and artful deviation, which in former times had been a singer's prerogative, even a requirement—as they are for the popular singer now—were outlawed in favour of fidelity to what a composer had written.

The second half of the 20th century produced a predictable reaction in favour of the singer, with a revival of public enthusiasm for nearly forgotten operas by Rossini, Donizetti, and Bellini, and even of the true *bel canto* operas of Handel, and the emergence of singers capable of acquiring the requisite technique and of accepting the creative responsibility imposed by music which left much to the singer's invention and discretion. The popular singer, too, relieved by the microphone of the necessity of raising his voice, and exploiting the improvisatory conventions of jazz, employs intuitively many ornaments and expressive devices nearly identical to those of *bel canto*. Concurrently, the vocal requirements of avant-garde music extend beyond those of traditional operatic singing to include wider flexibility of timbre, techniques such as *Sprechstimme* (musically pitched speech), and improvisational fantasy drawing on sounds formerly excluded from the trained singer's vocal resources. FOLK AND NON-WESTERN SINGING

Singers conform their style to the vocal and musical conventions of their culture as closely as their training and talent permit. When they overstep the bounds of proper vocalizing in a given cultural context, they rouse feelings of shame, amusement, or anger among their hearers. This is because singing, like speech, is a language. Therefore its use of tone, metre, and much more must be bound by formal conventions if it is to communicate effectively. An operatic performance of a folk song sounds just as inappropriate as would a folk rendition of Wagner at the Metropolitan Opera. Every vocalist is likely to feel that his tradition of singing is the most natural and beautiful one—and so it is—in its own cultural setting. In fact, history has witnessed a myriad of singing styles, as varied as culture itself, each one capable of bringing joy or ecstasy to one branch of the human family.

In this century, song hunters, armed with portable re-

corders, have explored the limits of this global ocean of song. In fact, no other aspect of human behaviour has been so universally recorded. A number of general conclusions about the relation of singing style and culture emerge from a survey of these recordings. In order to avoid culture bias on the part of the investigators, all aspects of song performance must be described?including, for example, voice qualities, dynamics, embellishment style, and the organization of the performing group, as well as melody, metre, and harmony. If so described, performance pattern seems to vary in clear-cut ways from culture to culture, defining culture areas and tracing the main human migrations, as do language and design. The discovery that singing style varies with culture pattern makes it possible to study song as a cultural phenomenon, to observe its symbolic and social functions, and to note how musical traits co-vary with known facts of human behaviour and geography.

The method employed in the above-mentioned survey was an empirical rating system of 37 measures in the form of numerical scales on which a trained observer could record his judgment of the relative presence or absence of such easily observable features of performance as level of volume, degree of ornamentation, or length of phrase. The specific scales chosen were those that produced the clearest and most consistent typology among more than 400 songs drawn from every world region. These judgmental rating scales, carefully defined and numerically weighted, were then applied to 4,000 song performances from cultures from every culture area. Coded numerical data on economy, politics, stratification, family, division of labour, religion, sexual mores, and other features of social organization were available for 233 of these cultures. The correlation between features of singing style and aspects of social and cultural organization was studied in relation to this small but representative sample of societies. With the help of the computer, a number of relationships of a high order of statistical significance were then established between singing style on the one hand and social structure and human geography on the other. These hypotheses seem very helpful in explaining the way song style varies from region to region.

Hypotheses relating singing style to social structure. Measured against a scale of economic productivity, the songs of simple producers such as hunters tend usually to be repetitious in text, slurred in enunciation, full of wide melodic intervals, non-embellished, and accompanied by no more than one or two instruments playing in simple rhythmic unison, often to a one-beat rhythm. It is much easier to join in music so relatively empty of information than in the singing of complex societies, in which songs usually have a heavy text load, precise enunciation, narrower intervals, and, if the society is highly stratified, employ many forms of embellishment along with complex orchestras playing polyrhythms, counterpoint, or heterophony. This finding suggests the existence of a general principle: dominant song style constantly restates the level of economic development a culture has reached and the order of complexity normal to its communications.

The organization and integration of the singing group, however, reflects another aspect of social structure—the texture of relations within groups. Solo performance is most frequent when the individual normally works on his own, as do hunters, fishers, and pastoralists, as well as modern farmers and free enterprisers. Group singing is the rule in collective agricultural societies, like those of black Africa, Oceania, and eastern Europe, where cooperative groups till the fields. Whether the chorus performs in unison or sings in parts, however, seems to be related to the sexual division of labour. Where males dominate production, as they generally do in hunting, pastoral, and Western farm economies, one melodic part or unison prevails. Part singing that allows for at least an upper (female) and a lower (male) voice part occurs among gatherers and collective agriculturalists. In these economies, women share or dominate the main productive activity, and usually take a prominent part—with males—in other public activities. Thus, polyphony, where indigenous, seems to stand for sexual complementarity.

The cohesiveness or level of voice blending in unrehearsed choral performance apparently depicts the relative solidarity or diffuseness of community life. Among small solitary groups, like permanent work teams or clan villages, such as those of the Pueblos of the southwest United States, unity flows out of lifelong sharing and cooperation. In cultures whose continuance depends upon impermanent teams, like hunting parties, or in complex cultures, in which highly individuated and changeful social relations are the rule, there is a preference for diffuse, highly individualized group singing in which every voice stands out. In diffusely organized performances one often observes a heavy load of text, consonants, and embellishments, as well as noisy features like harshness, nasality, and vocal narrowness or squeeze. These noisy qualities, which interfere with vocal blend and thus with part singing, are most common in non-complementary, usually male-dominated cultures. Vocal harshness or rasp appears among choruses of hunters, fishers, and other groups in which young males are trained for aggressiveness. Again, vocal narrowness and nasality are heard in societies in which fathers and brothers invoke severe sanctions against female premarital coitus. It is postulated that this male control of female sexuality produces tensions that are voiced in the familiar high-pitched wailing style heard in the Orient and the Mediterranean, where women, until recently, lived in purdah. In the survey of major singing styles that follows, principal musical and performance traits are discussed and at times related to the hypotheses set forth above.

Singing traits of major cultural regions. *African gatherers.* The Bushman and Pygmy people living close to the source of man's known beginnings have a music that might have come from the Garden of Eden. In their complementary, chiefless, egalitarian, and pacifist societies, men and women, old and young, are linked in close interdependence by preference and not by force. Here, where bands of gathering women bring home most of the food, group singing is not only contrapuntal but polyrhythmic, a playful weaving of four and more strands of short, flowing, canon-like melodies (each voice imitating the melody of the others), sounding wordless streams of vowels in clear, bell-like yodelling voices. Free counterpoint of this type may have been man's first song style, for variants of this style appear throughout the world in refuge areas and among gatherers—not only in Africa but also, for example, among the Sajak of Taiwan, the Dani of New Guinea, the Paleosiberian Yukaghir and Ainu, the Pomo of California, and the Jivaro, Motilonas, and Guarauno (Warao) of South America.

Siberian-American hunters. Solos are uncommon among collectivist gatherers, but frequent among hunters. A guttural, raspy, punchy, slurred, nonsense-syllable kind of soloizing seems to be one main style of the Arctic, from the Lapps of northern Europe across Siberia to the Chukchee and in the whole of aboriginal North America. Its special prominence in South America, especially among the primitive hunter-fishers of Patagonia, may be another piece of evidence that the first Americans arrived across the land bridge from Siberia. Many North American Indian songs are performed by men in a related style, notable for its vigour. It employs wide intervals, much nonsense material, and weaves generous, descending cadences into rather freely structured, big strophic forms (consisting of five or more phrases repeated in a set pattern). Vocal rhythms are often complexly irregular and accompanied by one-beat patterns. The main choral style of these freedom-loving, virile pathfinders and incipient producers is grandly noisy, pulsing, and freely diffuse. Among the surprisingly puritanical Plains Indians, a thrilling, narrow-voiced, high-pitched yelling style developed; in contrast, in the settled clan villages of the southeastern and southwestern United States and in eastern Brazil another variant of the basic style is performed in striking tonal and rhythmic blend with wider, deeper voices.

Nuclear American incipient. There is another great American singing style found from the Valley of Mexico south through the isthmus of Panama, in the whole ancient terrain of the Incas, and along the eastern jungle

American
links to
other
regions

rim of the Andes, thence blending with forms of the two previously mentioned styles in the riverine plains to the east. The geographical spread of this style, together with the rather complex, heterophonically related orchestras common to it, suggests that it once linked the ancient high cultures of Mexico and Peru and spread thence to simpler nearby peoples. Today it is practiced largely by seminomadic gardening peoples of the South American forests. Their unstable social relations are apparently reflected in diffuse, highly individualized choralizing, and their dependence on feminine agricultural labour correlates with their use of polyphony that often veers toward vocal heterophony. Frequency of irregular and one-beat metres, wide melodic intervals, and guttural vocalizing link the nuclear American style with that of the Sibero-American hunters, but the frequency of a pattern of soft, nonraspy, high-pitched delivery points in another direction. This gentle, somehow childlike vocal stance occurs, in combination with the heterophonic choral style just described, in only one other region on the globe—in tribal societies in Melanesia and Malaysia—one more indication of an ancient cultural connection between the two zones. In the Malaysian form, however, appear the sure signs of Old High Culture influence (see below)—vocal tensions, embellishment, and explicit text.

Pacific gardeners. Out of the complex weave of migrating cultures through the Pacific islands, three main Oceanic song style patterns emerge. The first is the noisy, unison, rhythmically complex, horn-accompanied style found throughout aboriginal Australia, reminiscent of American hunter singing. The second is the tense-voiced, wordy, highly ornamented, heavily orchestrated solo and heterophonic choral style occurring through the Malay Archipelago, where the influence of Far Eastern music is clear. The third is the varied polyphonic traditions of the gardening peoples of New Guinea, Melanesia, Micronesia, and Polynesia.

Only the third stylistic complex may be briefly considered here. One of its elements is a low-energy, diffuse, harmonizing style that seems old because it is found in enclaves of refugees in the interiors of islands from Taiwan to the Solomon Islands. A second, far more widespread strain might be called Papuan, since its centre seems to be the Eastern Highlands of New Guinea. Its prototypical performance setting is a ceremonial food exchange between two clans or two neighbouring gardener tribes, when tightly packed formations of males, body-painted, oiled, and wearing elaborate headdresses of feathers, flowers, and leaves parade for each other's admiration and display the yams and pigs that their women have, in the main, produced. As they dance, feast, and exchange gifts, they sing in thunderous unison choruses, each man rattling an irregular tattoo on the hourglass-shaped drum he carries. One-phrase melodies, slurred consonants, much repetition, and one-beat, unison-organized orchestras are musical traits correlating with the simplicity of these economies. The relatively wide, noise-free, often polyphonic choruses usually achieve remarkable unity, in spite of the irregular or free rhythms employed.

This endlessly fertile and powerful Papuan type has been often reinvented or widely diffused, because similar patterns are found in tribal India, the Balkans, and especially in East Africa, all through the zone of early tropical agriculture. In cantometric analysis this Papuan pattern links New Guinea with Micronesia and Melanesia as well, and, in other manifestations, it is found throughout Polynesia. The Polynesians also behave in social unison with an unsurpassed cohesiveness, in spite of the fact that their rather complex culture and their concern with genealogies motivate them to sing long, complexly textured poems in precise enunciation. Many of these chants are restrained within a narrow compass of notes, are dominated by free or irregular metres, and have a drone harmonic structure (*i.e.*, a melody sung against a long, sustained note). Just as characteristic is the dance drama, enacted by well-rehearsed male and female squads singing in polyvoiced antiphony (alternating groups of singers), the musical dynamics moving from a sinuous and

gentle attack to aggressive fortissimo in which no syllable should be missed and no ancestor's name mispronounced.

Black African. Black Africa's predominant style belongs to the set of wide-voiced, superbly cohesive, polyphonic choralizing found among tropical village gardeners from Nigeria to the South Pacific island of Pukapuka. To this stylistic complex black Africa adds very much from its endlessly rich rhythmic, harmonic, and orchestral traditions. African vocal style is so varied that it can be called playful; where most other singers take a vocal stance and maintain it, Africans play with register, rasp, volume, emphasis, nasality, narrowing, glottalizing, yodeling, and a dozen other vocal effects, using them as intermittent decorative ploys. Black African style is especially characterized by changefulness—by song leaders and instrumentalists constantly shifting roles, varying the melody, complicating the rhythmic pattern, finding new chords, increasing tension and volume, and then relaxing—with accompanying voices and instruments moving hard behind.

Indeed, in black African antiphony, choruses and ensembles do not allow a moment of silence before they respond; they leap in before the other part is finished and overlap theirs with it, a feat that is easier to describe than to perform. This sociable overlapping of parts, found wherever Africans make music—in the Sahara, in Madagascar, in America, as well as across the whole dark continent—makes the African such a master of synchrony that he can match and answer change as it occurs, so giving rise to the polyrhythmic interaction between voices and instruments and between choruses and orchestras for which Africa is famed.

As a symbol of social solidarity, the complexly integrated character of black African song style reinforces the complementary and unified structure of African society, in which ritual, work, socializing, and even politics are enlivened with multi-part group dancing and singing. Its open-throated, bawdy, body-rocking style reflects the high value that Africans place on the erotic. In all this it appears likely that tall black Africans, moving south from the northern savanna, learned much from the small aboriginal jungle dwellers, the Pygmies and the Bushmen, who still today excel at rhythm, playful vocalizing, and polyphony. The black Nilotes and Cushites of East Africa do not share all these gifts, though they are clearly Africans. The core style, however, gives most of black Africa, in spite of its musical diversity, a stylistic unity that no other such large area can boast of. The pattern survived virtually intact through the Atlantic passage and centuries of deculturation in slavery. In Brazil, among sizable minorities who still speak African languages, many songs are simply West African. West Indian song style is often indistinguishable from West African except that melodic fragments of western European or Creole origin appear. In the United States the slaves learned to create western European strophes, or stanzas, thus producing ballads such as "Frankie and Albert" and spirituals such as "Go Down Moses." Adapting western European harmonic materials, they created a new world of chords found in their spirituals and popular music. They learned to make European instruments sing in a playful African vein, and so produced fiddle breakdowns (improvisations), the minstrel tunes, piano ragtime, and instrumental jazz. Even so, their manner of playing and singing remained basically African.

European peasant. Perhaps the oldest of the three main European folk song traditions is the one found in central and eastern Europe, site of Neolithic agricultural villages. Here a highly cohesive, often polyphonic style, basically similar to those of Africa and Oceania, has endured for many centuries, apparently reflecting the communal, complementary culture pattern of the region. This area early received hard-grain plow agriculture and dairying from the Middle East as it also gradually acquired the musical instruments developed by the great ancient civilizations. Yet middle Europe remained sufficiently isolated so that a world of regional musical styles could flower alongside new and productive types of agriculture. Dozens of folk polyphonies, both instrumen-

Persistence
of the black
African
style

Pacific
choral
singing

tal and-vocal, can be found from the Caucasus Mountains north across the Russian plains, east along the Baltic, in the mountainous sectors of central Europe, and in the Balkans. This region, where the agricultural cycle, the country dance, and music making are all highly cohesive and integrated, is the most likely zone of origin for European fine art music. Its distinctive traits—clear, wide voices; complex texts, precisely enunciated, yet sung in perfect concert; strings of strophic melodies; orchestra; of strings and horns joined in accompanying rather than polyrhythmic relationships; and part singing based on separate melodic movement—are uniquely common in both its folk and fine art traditions.

This central Old European zone includes southern Germany, northern Italy, and Spain, with northeastern France and Wales as its westernmost extensions. It gave rise to art music institutions such as the orchestra and church choir and to the system of harmony and ensemble that influenced all western European popular music, vocal and instrumental. Since its inception, the popular music industry has been controlled by persons taking for granted Old European stylistic standards of vocal and instrumental style and circumstances of performance. Accordingly, the music of Tin Pan Alley is shaped to fit those standards, both in elements surrounding the vocal performance—such as the orchestras and the harmonies, tempi, and musical forms—and also in the concert of the choruses; and, above all, in vocal delivery and enunciation. Jazz was made to conform by dressing the players in uniforms and placing them in orchestral sections under a director's baton. Both the register-breaking black vocal style, with its gamut of vocal effects, and the thin, nasal voices of white Midwesterners were modified through voice lessons, disguised with close miking and echo chambers, and hidden behind large orchestras. Rock, the latest of the musical developments stemming from the crowded urban black ghettos, was given an overlay of Old European vocal and instrumental style by the Beatles and a regimented polish by professional techniques such as multi-track recording.

Northwestern European. Among the almost unbroken victories of this central European tradition, a few defeats have been caused by the stubborn preference of other cultures for their own singing traditions. Strongest of these in America was the ballad style of northwestern Europe. This zone of shepherds, fisherman, woodsmen, and isolated farmers has long favoured the turn-by-turn singing of unaccompanied solo narrative songs the purpose of which was to tell a tale rather than to create a musical mood. This tradition gave rise to most English-language folk songs of the United States and Canada—the workaday ballads of the lumberjacks, cowboys, and miners. What counted in a singer was a good memory and the ability to "sing it out plain and clear." The singer was a neutral-voiced storyteller, permitted a bit of embellishment in the Irish tradition but committed to maintaining a poker face and letting the story tell itself. The burdens, or refrains, of the sea chanteys were handled in roaring individualized unison.

In the southern backwoods of the United States the narrow-voiced, ornamented style of the Scots-Irish took hold and flowered, perhaps reflecting in its tense-voiced delivery the emotional tensions of frontier Protestantism with its painful sanctions against fleshly pleasure. At one time it was the pride of mountain singers to keep their tone a straight continuation of the wailing notes of a fiddle accompaniment. When the backwoods opened up to black five-string banjo and guitar music and little singing ensembles were formed, these individualized, high, lonesome mountain voices produced a thrilling steam-whistle unison; then, with town ways and mill employment freeing their women, it gave rise to the wailing harmonized style called "hillbilly."

Southern poor whites found a style to their liking in hillbilly as black urbanized workers had earlier found their favourite style in the blues. The blues, although it reflects its African roots in playful vocalizing, descending cadences, and polyrhythmic overlapping with its accompaniment, still joins the mainstream of northwestern

European music. The centre of this tradition is in its adherence to the brief three or four phrase strophe (stanza): set to simple metres. For centuries the great majority of the songs in this region have been such simple strophes, and the whole of American folk and pop songs are variations on this formal theme. Europe's herdsmen and husbandmen, and America's fiddlers, bluesmen, and popular song composers have been mainly preoccupied with the creation of these compact melodic packages.

Old High Culture. This zone of the ancient high civilizations, including the European southern Mediterranean, North Africa, the Middle East, India, and the Far East, is united by a common cultural heritage and a common performance style. The Middle Eastern culture complex of grain agriculture, hoofed animal husbandry, cities, writing, and empire spread through this vast area thousands of years ago, presumably carrying a suitable song style in its van. Sea and caravan trade routes kept alive the exchange between the farthest ends of this region so that in spite of its variety of languages, arts, and local historical developments it has many things in common. A complex system of irrigation agriculture supported by specialized pastoralism, a highly centralized political system, and a multilayered social stratification seem to be mirrored in the flowery textual style and in long through-composed (nonstrophic) melodies that are elaborately enunciated and heavily ornamented with passing notes, quavers, glottal shakes, melismata (many notes to one syllable), glides, and rhythmic variation. The Oriental bard addressing an all-powerful emperor, the priest supplicating the deity, the lover crying out to his distant adored, all employ a variant of this flowery, elaborate, and placatory style. Everywhere, from raspy-voiced west Sudan to the pressed-back and squeezed-white tone of Indonesia and Japan, the vocal delivery tends to be tense, high-pitched, and nasal, a symbolic parallel to the severe system of constraints that separate the sexes and bear, with painful heaviness, upon the women of this zone. Similarly, the radical centralization of authority in the state, the community, and the family and the radical system of punishment and law that reinforced this system may be related to the predominance of solo bardic performances, which comprise almost two-thirds of all singing in this region. Sometimes singing without accompaniment, more often accompanied by one heterophonically related instrument or by a large and elaborate orchestra, and in a wealthy setting, the bards of old High Culture for six or seven millennia have had free play with their passive and often reverent audiences. Because through the content of their recitations they supported and reinforced the centralized imperial systems, these bards had the leisure to specialize, to devote themselves exclusively to the arts of song style, gesture, music, and poetry and to develop systems of orchestration and music theory. European music owes much to these masters. Young Western composers and instrumentalists are turning to them today, finding excitement in the endless games of schooled elaboration, improvisation, and virtuosity, yet savouring also the endless and tender melancholy of their melodies. This is an unexpected development at the dawn of the atomic age, perhaps a sign of an Oriental level of stratification emerging in Western democratic society.

Sinkiang Uighur

Sinkiang Uighur Autonomous Region (in Pin-yin romanization Xin-jiang-wei-wu-er Zu-zi-chii) occupies the northwestern corner of the People's Republic of China. It is bordered by Mongolia to the northeast, the Soviet Union to the northwest, Afghanistan and the disputed territory of Jammu and Kashmir to the southwest, the Tibetan Autonomous Region to the southeast, and the Chinese provinces of Tsinghai and Kansu to the east. China's largest political unit, it covers 635,800 square miles (1,646,700 square kilometres), or one-sixth the national area. The population of about 8,000,000 is composed of numerous ethnic groups, the largest of which is the Uighurs. The Uighurs follow the Islāmic religion and work at agriculture and animal husbandry. The capital city of Urumchi is abusy commercial and industrial centre.

The Chinese name Sinkiang, or New Dominion, was applied to the area when it came under Chinese rule in the 3rd century BC. The region was long known to Westerners as Chinese Turkistan to distinguish it from Russian Turkistan.

Sinkiang is an area of lonely, rugged mountains and vast desert basins. Its indigenous population of agriculturalists and pastoralists inhabit oases strung out along the mountain foothills or wander the arid plains in search of pasturage. Since the establishment of firm Chinese control in 1949, serious efforts have been made to integrate the regional economy into that of the nation. Agriculture has been improved, mining increased, power stations built, and industry introduced. Previously isolated from the rest of China, Sinkiang is now connected to neighbouring provinces by road and rail, and transportation to the Soviet Union has been improved. Despite the great increase in the Chinese population, the ethnic groups are officially encouraged to develop their own cultures.

For related physical features, see ALTAI MOUNTAINS; KUNLUN MOUNTAINS; PAMIR MOUNTAIN AREA; TARIM RIVER; TAKLA MAKAN DESERT; and TIEN SHAN (MOUNTAINS). For a more detailed discussion of history, see TURKISTAN, HISTORY OF.

History. Southern Sinkiang was controlled by China during the Han dynasty (206 BC–AD 220). It then passed under the rule of local Uighur rulers until it was conquered by the Mongol leader Genghis Khan in the 13th century and in the 18th century by the Mongolian-speaking Kalmucks. Sinkiang again came under Chinese control during the Ch'ing (Manchu) dynasty (1644–1911) and was made a province of China in 1884. Because of the region's remote location, the rule of the central government was nominal; the province was governed by semi-independent warlords, occasionally under pressure from the Soviet Union. Sinkiang came under the rule of the Chinese Communists in 1949 and, in accordance with the government's ethnic policy, became the Sinkiang Uighur Autonomous Region in 1955.

The landscape. *Relief.* Sinkiang can be divided into five physiographic regions: the Northern Highlands, the Dzungarian Basin, the Tien Shan (Celestial Mountains), the Tarim Basin, and the Kunlun Mountains. These regions run roughly from east to west, the high mountains alternating with large, lower basins.

In the north, the Northern Highlands extend in a semi-circle along the Mongolian border. The major range in this area is the Altai Mountains, with average heights of approximately 4,500 feet above sea level. The slopes of the Altai Mountains on the Chinese (western) side are relatively gentle, with numerous rolling and dome-shaped hills.

The triangular-shaped Dzungarian Basin, or Dzungaria, with an area of 270,000 square miles (700,000 square kilometres), is bordered by the Altai Mountains on the northeast, the Tien Shan on the south, and the Chun-ka-erh-a-la-t'ao Shan on the northwest. The basin is open on both the east and west. It contains a ring of oases at the foot of the enclosing mountains and a steppe and desert belt in the centre of the depression.

The Tien Shan occupies nearly one-fourth of the area of Sinkiang. The mountains stretch into the region from the Soviet Union and run eastward from the border for about 1,000 miles. They are highest in the west and taper off slightly to the east. The highest peaks are Khan-tengri, which rises to an elevation of 22,949 feet (6,995 metres) on the Sino-Soviet border, and Sheng-li, which attains 24,406 feet (7,439 metres), 13 miles to the south. The Tien Shan is perpetually covered by snow, and numerous long glaciers descend its slopes from extensive snow fields.

The Tarim Basin is surrounded by the Tien Shan to the north, the Pamir Mountains to the west, and the Kunlun Mountains to the south. It occupies about 55 percent of Sinkiang, extending 850 miles from west to east and about 350 miles from north to south. The basin consists of a central desert, alluvial fans at the foot of the mountains, and isolated oases. The desert—the Takla Makan—covers more than 270,000 square miles (700,000 square kilometres) and is absolutely barren. The core of the basin has an elevation ranging from about 4,000 feet (1,200 metres) above sea level in the west to about 2,500 feet (760 metres) in the east. The Turfan Depression at

Economic development

The Tarim Basin

the eastern end of the Takla Makan, however, is 505 feet (154 metres) below sea level.

The Kunlun Mountains form the northern rampart of the Tibetan Plateau. With elevations up to 24,000 feet, the central part of the range forms an almost impenetrable barrier to movement from north to south. There are passes on the west and east such as the Karakoram in Kashmir and the K'u-erh-kan in Sinkiang. In the east the A-erh-chin Shan-mo turns northeast and eventually merges with the Nan Shan in southern Kansu Province, China.

Drainage and soils. The drainage pattern of Sinkiang is unique. The only stream whose waters reach the sea is the O-erh-ch'i-ssu, which rises in north central Sinkiang, crosses into the U.S.S.R., and joins the Ob, which empties into the Arctic Ocean. Other streams in Sinkiang issue from the mountains and disappear into inland deserts or salt lakes. The principal river is the Tarim, which is fed by largely intermittent streams that rise in both the Kunlun Mountains and the Tien Shan. It flows eastward across the Tarim Basin into the salt lake of Lop Nor and ends in marshes west of the lake.

Climate. Remote from the ocean and enclosed by high mountains, Sinkiang is cut off from marine climatic influences. It therefore has a continental dry climate. The Tien Shan separates the dry south from the slightly less arid north, and the northern slopes of the Tien Shan are more humid than those on the south.

Rainfall is not only small, but it fluctuates widely from year to year. Average January temperatures in the Tarim Basin are about 20° F (−7° C), compared with 5° F (−15° C), in many parts of Dzungaria. In the summer, average temperatures north of the Tien Shan are lower than they are south of the mountains. In Dzungaria, July averages vary from 70° F (21° C) in the north to 75° F (24° C) in the south. In the Tarim Basin, July temperatures average about 80° F (27° C). The hottest part of Sinkiang is the Turfan Depression, where a maximum of 118° F (48° C) and a July mean of 90° F (32° C) have been recorded.

Vegetation and animal life. Because of the great expanses of desert, the plant life of much of Sinkiang is monotonous. There are pine forests in the Tien Shan and turgak woods in many places on the edge of the Takla Makan Desert. Apart from these trees, the most common are varieties of poplars and willows. In the Tien Shan and other mountains, there is a great assortment of wild plants and flowers, many of which have never been classified and of which little is known.

Animal life is of greater interest, and big-game hunting is an attraction of the Tien Shan. These and other mountains are inhabited by antelopes, ibex (wild goats), wapiti (elks), various wild sheep, leopards, wolves, bears, lynx, and marmots (burrowing rodents). There are wild horses in the north, wild camels near Lop Nor, and wild yaks (large, long-haired oxen) and wild asses on the Tibetan frontier. Deer, wild boar, wild cats, foxes, and hares are also found. Bird life is extensive, especially in the Lop Nor district. The few varieties of fish are mostly of the carp family. Snakes are not numerous and appear to be harmless; scorpions and centipedes, however, abound. During the summer, horse flies, mosquitoes, flies, and midges are thick in the woods. A great variety of butterflies are seen in the mountains.

The people. Population groups. Sinkiang is inhabited by 13 different ethnic groups, of which the largest are the Uighurs and the Chinese. Other groups include the Mongolians and Khalkans, Hui (Chinese Muslims), Kazakhs, Uzbeks, Tungusic-speaking Manchus and Sibos, Tadjiks, Tatars, Russians, and Tahurs. In 1953 the Uighurs accounted for almost 75 percent of the total population of 4,900,000; there were only about 1,000,000 members of non-Chinese groups and about 300,000 Chinese. By the mid-1960s the Chinese population had increased to 2,600,000, or almost one-third of the total population of 8,000,000; there were 4,000,000 Uighurs.

The Chinese migration altered the pattern of population distribution. In 1953 only 1,300,000 people lived north of the Tien Shan in the Dzungarian Basin, and three-fourths

of the population lived south of the mountains in the Tarim Basin. The Chinese influx was directed mainly to Dzungaria because of its resource potential. By 1970 the population was believed to be evenly divided between the two basins, with a Uighur majority in the south and a majority of Chinese in the north. The Kazakhs, the third largest minority group, are nomadic herdsmen in the steppes of Dzungaria; they are especially concentrated in the Upper Ili Valley.

There are two major language groups in the region. The Mongolians speak languages of the Mongolian branch of the Altaic group, and the Uighurs, Kazakhs, and Uzbeks speak the Turkic branch of the Altaic group. The Tadjiks, however, belong to the Iranian branch of the Indo-European language group. Mongolian, Uighur, and Kazakh are written languages in everyday use; Mongolian has its own script, while Uighur and Kazakh are written in the Arabic script.

The largest Muslim groups in China are the Uighurs and the Hui. The Kazakhs and Tadjiks also follow Islām, and the Mongolians are adherents of Buddhism.

Settlement patterns. There are many differences in rural settlement patterns in the north and south. Oasis agriculture in the Tarim Basin occupies about 40 percent of the population, and only 2 percent are engaged in animal husbandry. North of the Tien Shan, the grasslands support 35 to 40 percent of the population, who are pastoralists.

In the early 1970s, there were four major cities in the province. Urumchi (Chinese Wu-lu-mu-ch'i), the regional capital, had grown from a population of 80,000 in 1949 to about 500,000 by 1970. Formerly an agricultural centre for the Dzungarian Basin, it has undergone considerable industrial development. Karamai, also in Dzungaria, had a population of more than 40,000 in 1958; in the early 1960s it was developed as a centre of the petroleum industry. Kuldja (Chinese I-ning) is located in the Upper Ili Valley near the Soviet border. With a population of 85,000 in 1958, it was an administrative town with a growing food-processing industry. Kashgar is the largest city of the Tarim Basin, with a population in 1960 of 140,000; it is an ancient centre for the manufacture of handicrafts such as textiles, rugs, and tanned leather.

Administration and social conditions. Government. The administrative structure of Sinkiang reflects the governmental policies of recognition of ethnic minorities and self-administration, in which local leaders are appointed to governmental positions. The Sinkiang Uighur Autonomous Region is divided on the subprovincial level into three types of administrative units. There are two municipalities (*shih*) of Karamai (K'o-la-ma-i) and Urumchi (Wu-lu-mu-ch'i); the area to the southeast of Urumchi—including the towns of Toksun (T'o-k'o-hsün), Turfan (T'u-lu-fan), and Shan-shan—is under direct regional administration. There are five autonomous districts (*tzu-chih-chou*): Bayan Gol Mongol (Pa-yin-kuo-leng-meng-ku), Boro Tala Mongol (Po-erh-t'a-la-meng-ku), Ch'ang-chi Hui (Chang-chi-hui-tsu), Ili Kazakh (I-li-ha-sa-k'o), and Kizil Su Kirghiz (K'o-tzu-lo-su-k'o-erh-k'o-tzu). The six areas (*ti-ch'ü*) include A-k'o-su, Ha-mi, Ho-t'ien, K'a-shih, A-le-t'ai, and T'a-ch'eng, the last two of which are under the administration of the Ili Kazakh Autonomous District.

Below the subprovince level, there are two municipalities of Kuldja and Kashgar, 73 counties (*hsien*), and six autonomous counties (*tzu-chih-hsien*).

Education. Before World War II the educational system was minimal; attendance appeared to be voluntary and the teaching halfhearted. Since 1949, educational facilities have been broadened. Institutions of higher learning, concentrated in Urumchi, include the Sinkiang University; the Sinkiang "August First" Institute of Agriculture, which offers a course on water conservation; the Sinkiang Institute of Minorities, which offers courses in art, Chinese language and literature, history, and science; the Sinkiang Medical College; and the Sinkiang Institute of Languages, which offers instruction in Russian, English, French, and German language and literature. The provincial library and museum are also in Urumchi.

The economy. *Sources of income.* Because of the dry climate, more than 90 percent of the cultivated land in Sinkiang depends entirely on irrigation. The various nationalities in the region have had rich experience in water-conservancy techniques, of which the Kareze system in the Turfan and Ha-mi depressions is a fine example. The present cultivated area can be more than doubled with the further utilization of Sinkiang's mountain glaciers, rivers, and underground water.

About half of the total crop area is sown into winter and spring wheat. Maize (corn), another important crop, is grown more extensively in the south than the north. Rice, kaoliang (Chinese sorghum), and millet are also produced in large quantities. Long-staple cotton is produced in the Turfan Depression and the greater Tarim Basin. Sinkiang is one of China's main fruit-producing regions; its sweet Ha-mi melons, seedless Turfan grapes, and Ili apples are well-known. Livestock includes about 25 percent of China's sheep, which yield about 60 percent of the nation's wool.

Mineral resources include deposits of lead, zinc, copper, and molybdenum and tungsten (metallic elements used in strengthening steel), none of which are of industrial significance. Gold is produced from placer and lode deposits on the southern slopes of the Altai Mountains, where uranium is also believed to be mined. Significant quantities of petroleum are produced at Karamai, whose Uighur name means Black Soil.

Sinkiang's industry is powered by thermal and hydroelectric stations in the major cities. Heavy industry includes an iron and steel works and a cement factory at Urumchi and a farm-tool plant at Kashgar. Industries processing agricultural products have been established near the sources of raw materials. They include the cotton mill in Kashgar, the silk mill in Khotan in the south, the cotton mill in Shih-ho-tze, the woolen-textile mill in the Kazakh pastoral area of northern Sinkiang, the beet-sugar mill in the Ma-na-ssu reclamation area (northwest of Urumchi), and processing factories for the animal products of the pastoral areas.

Transportation. Roads encircle the Tarim Basin, along the foothills of the surrounding mountains, and run along the northern foothills of the Tien Shan in Dzungaria. The two basins are connected by a road that crosses the Tien Shan near Urumchi. There are roads leading to the Soviet Union in the north through passes in Dzungaria and in the south through the pass at Kashgar, the historic gateway of the silk trade between Asia and Europe. The region is also connected by road to the Chinese provinces of Kansu and Tsinghai in the southeast.

A railway crosses Sinkiang from Kansu Province through Ha-mi, Urumchi, and the Dzungarian Gate (a pass in the Pamir Mountains); it connects with the Soviet railway system at Aktogay, Kazakh S.S.R. Air services radiate from Urumchi east to Ha-mi, south to Khotan, west to Kuldja, and north to A-lo-t'ai.

Cultural life. The various indigenous peoples of Sinkiang exhibit their own cultures. The dominant Uighurs are sedentary farmers whose social organization is centred upon the village. There is little political unity, and the villages are virtually autonomous. The Uzbeks, related to the population of the Uzbek S.S.R., are also agriculturists who exhibit some remnants of their ancient nomadic way of life. Tadzhiks are related to those of the Tadzhik S.S.R. Agriculturists, they are also skilled in handicrafts and trade.

The Kazakhs are pastoralists related to the people of the Kazakh S.S.R. They migrate seasonally in search of pasturage and live in dome-shaped, portable tents known as yurts. Livestock includes sheep, goats, and some cattle; horses are kept for prestige. The basic social unit is the extended family; political organization extends through a hierarchy of chiefs. Although there is a concept of national origin, the chiefs are seldom united.

Like the Kazakhs, the Mongolians are pastoralists who live in yurts, but their society is more firmly organized. The basic social unit is the nuclear family. There is an established political hierarchy of groups, the smallest of which is a group of several households known as a *bag*.

The average person, or free nomad (*arat*), owes allegiance to nobles (*taiji*) and princes (*noyan* or *wang*). National power, however, is fragmented.

Sino-Tibetan Languages

In the narrowest sense, the Sino-Tibetan languages include the Chinese and Tibeto-Burman languages. In terms of numbers of speakers, they comprise the world's second largest language family (after Indo-European), including over 300 languages and major dialects. In a wider sense, Sino-Tibetan has been defined as also including the Tai (or Daic), Karen, and Miao-Yao languages and even the Yenisey-Ostyak (or Ket) language in Northern Siberia (the latter affiliation seems rather untenable). Some linguists connect the Austro-Asiatic or Austronesian (Malayo-Polynesian) families, or both, with Sino-Tibetan; a suggested term for this most inclusive group, which seems to be based on premature speculations, is Sino-Austroic. Other scholars see a relationship of Sino-Tibetan with the Athapaskan and other languages of North America, but proof of this is beyond reach at the present state of knowledge.

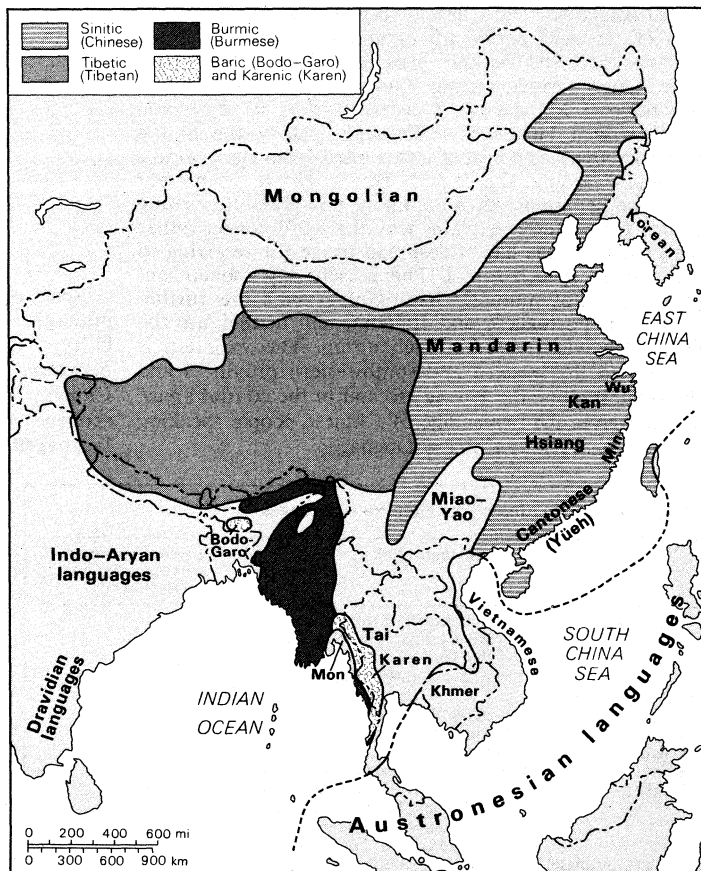

Sino-Tibetan languages were known for a long time by the name of Indochinese, which is now restricted to the languages of Indochina. They were also called Tibeto-Chinese until the now universally accepted designation Sino-Tibetan was adopted. The term Sinitic also has been used in the same sense, as well as for the Chinese subfamily exclusively. (In the following discussion of language groups, the ending *-ic*, as in Sinitic, indicates a relatively large group of languages, and *-ish* denotes a smaller grouping.)

Sinitic languages, commonly known as the Chinese dialects, are spoken in China and on Taiwan and by important minorities in all the countries of Southeast Asia (by a majority only in Singapore). In addition, Sinitic is spoken by Chinese immigrants in many parts of the world, notably in Oceania and in North and South America; altogether there are some 600,000,000 speakers of the Chinese dialects. Sinitic is divided into a number of languages, by far the most important of which is Mandarin (or Northern Chinese). Mandarin, which includes Modern Standard Chinese (which is based on the Peking dialect), is not only the most important language of the Sino-Tibetan family but also has the most ancient writing tradition still in use of any modern language. The remaining Sinitic language groups include Wu (including Shanghai dialect), Hsiang (Hunanese), Kan (or Kan-Hakka), Yiieh, or Cantonese (including Canton and Hong Kong dialects), and Min (including Fuchow, Amoy, and Taiwanese).

Tibeto-Burman languages are spoken in Tibet and Burma; in the Himalayas, including Nepal, Sikkim, and Bhutan; in Assam and in Bangladesh; as well as by hill tribes all over mainland Southeast Asia and West China (Kan-

Areas in which the languages are spoken

su, Tsinghai, Szechwan, and Yunnan provinces). The total number of speakers is approximately 25,000,000. **Tibetic** (*i.e.*, Tibetan in the widest sense of the word) comprises a number of dialects and languages in Tibet and the Himalayas. Burmic (Burmese in its widest application) includes Lolo, Kachin, Kuki-Chin, the obsolete Hsi-hsia, or Tangut, and other languages. The Tibetan writing system (from the 7th century) and the Burmese (from the 11th century) are derived from the Indo-Aryan (Indic) tradition; the Hsi-hsia system (11th–13th century in Northwest China) was based on the Chinese model. Pictographic writing systems, which show some influence from Chinese, were developed within the last 500 years by Lolo and Moso tribes in West China. In modern times many Tibeto-Burman languages have acquired writing systems in Roman (Latin) script or in the script of the host country (Thai, Burmese, Indic, and others).

Distribution of the Sino-Tibetan languages.

CLASSIFICATION OF THE LANGUAGES

The old literary languages, Chinese, Tibetan, and Burmese, are generally considered as representatives of three major divisions within Sino-Tibetan (Sinitic, Tibetic, and Burmic). A fourth literary language, Thai, or Siamese (written from the 13th century), represents what was accepted for a long time as a Tai or Daic division of Sino-Tibetan or as a division of a Sino-Tai family (see also **TAI LANGUAGES**). This relationship is now more commonly considered **nongenetic** in that most of the shared vocabulary is more likely to be cultural loans than derivations from a common ancestral language.

Sinitic stands apart from Tibetic and Burmic on many grounds (vocabulary, morphology, syntax, and phonology). Most scholars agree on combining Tibetic and Burmic into a Tibeto-Burman subfamily, which also includes Bodo-Garo or Baric but not Karenic. If Karenic is Sino-Tibetan, it must be set up as an independent member of a Tibeto-Karen group that includes Tibeto-Burman. The special affinities between Sinitic and Karenic (especially in syntax) are secondary. The two closely related language groups, Miao and Yao (also known as Mnong and Man), may be very remotely related to Sino-Tibetan;

they are spoken in West China and northern mainland Southeast Asia and may well be of Austro-Tai stock.

In attempting to determine the exact interrelationship of the Tai (Daic) languages, Karenic, Sino-Tibetan, and several other marginal tongues, scholars must keep in mind that a discernable layer of Sino-Tibetan features in a given language may have been superimposed upon an older, non-Sino-Tibetan foundation (called the substratum language). Attributing a language to Sino-Tibetan or to another family may depend entirely on the ability of scholars to identify the substratum. Thus, if Tai is not considered as a division of Sino-Tibetan, it is because the substratum has been recognized as Austronesian; if Karen is still included among Sino-Tibetan languages on some level, it is perhaps because identification of a substratum is still lacking. Among the languages classified as Sino-Tibetan, a great many are known only from word lists or have not yet been described in a way that makes valid comparisons possible.

A number of Sino-Tibetan languages are enumerated below together with their most likely affiliation. Some scholars believe the Tibetic and Burmic divisions to be premature and that for the present their subdivisions (such as Bodish, Himalayish, Kirantish, Burmish, Kachinish, Kukish) should be considered as the classificatory peaks around which the Sino-Tibetan languages group themselves as members or more or less distant relatives. Certainly the stage has not yet been reached in which definite boundaries can be laid down and ancestral Proto-, or Common, Tibetic and Proto-, or Common, Burmic can be undisputedly reconstructed.

Tibetic languages. The Tibetic (or Bodic, from Bod, the Tibetan name for Tibet) division comprises the Bodish-Himalayish, Kirantish, and Mirish language groups.

Table 1: Tibetic (Bodic) Languages*

	areas where spoken	number of speakerst
Bodish-Himalayish

Miju	Assam, Tibet	
Dhimial	Darjeeling area	

*Represents approximately 6,000,000 speakers. †Approximate.

Burmish languages. The Burmic division comprises Burmish, Kachinish, and Kukish.

A number of Tibeto-Burman languages that are difficult to classify have marginal affiliations with Burmic. The

Karenic languages. The Karenic languages of the Karen State of Burma and adjacent areas in Burma and Thailand include the two major languages of the Pho (Pwo) and Sgaw, which have about 2,000,000 speakers. Taungthu (Pa-o) is close to Pho, and Palaychi to Sgaw. There are several minor groups.

Chinese, or Sinitic, languages. Chinese as the name of a language is a misnomer. It has been applied to numerous dialects, styles, and languages from the middle of the 2nd millennium BC. Sinitic is a more satisfactory designation for covering all these entities and setting them off from the Tibeto-Karen group of Sino-Tibetan languages. *Han* is a Chinese term for Chinese as opposed to non-Chinese languages spoken in China. The Chinese terms for Modern Standard Chinese are *kuo-yü* "national language" and *p'u-t'ung-hua* "common language." Reconstructed prehistoric Chinese is known as Proto-Sinitic (or Proto-Chinese); the oldest historic language of China is called Archaic or Old Chinese (8th–3rd century BC), and that of the next period up to and including the T'ang dynasty (618–907) is known as Ancient or Middle Chinese. Later periods include Old, Middle, and Modern Mandarin ("Mandarin" is a translation of *kuan-hua* "civil servant language"). Through history the Sinitic language area has constantly expanded from the "Middle Kingdom" around the eastern Huang Ho to its present size. The persistence of a common, non-phonetic writing system for centuries explains why the word dialect rather than language has had widespread usage for referring to the modern speech forms. The present-day spoken languages are not mutually intelligible (some are further apart than Portuguese and Italian), and neither are the major subdivisions within each group. The variation is slightest in the western and southwestern provinces and the greatest along the Huang Ho and in the coastal areas. Table 4 gives the percentage of Chinese people speaking each of the various Chinese languages.

Absence of intelligibility between Chinese spoken languages

Table 4: Distribution of the Chinese Languages		
	areas where spoken	ratio of speakers to total population (percentage)
Mandarin	China, north of the Yangtze River; a narrow belt south of the Yangtze River in Kiangsi, Anhwei, and Kiangsu; Szechwan, Yunnan, and Kweichow; small parts of Hunan	70†
Wu	Kiangsu and Chekiang	8+
Hsiang	Hunan	5
Kan‡	Kiangsi and a corner of Hupei	2+
Hakka‡	east and north Kwangtung; parts of Fukien, Kiangsi, Kwangsi, Taiwan, Hunan, Szechwan; sporadically in other provinces	4
Yüeh (Cantonese)	Kwangtung, south Kwangsi, Hong Kong, Macao	5
Min§	Fukien, west Kwangtung, Hainan, Taiwan, south Chekiang	4+
*A Chinese estimate from the 1950s gives the following figures of number of speakers: Mandarin 387,000,000; Wu 46,000,000; Hsiang 26,000,000; Kan-Hakka 33,000,000; Yieh 27,000,000; Min 22,000,000. †Figure applies to those people speaking Mandarin as the mother tongue as opposed to speaking it as a second language. ‡Kan and Hakka are often combined as Kan-Hakka, or simply Kan. §Min is subdivided into Northern Min, in North Fukien with little over 1 percent of the national population, and Southern Min, in the remainder of the Min-speaking area with 3 percent of the population.		

A vernacular written tradition exists mainly in Peking Mandarin and in Cantonese. An unwritten storytelling tradition has survived in most languages. The school and radio language is Modern Standard Chinese in China as well as in Taiwan and Singapore. In Hong Kong, Cantonese prevails as the school language and in the communication media. Modern Standard Chinese is the accepted written language for all Chinese.

Non-Chinese Sino-Tibetan languages of China include some Lolo-type languages (Burmish)—I (Yi, or Nyi), with over 3,000,000 speakers in Yunnan, Szechwan, Kweichow, and Kwangsi; Hani (or Akha) with fewer than 100,000 speakers in Yunnan; Lisu, with approximately

Table 2: Burmic Languages

Lahupa languages§ (Tangkhuul, Maring, Khoibu)		
<i>Nāga branch</i>	Nāgāland	
Northern: Ao		
Eastern group: Rengma, Sema (<i>Simi</i>), Angami		
Lepcha (<i>Rong</i>)	Sikkim, east Nepal, west Bhutan	
*These stand in a not clearly defined relationship to Lolo. †For cultural, non-linguistic reasons, Maru, Lashi, and Atsi are often grouped with Kachin. ‡In Manipur and Cachar. §These languages are similar to Kuki. Usually compared to the northern Nāga branch of Kukish, but has Baric and Himalayish affinities.		

Luish languages (Andro, Sengmai, Kadu, Sak, and perhaps also Chairel) in Manipur and adjacent Burma resemble Kachin; Nung (including Rawang and Trung) in the Kachin State of Burma and in Yunnan has similarities with Kachin; and Mru, with 20,000 speakers in Arakan and Chittagong Hills, Meithei (Mhithlei) in Manipur, and Mikir in Assam seem close to Kukish.

Baric languages. The Baric, or Bodo-Garo, division consists of a number of languages spoken in Assam and falls into a Bodo branch (not to be confused with Bodic Tibetic, and Bodish, a subdivision of Tibetic) and a Garo branch.

A group of Sino-Tibetan languages in Nāgāland (Nagish, not to be confused with the Nāga branch of Kukish; including Mo Shang, Namsang, and Banpara) has affinities to Baric.

Table 3: Baric (Bodo-Garo) Languages		
	areas where spoken	number of speakers*

250,000 speakers in Yunnan; Lahu, with 150,000 speakers in Yunnan; Moso or Nasi, with 150,000 speakers in Yunnan and Szechwan; and Achang by the Burmese border. Other Sino-Tibetan languages in Yunnan and Szechwan (with fewer than 100,000 speakers each) are Kachin and the closely related Tsaiwa; Ch'iang, Gyarung, Hsifan; and Pai (or Minchia, perhaps an Austro-Asiatic language).

COMMON SINO-TIBETAN FEATURES

At the end of the 18th and during the first half of the 19th century, a great number of languages were discovered by Western scholars in the Himalayas, in India, and in China, and word lists and grammatical sketches began to appear. By the late 19th century a foundation had been laid for Sino-Tibetan comparative studies.

The comparative method for determining genetic relationship among languages was worked out for Indo-European during the latter part of the 19th century. It rests on the assumption that sound correspondences in related words and morphological units, as well as structural similarities on all levels (phonology, morphology, syntax), can be explained in terms of a reconstructed common language, or protolanguage. The morphology and syntax of Sino-Tibetan languages are for the most part rather simple and nonspecific, and the length of time involved in the separation of subfamilies and divisions is such that comparative phonological statements are often hard to reduce to the form of concise correspondences and laws.

A number of features have been delineated as common for the Sino-Tibetan languages. Many of them can be shown to be of a typological nature, the result of diffusion and underlying unrelated language strata.

Typological similarities. *Monosyllabicity.* The vast majority of all words in all Sino-Tibetan languages are of one syllable, and the exceptions appear to be secondary (*i.e.*, words that were introduced at a later date than Common, or Proto-, Sino-Tibetan). Some suffixes in Tibeto-Burman are syllabic, thus adding a syllable to a word, but they have a highly reduced set of vowels and tones ("minor syllables"). These features are, however, shared by contiguous languages not clearly attributable to Sino-Tibetan on the basis of shared basic vocabulary items (namely, Austro-Asiatic and Miao-Yao).

Tonality. Most Sino-Tibetan languages possess phonemic tones, which indicate a difference in meaning in otherwise similar words. There are no tones in Purik, a Western Tibetan language; Ambo, a Northern Tibetan tongue; and Newari of Nepal. Balti, another Western Tibetan language, has pitch differences in polysyllabic nouns. The tones of the remaining Tibetan dialects can be accounted for by positing an original and older system of voiced and voiceless initial sounds that eventually resulted in tones. In several Himalayish languages, tones are linked with articulatory features connected with the end of the syllable or are linked with stress features, as also in Kukish Lepcha.

Most Baric languages lack tones altogether; and Burmese, Karenic, and Sinitic tonal systems can be reduced to two basic tones ultimately probably accounted for by different syllabic endings. What can be reconstructed for Proto-Sino-Tibetan, the language from which all the modern Sino-Tibetan languages developed, are a set of conditioning factors (as, for example, certain syllabic endings) that resulted in tones; the tones themselves cannot be reconstructed. Again the features that encouraged the development of tones are not uniquely Sino-Tibetan; similar conditions have produced similar effects in Tai and Miao-Yao and—within the Austro-Asiatic languages—in Vietnamese and in the embryonic form of two registers (itches or musical range) also in Cambodian.

Affixation. Most Sino-Tibetan languages possess or can be shown to have at one time possessed derivational and morphological affixes—*i.e.*, word elements attached before or after or within the main stem of a word that change or modify the meaning in some way. Many prefixes can be reconstructed for Proto-Sino-Tibetan: *s-* (causative), *m-* (intransitive), *b-*, *d-*, *g-*, and *r-*, and many more for certain language divisions and units. Among the

suffixes, *-s* (used with several types of verbs and nouns), *-t*, and *-n* are inherited from the protolanguage. The problem of whether Proto-Sino-Tibetan made use of *-r*- and *-l*- infixes (besides perhaps semivocalic infixes) has not been solved. Whether clusters containing these sounds were the result of prefixation to roots beginning in *r* and *l* (and *y*) or came about through infixation is not clear.

Initial consonant alternation. Voiced and voiceless initial stops alternate in the same root in many Sino-Tibetan languages, including Chinese, Burmese, and Tibetan (voiced in intransitive, voiceless in transitive verbs). The German Oriental scholar August Conrady linked this morphological system to the causative *s-* prefix, which was supposed to have caused devoicing of voiced stops. (Voicing is the vibration of the vocal cords, as occurs, for example, in the sounds *b*, *d*, *g*, *z*, and so on. Devoicing, or voicelessness, is the pronunciation of sounds without vibration of the vocal cords, as in *p*, *t*, *k*, *s*.) Such alternating of the initial consonant cannot itself be reconstructed for the protolanguage.

Vowel alternation. The morphological use of vowel gradation ("ablaut") is well-known from Indo-European languages (*e.g.*, the vowel change in English "sing, sang, sung") and is found in several Sino-Tibetan languages, including Chinese and Tibetan. In Tibetan the various forms of verbs are differentiated in part by vowel alternation; in Sinitic some related words ("word families") are kept apart by vowel alternation. A conditioning factor outside the vowel (perhaps stress or sandhi, the modification of a sound according to the surrounding sounds) may have been responsible for the Sino-Tibetan ablaut systems.

Indistinct word classes. Especially in the older stages of Sino-Tibetan, the distinction of verbs and nouns appears blurred; both overlap extensively in the Old Chinese writing system. Philological tradition as well as Sinitic reconstruction show, however, that frequently when the verb and the noun were written alike, they were pronounced differently, the difference manifesting itself later in the tonal system. Verbs and nouns also used different sets of particles. In this respect, Chinese resembles Tai and Austro-Asiatic, whereas Tibetan is more similar to the Altaic languages (for example, Turkish, Mongol).

Use of noun classifiers. The Sino-Tibetan noun is typically a collective term, designating all members of its class—*e.g.*, "man" meaning "all human beings." In a number of modern Sino-Tibetan languages, such a noun can be counted or modified by a demonstrative pronoun only indirectly through a smaller number of non-collective nouns, called "classifiers," in constructions such as "one person man," "one animal dog," and so on, much like parallel cases in Indo-European (in English, "one head of cattle"; in German, *ein Kopf Salat* "one head of lettuce"). The phenomenon is absent in Tibetan and appears late in Burmese and Chinese. Furthermore, classifiers are not exclusively Sino-Tibetan; they exist also in Miao-Yao, Tai, Austric, and Japanese. In Classical Chinese, Tai, and Burmese, the classifier construction follows the noun; in modern Chinese, as in Miao-Yao, it precedes it. Classifiers are of later origin and do not belong to Proto-Sino-Tibetan.

Word order. Although the word order of subject-object-verb and modified-modifier prevails in Tibeto-Burman, the order subject-verb-object and modifier-modified occurs in Karenic. In this respect Chinese is like Karen, although Old Chinese shows remnants of the Tibeto-Burman word order. Tai employs still another order: subject-verb-object, and modified-modifier, like Austric but unlike Miao-Yao, which follows the Karen and Chinese model. Word order, even more than any of the other distinguishing features, points to diffusion from several centres, or to unrelated substrata.

Phonological correspondences. The hypothesis that the Sino-Tibetan languages are all related and derive from a common source depends on phonological correspondences in shared vocabulary more than on any other argument. It is ironic that the clearest and most convincing results should have been obtained from studies of the

ships

Sinitic-Tai similarities, which probably do not indicate a true case of genetic relationship. In 1942 it was shown that most of the words in this grouping were cultural loans (then thought of as Chinese loanwords in Tai, now believed to a very large extent to be borrowings in the opposite direction).

A comparison of Old Chinese and Old Tibetan made by Walter Simon in 1929, although limited in some ways, pointed to enough sound resemblances in important items of basic vocabulary to eliminate the possibility of coincidental similarities between unrelated languages. A few examples of similar words in Old Tibetan and Old Chinese, respectively, follow: "bent," *klzyog* and *khyuk*; "eye," *mig* and *myok*; "friend," *grogs* and *gyug*; "kill," *gsod* and *sat*; "die" *shi* and *syar*; "sun," *nyi* and *nye*; "life," *srog* and *serg*. The U.S. linguist Paul Benedict brought in material from other Sino-Tibetan languages and laid down the rule that the comparative linguist should accept perfect phonetic correspondences with inexact though close semantic equivalences in preference to perfect semantic equivalences with questionable phonetic correspondences. New material and competent descriptions later made it possible to reconstruct important features of common ancestral languages within major divisions of Sino-Tibetan (notably Lolo, Baric, Tibetic, Kachin, Kukish, Karenic, Sinitic).

Interrelationship of the language groups. The position of Proto-Sino-Tibetan can be defined in terms of a chain of interrelated languages and language groups: Sinitic is connected with Tibetic through a body of shared vocabulary and typological features, similarly Tibetic with Baric, Baric with Burmic, and Burmic with Karenic. The chain continues at both ends, connecting Sinitic to Tai and Tai to Austronesian (Malayo-Polynesian) and also connecting Karenic with Austro-Asiatic. Considerations of basic vocabulary versus cultural loans and diffusion versus inheritance have led scholars to believe that only the members of the chain from Sinitic to Karenic share a common ancestral language; especially Sinitic and Karenic are under suspicion for containing only superstrata of Sino-Tibetan origin.

Proto-Tibeto-Burman was monosyllabic. Some grammatical units may have had the form of minor syllables before the major syllable (**ma-*, **ba-*) or after the major syllable (**-ma*, **-ba*). (An asterisk [*] indicates that the form it precedes is unattested and has been reconstructed as a possible ancestral form.) The consonants were three voiceless stops (*p*, *t*, *k*), which were aspirated in absolute initial position, three voiced stops (*b*, *d*, *g*), and three nasal sounds (*m*, *n*, *ŋ* [as the *-ng* in "sing"]). There were five continuant sounds (*s*, *z*, *r*, *l*, and *h*) and two semivowels (*w*, *y*). In final position there was only one set of stops, but there were a number of initial and final clusters mainly resulting from the addition of prefixes and suffixes. Three degrees of vowel opening existed with two members in each: *i* and *u*, *e* and *o*, *a* and *aa* (short and long *a*). Length may have been relevant also with the *i* and *u* and *e* and *o* vowels. The conditioning factors that led to the development of tones can be shown to have been voiced-voiceless contrast in initial and final consonants and consonant clusters. Because the conditioning factors were involved with morphological process (affixation and consonant alternation), tonal systems could also acquire certain grammatical or structural functions. An independent morphological system was vowel alternation.

The sound system of Proto-Karenic appears closely related to that of Proto-Tibeto-Burman. The tonal classes can be reduced to two, which connect Karen to Burmic, Sinitic, Tai, and Miao-Yao.

Greater dissimilarity is encountered with respect to Proto-Sinitic. The contrast of aspirated and unaspirated voiceless stops in initial position is most likely the result of lost initial cluster elements as in Proto-Tibeto-Burman. The voiced stops also possess the aspirated-unaspirated distinction. Unlike Tibeto-Burman, two series of stops in syllable final position are posited for Old Chinese, but whether the contrast involved aspiration or voicing is not clear. One series is in general without an exact corre-

spondence in Tibeto-Burman languages, but Burmish Maru and Kuki-oid Mru both have final stops in a number of these words. Similar isolated cases are found in Tibetan and in Tai.

Old Chinese has two more relevant points of articulation, or sound-producing positions of the mouth, than Proto-Tibeto-Burman: palatal (in which the tongue surface touches the palate) and retroflex (in which the tip of the tongue is curled upward toward the palate). But these two types of sounds may be explained as the result of influence from lost Proto-Sinitic medial sounds (a palatal *-y-* and a retroflex *-r-*). The relationship between these specific medial sounds and similar elements in Tibeto-Karen is, however, not certain. Dental affricate sounds in Old Chinese, which begin as stops with complete stoppage of the breath stream and conclude as fricatives with incomplete air stoppage and audible friction, can at least be explained partly as metathesized (transposed) forms of prefix *s-* plus a dental sound in Proto-Sinitic (*e.g.*, *st* changes to *ts*). Old Chinese possessed initial consonant clusters containing *-l-* as a second element, so Proto-Sinitic can reasonably be supposed to have had the same three medial elements as Proto-Tibeto-Burman: *-y-*, *-l-*, and *-r-*. There are few, if any, traces in Old Chinese of the more complicated clusters and the minor syllables of Tibeto-Burman.

The vowel system of Old Chinese as reconstructed (1940) by the linguist Bernhard Karlgren to account especially for the language of the "Classic of Poetry" (a collection of poetry, entitled the *Shih Ching*, from around 800–600 BC) seems surprisingly complicated as compared to that of later Sinitic and to that of Proto-Tibeto-Burman. Probably some of the vowels were in reality diphthongs or combinations of vowels plus consonants.

As in Karen and Burmese-Loloish, the tones of Sinitic can be reduced to two (the modern Sinitic languages have from two to as many as eight or nine). Monosyllabicity of roots and morphological affixation were characteristic features of Proto-Sino-Tibetan as of Proto-Tibeto-Karen.

CHARACTERISTICS OF THE MODERN CHINESE LANGUAGES

All modern Sinitic languages—*i.e.*, the "Chinese dialects"—share a number of important typological features. They have a single syllabic structure of the type consonant-semivowel-vowel-semivowel-consonant. Some languages lack one set of semivowels, and, in some, gemination (doubling) or clustering of vowels occurs. The languages also employ a system of tones (pitch and contour) and sometimes glottal features and occasionally stress. For the most part, tones are lexical (*i.e.*, they distinguish otherwise similar words); in some languages tones also carry grammatical meaning. Non-tonal grammatical units (*i.e.*, affixes) may be smaller than syllables, but usually meaningful units consist of one or more syllables. Words can consist of one syllable, of two or more syllables each carrying an element of meaning, or of two or more syllables that individually carry no meaning. For example, Modern Standard Chinese *t'ien* "sky, heaven, day" is a one-syllable word; *jih-t'ou* "sun" is composed of *jih* "sun, day," a word element that cannot occur alone as a word, and the noun suffix *t'ou*; and *hu-t'ier* "butterfly" consists of two syllables, each having no meaning in itself (this is a rare type of word formation). The Southern languages have more monosyllabic words and word elements than the Northern ones.

The Sinitic languages distinguish nouns and verbs with some overlapping, as do Sino-Tibetan languages in general. There are noun suffixes that form different kinds of nouns (concrete nouns, diminutives, abstract nouns, and so on), particles placed after nouns indicating relationships in time and space, and verb particles for modes and aspects. Adjectives act as one of several kinds of verbs. Verbs can occur in a series (concatenation) with irreversible order (*e.g.*, the verbs "take" and "come" placed next to one another denote the concept "bring"). Nouns are collective in nature, and only classifiers (see above) can be counted and referred to singly. Specific particles are used to indicate the relationship of nominals (*e.g.*, noun

Chain of
interrelated
languages

Vowel

Chinese

Sinitic
gram-
matical
character-
istics

and noun phrases) to verbs, such as transitive verb-object, agent-passive verb; in some of the languages this system forms a sentence construction called ergative, in which all nominals are marked for their function and the verb stays unchanged. Final sentence particles convey a variety of meanings, such as "question, command, surprise, new situation." The general word order of subject-verb-object and complement and modifier-modified is the same in all the languages, but the use of the preposed particles and verbs in a series varies considerably. Grammatical elements of equal or closely related values in various languages are very often not related in sounds.

The Sinitic languages fall into a Northern and a Southern group. The Northern languages (or Mandarin dialects) are closer to each other than the Southern ones (Wu, Hsiang, Kan, Yueh, Min).

Modern Standard Chinese (Mandarin). Modern Standard Chinese is based on the Peking dialect, which is of the Northern, or Mandarin, type. It employs about 1,300 different syllables. There are 22 initial consonants, including stops (made with momentary, complete closure in the vocal tract), affricates (beginning as stops but ending with incomplete closure), aspirated consonants, nasals, fricatives, liquid sounds (*l*, *r*), and a glottal stop. The medial semivowels are *y* (*i*), *ɥ* (*u*) and *w* (*u*). In final position, the following occur: nasal consonants, *r* (retroflex *r*), the semivowels *y* and *w*, and the combinations *ɲr* and *wr*. There are nine vowel sounds, including three varieties of *i* (retroflex, apical, and palatal). Several vowels combine into clusters.

There are four tones: (1) high level; (2) high rising crescendo; (3) low falling diminuendo with glottal friction (with an extra rise from low to high when final); (4) falling diminuendo. Unstressed syllables have a neutral tone, which depends on its surroundings for pitch. Tones in sequences of syllables that belong together lexically and syntactically ("sandhi groups") may undergo changes known as tonal sandhi, the most important of which causes a third tone before another third tone to be pronounced as a second tone. The tones influence some vowels (notably *e* and *o*), which are pronounced more open in third and fourth tones than in first and second tones.

A surprisingly low number of the possible combinations of all the consonantal, vocalic, and tonal sounds are utilized. The vowels *i* and *ü* and the semivowels *y* and *ɥ* never occur after velar sounds (*e.g.*, *k*) and occur only after the palatalized affricate and sibilant sounds (*e.g.*, *tʃ*), which in turn occur with no other vowels and semivowels.

There are many alternative interpretations of the distinctive sounds of Chinese; the interaction of consonants, vowels, semivowels, and tones sets Modern Standard Chinese apart from many other Sinitic languages and dialects and gives it a unique character among the major languages of the world. The two most widely used transcription systems (romanizations) are Wade-Giles (first propounded by Sir Thomas Francis Wade in 1859 and later modified by Herbert A. Giles) and the official Chinese transcription system today, known as the pinyin zimu ("Pin-yin phonetic spelling") or simply Pin-yin (adopted in 1958). The accompanying romanization table presents both the Wade-Giles and the Pin-yin systems. In Wade-Giles, aspiration is marked by ' (*p'* *t'*, and so on). The semivowels are *y*, *yü*, and *w* in initial position; *i*, *ü*, and *u* in medial; and *i* and *u* (but *o* after *a*) in final position. Final retroflex *r* is written *rh*. The tones are indicated by raised figures after the syllables (1, 2, 3, 4).

The Pin-yin system indicates unaspirated stops and affricates by means of traditionally voiced consonants (*e.g.*, *b*, *d*) and aspirated consonants by voiceless sounds (*e.g.*, *p*, *t*). The semivowels are *y*, *yu*, and *w* initially; *i*, *iu*, and *u* medially; and *i* and *u* (*o* after *a*) finally. Final retroflex *r* is written *r*. The tones are indicated by accent markers, 1 = ^ˊ, 2 = ^{ˊˊ}, 3 = ^ˇ, 4 = ^ˋ, (*e.g.*, *mā*, *má*, *mǎ*, *md* = Wade-Giles *ma*¹, *ma*², *ma*³, *ma*⁴).

Wade-Giles is used in the following discussion of Modern Standard Chinese grammar.

The most common suffixes that indicate nouns are *-erh* (as in *ch'ang-erh* "song"; cf. *ch'ang* "sing"), *-tzu* (as in *fang-tzu* "house"), and *-t'ou* (as in *mu-t'ou* "wood"). A set of postposed noun particles express space and time relationships (*-li* "inside," *-hou* "after"). An example of a verbal affix is *-chien* in *Pan-chien* "see" and *t'ing-chien* "hear." Important verb particles are *-le* (completed action), *-kuo* (past action), *chih* or *-che* (action in progress). The directional verbal particles *-lai* "toward speaker" and *-ch'ü* "away from speaker" and some verbal suffixes can be combined with the potential particles *te* "can" and *pu* "cannot"—*e.g.*, *na-ch'ü-lai* "take out," *na-pu-ch'ü-lai* "cannot take out"; *t'ing-chien* "hear," *t'ing-te-chien* "can hear." The particle *te* indicates subordination and also gives nominal value to forms for other parts of speech (*e.g.*, *wo* "I," *wo-te* "mine," *wo-te shu* "my book," *lai* "to come," *lai-te* "coming," *lai-te jen* "a person who comes"). The most important sentence particle is *le*, indicating "new situation" (*e.g.*, *hsia-yii-le* "now it is raining," *pu-lai-le* "now there is no longer any chance that he will be coming"). *Ko* is the most common noun classifier (*i* "one," *i-ko-jen* "one person"); others are *so* (*i-so-fang-tzu* "one house") and *pen* (*liang-pen-shu* "two books").

Adjectives can be defined as qualitative verbs (*hao* "to be good") or stative verbs (*ping* "to be sick"). There are equational sentences with the word order subject-predicate—*e.g.*, *wo-ihih pei-ching-jen* "I am a Peking-person (*i.e.*, a native of Peking)"—and narrative sentences with the word order subject (or topic)-verb-object (or complement)—*e.g.*, *wo ch'ih-fan* "I eat rice," *wo chu tsai pei-ching* "I live in Peking." The proposed object takes the particle *ba* (*wo da ta* "I beat him," *wo ba ta da le yi dun* "I gave him a beating"), and the agent of a passive construction takes *bei* (*wo bei ta da le yi dun* "I was given a beating by him").

Standard Cantonese. The most important representative of the Yüeh languages is Standard Cantonese of Canton, Hong Kong, and Macao. It has fewer initial consonants than Modern Standard Chinese (*p*, *t*, *ts*, *k* and the corresponding aspirated sounds *ph*, *th*, *tsh*, *kh*; *m*, *n*, *ɲ*; *f*, *s*, *h*; *l*, *y*), only one medial semivowel (*w*), more vowels than Modern Standard Chinese, six final consonants (*p*, *t*, *k*, *m*, *n*, *ɲ*), and two final semivowels (*y* and *w*). The nasals *m* and *ɲ* occur as syllables without a vowel.

There are three tones (high, mid, low) in syllables ending in *-p*, *-t*, and *-k*; six tones occur in other types of syllables (mid level, low level, high falling, low falling, high rising, low rising). Two tones are used to modify the meaning of words (high level °, and low-to-high rising *), as in *yin*° "tobacco," but *yin** "smoke" and *nöy** "daughter," but *nöy* "woman." Some special grammatical words also have the tone °. There is no neutral tone and little tonal sandhi.

There are more than 2,200 different syllables in Standard Cantonese, or almost twice as many as in Modern Standard Chinese. The word classes are the same as in Modern Standard Chinese. The grammatical words, although phonetically unrelated, generally have the same semantic value (*e.g.*, the subordinating and nominalizing particle *ke*, Modern Standard Chinese *te*; *m* "not," Modern Standard Chinese *pu*; the verbal particle for "completed action" and the sentence particle for "new situation," both *le* in Modern Standard Chinese, are Standard Cantonese *tsɔ* and *lɔ*, respectively).

Min languages. The most important Min language is Amoy from the Southern branch of Min. The initial consonants are the same as in Standard Chinese. There are two semivowels (*y*, *w*), six vowels and several vowel clusters, plus the syllabic nasal sounds *m* and *ɲ* functioning as vowels, the same semivowels as in Standard Cantonese, and, in addition, a glottal stop (ʔ) and a meaning-bearing feature of nasalization, as well as a combination of the last two features. There are two tones in syllables ending in a stop, five in other syllables. Tonal sandhi operates in many combinations.

Fuchow is the most important language of the Northern branch of Min. The very extensive sandhi affects not only tones but also consonants and vowels, so that the phonetic manifestation of a syllable depends entirely on interac-

tion with the surroundings. There are three initial labial sounds (p, ph, m), five dental sounds (t, th, s, l, n), three palatal sounds (ts, tsh, n), and five velars (k, kh, h, ʔ, and ŋ). Syllables can end in -k, -ŋ, -ʔ (glottal stop), a semi-vowel, or a vowel. The tones fall into two classes: a comparatively high class comprising high, mid, high falling, and high rising (only in sandhi forms) and a rather low one, comprising low rising and low rising-falling (circumflex). Certain vowels and diphthongs occur only with the high class, others occur only with the low class, and the vowel a occurs with both classes. Sandhi rules can cause tone to change from low class to high class, in which case the special vowels also change.

Other Sinitic languages. *Hakka.* Of the Kan (Kan-Hakka) languages, Hakka of Mei-hsien in Kwangtung is best known. It has the same initial consonants, final consonants, and syllabic nasals as Standard Cantonese; the

vowels are close to Modern Standard Chinese. Medial and final semivowels are y and w. There are two tones in syllables with final stops, four in the other syllabic types.

Suchow. Suchow is usually quoted as representative of the Wu languages. It is rich in initial consonants, with a contrast of voiced and voiceless stops as well as palatalized and non-palatalized dental affricates, making 26 consonants in all. (Palatalized sounds are nonpalatal sounds formed with simultaneous movement of the tongue toward the hard palate. Dental affricates are sounds produced with the tongue tip touching the teeth and then drawing slightly away to allow air to pass through, producing a hissing sound.) Medial semivowels are as in Modern Standard Chinese. In addition, there are also ten vowels and four syllabic consonants (l, m, n, ŋ); -n and -ŋ occur in final position, as do the glottal stop and nasalization.

Shanghai dialect. The Shanghai dialect belongs to Wu. The prevalent tendency is for there to be only two tones or registers (high and low), which are related in an automatic way to the initial consonant type (voiceless and voiced).

Hsiang languages. The Hsiang languages, spoken only in Hunan, are divided into New Hsiang, which is under heavy influence from Mandarin and includes the language of the capital Ch'ang-sba, and Old Hsiang, closer to the Wu languages, as spoken for instance in Shuang-feng. Old Hsiang has 28 initial consonants, the highest number for any major Sinitic language, and 11 vowels, plus the syllabic consonants *m* and *n*. It also uses five tones, final *n* and *ŋ*, and nasalization, but no final stops.

HISTORICAL SURVEY OF CHINESE

Vocabulary. Old Chinese vocabulary already contained many words not generally occurring in the other Sino-Tibetan languages. The words for "honey" and "lion," probably also "horse," "dog," and "goose," are connected with Indo-European and were acquired through trade and early contacts. (The nearest known Indo-European languages were Tocharian and Sogdian.) A number of words have Austro-Asiatic cognates and point to early contacts with the ancestral language of Muong-Vietnamese and Mon-Khmer; e.g., the name of the Yangtze River, **klawŋ*, Cantonese *kɔŋ*, Modern Standard Chinese *chiang*, is still the word for "river," pronounced *kron* and *kloŋ*, in some modern Mon-Khmer languages. Words for "tiger," "ivory," and "crossbow" are also Austro-Asiatic. The names of the key terms of the Chinese calendar ("the branches") have this same non-Chinese origin. It has been suggested that a great many cultural words that are shared by Chinese and Tai are Chinese loanwords from Tai. Clearly, the Chinese received many aspects of culture and many concepts from the Austro-Asiatic and Austro-Tai peoples whom they gradually conquered and absorbed or expelled.

From the first century AD China's contacts with India, especially through the adoption of Buddhism, led to Chinese borrowing from Indo-Aryan (Indic) languages, but, very early, native Chinese equivalents were invented. Sinitic languages have been remarkably resistant to direct borrowing of foreign words. In modern times this has led to an enormous increase in Chinese vocabulary without a corresponding increase in basic meaningful syllables. For instance, *t'ieh-lu* "railroad" is based on the same concept expressed in the French *chemin de fer*, using *t'ieh* "iron" and *lu* "road"; likewise, *tien-hua* "telephone" is a compound of *tien* "lightning, electricity" and *hua* "speech." A number of such words were coined first in Japanese by means of Chinese elements and then borrowed back into Chinese. The reason that China has avoided the incorporation of foreign words is first and foremost a phonetic one; such words fit very badly into the Chinese pattern of pronunciation. A contributing factor has been the Chinese script, which is ill-adapted to the process of phonetic loans. In creating new words for new ideas, the characters have sometimes been determined first and forms have arisen that cannot be spoken without ambiguity ("sulfur" and "lutecium" coalesced as *liu*, "nitrogen" and "tantalum" as *tan*). It is characteristic of Modern Standard Chinese that the language from which it most freely borrows is one from its own past: Classical Chinese. In recent years it has borrowed from Southern Sinitic languages under the influence of statesmen and revolutionaries (Chiang Kai-shek was originally a Wu speaker and Mao Tse-tung a Hsiang speaker). Influence from English and Russian (in word formation and syntax) has been increasingly felt.

Historical periods: pre-Classical Chinese. The history of the Chinese language can be divided into three periods, pre-Classical (c. 1500 BC–c. AD 200), Classical (c. 200–c. 1920), and post-Classical Chinese (with important forerunners as far back as the T'ang dynasty).

The pre-Classical Chinese is further divided into Oracular Chinese (Yin dynasty [c. 1766–c. 1122 BC]), Archaic

Chinese (Chou and Ch'in dynasties [1122–206 BC]), and Han Chinese (Han dynasty [206 BC–AD 220]).

Oracular Chinese is known only from rather brief oracle inscriptions on bones and tortoise shells. Archaic Chinese falls into Early, Middle (c. 800–c. 400 BC), and Late Archaic. Early Archaic is represented by bronze inscriptions, parts of the "Classic of History" (*Shu Ching*), and parts of the "Classic of Poetry" (*Shih Ching*). From this period on, many important features of the pronunciation of the Chinese characters have been reconstructed (see below). The grammar depended to a certain extent on unwritten affixes. The writing system kept apart forms with or without infixes. Early Archaic Chinese possessed a 3rd person personal pronoun in three cases (nominative *kyag*, or *ghyag*, accusative *cyag*, genitive *kywat*). No other kind of written Chinese until the post-Classical period possessed a nominative of the 3rd person pronoun, but the old form survived in Cantonese (*khoi*) and is also found in Tai (Modern Thai *khaŋ*).

Middle Archaic Chinese comprises the earliest writings of the Confucian school. Important linguistic changes had taken place, which became still more pronounced in Late Archaic, the language of the two major Confucian and Taoist writers, Meng-tzu (Mencius) and Chuang-tzu, as well as of other important philosophers. The grammar by then had become more explicit in the writing system, with a number of well-defined grammatical particles, and it can also be assumed that the use of grammatical affixes had similarly declined. The process used in verb formation and verb inflection that later appeared as tonal differences may at this stage have been manifested in other suprasegmental features, such as different types of laryngeal phonation. The word classes included nouns, verbs, and pronouns, all with several subclasses and particles. The use of a consistent system of grammatical particles to form noun modifiers, verb modifiers, and several types of embedded sentences (i.e., sentences that are made to become parts of another independent sentence) disappeared in Han Chinese and was gone from written Chinese until the emergence of post-Classical Chinese. In Modern Standard Chinese the subordinating particle *te* combines the functions of several Late Archaic Chinese particles, and the verb particle *le* and the sentence particle *le* have taken over for other Late Archaic forms.

Han and Classical Chinese. Han Chinese developed more polysyllabic words and more specific verbal and nominal (noun) categories of words. Most traces of verb formation and verb conjugation began to disappear. An independent Southern tradition (on the Yangtze River), simultaneous with Late Archaic Chinese, developed a special style, used in the poetry *Ch'u Tzu* ("Elegies of Ch'u"), which was the main source for the refined fu (prose poetry). Late Han Chinese developed into Classical Chinese, which as a written idiom underwent few changes during the long span of time it was used. It was an artificial construct, which for different styles and occasions borrowed freely and heavily from any period of pre-Classical Chinese but in numerous cases without real understanding for the meaning and function of the words borrowed.

At the same time the spoken language changed continually, as did the conventions for pronouncing the written characters. Soon Classical Chinese made little sense when read aloud. It depended heavily on fixed word order and on rhythmic and parallel passages. It has sometimes been denied the status of a real language, but it was certainly one of the most successful means of communication in the history of mankind. It was the medium in which the poets T'ao Yüan-ming (365–427), Li Po (701–762), and Tu Fu (712–770) and the prose writer Han Yü (768–824) created some of the greatest masterpieces of all times and was the language of the Neo-Confucianist philosophy (especially of Chu Hsi [1130–1200]), which was to influence the West deeply. Classical Chinese was also the language in which the Italian missionary Matteo Ricci (1552–1610) wrote in his attempt to convert the Chinese Empire to Catholic Christianity.

Northern China, probably owes its origin to the Buddhist storytelling tradition; the tales appeared in translations from Sanskrit during the T'ang dynasty (618–907). During the Sung dynasty (960–1279) this vernacular type of language was used by Buddhists and Confucianists alike for polemic writings; it also appeared in indigenous Chinese novels based on popular storytelling. From the Yüan dynasty (1279–1368) the vernacular was used also in the theatre.

Modern Standard Chinese has a threefold origin: the written post-Classical language, the spoken standard of Imperial times (Mandarin), and the vernacular language of Peking. These idioms were clearly related originally, and combining them for the purpose of creating a practical national language was a task that largely solved itself once the signal had been given. The term National Language (*kuo-yü*) had been borrowed from Japanese at the beginning of the 20th century, and, from 1915, various committees considered the practical implications of promoting it. The deciding event was the action of the May Fourth Movement of 1919; at the instigation of the liberal savant Hu Shih, it rejected Classical Chinese (also known as *wen-yen*) as the standard written language. (Hu Shih also led the vernacular literature movement of 1917; his program for literary reform appeared on January 1, 1917.) The new written idiom has gained ground faster in literature than in science, but there can be no doubt that the days of Classical Chinese as a living medium are numbered. After the establishment of the People's Republic of China some government regulation was applied successfully, and the tremendous task of making Modern Standard Chinese understood all over China was effectively undertaken. In what must have been the largest scale linguistic plan in history, untold millions of Chinese, whose mother tongues were divergent Mandarin or non-Mandarin languages or non-Chinese languages, learned to speak and understand the National Language; with this effort literacy was imparted to great numbers of people in all age groups.

The writing system. The Chinese writing system is non-alphabetic. It applies a specific character to write each meaningful syllable or each nonmeaningful syllabic that is part of a polysyllabic word.

When the Chinese script first appeared, as used for writing Oracular Chinese (from c. 1500 BC), it must already have had a considerable development behind it. Although many of the characters can be recognized as originally depicting some object, many are no longer recognizable. The characters did not indicate the object in a primitive nonlinguistic way but only represented a specific word of the Chinese language (*e.g.*, a picture of the phallic altar to the earth is used only to write the word *earth*). It is therefore misleading to characterize the Chinese script as pictographic or ideographic; nor is it truly syllabic, for syllables that sound alike but have different meanings are written differently. Logographic (*i.e.*, a system using symbols representing entire words) is the term that best describes the nature of the Chinese writing system.

Verbs and nouns are written by what are or were formerly pictures, often consisting of several elements (*e.g.*, the character for "to love" depicts a woman and a child; the character for "beautiful" is a picture of a man with a huge head-dress with ram's horns on top). The exact meaning of the word is rarely deducible from even a clearly recognizable picture, because the connotations are either too broad or too narrow for the word's precise meaning. For example, the picture "relationship of mother to child" includes more facets than "love," a concept that, of course, is not restricted to the mother-child relation, and a man adorned with ram's horns undoubtedly had other functions than that of being handsome to look at, whereas the concept "beautiful" is applicable also to men in other situations, as well as to women. Abstract nouns are indicated by means of concrete associations. The character for "peace, tranquillity" consists of a somewhat stylized form of the elements "roof," "heart," and "(wine) up!" Abstract symbols have been used to indicate numbers and local relationships.

Related words with similar pronunciations were usually written by one and the same character (the character for "to love, to consider someone good" is a derivative of a similarly written word "to be good"). This gave rise to the most important invention in the development of the Chinese script—that of writing a word by means of another one with the same or similar pronunciation. A picture of a carpenter's square was primarily used for writing "work, craftsman; to work" and was pronounced *kun*; secondarily it was used to write *kun*—"to present," *ghun* "red," *kun* "rainbow," *klaw* "river," and others. During the Archaic period this practice was developed to such a degree that too many words came to be written as one character. In imitation of the characters that already consisted of several components an element was added for each meaning of a character to distinguish words from each other. Thus "red" was no longer written with a single component but acquired an additional component that added the element "silk" on the left; "river" acquired an additional component of "water," and so on. The original part of the character is now referred to as its phonetic and the added element as its radical.

During the Ch'in dynasty (221–206 BC) the first government standardization of the characters took place, carried out by the statesman Li Ssu. A new, somewhat formalized style known as seals was introduced—a form that generally has survived until now, with only such minor modifications as were necessitated by the introduction of the writing brush around the beginning of the Christian Era and printing around AD 600. As times progressed, other styles of writing appeared, such as the regular handwritten form *k'ai* (as opposed to the formal or scribe style *li*), the running hand *hsing*, and the cursive hand *ts'ao*, all of which in their various degrees of blurredness are explicable only in terms of the seal characters.

The Ch'in dynasty standardization comprised somewhat over 3,000 characters. In addition to archaeological finds, the most important source for the early history of Chinese characters is the huge dictionary *Shuo-wen*, compiled by Hsü Shu in c. AD 100. This work contains 9,353 characters, a number that certainly exceeds that which it was or ever became necessary to know offhand. Still, a great proliferation of characters took place at special times and for special purposes. The *Kuang-yün* dictionary of 1007 had 26,194 characters (representing 3,877 different syllables in pronunciation). The K'ang-hsi *tzu-tien*, a dictionary of 1716, contains 40,545 characters, of which, however, fewer than one-fourth were in actual use at the time. The number of absolutely necessary characters has probably never been much over 4,000–5,000 and is today estimated at fewer than that.

By the 20th century the feeling had become very strong that the script was too cumbersome and an impediment to progress. The desire to obtain a new writing system necessarily worked hand in hand with the growing wish to develop a written language that in grammar and vocabulary approached modern spoken Chinese. If a phonetic writing were to be introduced, the classical language could not be used at all because it deviates so markedly from the modern language. None of the earlier attempts gained any following, but in 1919 a system of phonetic letters (inspired by Japanese kana) was devised for writing Mandarin. (In 1937 it received formal backing from the government, but World War II stopped further progress.) In 1929 a National Romanization, worked out by the author and language scholar Lin Yü-t'ang, the linguist Yuen Ren Chao, and others, was adopted. This attempt also was halted by war and revolution. A rival Communist effort known as *Latinxua*, or Latinization of 1930, fared no better. An attempt to simplify the language by reducing the number of characters to little over 1,000 failed because it did not solve the problems of creating a corresponding "basic Chinese" that could profitably be written by the reduced number of symbols.

The government of the People's Republic of China has taken several important steps toward solving the problems of the Chinese writing system. The first and basic step of making one language, Modern Standard Chinese, known all over the country has been described above. In

graphic
form of
writing

1956 a simplification of the characters was introduced that made them easier to learn and faster to write. Most of the abridged characters were well-known unofficial variants, used in handwriting but previously not in printing; some were innovations. In 1958 a romanization known as the phonetic system, or pinyin zimu (see Table 5), was introduced. This system is widely taught in the schools and is used for many transcription purposes and for teaching Modern Standard Chinese to non-Chinese peoples in China and to foreigners. The Pin-yin is conceived as a script that will gradually replace characters.

Reconstruction of protolanguages. For reconstructing the pronunciation of older stages of Sinitic, the Chinese writing system offers much less help than the alphabetic systems of such languages as Latin, Greek, and Sanskrit within Indo-European or Tibetan and Burmese within Sino-Tibetan. Therefore, the starting point must be a comparison of the modern Sinitic languages, with the view of recovering for each major language group the original common form, such as Proto-Mandarin for the Northern languages, Proto-Wu and others for the languages south of Yangtze. Because data are still lacking from a great many places, the approach has until recently been to compare major representatives of each group for the purpose of reconstructing the language of the important dictionary *Ch'ieh-yün* of AD 601 (Sui dynasty), which mainly represents a Southern language type. One difficulty is that the language in a given area represents a mixture of at least two layers: an older one of the original local type, antedating the language of the *Ch'ieh-yün*, and a younger one that is descended from the *Ch'ieh-yün* language or a slightly younger but closely related tongue—the so-called T'ang-koine or the standard spoken language of the T'ang dynasty (618–907). The relationship of the protolanguages is further complicated by the fact that different substrata of non-Chinese stock underlie most if not all of the major languages.

Influence
of the
T'ang
layer on
Sinitic

The degree to which the Sinitic languages have been influenced by the T'ang (or Middle Chinese) layer varies. In the North the Old Chinese layer still dominates in phonology; in Min the two layers are kept clearly apart from each other and the Middle Chinese layer is most important in the reading pronunciation of the characters; in Yiieh both Chinese layers are of the Southern type and are typologically close to a Tai substratum.

The Old Chinese layer is characterized by early decay of final consonants, late development of tones from sounds or suprasegmental features located toward the end of the syllable, change of final articulation type because of similar initial type (as in syllables with voiced glottal activity both at the opening and at the end that lose the final voicedness; a phenomenon later manifested as a tonal change), and influence of sounds and tones in a syllable on those of surrounding ones (sandhi).

The New Southern stratum in Sinitic languages is characterized by early change of final articulation types into tones, extensive development of registers according to type of initial consonant, and late or no loss of final stops. The Old layer cannot be the direct ancestor of the New layer. The division into Northern and Southern dialects must be very old. It might be better to speak of a T'ang and a pre-T'ang layer or a T'ang or Han layer (the Han dynasty, 206 BC–AD 220, was one of extensive settling in most parts of what is now China proper).

For a long time it was assumed that the *Ch'ieh-yün* dictionary represented the language of the capital of the Sui dynasty, Ch'ang-an in the present province of Shensi, but recent research has demonstrated that its major component was the language of the present-day Nanking area with a certain attempt at compromise with Northern speech habits. As its first criterion for classifying syllables, the *Ch'ieh-yün* dictionary takes the tones, of which it has four: *p'ing*, *shang* (transcribed as :—e.g., pa:), *ch'ü* (transcribed as - —e.g., pa-), and *ju*, or even, rising, falling, and entering ("checked") tones. The entering tone comprised those syllables that ended in a stop (-p, -t, -k). The rising and falling tones may have retained traces of the phonetic conditioning factor of their origin, voiced and voiceless glottal or laryngeal features, respectively.

Tones of
the
Ch'ieh-yün
dictionary

The even tone probably was negatively defined as possessing no final stop and no tonal contour.

Next, the dictionary is divided according to rhymes, of which there are 61, and, finally, according to initial consonants. Inside each rhyme an interlocking spelling system known as fan-ch'ieh was used to subdivide the rhymes. There were 32 initial consonants and 136 finals. The number of vowels is not certain, perhaps six plus *i* and *u*, which served also as medial semivowels. There were probably more vowels than in either Archaic Chinese or in Modern Standard Chinese, another indication that the development of the Northern Chinese phonology has not passed the stage represented by *Ch'ieh-yün*.

There are additional sources for reconstructing the *Ch'ieh-yün* language: Chinese loanwords in Korean and Japanese (Japan has two different traditions—Go-on, slightly older than *Ch'ieh-yün* but representing a Southern language type like *Ch'ieh-yün*, and Kan-on, contemporary with *Ch'ieh-yün* but closer to the Northern tradition) and Chinese renderings of Indo-Aryan (Indic) words. Voiced stops are recovered through Wu, Hsiang, and Go-on (e.g., Modern Standard Chinese *r'ien* "field," Wu and Hsiang *di*, Go-on *den*, *Ch'ieh-yün* *dhien*), final stops especially through Yiieh and Japanese (e.g., Modern Standard Chinese *mu* "wood," Yiieh *muk*, Go-on *mok[u]*, *Ch'ieh-yün* *muk*), and retroflex initial sounds from Northern Chinese (e.g., Modern Standard Chinese *sheng* "to live," *Ch'ieh-yün* *ʃaŋ* [the *ʃ* is a retroflex]).

Early Archaic Chinese is the old stage for which the most information is known about the pronunciation of characters. The very system of borrowing characters to write phonetically related words gives important clues, and the rhymes and alliteration of the "Classic of Poetry" (*Shih Ching*) furnish a wealth of details. Even though scholars cannot always be sure that prefixes and infixes are correctly recovered, and though the order in which recoverable features were pronounced in the syllable is not always certain (rk- or kr-, -wk or -kw, and so on), enough details can be obtained to determine the typology of Old Chinese and to undertake comparative work with the Tibeto-Burman and Karenic languages. The method employed in this part of the reconstruction of Chinese has been predominantly internal reconstruction, the use of variation of word forms within a language to construct an older form. As knowledge of the old layer of modern languages and dialects increases, however, the comparative method, which draws on similarities in several related tongues, gains importance. Through further internal reconstruction, features of the Proto-Sinitic stage, antedating Archaic Chinese, can then be restored.

TIBETO-BURMAN LANGUAGES— HISTORY AND CHARACTERISTICS

The Tibeto-Burman languages have evolved from the ancestral language, Proto-Tibeto-Burman, in vastly different ways and at their own pace, in accordance with the geographical and social factors that have determined the fate of Central and South Asian peoples. Some tribes have been stationary; others have swept over huge areas. As a result, conservative or archaic features do not occur in only one contiguous part of the language area and innovations in another. The nearest genetic relations are often not identical with the closest typological ones.

Tibetan. Of the modern Tibetan languages and dialects, the Western ones have preserved initial consonant clusters and final stops most faithfully and have had the least compensational development of tones. Most Central languages and dialects, including Lhasa, have lost all consonant clusters and final stops and in the process have acquired a larger inventory of single consonants and a system of tones. These changes and reductions are linked to a similar reshaping of certain grammatical processes of word formation that now operate only through suprasegmental and syllabic elements. To a surprising degree, however, Modern Central Tibetan possesses grammatical categories identical with or very similar in content, though not in form, to those of Classical Tibetan (a similar relationship as that of Modern Standard Chinese to Old Chinese). The relationship of nouns to the main

Influence
of
geography
and social
factors on
Tibeto-
Burman
languages

verb is indicated through postposed particles, the agent of a transitive verb indicated as the one by whom the action is performed, and the subject of an intransitive verb expressed as the object or goal of the action. Nominal modifiers precede nouns, and verbal modifiers follow them. The main verb, always placed after all nouns, is followed by particles expressing aspect and tense.

Old Tibetan pronunciation can be reconstructed by comparison of modern dialects and through the very conservative alphabetic script of Indian origin that goes back to the 7th century AD and found its present form in the 9th century. The orthography is far removed from present-day Standard Tibetan pronunciation.

Old Tibetan is one of the most archaic of the Tibeto-Burman languages. It retained Tibeto-Burman final stops and final *-r*, *-l*, *-s* and also the initial voiced consonants. Many Old Tibetan consonant clusters may be referred to Proto-Tibeto-Burman. The case particles and complicated verbal conjugation perhaps represent an elaboration on somewhat simpler tendencies in the protolanguage.

Himalayish languages

Some Himalayish languages are in certain respects as archaic as Tibetan, although most initial clusters are gone. An old feature is the connection of voiced-voiceless initial consonants with intransitive-transitive verbs. Because they have developed the feature of incorporating agent and object pronouns in verbs (and of possessive pronouns in nouns), these have been known as "pronominalizing" languages. An influence from contiguous Indo-European languages seems possible, but not certain.

Some Kirantish languages retain consonant clusters and voiced initial consonants; others give up both. Bahing has maintained the connection between voicedness and transitivity. Within Mirish, which has kept voiced initial sounds, Abor retains final stops and Dafla has some initial consonant clusters. Kachinish is quite conservative; prefixes are well retained as are voiced initial consonants, although some reshuffling has taken place in this respect.

Burmese. Within Burmish, Modern Standard Burmese has undergone a set of radical changes. Initial *ts*- and *tsh*- have become *s*- and *sh*-; *s* has become *θ* (*th* as in "thin"); *y*- and *r*- have coalesced as *y*-, and *ky*- and *kr*- as a palatal *c* (*ty*). Furthermore, all final consonants except nasals have coalesced as glottal stops, and all nasals have resulted in nasalization of the preceding vowel. In addition, the quality of vowels has been greatly altered. As was the case in Tibetan, in spite of great phonetic changes, grammatical categories are close to those scholars envisage for Proto-Tibeto-Burman. Cases of nouns and aspects of verbs are expressed through postposed particles.

Among the Burmese dialects, Arakanese is especially conservative, and the closely related language Maru is one of the most archaic within Tibeto-Burman in respect to final consonants. The Lolo languages lost most consonant clusters, as did all Burmish languages, but tend otherwise to be conservative in their treatment of initial sounds and radical in the loss and change of final consonants. Nung has retained final stops lost in Burmish (*-r*, *-l*, *-s*) and possesses a set of prefixes like Kachin.

The Burmese writing system

Study of the Burmese writing system, in combination with comparative linguistic work, makes possible the reconstruction of Old Burmese. The language of the Myazedi inscription of 1113 is close in its sound system to written Burmese in its present form, which dates back to at least the 15th century. The writing system was taken over from the Mon people, who had developed their writing from Pyu, a Sino-Tibetan language known in Burma from c. AD 500. It is alphabetic of an Indian type but represents a separate Southern line of development.

Old Burmese is phonetically further from Proto-Tibeto-Burman than is Tibetan. Initial clusters are mostly gone but are felt in the development of initial consonants. Some clusters with *-w*- and liquid sounds were retained. The tonal system of Burmese (unlike that of Tibetan) developed to compensate for the loss of final features.

The Baric languages maintain a few older prefixes and developed some of their own. They tend to retain or merge *r* and *l*. The relationship of voicedness and transitivity is retained, but a great reshuffling of initial consonants took place, as it did also in Meithei and Kukish. The

Kukish languages are found in all stages of development, but many of them are among the most archaic and most important for the reconstruction of Tibeto-Burman. Prefixes are best preserved in Old Kuki and in the Naga branch, whereas vowels seem very archaic in Lushai of the Central branch (the Lushai vowels have a difference of length that mud in some way be explained in terms of Proto-Tibeto-Burman). Some Kukish languages incorporate pronouns in verbs. Mru, distantly related to Kukish, is noted for a number of archaic features, including final consonants lost elsewhere in Tibeto-Burman.

(S.C.E.)

Sinus

The word sinus is primarily an anatomical term meaning a hollow, cavity, recess, or pocket; a large channel containing blood; a suppurating tract; or a cavity within a bone. Two types of sinus, the blood-filled and the air-filled sinus, deserve particular attention.

The cranial venous sinuses are spaces between the layers of dura mater, which covers the brain, and are lined with endothelium similar to that lining veins. These sinuses receive blood from the veins of the brain, and all eventually drain into the principal vein of the neck—the internal jugular. Communications between these intracranial venous sinuses and veins outside the skull such as those in the nose, are important because they offer a direct path by which infection in the nose may reach the brain.

Among these sinuses the cavernous sinus is of particular interest, since it lies on each side of the pituitary gland and contains not only venous blood but also the internal carotid artery and several cranial nerves.

Paranasal air sinuses. The air sinuses, four on each side, are cavities in the bones that adjoin the nose. They are outgrowths from the nasal cavity and retain their communications with it by means of drainage openings or ostia. Consequently, their lining is mucous membrane similar to that found in the nose. The mucus secretion formed is propelled by small, hairlike processes called cilia through the ostia of the sinuses to the nasal cavity. From there it is eventually swallowed or expelled. All sinuses are absent or small at birth; they gradually enlarge until puberty, when they usually grow rapidly.

The two frontal sinuses are situated in the frontal bone immediately above and between the eye sockets or orbits. They are usually unequal in size and have the shape of an irregular pyramid with its apex directed upward. The thin bony wall separating the two cavities sometimes is absent.

It is rare to recognize the frontal sinuses until the age of seven years, and their maximum growth occurs after puberty. They vary considerably in size and are usually larger in the male than in the female, averaging, when fully developed, approximately 3 cm in height, 2.5 cm in width, and 2 cm in depth. The front or anterior wall is thick skull bone; behind the sinuses lies bone covering the brain, and the floor of the sinuses slopes toward their openings into the nose.

The maxillary sinuses are not only the largest of the air sinuses but also the first to appear, being present in the fourth month on intra-uterine life. Each is a pyramidal space, its roof formed by the floor of the orbit, or eye socket, and its floor by the palate and teeth-bearing bone. The roots of the upper jaw teeth may project through the floor into the sinus cavity or may be so closely related to the floor that extraction leads to the formation of an opening between mouth and sinus (oro-antral fistula). The maxillary sinuses reach their maximum size by about age 12, when all the permanent teeth except the third molars have erupted. The nerves supplying the upper teeth run through the front wall of the sinus and may be irritated during acute antral infections with resultant toothache.

The ethmoidal sinuses, from 3 to 18 thin-walled cavities between the nasal cavities and the eye sockets, make up the ethmoidal labyrinths. Their walls form most of the inner walls of the eye sockets and are joined together by a thin perforated plate of bone at the roof of the nose. This bone, the cribriform plate, transmits the olfactory nerves that carry the sense of smell.

The sinuses contained within each labyrinth are arranged in three noncommunicating groups, all of which open into the nasal cavity. All produce mucus whose function is to lubricate the cilia lining the nasal passages.

The sphenoidal sinuses are situated back of the nose in the sphenoidal bone, which forms a forward part of the base of the skull and contains the depression or fossa for the pituitary gland. The sinuses are separated from each other by a bony wall or septum that is rarely in the midline, and they discharge their mucus through an opening in the front wall of the sinus into the nose.

These sinuses appear before birth but remain small until the age of 10, when they grow rapidly; rapid growth also occurs at about puberty. Sphenoidal sinuses are important in the surgical approach to the pituitary gland for patients with breast cancer or pituitary tumours.

Functions of the paranasal sinuses. Comprehensive studies on the comparative anatomy and physiology of the nose and paranasal sinuses have been made in man and in lower animals. The presence of the sphenoidal and frontal sinuses in carnivores such as the dog, hyena, and tiger is related to an increased area of olfaction and consequent improvement in the sense of smell. Ethmoidal air cells are found only in higher apes and man and are probably the result of restriction of the olfactory area.

The maxillary sinuses are largest in man, in the higher apes, and in capuchin and howler monkeys; they are absent in baboons, lorises, and tapirs. It has been suggested that these sinuses play a part in phonation, that they aid

in conservation of heat from the nasal fossae, and that they serve to lighten the skull, but evidence for these theories is lacking.

Diseases of the sinuses. Acute infections of all the paranasal sinuses usually result from infections of the upper respiratory tract such as the common cold. Acute sinusitis may occur at any time after the sixth month. By the age of four years the maxillary sinus is the one most commonly affected. General diseases, such as measles, frequently precipitate acute sinusitis, as may the penetration of infected water from swimming.

Treatment is directed primarily toward overcoming the infecting organism by the use of systemic antibiotics such as penicillin and toward encouraging drainage of the sinuses with vasoconstricting nose drops and inhalations. In most cases the condition will resolve within several days. If infection persists, the pus localized in any individual sinus may need to be removed by means of a minor surgical procedure known as lavage, in which the maxillary or sphenoidal sinuses are irrigated with water or normal saline solution. Any residual infection will be displaced into the nasal cavity through the normal openings. Persistence of purulent nasal discharge after adequate antibiotic therapy or repeated lavage may indicate the presence of a chronic infection that necessitates surgery. Pain is not a feature of chronic sinusitis.

Polyps, consisting of swollen nasal lining, may grow from both the maxillary and ethmoidal sinuses and cause nasal obstruction. They occur most commonly as a result of nasal allergy and require surgical removal.

Cancers affecting the paranasal sinuses are rare, especially in the sphenoidal and frontal area. They occur most commonly among the Bantu of South Africa, where they are related to the long-term use of homemade carcinogenic snuff. Recently, however, it has been shown that certain woodworkers in the furniture industry have a greatly increased incidence of nasal sinus cancer.

PROETZ, *Essays on the Applied Physiology of the Nose* (1941).

(D.F.N.H.)

Siphonaptera

Fleas, which comprise the order Siphonaptera, are parasites that live on the exterior of the host (*i.e.*, are ectoparasitic); they are bloodsucking insects, important carriers of disease, and sometimes serious pests. As the chief agent transmitting the Black Death (bubonic plague) in the Middle Ages, they were an essential link in the chain of events that killed a quarter of the population of Europe.

Fleas are small, wingless insects with a tough cuticle bearing many bristles and frequently combs (ctenidia) of broad, flattened spines. The adult flea varies from about 0.1 to 1 centimetre in length and feeds exclusively on the blood of mammals (including man) and birds. With more than 1,600 species and subspecies known, the order is still a small one compared with many other groups of insects; however, it is widely distributed. The rat flea and the mouse flea have been carried all over the world by man; native species of fleas are found in the Arctic Circle and south polar regions, the Arabian deserts and tropical rain forests, as well as the more temperate zones.

Medical and economic importance. Infestation by fleas may cause severe inflammation of the skin and intense itching. Although many animals acquire partial immunity after constant or repeated attacks, occasionally individuals (especially man) become sensitized after exposure and develop allergies. Species that attack man and livestock include the cat flea (*Ctenocephalides felis*), the so-called human flea (*Pulex irritans*), the dog flea (*Ctenocephalides canis*), the sticktight flea (*Echidnophaga gallinacea*), and the jigger, or chigoe, flea (*Tunga penetrans*). Poultry may be parasitized by the European chicken flea (*Ceratophyllus gallinae*) and (in the U.S.) by the western chicken flea (*Ceratophyllus niger*).

Infections

Size and distribution

Frontal sinuses

Ethmoidal sinuses

Fleas as
carriers of
disease

Certain fleas that feed primarily on rodents or birds sometimes attack man, particularly in the absence of their usual prey. When rats are dying of bubonic plague, their hungry fleas, themselves infected with plague bacilli and seeking food elsewhere, can transmit the disease to man, especially in buildings heavily infested with rats. The Oriental rat flea (*Xenopsylla cheopis*) is the most efficient carrier of plague, but other species of fleas (e.g., *Nosopsyllus fasciatus*, *Xenopsylla brasiliensis*, *Pulex irritans*) can also transmit the disease to man. Although there are occasional cases of plague in tropical regions, the disease in man has been controlled by early diagnosis and antibiotics. Plague (sylvatic plague), a widespread disease in hundreds of species of wild rodents throughout the world, is maintained by fleas that parasitize these animals. More than 100 species of fleas are known to be infected by the plague bacillus, and an additional ten species are implicated as carriers of the classic type of urban plague. (See INFECTIOUS DISEASES.)

Fleas, particularly *Xenopsylla cheopis*, are believed to be the principal carriers of murine typhus, a rickettsial disease of man; rats and mice are sources of infection. Fleas are considered important in the maintenance and spread of many locally restricted infections among rodents and other mammals, including tularemia and Russian spring-summer encephalitis. Fleas transmit myxomatosis, a viral disease of rabbits used deliberately to control rabbits in areas where they are severe pests (e.g., in Australia). Fleas are probable carriers of a filarial worm of dogs and serve as the intermediate host of a common tapeworm (*Dipylidium caninum*) of dogs and cats (and occasionally children). If heavily infested, animals can suffer severe damage or be killed by the effects of flea bites and considerable loss of blood. Fleas are subject to parasitism by external mites; internal nematode worms; and bacterial, fungal, and protozoan infections.

The female chigger, or jigger, flea (not to be confused with "chigger," a larval mite), burrows into the skin of its host, generally on the feet, and lives within a cyst that forms around it. Intense itching accompanies the development and enlargement of the cyst as the abdomen of the pregnant flea swells to the size of a pea; secondary infections may constitute serious complications.

Natural history. Life cycle. Details of the life cycle are available for a few species only. The four stages are the egg, larva, pupa, and adult. Pearly white, oval eggs are deposited on the body of, or in the nest or habitat of, the

a silk cocoon that includes debris from the nest; this is the beginning of the pupal stage. The pupa emerges as an adult some days or months later. Depending upon the species or environmental conditions, the time required for a complete life cycle varies from two weeks to several months. The life-span of the adult flea varies from a few weeks (e.g., *Echidnophaga gallinacea*) to a year or more (*Pulex irritans*). The life cycle of the European rabbit flea (*Spilopsyllus cuniculi*) and its host are perfectly synchronized. The sexual development of male and female fleas is under the direct control of the rabbit's sex hormones. Thus, the eggs of the female flea mature successfully only if she is feeding on a pregnant doe rabbit. When the young rabbits are born, both flea sexes now mature and leave the parturient doe for the nestlings and the nest, where they copulate and lay their eggs, thus assuring the flea larvae a suitable habitat for development. If the sex hormones of the female rabbit are controlled artificially by the administration of synthetic progestins (contraceptives), the sexual development of the female flea is also arrested. Although no similar case is yet known among other species of fleas, it has been recorded that rat fleas are less fertile if fed on baby mice than on their parents and that the mouse flea (*Leptopsylla segnis*) is more prolific if reared on family units rather than on individual adult mice. It seems likely, therefore, that the influence of the hosts' hormones is more widespread than hitherto suspected.

Parasitism. Some fleas (e.g., shrew fleas and rabbit fleas) are highly host specific; other species parasitize a variety of mammals. The cat flea infects not only the domestic cat but dogs, foxes, civets, mongooses, opossums, leopards, and other mammals including man if accustomed hosts are not available. Related mammals tend to be parasitized by fleas that are themselves related. Thus the rabbitlike pikas (*Ochotona*) living in the Rocky Mountains are infested with two peculiar genera of fleas that occur also on pikas in the mountains of Asia; this indicates a close phylogenetic relationship between these geographically separated hosts. Bird fleas have adapted themselves in relatively recent times to their avian hosts. These share several common adaptive features; one of the most obvious responses to the new environment is an increase in the number of comb spines on the upper surface of the thorax.

It is interesting that monkeys and apes do not harbour fleas, nor do horses or the majority of ungulates. The most heavily parasitized group of mammals are the rodents (e.g., rats, mice, squirrels). Their habit of nest building in holes favours development of flea larval stages; animals with no permanent home tend to have fewer fleas.

Although both flea sexes feed avidly and repeatedly on blood (a single male exception never feeds), they survive for various periods away from the host. The rabbit flea, for example, can live for nine months at temperatures around the freezing point without feeding.

Form and function. Anatomically, adult fleas are a rather uniform but distinctive group, with many interesting modifications and few obvious links with other orders. The compressed body and backwardly projecting spines or combs enable them to move swiftly through hairs or feathers of the host. The mouthparts, modified for sucking blood, include barbed **stylets** that aid both in penetration of the flea into the host skin and in attachment of species that spend long periods fixed to the host (e.g., the stick-tight fleas). Generally fleas that live on diurnal hosts have well-developed eyes; species that parasitize subterranean hosts (e.g., moles or nocturnal animals like bats) have poorly developed eyes or none at all. The most impressive adaptations are highly developed jumping legs and the powerful muscles that control them. During their evolution, fleas, like the majority of parasitic insects, lost their wings. Certain parts of the flight mechanism have been retained, however, and incorporated in the jumping mechanism. Because fleas are able to leap horizontal or vertical distances 200 times their body length and to develop an acceleration of 200 gravities, they have been described as insects that fly with their legs. Certain species that live in nests high above the ground or in other unusual habi-

host animal. The larva, a small legless caterpillar, feeds on organic debris, such as dried excrement, dried bits of skin, dead mites, or dried blood found in the host's nest. The parent fleas pass freshly imbibed blood rapidly through their gut to produce fecal matter for the nourishment of their offspring, which is essential to the successful metamorphosis of certain species of flea larvae. After three (exceptionally, two) molts, the larva spins

Loco-
motion

tats crawl rather than jump. An incidental use of the unusual strength of fleas is in "flea circuses" in which they pull miniature carts and perform other feats.

Control. In controlling fleas it is best to treat simultaneously both the breeding sites of fleas and the infested host, since, as mentioned earlier, the larval and pupal stages usually develop away from the host's body. For infested animals a commercial dust, spray, dip, or aerosol containing an insecticide such as pyrethrum, rotenone, malathion, or methoxychlor is used: Methoxychlor and malathion may continue to kill fleas for a few weeks after application. The long-acting chlorinated hydrocarbons, such as lindane and chlordane, can be applied to the fur of certain infested animals (but not to cats or dogs). In some regions, however, fleas have become resistant to these hydrocarbon insecticides, and new toxicants are required. Organic phosphorus compounds offer promise as systemic insecticides. When animals to be protected are fed these compounds, the fleas feeding on them die. For the control of larval and adult fleas away from the host, dieldrin, lindane, or malathion may be applied to the pens and haunts of the affected animals. Repellents containing benzyl benzoate, phthalate compounds, or diethyltoluamide are effective in preventing attack by fleas.

Evolution, paleontology, and classification. The Siphonaptera form a small group of insects probably descended from an ancestor of the Mecoptera (scorpionflies), with which they share certain characteristics. Both groups have a spined gizzard (proventriculus), sexual differences in the number of ganglia in the ventral nerve cord, six rectal glands, and a simple type of ovary. The males have a similar type of spermatozoon, unique in the phylum Arthropoda, in which a motile flagellum, or tail, lacking the outer ring of nine tubules, is deployed around the mitochondria (cell organelles). A fossil flea, discovered in Australia, is claimed to be 200,000,000 years old. Two other known fossil fleas come from the Baltic amber (Oligocene) and are similar to "modern" fleas in all but specific details.

Distinguishing taxonomic features. Although taxonomic separation of these groups rests upon a combination of superficially trivial morphological characteristics, they do reflect the fundamental differences between the groups. At the family or generic levels, classification is based principally upon shape of head and thorax, arrangement of combs, various modifications of the highly specialized male copulatory organ and female reproductive organs, general chaetotaxy (arrangement of bristles), and other characteristics.

Annotated classification. Fleas of today can be divided into three superfamilies: the Pulicoidea, Malacopsylloidea, and Ceratophylloidea. The Pulicoidea are generally adapted more to life on the host's body than are the latter two, which spend more time in the nest.

Order Siphonaptera (fleas)

Small, wingless, laterally compressed insects; adults ectoparasitic on warm-blooded vertebrates; eyes present or lack-

ing; antennae short and stout, reposing in grooves; mouthparts adapted to piercing and sucking, maxillary and labial palps present; thoracic segments free; legs with large coxae, tarsi five-segmented; larvae elongated, legless, caterpillar-like; pupae with appendages free, enclosed in cocoons.

Superfamily Pulicoidea. Outer internal ridge of midcoxa of leg absent; mesonotum (dorsal sclerite of mesothorax) without pseudosetae under collar; metepimeron extending far upward, with first abdominal spiracle placed above the metepisternum; metanotum (dorsal sclerite of metathorax) and abdominal terga (dorsal surface) without apical spines or spinelets; spiracles circular; abdominal terga (segments II–VII) with, at most, one row of bristles; no bristles above spiracle of terga VIII; sensillum with either 8 or 14 pits each side; hind tibia of leg without an apical tooth outside; one family Pulicidae with genera *Pulex*, *Xenopsylla*, *Tunga*, and others.

Superfamily Malacopsylloidea. Rod of the lateral sclerites of the mesothorax (mesopleural rod) not forked; anterior tentorial arm present in head; no genal combs (spines on the anteroventral border of head) or pronotal combs (spines on the dorsal sclerite of the prothorax); ventral margin of pronotum never bilobed; fifth tarsal segment of leg always with four pairs of bristles (Neotropical region and extreme south Nearctic); two families, Malacopsyllidae and Rhopalopsyllidae.

Superfamily Ceratophylloidea. All fleas that do not possess combinations of characters listed above are included with the Ceratophylloidea, 12 families are included.

Critical appraisal. There is general agreement among flea specialists regarding the basic classification of the order, but it is probable that the family Hystrichopsyllidae will be accorded the rank of a superfamily.

(M.L.R./R.T.)

Sipuncula

Peanutworms (phylum Sipuncula) are elongated, often spindle-shaped, unsegmented marine worms. The head usually has one or more rings of tentacles. The worms vary in length from a few to 300 millimetres or more in length. Though rare, they may be locally common on seabeds throughout the oceans of the world. Peanutworms are bottom-dwelling (benthic) animals; most burrow in the mud or sand between tide levels or in oozes of the deepest ocean trenches. Some species have other habitats and live in discarded mollusk shells, in sponge siphons, in corals, among the twisted tubes of encrusting polychaetes (marine annelid worms), and even in tangled roots of marine plants.

Life cycle. Externally the sexes are alike and separate, with one exception. Gametes (mature germ cells) are shed into the body cavity and collect in nephridia (excretory organs) that become modified as egg- and sperm-storage organs; they are emitted into the sea from nephridiopores. Fertilization takes place outside the body. The trocho-

Sipunculids.
(Left) *Sipunculus nudus*. (Top) *Aspidosiphon*. (Bottom) *Phascolion*.

phore (free swimming) larva, which results from spiral cleavage of the zygote (cell formed by two gametes), undergoes metamorphosis to its characteristic shape.

Form and function. Peanutworms consist of a muscular trunk, cylindrical to globular in shape, and a slender, anterior introvert (retractible proboscis) that is muscular, highly extensible, and capable of being withdrawn into the trunk by retractor muscles. Hooks or spines are often present toward the tip of the introvert, while glandular pores and papillae are scattered over both trunk and introvert. Within the body cavity (coelom) a long alimentary canal spirals backward from the mouth to the posterior region of the trunk, then forward to the dorsal anus near the anterior end of the trunk. A contractile vessel, or compensatory sac associated with the esophagus, extends forward to the tentacles. Fluid passes to extended tentacles, returning to the vessel as they contract; both this and coelomic fluid contain blood cells with hemerythrin. One or two nephridia discharge to the exterior. Gonads develop at the base of the ventral retractor muscles.

Classification and phylogeny. Peanutworms have few external characters and, apart from the arrangement of tentacles in relation to the mouth and the presence of a cap or shield at the anterior and posterior ends of the trunk, most distinguishing features can be detected only by dissection. Longitudinal trunk muscles may be in the form of bands or fused into a continuous sheet. The number of retractor muscles and the presence of protractor muscles in the musculature of the introvert are important. Other internal characters include presence of integumentary canals, the number of nephridia, and the presence of a postesophageal loop in the intestine.

Annotated classification. The following classification is based on the system proposed by A.C. Stephen and S.J. Edmonds (1972). Peanutworms once were included with priapulans and spoonworms (see *Echiura*) in the phylum Gephyrea; Adam Sedgwick (1898) gave them phylum rank. Presently four families are recognized.

PHYLUM SIPUNCULA

Unsegmented, coelomate, bilaterally symmetrical marine invertebrates; body divided into muscular trunk and protus-

ible introvert; mouth, situated at extremity of introvert, usually partly or wholly surrounded by tentacles or by a tentacular fold; long alimentary canal; anus situated anteriorly in the mid-dorsal line near or on the base of the introvert; setae (bristles) and anal vesicles absent; about 320 species.

Family Sipunculidae

Numerous tentacles or a tentacular fold form a ring around mouth; anterior cap or shield absent; integumentary canals or sacs in body wall; longitudinal body wall musculature in separate bundles.

Family Golfingiidae

Tentacles variable, digitiform, leaflike, dendritic (branching) or lobular; anterior cap or shield and integumentary canals or sacs absent; longitudinal body wall musculature a continuous sheet.

Family Aspidosiphonidae

Tentacles wholly or partly surround mouth; anterior cap or shield present; integumentary canals or sacs absent; longitudinal body wall musculature in bundles or a continuous sheet.

Family Phascolomatidae

Tentacles never surround mouth, form a horseshoe-shaped, broken ring; anterior cap or shield absent; integumentary canals or sacs usually absent; longitudinal body wall musculature in bundles or a continuous sheet.

Critical appraisal. The affinities of the peanutworms are obscure. Their development, like that of spoonworms, resembles that of annelids in that spiral cleavage and a trochophore larva occur. They differ from annelids, however, in their unsegmented bodies and absence of setae. They differ from spoonworms by the absence of setae, anterior anus, absence of anal vesicles, and presence of tentacles surrounding the mouth at the tip of the introvert. Fossils from the Middle Cambrian have been considered to be sipunculan (see FOSSIL RECORD).

Sirenia

Sirenians, or sea cows, are a group of large aquatic mammals that have become rare or extinct as a result of exploitation by man for meat and oil. The largest, Steller's sea cow (*Hydrodamalis gigas*), which reached lengths of about 8 metres (about 24 feet), was eaten out of existence by hungry seal hunters within a few decades of its discovery in 1741 in the Bering Sea. The remaining forms, the dugong (*Dugong dugon*) and manatees (three species of *Trichechus*), if their stocks were allowed to rebuild themselves, could again become of economic importance. Being the only large aquatic herbivores, other than some turtles, they could provide meat from the vast expanses of marine and freshwater vegetation, at present quite unused by man, and so bring another marginal area into production.

Dugongs and manatees are both usually seen up to lengths of three to four metres (10 to 13 feet), but larger specimens, up to 6 metres (20 feet), have been mentioned in tales of early travellers.

The dugong seems to have had a wider distribution in the past, but in recent times it has been restricted to the warm coastal waters of the Indo-Pacific region. Throughout most of its range it is now much depleted in numbers but exists from the Solomon Islands in the east to the head of the Red Sea in the west and from the Philippine Islands and the Persian Gulf in the north to Brisbane, Perth, and Mozambique in the south. It is entirely marine and rarely even enters estuaries. Manatees, however, seem more adaptable and inhabit the coastal, estuarine,

and riverine waters of the tropical and subtropical Atlantic region: *T. senegalensis* from West Africa; *T. manatus*, with two subspecies, from the Caribbean; and *T. inunguis*, landlocked in the Amazon Basin.

Body plans of two major sirenian groups. (Top) dugong (*Trichechus inunguis*); (bottom) manatee (*Trichechus manatus*).

Natural history. Sea cows tend to live in groups, and dugongs particularly may be highly gregarious at times. An enormous herd, three and a half by one and a half miles in extent, was recorded off Brisbane, Australia, early in the last century. Both genera are totally aquatic, living almost continuously submerged, and this, coupled with their wary and surreptitious habits, makes them exceptionally difficult to study. They are unable to come out of the water, but manatees placed on land nearby may just manage to return to their natural environment by vigorous wriggling of the body. Breathing is by frequent brief visits to the surface, where the tip of the snout is protruded and the nostrils silently opened by muscular valves. A manatee has been known to last as much as 16½ minutes between taking breaths. Manatees may also be seen lying at the surface, usually with only their backs visible above the water. Even when basking thus, they are extremely sensitive to sound or disturbance and will silently submerge. On occasion both dugongs and manatees will thrust their heads entirely out of the water, and they sometimes may even disport themselves like cumbersome seals.

Extremely little is known of the breeding biology of sea cows and particularly of the time scale involved. Manatees are known to be long-lived, and dugongs are believed to have similar lifespans. But there is no information about age of maturity, rate of growth, or number of young produced in a lifetime. Mating in manatees has been observed with the animals in very shallow water lying on their sides. Gestation is known to occupy more than 152 days, and the normal birth is a single calf, which receives much maternal care. Very occasionally twin fetuses are found in dugongs. Suckling from the single pair of pectoral mammary glands normally occurs in a horizontal position, but the occasional suckling of a young one held vertically by a flipper may have given rise to the mermaid myth. There is no marked difference in size between the sexes.

Sea cows are totally herbivorous. Whereas Steller's sea cow fed on marine algae, the dugong and manatees feed entirely on green higher plants, a circumstance that limits their distribution to relatively shallow waters. The habit of the dugong is to feed where there is good growth of "dugong grass" (*Zostera*, etc.), the leaves and underwater stems of which are pulled off by the animal's powerful lips. Manatees seem prepared to feed on marine or freshwater plants whether growing on the bottom, floating at the surface, or even growing on banks of rivers up to a foot above water level. It is this catholicity that has led to the experimental use of manatees in Guyana to keep clear

irrigation and transport channels in cane fields that otherwise must be cleared by hand. Virtually the sole enemy of both the dugong and manatees is man. There does not seem to be any commercial exploitation of these animals at present, but both are hunted sporadically and locally for food with the use of nets or harpoons. The dugong still has a considerable residual stock off northern Australia and with protective legislation enforced, could have a valuable future. Manatees, because they come into more confined waters, are still in danger of extermination.

Form and function. Sea cows have torpedo-shaped bodies and, like whales, have lost all external trace of hindlimbs. Their tails likewise are flattened horizontally and provide the main propulsive force in swimming. The forelimbs are small and may help in turning and manoeuvring. Though usually somewhat sluggish, sea cows are capable of considerable speeds for short distances.

The main distinguishing characteristics between the dugong and the manatees are that the former have a downturned snout and a forked tail, while the latter have a straight snout and rounded tail. Both have immensely thick, tough skin, which is nearly hairless. In the dugong there are individual hairs about six millimetres (¼ inch) long, spaced five to seven centimetres (two or three inches) apart. There is no substantial layer of blubber beneath the skin, but the body contains much fat. The eyes are small and circular, without lids, and the minute external ear openings are to be found only by careful examination. All of the bones are of exceptional density. Sea cows, particularly the dugong, have a much enlarged and intensely muscular upper lip, the corners of which serve to pluck the vegetation on which the animal feeds. In the dugong there are remains of two incisors, the second of which becomes large in the adult, remaining unerupted in the female and erupting to form a tusk in the male. There are basically six cusped molars in each jaw, which fall out progressively from the front so that only two remain in the adult. These teeth, together with horny pads at the front of each jaw, crush the food. In manatees each jaw has a series of 20 to 30 crushing molars, which move progressively forward during the life of the animal. Manatees are also exceptional in having only six vertebrae in the neck, instead of the seven standard in mammals. Almost nothing is known about the physiological processes of these animals.

Classification and paleontology. Sea cows comprise the order Sirenia of the superorder Subungulata, which also includes elephants and hyraxes. Two points of resemblance with elephants are the mode of tooth succession and the pectoral position of the mammary glands. The extensive fossil record indicates that the Sirenia date from the Eocene, about 50,000,000 years ago. More than 20 genera of fossil sirenians have been described. They seem to have been widespread near the coasts of the warmer seas of the world, and some think that the manatee is of more recent origin and has replaced the dugong in the Atlantic region.

Śivaji

Sivaji (Shivaji), called the "Grand Rebel," a Marāthā hero of 17th-century India, was the founder of an independent Marāthā kingdom in the Deccan, in the south central part of the subcontinent. A great statesman and social reformer, he was also a master of guerrilla warfare. He breathed new life into a moribund race that for centuries had resigned itself to abject serfdom and led them against Aurangzeb, a powerful Mughal ruler. Above all, in a place and age stained by religious savagery, he stands

Aquatic
behav-
iour

Distin-
guishing
features

almost alone as one who practiced true religious tolerance.

Śivaji was probably born on February 19, 1630 (some say April 1627), of a line of prominent nobles. India at that time was under Muslim rule: the Mughals in the north and the Muslim sultans of Bijjipur and Golkundā in the south. All three ruled by right of conquest, with no pretense that they had any obligations toward the ruled. Śivaji, whose ancestral estates were situated in the Deccan, in the realm of the Bijjipur sultans, found the Muslim oppression and religious persecution of the Hindus so intolerable that, by the time he was 16, he had already convinced himself that he was the divinely appointed instrument of the cause of Hindu freedom—a conviction that was to sustain him throughout his life. Collecting a band of followers, about 1655 he began to seize the weaker Bijāpur outposts. In the process, he destroyed a few of his influential coreligionists who had aligned themselves with the sultans. All the same, his daring and military skill, combined with his sternness toward the oppressors of the Hindus, won him the heart and mind of the common man. His depredations grew increasingly audacious, and several minor expeditions sent to chastise him proved ineffective.

When the Sultan of Bijjipur, in 1659, sent agianst him an army 20,000 strong under Afzal Khiin, Śivaji, pretending to be intimidated, enticed the force deep into difficult mountain terrain and then killed Afzal Khiin at a meeting to which he had lured him by submissive appeals. Meanwhile, picked troops that had been previously positioned swooped down on the unwary Bijāpur army and routed it. Overnight, Śivaji had become a formidable warlord, possessing the horses, the guns, and the ammunition of the Bijjipur army.

Alarmed by Śivaji's rising strength, the Mughal emperor Aurangzeb ordered his viceroy of the south to march against him. Śivaji countered by carrying out a daring midnight raid right within the Viceroy's encampment, in which the Viceroy lost the fingers of one hand and his son was killed. Discomfited by this reverse, the Viceroy withdrew his forte. Śivaji, as though to provoke the Mughals further, attacked the rich coastal town of Surat and took immense booty.

Aurangzeb could hardly ignore so flaunting a challenge and sent out his most prominent general, Mirza Raja Jai Singh, at the head of an army said to number 100,000 men. The pressure exerted by this vast force, combined with the drive and tenacity of Jai Singh, soon compelled Śivaji to sue for peace and to undertake that he, accompanied by his son, would attend Aurangzeb's court at Agra to be formally accepted as Mughal vassals. In Agra, hundreds of miles from their homeland, Śivaji and his son were placed under house arrest, where they lived under the threat of execution. Undaunted, Śivaji feigned illness and, as a form of penance, began to send out enormous baskets filled with sweets to be distributed among the poor. On August 17, 1666, he and his son had themselves carried past their guards in these baskets. His escape, possibly the most thrilling episode in a life filled with high drama, was to change the course of Indian history. His followers welcomed him back as their leader, and within two years he not only had won back all the lost territory but had expanded his domain. He collected tribute from Mughal districts and plundered their rich mart; he reorganized the army and instituted reforms for the welfare of his subjects. Taking a lesson from the Portuguese and English traders who had already gained footholds in India, he began the building of a naval force and was thus the first Indian ruler in modern times to appreciate that sea power was essential for trade as well as defense.

Almost as though prodded by Śivaji's meteoric rise, Aurangzeb intensified his persecution of Hindus; he imposed a poll tax on them, connived at forcible conversions, and demolished temples, erecting mosques in their places.

In the summer of 1674, Śivaji had himself enthroned with great fanfare as an independent sovereign. The suppressed Hindu majority rallied to him as their leader. He ruled his domain for six years, through a Cabinet of eight ministers. A devout Hindu who prided himself as the protector of his religion, he broke tradition by command-

ing that two of his relatives, who had been forcibly converted to Islām, should be taken back into the Hindu fold (Hinduism admits no converts); yet even though both Christians and Muslims often imposed their creeds on the populace by force, he respected the beliefs and protected the places of worship of both communities. Many Muslims were in his service. After his coronation, his most noteworthy campaign was in the south, during which he forged an alliance with the sultans and thereby blocked the grand design of the Mughals to spread their rule over the entire subcontinent.

Śivaji had several wives and two sons. His last years were shadowed by the apostasy of his elder son, who, at one stage, defected to the Mughals and was brought back only with the utmost difficulty. The strain of guarding his kingdom from its enemies in the face of bitter domestic strife and discord among his ministers hastened his end. The man Macaulay called "the Great Śivaji" died after an illness on April 3, 1680, in the mountain stronghold of Rājgarh, which he had made his capital.

(R.R.D.)

Skeletal System, Human

Man, as a member of the great group of vertebrates, has an internal skeleton as framework for his body as a whole. This framework consists of many individual bones and cartilages. There are bands of fibrous connective tissue, the ligaments and tendons, in intimate relationship with the parts of the skeleton, but they are not, in a strict sense, considered a part of it.

The present article is concerned primarily with the gross structure and the function of the skeleton of the normal human adult. Details of tissue structure of cartilage and bone, of the complex developmental processes that bring the skeleton to its mature state, and of the diseases that affect the skeletal tissues and the joints are dealt with in the articles BONE; BONE DISEASES AND INJURIES; JOINT; JOINT DISEASES AND INJURIES.

The human skeleton, like that of other vertebrates, consists of three subdivisions, each with origins distinct from the others and each presenting certain individual features. These are (1) the axial, comprising the vertebral column—the spine—and much of the skull; (2) the visceral, comprising the lower jaw, some elements of the upper jaw, and the branchial arches, including the hyoid bone (the branchial arches are barlike ridges and the bones and cartilages that derive from them on either side of the throat and the head of the embryo, corresponding to the bars that support the gills of fish; for the hyoid, see below *The hyoid: example of the anchoring function*); and (3) the appendicular, to which the hip and shoulder girdles and the bones and cartilages of the limbs belong.

When the relation of these three divisions of the skeleton to the soft parts, such as the nervous system, the alimentary respiratory, and circulatory systems, and the voluntary muscles, are considered, it is clear that the functions of the skeleton are of three different types—support, protection, and motion. Of these functions, support is the most primitive and the oldest, just as the axial part of the skeleton was the first to evolve. The vertebral column, corresponding to the notochord in lower organisms, is the main support of the trunk.

The central nervous system lies largely within the axial skeleton, the brain being well protected by the cranium (see below *The cranium: example of the protective function*) and the spinal cord by the vertebral column, by means of the bony neural arches (the arches of bone that encircle the spinal cord) and the intervening ligaments.

other mammals is his erect posture. The human body is, to some extent, like a walking tower that moves on pillars, represented by the legs. Tremendous advantages have been gained from this erect posture, the chief among which has been the freeing of the arms for a great variety of uses. Nevertheless, erect posture has created a number of mechanical problems; in particular, weight bearing. These problems have had to be met by adaptations of the skeletal system.

Protective
function
of
skeleton

Protection of the heart, lungs, and other organs and structures in the chest creates a problem somewhat different from that of the central nervous system. These organs, the function of which involves motion, expansion, and contraction, must have a flexible and elastic protective covering. Such a covering is provided by the bony thoracic basket, or rib cage, which forms the skeleton of the wall of the chest, or thorax. The connection of the ribs to the breastbone—the sternum—is in all cases a secondary one, brought about by the relatively pliable rib (costal) cartilages. The small joints between the ribs and the vertebrae permit a gliding motion of the ribs on the vertebrae during breathing and other activity. The motion is limited by the ligamentous attachments between ribs and vertebrae.

The third general function of the skeleton is that of motion. The great majority of the skeletal muscles are firmly anchored to the skeleton, usually to at least two bones and, in some cases, to many bones. Thus, the motions of the body and its parts, all the way from the lunge of the football fullback to the delicate manipulations of a handicraft artist or of the use of complicated instruments by a scientist, are made possible by separate and individual engineering arrangements between muscle and bone.

In this article, the cranium, the hyoid bone, the rib cage, and other parts of the skeleton are considered in terms of their sharing in these functions.

BONES OF THE AXIAL AND VISCERAL SKELETON

The cranium: example of the protective function. The cranium—that part of the skull that encloses the brain—is sometimes called the braincase, but its intimate relation

to the sense organs for sight, hearing, smelling, and taste and to other structures makes such a designation somewhat misleading.

The cranium is formed of bones of two different types of developmental origin—the cartilaginous, or substitution, bones, which replace cartilages preformed in the general shape of the bone; and membrane bones, which are laid down within layers of connective tissue. For the most part, the substitution bones form the floor of the cranium, while membrane bones form the sides and roof.

The range in the capacity of the cranial cavity is wide but is not directly proportional to the size of the skull, because there are variations also in the thickness of the bones and in the size of the air pockets, or sinuses. The cranial cavity has a rough, uneven floor, but its landmarks and details of structure generally are consistent from one skull to another.

The cranium forms all the upper portion of the skull, with the bones of the face situated beneath its forward part. It consists of a relatively few large bones, the frontal bone, the sphenoid, two temporal bones, two parietal bones, and the occipital bone (see below). The frontal bone underlies the forehead region and extends back to the coronal suture, an arching line that separates the frontal bone from the two parietal bones, on the sides of the cranium. In front, the frontal bone forms a joint with the two small bones of the bridge of the nose and with the zygomatic bone (which forms part of the cheekbone; see below *The facial bones and their complex function*), the sphenoid, and the maxillary bones. Between the nasal and zygomatic bones, the horizontal portion of the frontal bone extends back to form a part of the roof of the eye socket, or orbit; it thus serves an important protective function for the eye and its accessory structures.

Each parietal bone has a generally four-sided outline. Together, they form a large portion of the side-walls of the cranium. Each adjoins the frontal, the sphenoid, the temporal, and the occipital bones and its fellow of the opposite side. They are almost exclusively cranial bones, having less relation to other structures than the other bones that help to form the cranium.

Develop-
ment of
cranial
bones

Parietal
bones

Figure 2: Internal surface of base of skull.

From Cunningham's Textbook of Anatomy edited by G.J. Romanes and published by Oxford University Press as an Oxford Medical Publication

Important landmarks of the skull, useful not only in measurement but also in specifying the location of injury and of X-ray examination, are found at the four angles of the parietal bone: the upper rear angle is the **lambda**; the lower rear, the **asterion**; the upper front angle, the **bregma**; and the lower front, the **pterion**. At the **lambda**, the two parietal bones meet the occipital bone, which forms the back of the cranium. The **asterion** marks the location, within the cranium, of the lateral venous sinus, a large channel for venous blood that runs between layers of the outermost covering of the brain, the **dura mater**. The **asterion** is also the point at which parietal, occipital, and temporal bones meet. The **bregma**, the upper front corner, lies at the juncture of the parietal bones with the frontal bone. The **pterion**, the lower front joint, is the region of juncture of frontal, parietal, and sphenoid bones and, in some skulls, is the site of an irregular, isolated bone, called a **wormian bone**.

The interior of the cranium shows a multitude of details, reflecting the shapes of the softer structures that are in contact with the bones.

The internal surface of the vault is relatively **uncomplicated**. In the midline front to back, along the seam, called the **sagittal suture**, between the two parietal bones, is a shallow depression—the groove for the superior **longitudinal venous sinus**, a large channel for venous blood. A number of depressions on either side of it mark the sites of the **pachionian bodies**, structures that permit the venous system to absorb cerebrospinal fluid. The large, thin-walled venous sinuses all lie within the cranial cavity. While they are thus protected by the cranium, in many places, they are so close beneath the bones that a fracture or penetrating wound may tear the sinus wall and lead to bleeding. The blood frequently is trapped beneath the outermost and toughest brain covering, the **dura mater**, in a mass called a **subdural hematoma**.

Conspicuous **markings** on the internal surface of the projection of the sphenoid, called the **great wing**, and on the internal surfaces of the parietal and the temporal bones are formed by the **middle meningeal artery** and its branches, which supply blood to the brain coverings. Injury to these vessels may lead to **extradural hematoma**, a mass of blood between the **dura mater** and the bone.

In contrast to the vault and sides of the cranium, the base presents an extremely complicated aspect. It is divided into three, major depressions, or **fossae**, in a descending stair-step arrangement from front to back. The fossae are divided strictly according to the borders of the bones of the cranium but are related to major portions of the brain. The **anterior cranial fossa** serves as the bed in

which rest the frontal lobes of the cerebrum, the large forward part of the brain. The **middle cranial fossa**, sharply divided into two lateral halves by a central eminence of bone, contains the temporal lobes of the cerebrum. The **posterior cranial fossa** serves as a bed for the hemispheres of the cerebellum (a mass of brain tissue back of the brainstem and beneath the rear portion of the cerebrum) and for the forward and middle portion of the brainstem. Major portions of the brain are thus partially enfolded by the bones of the cranial wall.

There are openings in the three fossae for the passage of nerves and blood vessels, and the markings on the internal surface of the bones are from the attachments of the brain coverings—the **meninges**—and venous sinuses and other blood vessels.

The **anterior cranial fossa** shows a crestlike projection in the midline, the **crista galli** ("crest of the cock"). This is a place of firm attachment for the important **falx cerebri**, a subdivision of **dura mater** that separates the right and left cerebral hemispheres. On either side of the crest is the **cribriform** (pierced with small holes) plate of the **ethmoid**, a midline bone important as a part both of the cranium and of the nose. Through the perforations of the plate run many divisions of the olfactory, or first cranial, nerve, coming from the mucous membrane of the nose. At the sides of the plate are the orbital plates of the frontal bone, which form the roofs of the eye sockets. Their inner surfaces are relatively smooth but have a number of sharp irregularities more obvious to the touch than to the sight. These irregularities mark attachments of **dura mater** to bone.

The rear part of the **anterior cranial fossa** is formed by those portions of the sphenoid bone called its body and lesser wings. Projections from the lesser wings, the **anterior clinoid** (bedlike) processes, extend back to a point beside each optic foramen, an opening through which important optic nerves, or tracts, enter into the protection of the cranial cavity after a relatively short course within the eye socket.

The central eminence of the **middle cranial fossa** is specialized as a throne-like or saddle-like seat for the **pituitary gland**. The posterior portion of this seat, or **sella turcica** ("Turk's saddle"), is actually wall-like and is called the **dorsum sellae**. The pituitary gland is, thus, situated in almost the centre of the cranial cavity. It is covered over also by the brain coverings and has no connection with the exterior of the cranium except by blood vessels.

The deep, lateral portions of the **middle cranial fossa** contain the temporal lobes of the cerebrum. In the forward part of the fossa are two important openings: one, the **superior orbital fissure**, opening into the eye cavity, and the other, the **foramen rotundum**, for the passage of the maxillary nerve, which serves the upper jaw and adjacent structures. Farther back are the conspicuous **foramen ovale**, an opening for the mandibular nerve to the lower jaw, and the **foramen spinosum**, for the middle meningeal artery, which brings blood to the **dura mater**.

Also in the **middle fossa**, near the apex of that part of the temporal bone called the **petrous** (stonelike) temporal bone, is the jagged opening called the **foramen lacerum**. The lower part of the **foramen lacerum** is blocked by fibrocartilage, but through its upper part passes the internal carotid artery, surrounded by a network of autonomic nerves, as it makes its way to the interior of the cranial cavity.

The delicate structures of the internal ear are not entrusted to the cranial cavity as such but lie within the petrous portion of the temporal bone in a bony labyrinth into which the thin-walled membranous labyrinth, with its areas of sensory cells, is more or less accurately fitted but with an adequate space for protective fluid, the **perilymph**, between bone and membrane.

The **posterior cranial fossa** is above the vertebral column and the muscles of the back of the neck. The **foramen magnum**, the opening through which the brain and spinal cord make connection, is in the lowest part of the fossa. Between its forward margin and the base of the **dorsum sellae** is a broad, smooth, bony surface called the **clivus** (Latin for "hill"). The bridge-like pons and the

Anterior

cranial
fossa

Internal
surface
of the
vault

pyramid-like medulla oblongata of the brainstem lie upon the clivus, separated from the bone only by their coverings. Near the foramen magnum are ridges for attachment of folds of the dura mater.

In the sides of the posterior cranial fossa are two transverse grooves, each of which, in part of its course, is separated by extremely thin bone from the mastoid air cells back of the ear. Through other openings, the jugular foramina, pass the large blood channels called the sigmoid sinuses and also the 9th (glossopharyngeal), 10th (vagus), and 11th (spinal accessory) cranial nerves as they leave the cranial cavity.

The vessels, as well as the cranial nerves, are subject to injury at the openings into or from the cranial cavity and in special areas, such as close to the mastoid air cells. In the latter location, mastoiditis may lead to enough breakdown of bone to allow disease-bearing organisms to reach the other structures within the cranial cavity.

The hyoid: example of the anchoring function. The primary function of the hyoid bone is to serve as an anchoring structure for the tongue. The bone is situated at the root of the tongue in the front of the neck and between the lower jaw and the largest cartilage of the larynx, the voice box. It has no articulation with other bones and has, thus, a purely anchoring function.

The hyoid consists of a body, a pair of larger horns, the greater cornua, and a pair of smaller horns, the lesser cornua. The bone is more or less in the shape of a U, and the body forms the central part, or base, of the letter. In the act of swallowing, the hyoid bone, tongue, and larynx all move upward rapidly.

From Cunningham's Textbook of Anatomy edited by G.J. Romanes and published by Oxford University Press as an Oxford Medical Publication

Figure 3: Hyoid bone.

The greater cornua are the limbs of the U. Their outer ends generally are overlapped by the large sternocleidomastoid muscles. The lesser cornua are small projections from the places somewhat arbitrarily called the junctions of the body and the greater cornua. The hyoid bone has certain of the muscles of the tongue attached to it.

The hyoglossus muscles originate on each side from the whole length of the greater cornua and also from the body of the hyoid. They are inserted into the posterior half or more of the sides of the tongue. The hyoid bone anchors them when they contract to depress the tongue and to widen the oral cavity. The two geniohyoid muscles originate close to the point at which the two halves of the lower jaw meet; the fibres of the muscles extend downward and backward, close to the central line, to be inserted into the body of the hyoid bone. Contraction of the muscles pulls the hyoid bone upward and forward.

Inserting into the middle part of the lower border of the hyoid bone are the sternohyoids, long muscles arising from the breastbone and collarbone and running upward and toward each other in the neck.

Other muscles attached to the hyoid bone are the two mylohyoid muscles, which form a sort of diaphragm for the floor of the mouth; the thyrohyoid, arising from the

thyroid (the largest) cartilage of the larynx; and the omohyoid, which originates from the upper margin of the shoulder blade and from a ligament, the suprascapular ligament.

The position of the hyoid bone with relation to the muscles attached to it has been likened to that of a ship steadied as it rides when anchored "fore and aft." Through the muscle attachments, the hyoid plays an important role in mastication, in swallowing, and in voice production.

At the beginning of a swallowing motion, the geniohyoid and mylohyoid muscles elevate the bone and the floor of the mouth simultaneously. These muscles are assisted by the stylohyoid and digastric muscles. The tongue is pressed upward against the palate and the food is forced backwards.

The facial bones and their complex functions. The larger part of the skeleton of the face is formed by the maxillae. Though they are called the upper jaws, the extent and functions of the maxillae include much more than serving as complements to the lower jaw, or mandible. They form the middle and lower portion of the eye socket. They have the opening for the nose between them, beneath the lower borders of the small nasal bones. A sharp projection, the anterior nasal spine, is formed by them at the centre of the lower margin of the opening for the nose, the nasal aperture.

The infraorbital foramen, an opening into the floor of the eye socket, is the forward end of a canal through which passes the infraorbital branch of the maxillary nerve, the second division of the great fifth cranial nerve. It lies slightly below the lower margin of the socket.

The alveolar margin, containing the alveoli, or sockets, in which all the upper teeth are set, forms the lower part of each maxilla, while a lateral projection from each forms the zygomatic process, forming a joint with the zygomatic, or malar (cheek), bone.

The left and right halves of the lower jaw, or mandible, originally are two distinct bones, but in the second year the two bones fuse at the midline to form one. The horizontal, central part on each side is the body of the mandible. The upper portion of the body is the alveolar margin, corresponding to the alveolar margins of the maxillae. The projecting chin, at the lower part of the body in the midline, is said to be characteristic of the human skull. On either side of the chin is the mental foramen, an opening for the mental branch of the mandibular nerve, the third division of the fifth cranial nerve.

The ascending parts of the mandible at the side are called **rami** (branches). The joints by means of which the lower jaw is able to make all its varied movements are between a rounded knob, or condyle, at the upper back corner of each ramus and a depression, called a glenoid fossa, in each temporal bone. Another, rather sharp projection at the top of each ramus and in front, called a coronoid process, does not form part of a joint. Attached to it is the temporalis muscle, which serves with other muscles in shutting the jaws.

On the inner side of the ramus of either side is a large, obliquely placed opening into a channel, the mandibular canal, for nerves, arteries, and veins.

The zygomatic arch, forming the cheekbone, consists of portions of three bones: the maxilla, in front; the zygomatic bone, centrally in the arch; and a projection from the temporal bone to form the rear part. The zygomatic arch actually serves as a firm bony origin for the powerful masseter muscle, which descends from it to insert on the outer side of the mandible and which shares with the temporalis and lateral and medial pterygoid muscles the function of elevating the mandible to bring the lower against the upper teeth, thus achieving bite.

The spine: its role in protection, anchoring, and weight bearing. In speaking earlier of the three major functions of the skeleton (support, protection, motion), it was indicated that the assumption of the erect posture during the development of the human species has led to a need for adaptation and changes from the arrangements seen in the quadrupeds. The very form of the human vertebral column is due to such adaptations and changes.

by the
hyoid bone

The curvature of the spine

The vertebral column is not actually a column but, rather, a sort of spiral spring in the form of the letter **S**. The newborn child has a relatively straight backbone. The development of the curvatures occurs as the supporting functions of the vertebral column in man—holding up the trunk, keeping the head erect, serving as an anchor for the extremities—are developed.

The S-curve makes it possible for the vertebral column to absorb the shocks of walking on hard ground or on pavement; a straight column would conduct the jarring shocks directly from the pelvic girdle to the head. The curvature meets the problem of the weight of the viscera. In an erect animal with a straight column, the column would be pulled forward by the viscera. Additional space for the viscera is provided by the concavities of the thoracic and pelvic regions.

From *Cunningham's Textbook of Anatomy* edited by G.J. Romanes and published by Oxford University Press as an Oxford Medical Publication

Figure 4: Backbone, from the left side.

Weight distribution of the entire body is also effected by the S-curve. The upper sector, to a large extent, carries the head; the central sector, the thoracic viscera—the organs and structures in the chest—and the lower sector,

the abdominal viscera. If the column were straight, the weight load would increase from the head downward and be relatively great at the base. Lastly, the S-curve protects the vertebral column from breakage. The doubly bent spring arrangement is far less vulnerable to fracture than would be a straight column.

The protective function of the skeleton is perhaps most conspicuous in relation to the central nervous system, although it is equally important for the heart and lungs and some other organs. A high degree of protection for the nervous system is made possible by the relatively small amount of motion and expansion needed by the component parts of this system and by certain physiological adaptations relating to circulation, to the cerebrospinal fluid, and to the meninges, the coverings of the brain and spinal cord. The brain itself is snugly enclosed within the boxlike cranium. Sharing in the protection afforded by the cranium is the pituitary gland, or hypophysis.

For the spinal cord, with its tracts of nerve fibres travelling to and from the brain, the placement in relation to the spinal column is somewhat like that of a candle in a lantern. Normally, there is considerable space between the nervous and the bony tissue, space occupied by the meninges, by the cerebrospinal fluid, and by a certain amount of fat and connective tissue. In front are the heavy **centrums**, or bodies, of the vertebrae and the **intervertebral disks**—the tough, resilient pads between the vertebral bodies—while in back and on the sides the cord is enclosed and protected by the portion of each vertebra called the neural arch. Between the neural arches are sheets of elastic connective tissue, the **interlaminar ligaments**, or **ligamenta flava**. Here some protective function has to be sacrificed for the sake of motion, because a forward bending of part of the column leads to separation between the laminae and between the spines of the neural arches of adjoining vertebrae. It is through the **ligamenta flava** of the lower lumbar region (the small of the back) that the needle enters the subarachnoid space in the procedure of lumbar puncture.

Besides its role in support and protection, the vertebral column is important in the anchoring of muscles. Many of the muscles attached to it are so arranged, in fact, as to move either the column itself or various segments of it. Some are relatively superficial, and others are deep lying. The large and important **erector spinae**, as the name implies, holds the spine erect. It begins on the sacrum (the large triangular bone at the base of the spinal column) and passes upward, forming a mass of muscle on either side of the spines of the lumbar vertebrae. It then divides into three columns, ascending over the back of the chest. Although slips (narrow strips) of the muscle are inserted into the vertebrae and ribs, it does not terminate thus, for fresh slips arise from these same bones and continue on up into the neck, until one of the divisions, known as the **longissimus capitis**, finally reaches the skull.

Small muscles run between the transverse processes (projections from the sides of the neural rings) of adjacent vertebrae, between the vertebral spines (projections from the centres of the rings), and also from transverse process to spine, giving great mobility to the segmented bony column.

The anchoring function of the spinal column is of great importance for the muscles that arise on the trunk, in whole or part from the column or from ligaments attached to it, and that are inserted on the bones of the arms and legs. Of these muscles, the most important for the arms are the **latissimus dorsi** (drawing the arm backward and downward and rotating it inward), the **trapezius** (rotating the shoulder blade), the **rhomboides**, and the **levator scapulae** (raising and lowering the shoulder blade); for the legs, the **psaos** (loin) muscles.

The rib cage. The rib cage, or thoracic basket, consists of the 12 thoracic (chest) vertebrae, the **24** ribs, and the breastbone or sternum. The ribs are curved, compressed bars of bone, each succeeding rib, from the first, or uppermost, becoming more open in curvature. The place of greatest change in curvature of a rib, called its angle, is found several inches from the head of the rib, the end that forms a joint with the vertebrae.

Anchoring function of the spine

Structure
and
functions
of ribs

The first seven ribs are attached to the breastbone by cartilages called costal cartilages; these ribs are called true ribs. Of the remaining five ribs, which are called false, the first three have their costal cartilages connected to the cartilage above them. The last two, the floating ribs, have their cartilages ending in the muscle in the abdominal wall.

Through the action of a number of muscles, the rib cage, which is semirigid but expansile, increases its size. The pressure of the air in the lungs thus is reduced below that of the outside air, which moves into the lungs quickly to restore equilibrium. These events constitute inspiration (breathing in). Expiration (breathing out) is a result of relaxation of the respiratory muscles and of the elastic recoil of the lungs and of the fibrous ligaments and tendons attached to the skeleton of the thorax. A major respiratory muscle is the diaphragm, which separates the chest and abdomen and has an extensive origin from the rib cage and the vertebral column. The configuration of the lower five ribs gives freedom for the expansion of the lower part of the rib cage and for the movements of the diaphragm.

BONES OF THE APPENDICULAR SKELETON

Shoulder girdle and pelvic girdle compared and contrasted. The upper and lower extremities of man offer many interesting points of comparison and of contrast. They and their individual components are homologous; *i.e.*, of a common origin and patterned on the same basic plan. A long evolutionary history and profound changes in function of these two pairs of extremities have led, however, to considerable differences between them.

The pelvic
girdle

The girdles are those portions of the extremities that are in closest relation to the axis of the body and that serve to connect the free extremity (the arm or the leg) with that axis, either directly, by way of the skeleton, or indirectly, by muscular attachments. The connection of the pelvic girdle to the body axis, or vertebral column, is by means of the sacroiliac joint. On the contiguous surfaces of the ilium—the rear and upper part of the hipbone—and of the sacrum—the part of the vertebral column directly connected with the hipbone—are thin plates of cartilage. The bones are closely fitted together in this way, and there are irregular masses of softer fibrocartilage in places joining the articular cartilages; at the upper and posterior parts of the joint there are fibrous attachments between the bones. In the joint cavity there is a small amount of synovial fluid. Strong ligaments, known as anterior and posterior sacroiliac and interosseous ligaments, bind the pelvic girdle to the vertebral column. These fibrous attachments are the chief factors limiting motion of the joint, but the condition, or tone, of the muscles in this region is important in preventing or correcting the sacroiliac problems that are of common occurrence.

The pelvic girdle consists originally of three bones, which become fused and each of which contributes a part of the acetabulum, the deep cavity into which the head of the thighbone, or femur, is fitted. The flaring upper part of the girdle is the ilium; the lower anterior part, meeting with its fellow at the midline, is the pubis; and the lower posterior part is the ischium. Each ischial bone has a prominence, or tuberosity, and it is upon these tuberosities that the body rests when seated.

The
pectoral
girdle

The components of the girdle of the upper extremity, the pectoral girdle, are the shoulder blade, or scapula, and the collarbone, or clavicle. The head of the humerus, the long bone of the upper arm, fits into the glenoid cavity, a depression in the scapula. The pectoral girdle is not connected with the vertebral column by ligamentous attachments, nor is there any joint between it and any part of the axis of the body. The connection is by means of muscles only, including the trapezius, rhomboids, and levator scapulae, while the serratus anterior connects the scapula to the rib cage. The range of motion of the pectoral girdle and, in particular, of the scapula is enormously greater than that of the pelvic girdle.

Another contrast, in terms of function, is seen in the shallowness of the glenoid fossa, as contrasted with the

depth of the acetabulum. It is true that the receptacle for the head of the humerus is deepened somewhat by a lip of fibrocartilage, the glenoid labrum, which, like the corresponding structure for the acetabulum, aids in grasping the head of the long bone. The range of motion of the free upper extremity is, however, far greater than that of the lower. With this greater facility of motion goes a greater risk of dislocation, and, of all joints of the body, that of the shoulder is most often the site of dislocation.

Long bones of arms and legs: comparison and contrast. The humerus and the femur are corresponding bones of the arms and legs, respectively. While their parts are similar in general, their structure has been adapted to differing functions. The head of the humerus is almost hemispherical, while that of the femur forms about two-thirds of a sphere. There is a strong ligament passing from the head of the femur to further strengthen and ensure its position in the acetabulum.

The anatomical neck of the humerus is only a slight constriction, while the neck of the femur is a very distinct portion running from the head to meet the shaft at an angle of about 125°. Actually, the femoral neck is developmentally and functionally a part of the shaft. The entire weight of the body is directed through the femoral heads along their necks and to the shaft. The structure of the bone within the head and neck and the upper part of the shaft of the femur would do credit to an engineer who had worked out the weight-bearing problems involved.

From *Cunningham's Textbook of Anatomy* edited by G.J. Romanes and published by Oxford University Press as an Oxford Medical Publication

Figure 5: (Left) Forearm, radius and ulna bones. (Right) Lower leg, fibula and tibia bones.

The forearm and the lower leg have two long bones each. In the forearm are the radius---on the thumb side of the forearm---and the ulna; in the lower leg, the tibia (the shinbone) and the fibula. The radius corresponds to the tibia and the ulna to the fibula. The knee joint not only is the largest joint in the body but also is perhaps the most complicated one. The bones involved in it, however, are only the femur and the tibia, although the smaller bone of the leg, the fibula, is carried along in the movements of flexion, extension, and slight rotation that this joint permits. The very thin fibula is at one time in fetal development far thicker relative to the tibia than in the adult.

At the elbow, the ulna forms with the humerus a true hinge joint, in which the actions are flexion and extension. In this joint, a large projection of the ulna, the olecranon, fits into the well-defined olecranon fossa, a depression of the humerus.

Radius
and ulna

The radius is shorter than the ulna. Its most distinctive feature is the thick, disk-shaped head, which has a smoothly concave superior surface to articulate with the head, or capitulum, of the humerus. The head of the radius is held against the notch in the side of the ulna by means of a strong annular, or ring-shaped, ligament, which, at the same time, leaves the head free to rotate. As the head rotates, the shaft and outer end of the radius are swung in an arc. In the position of the arm called supination, the radius and ulna are parallel, the palm of the hand faces forward, and the thumb is away from the body. In the position called pronation, the radius and ulna are crossed, the palm faces to the rear, and the thumb is next to the body. There are no actions of the leg comparable to the supination and pronation of the arm.

Hands and feet: comparison and contrast. The skeleton of the wrist, or carpus, consists of eight small carpal bones, in two rows of four each. That of the ankle, or tarsus, has seven bones, and, because of the angle of the foot to the leg and the weight-bearing function, they are arranged in a more complicated way. The bone of the heel, directed downward and backward, is the calcaneus, while the "keystone" of the tarsus is the talus, the superior surface of which articulates with the tibia.

In the skeleton of the arms and legs, the outer portion is specialized and consists of elongated portions made up of chains, or linear series, of small bones. In an evolutionary sense, these outer portions appear to have had a complex history and, within man's own mammalian ancestry, to have passed first through a stage when all four would have been "feet," serving as the weight-bearing ends of extremities, as in quadrupeds in general. Second, all four appear to have become adapted for arboreal life, as in the lower primates, the "four-handed folk." Third, and finally, the assumption of an upright posture has brought the distal portions of the hind, now lower, extremities back into the role of feet, while those of the front, now upper, extremities have developed remarkable manipulative powers and are called hands. At what place in the primates a foot becomes a hand is difficult to say, and one might be justified, in fact, in speaking of hands in raccoons, squirrels, and some other nonprimates.

In man, the metatarsal bones, those of the foot proper, are larger than the corresponding bones of the hands, the metacarpal bones. The tarsals and metatarsals form the arches of the foot, which give it strength and enable it to act as a lever. The shape of each bone and its relations to its fellows are such as to adapt it for this function.

The phalanges—the toe bones—of the foot have bases relatively large compared to the corresponding bones in the hand, while the shafts are much thinner. The middle and outer phalanges in the foot are short in comparison to those of the fingers. The phalanges of the great toe have special features.

The hand is an instrument for fine and varied movements. In these, the thumb with its skeleton, the first metacarpal bone and the two phalanges, is extremely important. Its free movements include, besides flexion, extension, abduction (ability to draw away from the first finger), and adduction (ability to move forward of the fingers), which are exercised in varying degrees by the great toe also, a unique action, that of opposition, by which it can be brought across, or opposed to, the palm and to the tips of the slightly flexed fingers. This motion forms the basis for the handling of tools, weapons, and instruments.

ture and Function (1960; pub. orig. in German, 1939), a treatment of the subject for the interested lay reader.

(W.A.)

Skeletal Systems

The skeleton is the supportive framework of an animal body. In vertebrates it is mainly internal and consists mostly of bone and cartilage; in invertebrates it is sometimes external and may consist of a variety of nonbony, noncartilaginous materials. In addition to its supportive function, the animal skeleton may provide protection, facilitate movement, and aid in certain sensory functions.

Support of the body is achieved in many Protozoa by a simple stiff, translucent, nonliving envelope called a pellicle. In nonmoving (sessile) coelenterates, such as coral, whose colonies attain great size, it is achieved by dead structures, both internal and external, which form supporting axes. In the many groups of animals that can move it is achieved either by external structures known as exoskeletons or by internal structures known as endoskeletons. Many animals remain erect or in their normal resting positions by means of a hydrostatic skeleton; *i.e.*, fluid pressure in a confined space.

The protective function alone of a skeleton may be provided by structures situated on the body surface; *e.g.*, the lateral sclerites of centipedes and the shell (carapace) of crabs. These structures carry no muscle and form part of a protective surface armour. The scales of fish, the projecting spines of echinoderms (*e.g.*, sea urchins), the minute, needlelike structures (spicules) of sponges, and the tubes of hydroids, raised from the body surface, are similarly protective. The bones of the vertebrate skull protect the brain. In the more advanced vertebrates and invertebrates many skeletal structures provide a rigid base for the insertion of muscles as well as providing protection.

The skeleton facilitates movement in a variety of ways, depending on the nature of the animal. The bones of vertebrates and the exoskeletal and endoskeletal units of the cuticle of arthropods (*e.g.*, insects, spiders, crabs) support opposing sets of muscles (*i.e.*, extensors and flexors). In other animal groups the hydrostatic skeleton provides such support.

In a limited number of animals, the hard skeleton transmits vibrations that are sensed by the hearing mechanism. In some forms—*e.g.*, bony fishes and fast-swimming squids—it aids in the formation of buoyancy mechanisms that enable the animal to adjust its specific gravity for travelling at different depths in the sea.

SKELETAL ELEMENTS

General features. Certain types of skeleton usually characterize particular animal phyla, but there are a limited number of ways in which an animal can form its skeleton. Similar modes of skeleton formation have been evolved independently by different groups to fulfill similar needs. The cartilaginous braincase of the octopus and squid, which are invertebrates, has a microscopic structure similar to the cartilage of vertebrates. The calcareous (*i.e.*, calcium-containing) internal skeleton of the echinoderms is simply constructed but is essentially not far different from the much more elaborate bones of vertebrates. Skeletal fibres of similar chemical composition occur in unrelated animal groups; for example, coiled shells of roughly similar chemical composition are present in gastropods (*e.g.*, snails), brachiopods (*e.g.*, lamp shells), and cephalopods (*e.g.*, chambered nautilus). The mechanical properties of different skeletal types vary considerably according to the needs of animals of particular size ranges or habits; *e.g.*, aquatic, terrestrial.

Skeletal elements are of six principal types: so-called hard structures, semirigid structures, connective tissue, hydrostatic structures, elastic structures, and buoyancy devices.

Cuticular structures. Hard structures may be either internal or external. They may be composed of bone (calcareous or membranous structures that are rigid), crystals, cuticle, or ossicles (*i.e.*, minute plates, rods, or spicules).

The scales of some fishes (*e.g.*, sturgeon) may be heavy, forming a complete external jointed armour; calcareous

Fish scales

Fingers and toes

deposits make them stiff. They grow at their margins, and their outer surfaces become exposed by disintegration of the covering cell layer, epithelium. Other fish *scales*—*i.e.*, those of most modern bony fishes—are thin, membranous, and flexible. The external shells of gastropods and bivalve mollusks (*e.g.*, clams, scallops) are calcareous, stiff, and almost detached from the body. The laminated, or layered, shell grows by marginal and surface additions on the inner side. Muscles are inserted on part of the shell, and the body of the animal can be withdrawn into the protection of the shell. Chambered calcareous shells formed by cephalopods and by protozoans of the order Foraminifera become so large and so numerous that the broken remains of the shells may constitute a type of sand covering large areas of tropical beaches; the pieces may also consolidate into rock. Protozoa of the order Radiolaria form skeletons of silica in the form of very complicated bars. The body of the animal flows partly inside and partly outside among the bars.

Coral skeletons are also partly inside and partly outside the animal. Calcareous depositions below a young coral polyp (*i.e.*, an individual member of the animal colony) are secreted by the ectoderm (generally, the outermost of three basic tissue layers), fixed to the surface to which the animal is attached, and thrown up into ridges, which form a cup into which the polyp can contract. A spreading of the base and the formation of more polyps on the base are followed by a central humping up of the soft tissue and further secretion of skeleton. An upright branch is thus formed, and, in time, large branching corals many feet high may arise from the sea floor. Most of the soft tissue is then external to an axial calcareous skeleton, but in rapidly growing corals the skeleton is perforate, and soft tissue lies both inside and outside it. Protection of the animal is provided by the skeletal cups into which each polyp can contract, but usually neither the whole colony nor a single animal has mobility.

The starfishes, brittlestars, and crinoids (*Echinodermata*) have many types of calcareous ossicles in the mesoderm (generally, the tissue layer between the gut and the outermost layer). These form units that articulate with each other along the arms, spines that project from the body covering and articulate with ossicles, and calcareous jaws (in sea urchins), functioning in complex *endoskeletal* systems. Less well organized calcareous deposits stiffen the body wall between the arms of the starfish.

Crystals

Crystals form the basis of many skeletons, such as the calcareous triradial (three-armed) and quadriradial (four-armed) spicules of calcareous sponges. The cellular components of the body of the sponge usually are not rigid and have no fixed continuity; cells from the outer, inner, and middle layers of a sponge are freely mobile. Spicules, which may be of silica, often extend far from the body. They can be shed at times and replaced by new spicules. Skeletal fibres are present in many sponges.

Calcareous spicules, large and small, form an important part of the skeleton of many coelenterates. Huge, needle-like spicules, projecting beyond the soft tissue of sea pens (pennatulids), for example, both support the flanges that bear feeding polyps and hinder browsing by predators. Minute internal spicules may be jammed together to form a skeletal axis, as in the red coral. In some corals (*Alcyonaria*), spicules combine with fibres made of keratin (a protein also found in hair and feathers) or keratins with amorphous calcite (noncrystalline calcium carbonate) to form axial structures of great strength and size, enabling colonies to reach large, bushlike proportions.

Skeletons consisting of cuticle but remote from the body surface give support and protection to other coelenterates, the colonial sedentary hydroids, and form tubes in which pogonophores (small, threadlike aquatic animals) live. Exoskeletons that are *superficially* similar but quite different from hydroids and pogonophores in both manner of growth and internal support occur in the *graptolites*, an extinct group, and in the protochordates, *Rhabdopleura* and *Cephalodiscus*. Some graptolites, known only from fossil skeletal remains many millions of years old, had skeletons similar to those of *Rhabdopleura*.

In segmented and in many nonsegmented invertebrates,

cuticle is secreted by the ectoderm and remains in contact with it. It is thin in annelid worms (*e.g.*, the earthworm) and thicker in roundworms (nematodes) and arthropods. In many arthropods the cuticle is infolded to form *endoskeletal* structures of considerable complexity. Rigidity is imposed on parts of the cuticle of arthropods either by sclerotization or tanning, a process involving dehydration (as in crustaceans and insects), by calcification (as in millipedes), or by both, as in many crabs. In most arthropods the body and legs are clearly segmented. On the dorsal (upper) side of each segment is a so-called *tergal* sclerite of calcified or *sclerotized* cuticle, usually a ventral (lower) sternite and often lateral pleurites; *i.e.*, side plates. There may be much fusion of sclerites on the same segment. Sometimes fusion occurs between dorsal *sclerites* of successive segments, to form rigid plates. Leg sclerotizations are usually cylindrical.

Internally, apodemes are hollow rods or flanges derived from the cuticle; they extend inward from the exoskeleton. Apodemes have a function similar to the bones of vertebrates, for they provide sites for muscle insertion, thereby allowing the leverage that can cause movement of other parts of the skeleton independent of hydrostatic forces. The apodemal system is most fully developed in the larger and more swiftly moving arthropods. The cuticle is a dead secretion and can only increase in thickness. At intervals an arthropod molts the entire cuticle, pulling out the apodemes. The soft body rapidly swells before secreting a new, stiff cuticle. The molting process limits the upper size of cuticle-bearing animals. Arthropods can never achieve the body size of the larger vertebrates, in which the bones grow with the body, because the mechanical difficulties of molting would be too great. The mechanical properties of bone limit terrestrial mammals to about the size of a 12-ton elephant. In water, however, bone can support a heavier animal, such as a blue whale weighing 100 tons. Bone is mechanically unsuited to support an animal as bulky as, for example, a large ship.

Semirigid structures. Flexible cuticular structures on the surface of unsegmented roundworms and arthropods are just as important in providing support as are the more rigid sclerites. Mobility between the sclerites of body and legs is maintained by regions of flexible cuticle, the *arthrodial* membranes. Some sclerites are stiffened by closely packed cones of sclerotization at their margins, forming structures that combine rigidity and flexibility.

The so-called mesoglea layer, which lies between the ectoderm and endoderm (the innermost tissue layer) of coelenterates, is thin in small species and massive in large ones. It forms a flexible skeleton associated with supporting muscle fibres on both the ectodermal and *endodermal* sides. In many branched alcyonarian, or soft corals, the mesoglea is filled with calcareous spicules, which are not tightly packed and thus permit the axis of each coral branch to bend with the swell of the sea. As a result, soft corals, which are sessile and colonial, are very strong and can resist water movements without breaking. In this respect they are unlike the calcareous corals, which break in violent currents of water. The often beautifully coloured, gorgonian corals, or sea fans, are supported by an internal horny axis of keratin. They, too, bend with the water movements, except when very large. In some forms the horny axis may be impregnated with lime. The horny axes are often orientated in complex branches set in one plane, so that the coral forms a feeding net across a prevailing current. Certain chordates also possess a flexible endoskeleton; the *rodlike* notochord occurs in adult lampreys and in most young fishes. Running just within the dorsal midline, it provides a mechanical basis for their swimming movements. In the higher vertebrates the notochord is surrounded by cartilage and finally replaced by bone. In many protochordates, however, the notochord remains unchanged. Cartilage, too, forms flexible parts of the endoskeletal system of vertebrates, such as between articulating bones and forming sections of ribs.

Connective tissue. Connective tissue forms sheets of varying complexity below the ectoderm of many animals, existing as fine membranes or as complex superficial layers of fibres. Muscles inserted on the fibres form sub-

Limitation
of size
by molting

epithelial complexes in many invertebrates; and vertebrate muscles are often inserted on firm sheets of connective tissue (fascia) deep in the body that are also formed by these fibres. Particular concentrations of collagen fibres, oriented in different directions, occur superficially in the soft-bodied *Peripatus* (a caterpillar-like terrestrial invertebrate). In coelenterates they also occur deep in the body. In many arthropods, collagen fibres form substantial endosternites (*i.e.*, ridges on the inner surface of the exoskeleton in the region of the thorax) that are isolated from other skeletal structures. These fibres are not shed during molting, and the endosternites grow with the body. The fibres do not stretch, but their arrangement provides firm support for muscles and sometimes permits great changes in body shape.

The hydrostatic skeleton. The hydrostatic skeleton is made possible by closed, fluid-filled internal spaces of the body. It is of great importance in a wide variety of animal groups because it permits the antagonistic action of muscles used in locomotion and other movements. The fluid spaces are part of the gastrovascular cavity in the Coelenterata, part of the coelomic cavity (between the gut and the body wall) in the worms, and hemocoelic (*i.e.*, in a type of body cavity consisting of a complex of spaces between tissues and organs) or vascular in mollusks and arthropods. As the exoskeleton becomes more rigid and the apodemal endoskeleton more fully developed in arthropods, the importance of the hemocoel in promoting antagonistic muscle action decreases. In larger and more heavily sclerotized species the hydrostatic skeleton is no longer of locomotory significance; the muscles work directly against the articulated skeleton, as in vertebrates.

Skeletal structure of jellyfishes

Elastic structures. In the larger medusae, or jellyfishes (Coelenterata), the musculature is mainly circular. By contracting its bell-shaped body, the jellyfish narrows, ejecting water from under the bell thus pushing the animal in the opposite direction from that of the water. There are no antagonistic muscles to counteract the contracted circular muscles. A passive, slow return of the bell to its expanded shape is effected largely by the elasticity of the mesoglea layer, which crumples during the propulsive contraction. After the circular muscles relax, the distorted mesoglea fibres pull them out to expand the bell. In many of the larger mammals, elastic fibres are used more extensively. The elephant and whale for example, possess an abundance of elastic tissue in their musculature.

Elasticity of surface cuticle assists recovery movements in roundworms and arthropods, but the stresses and strains that cuticle can withstand are limited. Special sensory devices (chordotonal organs) convey the extent of stress in the cuticle to the animal's nervous system, thus preventing the generation of stresses great enough to damage the structure. There are also elastic units in the base of the wings of some insects. These rather solid elastic structures alternately store and release energy. They have probably been important in the evolution of the extremely rapid wing beat of some insects.

Buoyancy devices. Buoyancy devices are complex structures that involve both hard and soft parts of the animal. In vertebrates they may be closely associated with or form part of the auditory apparatus. A chain of auditory ossicles in mammals transmits vibrations from the tympanic membrane to the internal ear; simpler devices occur in the cold-blooded land vertebrates. In the roach fish, which has sensitive hearing, a chain of four so-called Weberian ossicles connects the anterior, or forward, end of the swim bladder to the auditory organs of the head. Sound vibrations cause changes in volume in the anterior part of the bladder and are transmitted to the nervous system through the ossicles. The swim bladder of other fishes appears to be a buoyancy organ and not skeletal; however, cephalopods capable of swimming rapidly in both deep and shallow water possess air-filled buoyancy organs. The calcareous coiled shell of the bottom-living *Nautilus* is heavy and chambered; the animal lives in the large chamber. The shell behind is coiled and composed of air-filled chambers that maintain the animal in an erect position. When the

entire, coiled, lightly constructed shell of *Spirula* sinks into the body, the animal has internal air spaces that can control its buoyancy and also its direction of swimming. In cuttlefish and squids, a shell that was originally chambered has become transformed into a laminated cuttlebone. Secretion and absorption of gases to and from the cuttlebone by the bloodstream provide a hydrostatic buoyancy mechanism enabling the squids to swim with little effort at various depths. This device has probably made it possible for some species to grow to a length of 18 metres (59 feet). Some siphonophores (Coelenterata) have a chambered, gas-filled float, its walls stiffened with a chitin-like structure in *Velella*.

Cuttlebone

INVERTEBRATE SKELETON

Skeleto-musculature of a mobile coelenterate. A sea anemone provides an example of the way in which a hydrostatic skeleton can act as the means by which simple sheets of longitudinal and circular muscle fibres can antagonize each other to produce contrasting movements. The fluid-filled space is the large digestive, or internal, cavity of the body. If the mouth is slightly open when both longitudinal and circular muscles of the trunk contract, fluid flows out of the internal space, and the body shrinks. If the mouth is closed, the internal fluid-filled space cannot be compressed; thus, the body volume remains constant, and contraction of the longitudinal muscles of the trunk both shortens and widens the body. Contraction of the circular muscles pulls out relaxed longitudinal muscles, and the body lengthens. Appropriate coordination of muscular action working against the hydrostatic skeleton can produce locomotion movements—such as burrowing in sand or stepping along a hard surface—by billowing out one side of the base of the animal, the other side of the base contracting and forcing fluid into the relaxed, dilated portion. The forward dilated part sticks to the surface, and its muscles contract, pulling the animal forward.

Figure 1: Skeletal systems of lower invertebrates. (A) *Metridium* in three conditions; (B) *Obelia*; (C) *Rhabdopleura*; (D) *Grantia*.

The circular muscles lie outside a substantial layer of skeletal mesoglea fibrils; longitudinal muscles are internal to the layer. The muscle fibres are attached at either end to the mesoglea fibres, which, like vertebrate bones, cannot stretch. Unlike bones, however, the mesoglea sheet is able to change its shape, because its components (fibrils) are set in layers at an angle to each other and to the long axis of the body. Alteration in length and width of the body is accompanied by changes in the angle between two sheets of mesoglea fibrils; thus, support for the muscles can vary greatly in position. The range in change of shape of the sea anemone is implemented by simple muscles and connective tissue mesoglea fibrils. The movements are characteristically slow, often occurring so slowly as to be invisible to the naked eye. Faster movements would en-

gender greater increases in internal pressures, thus placing a needless burden on the musculature. All coelenterates utilize this slow hydrostatic-muscular system, but, as described for the jellyfish, some faster movements are also possible.

Skeleto-musculature of an earthworm. The hydrostatic skeleton of many other animals is provided by the body cavity, or coelom, which is situated outside the alimentary canal and inside the body wall. In an earthworm the body cavity of each segment of the trunk is separated from that of the next by a partition, so that the segmented body possesses a series of more or less isolated coelomic, fluid-filled spaces of fixed volume. The body wall contains circular and longitudinal muscles and some minor muscles. As in the sea anemone, skeletal connective-tissue fibres form the muscle insertions. As a worm crawls or burrows, a group of segments shorten and widen, their total volume remaining the same; contact with the ground is maintained by projection of bristle-like structures from the cuticle (setae). Groups of short, wide segments are formed at intervals along the body; the segments between these groups are longer, narrower, and not in contact with the ground. As the worm crawls, the thickened zones appear to travel backward along the body, because the segments just behind each zone thicken, widen, and cling to the ground, while the segments at the front end of each wide zone free themselves from the ground and become longer and narrower. Thus, the head end of the body intermittently progresses forward over the ground or enters a crevice as the longitudinally extending segments are continuously being lengthened outward from the front end of each thickened zone. It is therefore only the long narrow segments that are moving forward. This mechanism of crawling by the alternate and antagonistic action of the longitudinal and circular muscles is made possible by the hydrostatic action of the incompressible coelomic spaces. The movements of most other annelid worms are also controlled by a hydrostatic skeleton.

Skeleto-musculature of arthropods. In arthropods the skeleton is formed in part by the cuticle covering the body surface; by internal connective-tissue fibres; and by a hydrostatic skeleton formed by the hemocoel, or enlarged, blood-filled spaces. The cuticle may be flexible or stiff, but it does not stretch. In the Onychophora (e.g., *Peripatus*) the cuticle is thin and much folded, thus allowing great changes in the body shape. The muscular body wall, as in annelids, works against the hydrostatic skeleton in the hemocoel. Each leg moves in a manner similar to the body movement of a sea anemone or *Hydra*. But a unique lateral isolating mechanism allows suitable hydrostatic pressures to be available for each leg. Muscles of a particular leg thus can be used independently, no matter what the other legs may be doing or what influence the body movements may be having on the general hemocoel.

In most adult arthropods the cuticle is less flexible than is that in the Onychophora, localized stiff sclerites being separated by flexible joints between them; as a result, the hydrostatic action of the hemocoel is of less importance. Cuticle, secreted by the ectodermal cells, may be stiffened by deposition of lime or by tanning (sclerotization). Muscle fibres or their connective-tissue supports are connected to the cuticle by tonofibrils within the cytoplasm of ectodermal cells.

The joints between the stiffened sclerites consist of undifferentiated flexible cuticle. Between the distal (i.e., away from the central body axis) leg segments of many arthropods the flexible cuticle at the joint is relatively large ventrally (i.e., on the lower side) and very short dorsally (i.e., on the upper side), thus forming a dorsal hinge. Flexor muscles (for drawing the limb toward the body) span the joint and cause flexure of the distal part of the leg. There are no extensor muscles, however, and straightening of the leg when it is off the ground is effected by hydrostatic pressure of the general hemocoel and by proximal depressor muscles that open the joint indirectly. Between the proximal leg segments (i.e., those closer to the point of insertion of the limb into the body), pivot

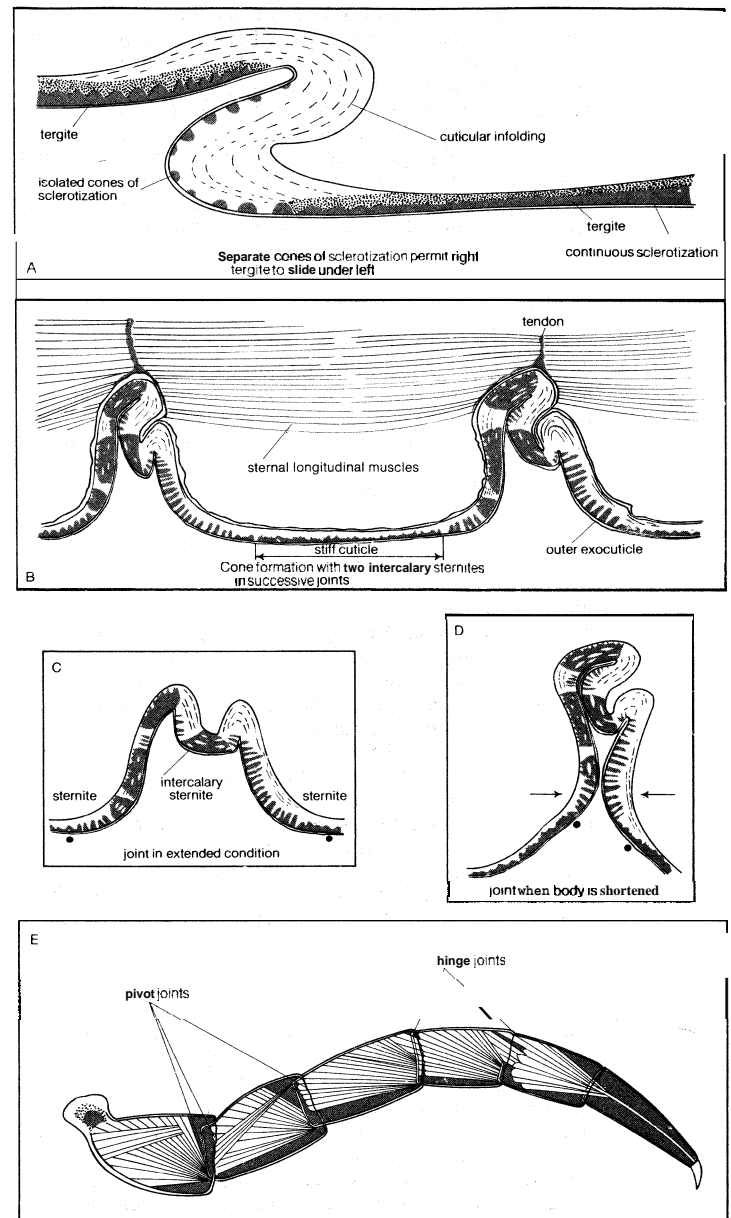

Figure 2: Skeletal features of a centipede and a millipede. (A–D) Trunk intersegments of burrowing centipede, *Geophilus*, allow the body to change shape while still presenting a complete external armour of sclerites. (E) The proximal joints in a millipede leg function in a pivotal fashion; the distal joints act as hinges.

From (A–D) *Zoological Society of the Linnean Society* (1965) and (E) (1958)

joints are usually present. They are composed of a pair of imbricating, or overlapping, facets near the edges of the overlapping cylinders that cover the leg segments, one pair on the anterior face of the leg and another on the posterior face. A pair of antagonistic muscles span the leg joint and move the distal segment up or down, without reference to hydrostatic pressure.

The more advanced arthropods—those with the most elaborate sclerites and joints—are no longer dependent upon hydrostatic forces for skeleto-muscular action. Evolution away from the hydrostatic skeleton has made possible faster and stronger movements of one cuticular unit upon another. The type of skeleto-musculature appropriate for fast movements, such as rapid running, jumping, or flying, are quite different from those producing strong movements, such as those used by burrowing arthropods.

The flexible edges of the sclerites of burrowing centipedes (*Geophilomorpha*) enables them to change their shape in an earthworm-like manner, while preserving a complete armour of surface sclerites at all times. This is made possible by the fact that the marginal zones of the

Advanced arthropods

Role of the skeleton in crawling

sclerites bear cones of sclerotization that are set in the flexible cuticle, thus permitting flexure in any direction without impairing strength. The surface of the arthropodan cuticle is rendered waterproof, or hydrofuge, by a variety of structures, such as waxy layers, scales, and hairs. These features enable the animals not only to resist desiccation on land but to exist in damp places without uptake of water—a process that could cause swelling of the body and lead to death. The cuticular endoskeleton is formed by an infolding of surface cuticle. Sometimes transverse plates are formed, as in the cephalothorax of lobsters, which covers both head and the thorax.

Connective-tissue fibres form substantial endoskeletal units in arthropods. The fibres are not united to the cuticle and are not shed during molting; rather, they grow with the body. A massive and compact endosternite (internal sternite), formed by connective-tissue fibres, frequently lies below the gut and above the nerve cord. In *Limulus*, the horseshoe crab, muscles from the anterior margin of the coxa (the leg segment nearest the body) are inserted on the endosternite, as are other muscles from the posterior margin.

The jointed cuticular skeleton of arthropods enables them to attain considerable size, up to a few metres in length, and to move rapidly. These animals have solved most of the problems presented by life on dry land in a manner unequalled by any other group of invertebrates. They have also evolved efficient flight by means of wings derived from the cuticle. The arthropods can never achieve the body size of the larger vertebrates, although mechanically they perform as well as smaller vertebrates. As mentioned above, the major limiting factor to size increase is the need to molt the exoskeleton.

Skeleton of echinoderms. Among the invertebrates, only the echinoderms possess an extensive mesodermal skeleton that is stiffened by calcification—as in vertebrates—and also grows with the body. The five-rayed symmetry of echinoderms may be likened to the vertebral axis of vertebrates. It is similarly supported; a series of ambulacral ossicles in each ray roughly corresponds with the vertebrae of vertebrates. The ossicles articulate with each other in mobile echinoderms such as starfishes and form the basis of the rapid movements of the arms of crinoids, brittlestars, and similar forms. The ambulacral ossicles and, in many cases, the surface spines provide protection for superficial nerve cords, which extend along the arms and around the mouth. The ossicles also protect the tubes of the water-vascular system, a hydraulic apparatus peculiar to echinoderms. In sea urchins a spherical, rigid body is formed by the five arms coming together dorsally around the anus; the ambulacral ossicles are immobile, and the body wall between the ambulacra is made rigid by a layer of calcareous plates below the ectoderm, which completes the continuous spherical skeleton. Locomotion is carried out by extensible tubefeet, soft structures that are pendant from the water-vascular system. Mobile spines also serve for locomotion in many classes, the base of the spine articulating with a part of some stable ossicle. The fine internal structure of echinoderm sclerites bears no resemblance to that of bone. (S.M.M.)

VERTEBRATE SKELETON

General features. In vertebrates the adult skeleton is usually formed of bone or cartilage, living substances that grow with the animal, in contrast to the many types of invertebrate skeleton that do not grow or are dead secretions, deposits, or crystals. The internal position of bones and their central position in limbs provide firm support for small and large animals. Muscles can be inserted on all surfaces of the skeleton, in contrast to the limitations of the cuticular skeleton of arthropods, in which muscles occur on only one side. Antagonistic muscles are easily placed upon vertebrate bones to allow contrasting movements at the joints between them.

The component parts of the skeletons of vertebrates, although remarkably uniform in basic plan, are subject to wide superficial differences, which are associated with each class and with adaptations for particular habits or environments. The axial skeleton consists of the skull and

the vertebral column. The appendicular skeleton supports the fins in fish and the legs in tetrapods (four-legged animals) and is associated with limb girdles, which become progressively more closely linked with the vertebral column in the higher vertebrates. Superficially there may be an exoskeleton of scales; some scales on the head may be incorporated into the skull.

Swimming of a typical fish occurs by undulations passing along a greater or lesser part of the body. The mechanism for caudal (tail) propulsion involves the vertebral column, the axial musculature, and the lateral surfaces of the body and caudal fin. The vertebral column of the fish can be regarded as a series of rigid units hinged to each other by surfaces that allow the body to bend only sideways. On each side of the vertebral chain lie the great axial muscles of the body; the fibres of this complex group of muscles are more or less parallel to the long axes of the vertebrae. One pair of vertebrae and their associated musculature form the fundamental unit of propulsion. The muscles on the two sides of each vertebral articulation shorten alternately, the surface of the body becoming concave, or bent inward, on the side on which the muscles are shortened and convex, or bent outward, on the side on which they are stretched. The whole tail of the fish is essentially a chain of such units in which the phase of muscular contraction at any one link is slightly ahead of that of the next posterior unit and slightly behind that of the next anterior unit. Each wave of contraction passes tailward along the body, which is thus propelled forward. The greatest thrust against the water is exerted by the tail end. Ribs of various kinds lie between and support the segmental muscles. The fins and their skeletal supports are used as balancing and steering organs. The paired fins are set horizontally in cartilaginous fish, which do not have a swim bladder, and vertically in most bony fishes, in which rapid vibrations or small angular movements provide exact steering. In the air-breathing lungfish, fins are used for stepping on the bottom in a manner that superficially resembles stepping by the legs of a salamander. Indeed, the land vertebrates evolved from extinct fishes that used their fins for stepping; the pentadactyl (*i.e.*, with five digits) skeleton and the form of the forelegs and hindlegs of land vertebrates similarly evolved from the fins of such fishes.

An unjointed elastic notochord is present in the protochordate amphioxus, in the tail of larval ascidians (tunicates), and in the adult cyclostomes (lamprey and hagfish), but there are no vertebrae. Segmental series of muscles are present as in fish, and the resultant swimming movements of these muscles, working with the elastic notochord, are similar to those in fish.

The lateral body undulations caused by the trunk musculature, as seen in fish, are the main propulsive agents in amphibians such as the newt. The feet raise the body from the ground but otherwise serve only to anchor the body while the vertebral musculature allows forward progression by straightening the flank. The same propulsive mechanism serves for locomotion in water and on land. In the reptiles, birds, and mammals a transition of the locomotory force from the body to the limbs occurs. When the vertebral muscles contract isometrically (*i.e.*, against such great pressure that the muscle is unable to shorten), so as to prevent body undulations, the energy for propulsion comes from the limbs. Hands and feet are directed forward, as is the knee; and the elbow is directed backward. The limbs are no longer outstretched laterally but move ventrally below the body. The bones at the heel and elbow are extended to form levers that give origin to powerful extensor muscles of the foot and hand, thus contributing to a locomotory thrust against the ground. The elimination of lateral undulations of the vertebral column as the main propulsive agent is accompanied by the development of dorso-ventral flexibility of the chain of vertebrae; the distance between successive footfalls would be less if the vertebral column remained rigid. Swimming in whales is accomplished by dorso-ventral tail beats, in contrast to that in fish (which beat the tail laterally). The swimming musculature of whales evolved from the nonswimming musculature of terrestrial ances-

The fish skeleton in swimming

The whale skeleton in swimming

tors. Long antagonistic muscles extend from the whale's skull to the tail and implement the dorso-ventral motion, in contrast to propulsion by means of segmental muscles in fish.

The structure of the vertebrae provides a basis for many movements, including those mentioned above. Mobility sometimes is extreme, as in the necks of certain birds, in which the imbricating, or overlapping, centra (*i.e.*, the main, ventral portion of a vertebra that articulates with that of the adjacent vertebrae) can flex in any direction yet remain firmly interlocked, because the adjacent articular surface of the bony centra are saddled-shaped. The extensive mobility of snakes is mediated by its vertebral structure and its well-developed ribs; in this case, mobility is lost but greater stability achieved by fusion of two or more vertebrae.

The limbs of tetrapods and their limb girdles have become much modified in association with particular habits, such as rapid running, jumping, swimming, and burrowing. The limb bones remain relatively unspecialized in slow-moving animals and in those with climbing ability. Accomplished runners differ from man and the monkeys in that the proximal sector of the leg (humerus in the forelimb, femur in the hindlimb)—*i.e.*, the portion closer to the limb's insertion in the body proper—is short. This sector carries many locomotory muscles but does not project far—if at all—from the trunk. Beyond the short, strong femur and humerus, the limb bones of running animals are elongated, slender, and strong. The distal part of the leg (*i.e.*, that portion further from the trunk) must be narrow and light if it is to move rapidly through a wide angle. The wrist and knee are far from the ground, and in horses and other ungulates (*i.e.*, hoofed animals) the animal stands on its toenails and fingernails (hooves); the whole hand and foot are raised from the ground, thus contributing to leg length.

Embryology of vertebrate skeletons. When the early embryo consists of only two tissue layers, ectoderm and endoderm, a longitudinal thickening appears as the result of multiplication of the ectodermal cells. This thickening, the primitive streak, gives rise to the notochord and to the third basic layer, the mesoderm. The longitudinal axis of the embryo is first laid down by the formation of a cylindrical mass of cells, the notochord, proliferated from the primitive (Hensen's) node at the anterior end of the streak. The notochord lies ventral to the developing central nervous system and forms the first supporting structure for the developing embryo.

In fishes such as the shark, cartilaginous vertebrae form around the notochord and to some extent compress it. It persists, nevertheless, as a continuous structure through the length of the vertebral column. In the higher vertebrates, including man, the notochord is a temporary structure, persisting only as a minute canal in the bodies of the vertebrae and in the central part of the so-called nucleus pulposus of the intervertebral disks.

As the notochord is being laid down, cells proliferate from each side of the primitive streak, forming the mesoderm, which spreads out laterally and, as a result of migration and multiplication of cells, soon comes to occupy most of the space between the ectoderm and the endoderm on each side of the notochord. The mesodermal sheets soon become differentiated into (1) a mass lying on each side of the notochord (paraxial mass) that undergoes segmentation into hollow blocks, the mesodermal somites; (2) a lateral plate that becomes separated into an outer layer, the somatopleuric mesoderm, against the future body wall, and an inner layer, the splanchnopleuric mesoderm, against the endoderm of the future gut; and (3) an intermediate mass, the nephrogenic cord, which gives rise mainly to the genitourinary system.

The segmentation of the paraxial mesoderm is a fundamental feature of the development of the vertebrates. The axial skeleton and associated structures develop from part of the mesodermal somite; the appendicular skeleton arises from the somatopleuric mesoderm of the lateral plate. Each somite differentiates into (1) a lateral and superficial plaque, the dermatome, which gives rise to the integumentary tissue; (2) a deeper lateral mass, the myo-

tome, which gives rise to the muscles; and (3) a medial ventral mass, the sclerotome. The sclerotomic cells from each pair of somites migrate until they enclose the notochord, separating it from the neural tube dorsally and from the aorta (the principal blood vessel) ventrally. The sclerotomic tissue retains its original segmentation and condenses to form the forerunner, or blastema, of the centrum of the future vertebra. From each posterolateral half of the condensation, extensions pass backward and eventually meet posteriorly around the neural tube to form the blastema of the neural (dorsal) arch of the vertebra. In the interspaces between adjacent myotomes of each side, an extension from each sclerotomic mass passes laterally and forward to form the costal, or rib, element. It is only in the thoracic (midbody) region that the costal elements develop into ribs. In the other regions the costal elements remain rudimentary (undeveloped). The mesenchymal blastema of the future vertebra becomes chondrified; *i.e.*, the mesenchymal cells are converted into cartilage cells. In this cartilaginous vertebra, ossification (bone-forming) centres appear, and the cartilage is gradually replaced by bone. The mesenchyme of the embryonic ribs also undergoes chondrification and later ossification. In the thoracic region, in which costal elements are best developed, a cartilaginous sternal bar forms, connecting the anterior, or growing, ends.

The appendicular skeleton begins to develop in the primitive limb bud in the core of mesenchyme that is derived directly from the unsegmented somatopleuric mesoderm. This mesenchyme condenses to form the blastemal masses of the future limb bones. Soon the mesenchyme becomes transformed into the cartilaginous precursors of the individual bones (except in the clavicle). The cartilaginous models determine the general shape and relative size of the bones. There is convincing evidence that the shape of the bones of higher vertebrates is determined by factors inherent in the tissues, and that, once development has begun, extrinsic influences provide the proper conditions for maintaining the normal structure.

The first mesenchymal condensations of the appendicular skeleton are in the region of the future girdles; those for the shoulder girdle appear a little earlier than those for the pelvic girdle. The mesenchymal condensations for the other bones of the limbs appear in order of their proximity to the trunk.

Vertebral column and thoracic skeleton. The notochord constitutes the earliest structure that stiffens the embryo and appeared in animals before the true vertebral column evolved. A vertebra includes a centrum and a neural arch surrounding the spinal cord.

Lower chordates and fishes. Possession of the notochord distinguishes members of the most advanced phylum, Chordata. In the sea squirts (Urochordata) the notochord is present in the tail region of the larva but disappears after the animal transforms into the adult. In amphioxus (Cephalochordata), the notochord is permanent and extends the whole length of the body. In the cyclostome fishes (Agnatha), the most primitive group within the subphylum Vertebrata, the notochord and its sheath persist throughout life; rudimentary cartilaginous neural arches are found in the adult lamprey. Among the sharks (Selachii), modern representatives possess a vertebral column composed of cartilaginous, partly calcified centra that have their origin within the sheath of the notochord, thus causing its partial absorption. Among the bony fishes (Osteichthyes), the sturgeon has a persistent notochord with a fibrous sheath upon which appear paired cartilaginous arches: dorsally, the neural arches and, ventrally, the hemal arches. The vertebrae of the more advanced bony fishes, such as the salmon and cod, are completely ossified; each centrum develops in the sclerotomic mesoderm outside the notochordal sheath. This is known as perichordal development.

Amphibians and higher vertebrates. In amphibians a vertebra is formed from the sclerotomic tissues of two somites, the tissue from the posterior part of one somite joining that from the anterior part of the somite behind it. In living reptiles the vertebrae are completely ossified.

ular
skeleton

The neural arch has a spinous process and pre- and post-zygapophyses (additional articulating surfaces); at the junction of the arch and centrum is a facet for articulation of the head of a rib. Groups of vertebrae can be distinguished; *e.g.*, the cervical vertebrae are recognizable because the neck is differentiated from the body.

The fibrocartilaginous intervertebral disks uniting the centra of crocodiles have been identified as representing so-called intercentra. Ribs are present in the cervical, thoracic, and lumbar regions of the column.

The sternum may be calcified but is seldom ossified in the reptiles. In the lizards it is a cartilaginous plate articulated with the coracoid processes of the pectoral girdle and with the anterior thoracic ribs. The sternum is absent in the turtles and in the snakes; in the crocodiles it is a wide plate joined by the coracoid processes and by two pairs of ribs.

The skeletons of modern birds show reptilian features with some specialized adaptations to their bipedal locomotion (*i.e.*, by means of one pair of legs) and their power of flight. The neck is very flexible. With its variation in length the number of cervical vertebrae ranges from 25 in the swan to nine in certain small birds. The tendency for the vertebrae to fuse in certain regions is characteristic of birds. The sternum, a very large bone, is positioned like a shield in front of the chest. In flying birds a median keel, the carina, projects ventrally, providing additional surface for the attachment of the pectoral muscles that move the wings. The flightless birds, such as the ostrich, have a keelless, raftlike sternum.

In mammals the vertebral centra articulate by means of intervertebral disks of fibrocartilage. Bony disks (epiphyses) formed on the generally flat ends of the centra are characteristic of mammals. Regional differentiation in the mammalian backbone is marked. The number of vertebrae in each group, excepting the caudal vertebrae, is moderately consistent, though there are some exceptions to the group averages. Whereas seven cervical vertebrae are the rule, there are nine or ten in the three-toed sloth and only six in the two-toed sloth and the manatee. The thoracic vertebrae commonly number 13 or 14, although they vary from nine in some whales to 24 in the two-toed sloth. The average number of lumbar vertebrae is about six; but there are two in the duck-billed platypus and 21 in the dolphin. Rib elements are fused to the transverse processes of the cervical vertebrae, and in the lumbar vertebrae they form the so-called transverse processes.

There is an increase in the number of vertebrae that compose the sacrum. In the early developmental stages of the human fetus, the beginnings of the hipbones lie opposite those segments of the spinal column that form the lower lumbar and upper sacral vertebrae. As development proceeds, the sacroiliac joints become established between the hipbones and the upper sacral vertebrae. The sacrum, derived from the 25th to the 29th vertebrae, inclusive, becomes a single bone by their fusion. The whales and sea cows lack a sacrum, although vestiges of a pelvis occur. In some anteaters the posterior sacral vertebrae are fused with the ischium (a bone on each side of the pelvic girdle) through ossification of a connecting ligament. The sacrum of some armadillos consists of 13 vertebrae, caudal vertebrae having become fused with it. The cervical vertebrae of some whales are fused together, because the whale is spindle-shaped for swimming and has no need for a mobile neck such as occurs in most mammals. The centrum of the atlas (first cervical vertebra) of most mammals fuses with that of the axis (second cervical vertebra) and projects from it, but in the duck-billed platypus, as in the reptiles, it is a separate bone.

The spinous processes of the thoracic vertebrae, excepting the last, point caudally (*i.e.*, toward the tail), and those of the lumbar vertebrae generally point cranially (*i.e.*, toward the head) at the transitional zone between these groups. Spines of one or two thoracic vertebrae are upright; these are known as anticlinal spines. Lying ventral to the intervertebral disks in some mammals (*e.g.*, whale, pangolin) are paired ossicles, the intercentra, which are homologous (of similar origin) with the ante-

rior arch of the atlas. The tail vertebrae vary in number from none in the bat to 49 in the pangolin.

The ribs in mammals correspond in number of pairs to the number of thoracic vertebrae. The ventral ends of the ribs join the costal cartilages, the relations of which follow, with minor variations, the pattern for the human skeleton. Sternal ribs, connecting the more anterior vertebral ribs with the sternum, may be cartilaginous, calcified, or ossified. The mammalian sternum is composed of several pieces: the presternum anteriorly, followed by the mesosternum, made up of a number of segments, and a terminal xiphisternum.

Appendicular skeleton. General features. Paired appendages are not found in ancestral vertebrates and are not present in the living cyclostomes (*e.g.*, lampreys, hagfishes). Appendages first appeared during the early evolution of the fishes. Usually two pairs of appendages are present, fins in fish and limbs in land vertebrates. Each appendage includes not only the skeletal elements within the free portion of the limb but also the basal supporting structure, the limb girdle. This portion of the appendage lies partly or wholly within the trunk and forms a stable base for the fin or limb. Each girdle consists of ventral and dorsal masses. In lower fishes these are composed of cartilage; in bony fishes and in land vertebrates they become partly or completely ossified.

The anterior appendages, the pectoral fins or forelimbs, articulate with the pectoral girdle, which is situated just behind the gill region in fish and in a comparable position at the junction of the neck and thorax in land vertebrates.

The posterior appendages, called pelvic fins, or hindlimbs, articulate with the pelvic girdle, which is situated in the trunk region usually just in front of the anus or cloaca (the ventral, posterior body opening in many lower vertebrates). It is by way of the girdles that the weight of the body of land vertebrates is transmitted to the limbs. Because the hindlimb is usually of greater importance in weight bearing, especially in bipedal vertebrates, it articulates with the vertebral column by means of the costal elements of the sacral vertebrae. The vertebrae to which the pelvic girdle are attached usually fuse to form the sacrum. In fishes, however, a sacrum as such does not develop, since the posterior appendages usually do not support the body weight but are used only in locomotion.

The origin of paired fins has been much debated, and many theories have been put forward in explanation. According to the widely accepted fin-fold theory, the paired limbs are derived from the local persistence of parts of a continuous fold that, in ancestral vertebrates, passed along each side of the trunk and fused behind the anus into a single fin. The primitive paired fins were attached to the body by a broad base and carried no weight. Their main function, it would appear, was to act as horizontal stabilizing keels, which tended to prevent rolling movements and possibly also front-to-back pitching movements.

Most authorities agree that the limbs of land vertebrates evolved from the paired fins of fishes. Limbs and fins are thought to have their ancestral counterparts in the fins of certain lobe-finned fishes (Crossopterygii, a nearly extinct group of which the coelacanth is a living example). The skeleton of the primitive fin consists of a series of endoskeletal rods, each of which undergoes subdivision into a series of three or four pieces. The basal pieces tend to fuse into larger pieces. The most anterior of the basal pieces fuses across the midline with its fellow of the opposite side to form a primitive girdle in the form of a cartilaginous bar. The more distal pieces persist to form the dermal (*i.e.*, on or near the body surface) fin rays.

Pectoral girdle. In a cartilaginous fish such as the dogfish the pectoral girdle consists of a U-shaped endoskeletal, cartilaginous, inverted arch with its ends extending dorsally.

In all other major groups of vertebrates the pectoral girdle is a composite structure. It consists of endoskeletal structures to which secondary dermal components are added as the result of ossification of dermal elements. The components become ossified to form dermal bones.

Origin
of paired
fins

In primitive bony fishes such as the lungfishes, sturgeon, and coelacanth, the main element added is a vertically placed structure, the cleithrum, which supports the **scapula**.

la. The cleithrum may be joined by a supracleithrum, which in turn is surmounted by a posttemporal element (*i.e.*, at the rear of the skull). The most ventral of the added dermal bones are the clavicles, which unite below the gill chambers with each other or with the sternum. In the holostean fishes (*e.g.*, gar) the clavicle is lost, leaving only the cleithrum.

In tailed amphibians such as newts and salamanders the dermal elements of the pectoral girdle have been completely lost, and only the endoskeletal parts remain, mainly as cartilaginous bars. This retrogression is probably the result of their adaptation chiefly to an aquatic mode of life in which less support is required by the girdles. The ventral part of the girdle forms the coracoid process and the dorsal part the scapula; the latter is the only part that becomes ossified. Only a rudimentary sternum develops.

In most reptiles the primary girdle for the forelimb consists of a scapula and a single coracoid process. The pectoral girdle of the lizard consists of bones formed in cartilage: the scapula and the large coracoid process, forming the glenoid cavity (*i.e.*, the cup-shaped structure in which the humerus articulates), and the dermal bones—the clavicle and interclavicle. The latter is a single T-shaped bone, with the stem in the midline; it is in contact with the sternum. The curved clavicles articulate with each other at their medial ends (*i.e.*, toward the body midline). The cartilaginous suprascapula is present.

In birds the pectoral girdle is essentially similar to that in reptiles. The precoracoid process forms a stout bar that reaches to the sternum. The wishbone, or furcula, which forms from the dermal part of the girdle, consists of two clavicles united in the midline by the interclavicle. Carinate birds (those with a keeled sternum) have a **sabre-shaped** scapula and a stout coracoid process joined by ligaments at the point at which is found the glenoid cavity for articulation with the humerus. The coracoid process is joined to the sternum; at its dorsal end is the **acrocoracoid** process. The furcula stands in front of the coracoid processes, its ends connected by ligaments with the **acrocoracoid** process and with the rudimentary acromion process of the scapula. The girdle of the flightless ratite birds (those with a flat sternum) is little developed, being represented by an ankylosed, or fused, scapula and **coracoid** process.

Among mammals, the monotremes have two coracoid processes, which articulate medially with the presternum and laterally with the scapula. The coracoids enter into the formation of the glenoid cavity. Also present are an interclavicle (episternum) and an investing clavicle, resembling the bones in reptiles. The clavicle articulates with the acromion process of the scapula. In the opossum the scapula has a spine ending in the acromion, with which

the clavicle articulates. A much-reduced coracoid fuses with the scapula and does not meet the sternum. The scapula of placental mammals has a spine ending, generally, in an acromion; the body of the bone is triangular. In mammals that use the forelimb for support in standing, the vertebral margin is the shortest, and the long axis of the scapula runs from it to the glenoid cavity; but in those whose forelimb is used for prehension, or grasping, such as in the primates, or for flight, such as in the bats, the vertebral margin is elongated, and the distance from it to the glenoid cavity is decreased. The long axis is thus parallel with that of the body instead of being transverse. In the placental mammals the coracoid, although developing independently, has dwindled to a **beaklike** process and fuses with and becomes part of the scapula. It does not articulate with the sternum.

The clavicle is present generally in those placental mammals that have prehensile (capable of grasping) forelimbs (primates, many rodents and marsupials, and others) or whose forelimbs are adapted for flying (bats). In many mammals it is suppressed or reduced, as in cats, or absent, as in whales, sea cows, and hoofed animals.

Pelvic girdle. The pelvic girdle of the elasmobranch fishes (*e.g.*, sharks, skates, and rays) consists of either a curved cartilaginous structure called the puboischial bar or a pair of bars lying **transversely** in the ventral part of the body anterior to the cloaca; projecting dorsally on each side is a so-called iliac process. Connected with the process is a basal cartilage carrying a series of radialia, the skeleton of the paired pelvic fins. The pelvic girdles of many bony fishes are situated far forward, near the gills.

There are marked variations in the form of the pelvic girdle in the amphibians. In the frog the three parts of the hipbone (ilium, **ischium**, and pubis) are present. The pubic elements, however, remain wholly cartilaginous. The hipbone is characterized by the great length and forward extension of the ilium. The girdle is connected with the costal element of one vertebra, thus establishing a sacral region of the vertebral column. The acetabulum (the cup-shaped structure in which the femur articulates) is situated at the junction of the three elements.

The pelvic girdle of some reptiles has a loose connection with the spine. In most reptiles the ilium is joined to two sacral vertebrae. Both the pubic and the ischial parts usually meet in the so-called ventral symphysis, from which a cartilage or bone, the **hypoischium**, projects backward to support the margin of the **cloacal** orifice, and another, the epipubis, projects forward. A few snakes (*e.g.*, boas) retain vestiges of a pelvic girdle and **limb** skeleton.

In most birds the ilium extends forward and backward and is fused with the many vertebrae, forming a **synsacrum**. The slender ischia and pubes do not form **sympyses** except in the ostrich.

In most mammals the ilium articulates with the sacrum, and the pubes meet in a symphysis anteriorly. A cotyloid bone, formed in the cartilage in the bottom of the **acetabulum**, is usually found. The symphysis pubis is not present in certain mammals (*e.g.*, **moles**). In monotremes and marsupials, the marsupial bones that support the pouch have been regarded as part of the epipubis.

Limbs. The pectoral fin of the elasmobranchs has basal cartilages articulating with the pectoral girdle. They carry a number of radial cartilages consisting of varying numbers of short segments; beyond these are delicate fin rays.

The proximal segment of the pelvic fin of sharks is supported by a single basal cartilage and by one or two radialia. In the pectoral fin of the primitive ray-finned fish *Polypterus*, three elements constitute the proximal segment of the fin: two bony rods, the propterygium and the metapterygium, on the margins and an intermediate, partly ossified cartilage, the mesopterygium.

The adoption of an upright position of the trunk, as seen in certain lemurs and in the great apes, has brought about further modification. In man the lower limbs are used for bipedal locomotion, thus freeing the upper **limbs** for prehensile use. Many of the great apes have developed the use of the upper limb for an arboreal life; hence, they are

sometimes distinguished as brachiators; *i.e.*, animals whose locomotion is by swinging with the arms from branches or other supports.

From (top) Zoological Journal of the Linnean Society (1956)

Figure 4: (Top) Left forelimbs of horse and wombat; (bottom) left forefeet of ungulates.

The skeleton of the free limb of the land vertebrate is divisible into three segments: proximal, medial, distal.

The proximal segment consists of a single bone (the humerus in the forelimb, the femur in the hindlimb). The humerus articulates by its rounded head with the glenoid cavity of the scapula and by condyles with the bones of the forearm. Its shaft is usually twisted and has ridges and tuberosities for the attachment of muscles.

The femur is essentially cylindrical; the ends are expanded. At the proximal end, for articulation with the acetabulum, is the rounded head; near it are usually two elevations (trochanters) for muscle attachment. Three trochanters are characteristic of certain mammals; *e.g.*, horse and rhinoceros. Distally, the femur expands into two condyles for articulation with the tibia. In many types there is an articular facet on the lateral surface for the head of the fibula.

The medial segment of the limb typically contains two bones, the radius and the ulna in the forelimb, the tibia and the fibula in the hindlimb. In the forelimb the radius is anterior, or preaxial (*i.e.*, its position is forward to that of the ulna), in the adjustment of the limb for support and locomotion on land. Mammals in which the radius is fixed in **pronation**—*i.e.*, in which the forelimb is rotated so that the shaft of the radius crosses in front of that of the ulna—are called pronograde. The radius transmits the weight of the forepart of the body to the forefeet; but it is the ulna that makes the elbow joint with the humerus; into its proximal end are inserted the flexor and extensor muscles of the forelimb.

The tibia and fibula are separate in salamanders and newts, united in frogs and toads. In land reptiles the tibia articulates with both condyles of the femur and with the so-called tritibiale of the ankle. The fibula articulates with the postaxial femoral condyle and with the tritibiale and fibulare. The tibia of birds is long, the fibula reduced. In mammals the fibula is generally reduced and may be fused with the tibia and excluded from the knee joint.

The distal segment of the limb comprises the carpus, metacarpus, and phalanges in the forelimb and the tarsus,

metatarsus, and phalanges in the hindlimb. A typical limb has five digits (fingers or toes), which contain the phalanges.

The carpus and tarsus of the higher vertebrates have probably been derived from a primitive structure by the fusion or suppression of certain of its elements. The bones of a generalized carpus (or tarsus) end in three transverse rows of three bones, the **radiale** (or **tibiale**), **intermedium**, and **ulnare** (or **fibulare**); a distal row of five **carpalia** (or **tarsalia**), numbered one to five from the radial (or **tibial**) margin; and an intermediate row of one or two **centralia**.

In many urodele amphibians (*e.g.*, salamanders) the carpus is generalized. In the frogs and toads, however, it is more specialized, only six carpals being present, the third, fourth, and fifth carpalia probably having fused with either or both centralia. In birds the radiale and ulnare are distinct, but the distal bones are fused with the metacarpus to form a **carpometacarpus**. In mammals various examples of fusion and suppression occur. In man the radiale forms the scaphoid bone; the **intermedium** forms the lunate bone; the **ulnare** forms the triquetrum. The pisiform bone in man is probably the remains of an extra digit. It may, however, be a **sesamoid bone**; *i.e.*, an ossification within a tendon. The trapezium and trapezoid are carpalia 1 and 2; the **capitate** is derived from carpal 3; carpalia 4 and 5 have fused to form the **hamate**. An os centrale is present in the carpus of many monkeys. In mammals the number of digits varies, but the number of phalanges in each digit present usually corresponds with that of man. In some species, however, the phalanges are more numerous, as when the limb is modified to form a paddle (*e.g.*, in whales).

Fusion and suppression of carpal bones

The tarsus of urodele amphibians has the typical arrangement of bones. In the frogs and toads the **intermedium** is absent; two long bones are the **tibiale** and **fibulare**. Among the reptiles there is much variation in the composition of the tarsus. Generally, the joint of the ankle is **intratarsal**, the row of tarsalia being distal to the hinge. In most living reptiles the tibiale and intermedium fuse to form the **talus**. In birds the ankle hinge is of the reptilian pattern in being **intratarsal**. The three tarsal cartilages of the embryo fuse to form the **talus**, which fuses with the tibia to form the **tibiotarsus**. The tarsalia fuse with the ends of the united metatarsals to make a **tarsometatarsus**. In the mammalian tarsus the **talus** is generally composed of the fused tibiale and intermedium, but in some a centrale is included to form a **tritibiale**. The ankle joint is not **intratarsal** but is located between the bones of the leg and the first row of tarsal bones, usually the tibia and the talus.

Suppression of digits in hoofed mammals frequently has occurred in the following sequence: the **pollex** (first digit) is the first to be suppressed, then the **minimus** (fifth digit), the **index** (second digit), and finally the **annularis** (fourth digit). Among the even-toed ungulates (*i.e.*, the **artiodactyls**; *e.g.*, pig and hippopotamus) the **pollex** has disappeared, and the other four digits are present, although the second and fifth digits are much reduced. In the camel only the third and fourth digits persist and are of equal importance. Among the odd-toed ungulates (*i.e.*, the **perissodactyls**; *e.g.*, horse) the right digit is dominant; the others are reduced to rudiments or splints.

Joints. The junctions between the bony or cartilaginous units of vertebrate skeletons and between the body-wall ossicles of sea urchins (Echinodermata) are often kept rigid by dovetailed margins. One skeletal unit, however, may move freely on another, as shown by the ambulacral ossicles along the arms of brittlestars, crinoids, and starfishes among the echinoderms and by the leg bones and vertebrae of vertebrates in which joints that permit various types of movement exist.

Joints between the bony or cartilaginous units of vertebrate skeletons are very simple in animals with a cartilaginous skeleton. When bone replaces cartilage, however, stronger and more elaborate joints form. Flat, articulating, cartilaginous surfaces between the vertebral centra of sharks do not permit extensive movement, but it is sufficient for these animals. In sharks, intervertebral cones of notochord persist, with conical ends projecting into the ends of adjacent vertebrae. Joints between bones and cuticular sclerites may permit movement in one plane only, as in most arthropodan joints and the interphalangeal joint in man. Between some bones (e.g., the human femur and pelvis) there is a ball-and-socket device, by which a ball-like articular facet rotates in a concavity, the acetabulum. The femur can thus move in a variety of planes. The bony vertebrae of fishes, amphibians, reptiles, and birds possess centra articulating with one another in a ball-and-socket manner. The terrestrial animals strengthen the ball-and-socket articulation and sometimes restrict its movement by additional imbricating facets (zygapophyses). Snake vertebrae interlock firmly with one another; a hemispherical posterior projection from each articulates with an anterior concavity (i.e., a cup-shaped depression) on the vertebra in front of it. The freely moving joints permit a twisting movement, with extra support being gained by two sets of sliding facets between each pair of consecutive vertebrae. Ball-and-socket joints, common in vertebrates, are easily contrived in animals with an endoskeleton. Among invertebrates are some remarkable parallels. In certain millipedes (*Juliformia*) heavy circular sclerites encompass each segment and slightly overlap. Rotation of one skeletal ring upon the next, as well as flexion, is possible. The animal can thus curve its hard body in any direction. It can curl up dorso-ventrally with the legs in the middle of a spiral, then walk with the legs on the ground and at right angles to the coiled position. Echinoderms also possess many ball-and-socket joints, such as at the base of spines in sea urchins.

Various types of strong hinge joints, easily contrived by an arthropod, also occur in vertebrates. The joint between the skull and the first vertebra in mammals is a strong hinge. A pair of occipital condyles on the skull that articulate against shallow concavities on the anterior face of the vertebra permit a nodding movement of the head. The strongest hinge joints in arthropods also bear a double articulation, as in the leg of the spider and in *Scutigera*, the fastest running centipede. Hinge joints in vertebrates are often composite, being formed or supported by the incorporation of several small bones, as in the human wrist. To facilitate cursorial, or running, habits, flexion is limited to one plane.

A series of small bones at the wrist or ankle can, in contrast, provide, in addition to strength, a marked flexibility in many directions. A leg that can flex in various directions is usually achieved in arthropods by a series of pivot joints. Each joint is set in a different plane along the leg, so that the combined action of the several joints enables the leg to move in any direction. Single endoskeletal joints of vertebrates supply a variety of movements with greater ease; no duplication is necessary.

In vertebrates, the joints between bones are constructed in a variety of ways. They fall, however, into two main categories, the synovial joint and the nonsynovial joint. In the former, known also as diarthrosis, a cleft occurs between the free surfaces of two skeletal parts; during movements these surfaces slide on each other. In the nonsynovial type, known also as synarthrosis, the skeletal parts are connected by nonosseous material that permits bending or twisting. The range of movement is greater in

the synovial than in the nonsynovial type. In the course of vertebrate evolution the nonsynovial type appears to have preceded the synovial. The latter is unusual in fishes, but the majority of the joints in man and other mammals are of this form. The amphiarthrosis is an intermediate type of joint in man. In this type the connecting material between the bones contains a cavity, but movement depends on bending of the connecting material.

Some of the strongest movements in arthropods (e.g., in the legs of Polydesmida, an order of millipedes) are also implemented by a joint possessing cavities that contain synovial fluid in which imbricating cuticular facets slide against one another. Levers exist in vertebrates in the heel bone and in the human elbow projection (olecranon process).

Movements at joints are commonly produced by voluntary muscular action. Such movements are distinguished as "active," as against those produced by the application of external force, whether by manipulation or by the energy of moving parts or gravity, which are known as "passive" movements.

Muscles may be situated to act only on one joint (uni-articular muscles), but many muscles can act on two or more joints (bi- and multi-articular muscles). A multi-articular muscle will act on only one joint if the remaining joints under its control are fixed by other muscles. Muscles, however, rarely contract as isolated units. They usually act as a group; this is known as the "group action of muscles." The intricate adjustment and coordination of muscular tensions that are required for posture and movement are under the control of the central nervous system.

PROPERTIES OF BONE AND ITS DEVELOPMENT

Vital properties. The essential bone-forming cell is the osteoblast. It can give rise to bone even if transplanted to tissue in which bone formation does not usually occur. If a portion of the whole thickness of the periosteum (the fibrous tissue that surrounds bone) is transplanted, it forms bony tissue. It can thus be employed for reconstruction of bone following disease or injury.

Although the general form of the skeleton is hereditary, it is also influenced by mechanical factors, such as pressure on the cartilage at the end of a bone (epiphysis) or stresses applied to the external surface; e.g., from adjacent muscles. The effect of pressure on bone depends on whether the bony surface is covered by periosteum or by cartilage. In the case of the periosteum, which has blood vessels, pressure causes impairment of blood supply and absorption of underlying bone. The direct pressure exerted by an abnormal expansion of the aorta on the sides of the vertebrae thus brings about absorption of bone but not of the cartilaginous intervertebral disks. The impressions corresponding to the gyri, or ridges of the brain's cerebral cortex that are found on the internal surface of the skull, are probably produced by the slight but constant pressure of the growing brain in the young person. On the other hand, pressure on cartilage, which has no blood supply, does not cause absorption.

Internal strains stimulate bone formation. If a tibia is removed, thus leaving the fibula to bear more weight, the fibula's thickness tends to approach that of the tibia. If strains are reduced—e.g., by muscular paralysis—the trabeculae, or layers of bone, become thinner, though there may be no change in external form; meanwhile, the lacunae, or spaces within the bone, and the haversian canals (structures that contain nerves and blood vessels) of compact bone become larger. If a bone becomes bent through pathological softening (e.g., from rickets), a thick strut of bone forms along the concavity of the bend.

When the direction of stress is altered, bony reconstruction takes place. The internal structure is thus changed in the bones of the feet when their customary relative positions are disturbed. If the tibia and femur are united by surgical removal of the knee-joint surfaces, with resultant bony union (i.e., ankylosis) at the knee, the internal bone structure is altered in such a way as to correspond closely with what are believed to be the lines of stress under the new conditions. The fact that the bony fragments in a

Absorption of bone due to pressure

Ball-and-socket joint

Synovial and non-synovial joints

badly set fracture become smoothed with an internal reconstruction at the site of union is further evidence of the structural adaptation of bone to changed conditions.

When a bone is fractured, some bone tissue adjacent to the fracture is absorbed, and a mass of tissue termed callus, at first uncalcified, makes its appearance between and around the broken ends. Cartilage formation commonly takes place in the callus even when the fracture is in a membrane bone; *e.g.*, the parietal bone of the skull. Callus also contains osteoblasts derived from both periosteum and endosteum, the connective tissue within a bone. The formation of callus is greater if there is pressure and movement between the broken ends of the bone and is most pronounced on the concave side when the bony fragments are at an angle. Bony union is effected by calcification and subsequent ossification of the callus. Regeneration of bone is more active in the shafts of long bones, lower jaw, and ribs than in the skull and the spongy ends of long bones.

Bone
elasticity

Physical properties. Bones are not absolutely rigid but possess some degree of elasticity. By virtue of this quality, stresses can produce a transient deformation that is followed by recovery of the original form. The bones of a young person are more elastic than are those of an elderly person.

A fracture is produced when stresses exceed the normal limits of elasticity. Adult bone gives way suddenly when the breaking point is reached. The degree of force necessary to produce a fracture depends partly on the thickness of the bone and partly on the direction of the force in relation to structure. It has also been shown that the speed at which the force is applied affects the breaking point.

The primary stresses may be classified as compression, tension, and shear. Combinations of these may secondarily give rise to bending and twisting. A shear stress is encountered in a long bone when a force is exerted obliquely to the long axis. When directed at an angle of 45°, the shear stress equals the compression stress. Twisting stresses represent a special variety of shear, and their results are well exemplified in the spiral form of many so-called torsion fractures. Bending stresses produce compression on one side of the shaft and tension on the other side; in the bone's interior, however, there is a zone in which no stress occurs; this zone is occupied by marrow. The cortical (non-marrow) layer is especially thick in the middle of the shaft, the point at which the greatest bending stresses usually occur.

In compact bone the breaking stresses are comparable with those of materials widely employed in engineering. In the case of tension stresses, compact bone is comparable to cast iron; for compression stresses it is comparable to wrought iron, with minor variations depending on the direction of the stress relative to the "grain" of the haversian canals. Breaking stresses have a lower value in the bone of old persons and in paralyzed limbs, because of the relative diminution of calcium salts and the thinning of trabeculae (layers of bone).

The skull bones respond to stress in a manner quite unlike that of the long bones. The force of impact of a penetrating object on the outer layer of compact bone in the skull is transmitted through the diploe, the middle, spongy layer of bone, to a larger area of the inner wall, also of compact bone; damage to the inner wall is correspondingly more extensive.

Greenstick
fracture

The bones of young persons, although richer in fibrous tissue than are those of adults, are poorer in calcium salts and therefore less resistant to tension than to compression. For this reason, bending of the long bones frequently produces a greenstick fracture, in which the bone breaks only partially, on the side opposite that toward which the bending occurs.

The smaller bones and the ends of long bones have a thinner cortical layer than the shafts of long bones, and their internal trabeculated structure enables them to withstand a great variety of stresses applied in many directions. In the neck of the femur, for example, a series of bony sheets running in one direction is intersected by another series situated approximately at right angles to it.

The arrangement of the trabeculae corresponds approximately to the lines of pressure and possibly also to the lines of tension. Stress apparently plays some direct part in determining both the direction of bone formation in the young and the reorganization of pre-existing bone in the adult.

Development of bone. General features. In most parts of the body, bone formation takes place in relation to an existing cartilaginous model, which it eventually replaces (endochondral ossification). In certain situations, on the other hand, bone formation takes place in dense connective tissue (intramembranous ossification). The former type is seen in the early stages of the development of most bones of the body; the latter occurs mainly in the calvaria (*i.e.*, the outer surface) of the skull and around the shafts of long bones. In both cases the process of ossification generally commences in a localized region called a centre of ossification and then spreads. Some of these centres appear long before birth; others (epiphyseal centres) appear only after birth (or sometimes immediately before).

Intramembranous ossification. Intramembranous ossification is the simpler of the two types of osteogenesis, or bone development, and probably the more primitive. As in the formation of cartilage, the first indication of membrane bone formation is a condensation produced by multiplication of mesenchymal cells to form a membranous mass. The cells, which lie parallel to each other, are compressed to form either smooth membranous sheets that may be very extensive, as in the blastemal vault of the cranium, or irregular membranous condensations, as in the regions in which irregular-shaped bones will be laid down. In further development, intercellular fibres of collagen, a rather inelastic protein, are deposited by the mesenchymal cells of the condensations.

In the region in which an ossification centre develops, the osteoblasts become arranged in closely packed layers along small bundles of the collagenous fibres. Their cytoplasm increases considerably, and their nuclei become eccentrically located. The fibrous material between the osteoblasts swells until it occupies all of the intercellular space. Prior to the deposition of calcium, this material, called osteoid, represents the organic matrix of the bone. Soon after the appearance of the osteoblasts and presumably by virtue of the physiological action of these cells, calcium salts in the form of crystalline spicules are deposited in the intercellular spaces and within the immediately adjacent osteoid. These spicules constitute primary bone. A noticeable increase in the number of very small blood vessels (capillaries) occurs at these ossification centres. This increased vascularity is probably correlated with special metabolic activity. Later, the blood vessels become those of the blood-forming bone marrow, which is invariably associated with the later stages of bone formation.

Osteoid

As development proceeds, transformation of more mesenchyme cells into osteoblasts occurs; the latter form further spicules, extending in all directions through the membrane. In flat bones this extension is largely two-dimensional in direction; the spicules and trabeculae of the young bone thus form a radiate pattern from the centre. The structure of such an ossification area now consists of a mass of vascular primary bone with a condensed sheet of vascular mesenchyme (periosteum) on its surfaces. Most of the differentiated osteoblasts are located on the inner surface of the periosteum, where the skeletal element can be thought of as growing by accretion. This inner cellular layer of the periosteum is called the cambium layer, in contrast to the outer, much thicker section, known as the fibrous layer. A rich network of fine blood vessels and capillaries occupies the zone of transition between the cambium and fibrous layers.

For a while, such a membrane bone is more or less spongy throughout, but in the early fetal stages a process of absorption and redeposition of bony substance commences. This process continues until full growth has been attained. Soon after it begins, spongy, or cancellous, bone occupies the central portion of the mass, and a layer of compact bone forms on each surface by the continued addition of new sheets of bone from the cambium layer

of the periosteum. Compact bone is therefore often called periosteal bone. Vascular tissue is very sparse in the compact bone but fills all the spaces in the cancellous bone. Here it soon becomes hematopoietic (*i.e.*, capable of producing blood cells) and is called red bone marrow.

As each successive layer of compact bone is laid down, some osteoblasts become trapped in the newly deposited matrix. Each cell so isolated becomes a bone cell, or osteocyte, and occupies a small space, a bone lacuna, in the interstitial bony substance. New osteoblasts develop from the outer periosteal layer which, in its turn, is reinforced by new cells from the undifferentiated surrounding mesenchyme. The osteoblasts that remain on the surface of the bone persist as the deepest cells of the periosteum and assume a fibroblast-like appearance unless stimulated to form new bone. If this occurs, they assume the characteristics of osteoblasts.

Endochondral ossification. The first indication that ossification is about to occur is an enlargement of the chondrocytes (cartilage cells) in the centre of the bone shaft. Glycogen (animal starch) accumulates within them, and their cytoplasm becomes highly vacuolated; *i.e.*, filled

spaces of which are called secondary areolae. In addition to the chondroclasts and osteoblasts, **multinucleate giant cells** (osteoclasts) also appear in the vascular bud. The osteoclasts seem to be active in absorbing bone in situations in which redeposition and rearrangement of bone is to occur.

The changes considered thus far result in the establishment of the primary, or diaphyseal, centre of ossification. At each end of the centre the cartilage cells and lacunae are arranged in parallel rows, with the largest cells and lacunae in continuity with the region of ossification. The enlarged cartilage cells show degenerative changes, and the matrix around them becomes calcified. If cartilage from this zone of provisional calcification is examined, and inspection is made progressively toward a free end of the combined bony-cartilaginous model, the cells of the columns are found to decrease in size and the columnar arrangement to disappear. The cells, however, are still crowded. Such a growth region is found usually near each extremity of the cartilaginous portion of the developing bone. By the activity of the growth region the cartilage at each end of the model increases in length. The region of cartilage proliferation is carried progressively away from the original site of ossification, since most of the new cartilage cells proliferate toward the diaphyseal ossification centre. As they approach the region of ossification, the cartilage cells thus produced become arranged in columns. They also show progressive degenerative changes, and calcification of the matrix occurs preparatory to the extension of the ossification into it. This extension results from the activity of the osteoblasts and associated blood vessels, which together form an advancing zone of bone formation in the degenerating calcified cartilage. The latter is continuously replaced by the activity of the cartilage growth centre.

The process of cartilage growth and the extension of ossification into it proceeds until, at birth, the result is a bony shaft with cartilaginous extremities. The latter are, for the most part, ossified after birth by the appearance within them of secondary (epiphyseal) centres of ossification. These are established in a manner similar to that of the endochondral primary (diaphyseal) centre. When this occurs, a gradient is formed in two directions from the cartilaginous growth centre—short columns of cartilage cells extending toward the epiphyseal centre and longer ones toward the diaphysis. This arrangement ensures growth in length on the diaphyseal side of the growth centre and increase in size of the cartilaginous epiphysis. Some growth also takes place from the epiphyseal centre toward the articular surface, but this appears to be merely enough to ensure the proper modelling of the extremities of the bone. Increase in thickness of the cartilage model distal to the region of periosteal ossification takes place by continued transformation of the inner perichondrium into cartilage.

The diaphysis increases in girth by the deposition (by accretion) of periosteal bone. This is accompanied by resorption of the original endochondral bone of the shaft and the establishment of the marrow cavity. The epiphysis appears to grow in width chiefly by the lateral (peripheral) extension of the epiphyseal endochondral ossification centre. In later postnatal stages of bone growth the mass of cartilage between diaphysis and epiphysis decreases in thickness to form a comparatively thin structure, the epiphyseal cartilage, or epiphyseal plate, which is of great importance for the growth of the bone. At the termination of growth in any bone the epiphyseal plate disappears, and the epiphysis unites with the diaphysis. As a result, no further longitudinal growth of the bone is possible. The number and situation of epiphyseal centres vary in different bones. In a long bone such as described, there is at least one epiphyseal centre at each end; in some there may be two or more. In some smaller bones (phalanges, metacarpals, metatarsals), an epiphyseal centre is found only at one extremity, the other end being ossified by the extension of the diaphysis to the articular cartilage. In small bones, such as carpals and tarsals, ossification proceeds from a single endochondral centre until the definitive adult size is reached. In irregular bones,

Cellular changes prior to ossification

(A) Cartilaginous stage; (B) and (C) deposit of spongy endochondral bone (seb) and compact perichondral bone (cpb); (D) appearance of epiphysis (e) at either end; (E) appearance of marrow cavity (mc); (F) union of epiphysis with shaft and enlargement of marrow cavity.

with globule-like spaces. The matrix between these cells becomes impregnated with calcium salts, and the cartilage cells degenerate. As these changes in the cartilage occur, the perichondrium of the middle of the shaft acquires osteogenic (*i.e.*, bone-producing) properties and is then called the periosteum. The cells of its internal layer become transformed into osteoblasts, which rapidly lay down a delicate cylinder of compact periosteal bone around the centre of the shaft. This cylindrical ossification is intramembranous because it is formed by the periosteum and does not actually replace any preformed cartilage. Accompanying these changes, a vascular bud derived from the inner layer of the periosteum penetrates to the calcified cartilaginous matrix in the centre of the shaft (the future diaphysis, or bone shaft proper) at the so-called irruption canal. This vascular bud consists of a network of actively growing capillaries together with mesenchymal cells, some of which become osteoblasts, others chondroclasts, which break down and remove the calcified cartilage matrix, causing several cartilage lacunae to coalesce. The larger spaces, called primary areolae, are occupied immediately by osteogenic tissue. The osteoblasts range themselves along the remaining strands of calcified cartilage. As a result of their activity, layers of bone are deposited on the cartilaginous strands, just as they are upon the fibrous strands in the case of membrane bone formation. These bony layers unite with one another and with the superficial layer of compact bone, forming primitive cancellous bone, the

such as the scapula, pelvic girdle, and the vertebrae, one or more primary centres occur, and usually several secondary centres take part in the ossification of the borders and processes. (W.J.H.)

Skepticism

As a philosophical Attitude, skepticism is the doubting of knowledge claims set forth in various areas. Skeptics have challenged the adequacy or reliability of these claims by asking what they are based upon or what they actually establish. They have raised the question whether such claims about the world are either indubitable or necessarily true, and they have challenged the alleged grounds of accepted assumptions. Practically everyone is skeptical about some knowledge claims; but the Skeptics have raised doubts about any knowledge beyond the contents of directly felt experience. The original Greek meaning of *skeptikos* was "an inquirer," someone who was unsatisfied and still looking for truth.

From ancient times onward Skeptics have developed arguments to undermine the contentions of dogmatic philosophers, scientists, and theologians. The Skeptical arguments and their employment against various forms of dogmatism have played an important role in shaping both the problems and the solutions offered in the course of Western philosophy. As ancient philosophy and science developed, doubts arose about basic accepted views of the world. In ancient times Skeptics challenged the claims of Platonism, Aristotelianism, and Stoicism, and in the Renaissance those of Scholasticism and Calvinism. After Descartes, Skeptics attacked Cartesianism (*q.v.*) and other theories justifying the "new science." Later, a Skeptical offensive was levelled against Kantianism and then against Hegelianism. Each Skeptical challenge led to new attempts to resolve the difficulties. Skepticism, especially since the Enlightenment, has come to mean disbelief—primarily religious disbelief—and the Skeptic has often been likened to the village atheist.

VARIOUS SENSES AND APPLICATIONS

Skepticism developed with regard to various disciplines in which men claimed to have knowledge. It was questioned, for example, whether one could gain any certain knowledge in metaphysics (the study of the nature and significance of being as such) or in the sciences. In ancient times a chief form was medical Skepticism, which questioned whether one could know with certainty either the causes or cures of diseases. In the area of ethics doubts were raised about accepting various mores and customs and about claiming any objective basis for making value distinctions. Skepticisms about religion have questioned

the doctrines of different traditions. Certain philosophies, like those of Hume and Kant, have seemed to show that no knowledge can be gained beyond the world of experience and that one cannot discover the causes of phenomena. Any attempt to do so, as Kant argued, leads to antinomies, contradictory knowledge claims. A dominant form of Skepticism, the subject of this article, concerns knowledge in general, questioning whether anything actually can be known with complete or adequate certainty. This type is called epistemological Skepticism.

Kinds of epistemological Skepticism can be distinguished in terms of the areas in which doubts are raised; that is, whether they be directed toward reason, toward the senses, or toward knowledge of things-in-themselves. They can also be distinguished in terms of the motivation of the Skeptic—whether he is challenging views for ideological reasons or for pragmatic or practical ones to attain certain psychological goals. Among the chief ideological motives have been religious or antireligious concerns. Some Skeptics have challenged knowledge claims so that religious ones could be substituted—on faith. Others have challenged religious knowledge claims in order to overthrow some orthodoxy. Kinds of Skepticism also can be distinguished in terms of how restricted or how thoroughgoing they are—whether they apply only to certain areas and to certain kinds of knowledge claims or whether they are more general and universal.

ANCIENT SKEPTICISM

Historically, skeptical philosophical attitudes began to appear in pre-Socratic thought. In the 5th century BC, the Eleatic philosophers, known for reducing reality to a static One (see ELEATICISM), questioned the reality of the sensory world, of change and plurality, and denied that reality could be described in the categories of ordinary experience. On the other hand, the Ephesian philosopher of change Heraclitus and his pupil Cratylus thought that the world was in such a state of flux that no permanent, unchangeable truth about it could be found; and Xenophanes, a wandering poet and philosopher, doubted whether man could distinguish true from false knowledge.

A more developed Skepticism appeared in some of Socrates' views and in a couple of the Sophists (*q.v.*). Socrates, in the early Platonic dialogues, was always questioning the knowledge claims of others; and in the *Apology*, he said that all that he really knew was that he knew nothing. Socrates' enemy, the Sophist Protagoras, contended that man is the measure of all things. This thesis was taken as a kind of skeptical relativism: no views are ultimately true, but each is merely one man's opinion. Another Sophist, Gorgias, advanced the skeptical-nihilist thesis that nothing exists; and if something did exist, it could not be known; and if it could be known, it could not be communicated.

The putative father of Greek Skepticism is Pyrrho of Elis (c. 360–c. 270 BC), who tried to be a living Skeptic. He avoided committing himself to any views about what was actually going on and acted only according to appearances. In this way he sought happiness or at least mental peace.

The first school of Skeptical philosophy developed in Plato's Academy (see PLATONISM AND NEOPLATONISM) in the 3rd century BC and was thus called "Academic" Skepticism. Starting from the skeptical side of Socrates, its leaders, Arcesilaus (c. 315–c. 240 BC) and Carneades (214/213–129/128 BC), set forth a series of epistemological arguments to show that nothing could be known, challenging primarily the two foremost schools, those of the Stoics and Epicureans. They denied that any criteria could be found for distinguishing the true from the false; instead, only reasonable or probable standards could be established for knowledge. This limited or probabilistic Skepticism was the view of the Academy until the 1st century BC, when Cicero was a student there. His *Academica* and *De natura deorum* are the main sources for knowledge of this movement. (St. Augustine's *Contra academicos* is an answer to Cicero's views.)

The other major form of ancient Skepticism was Pyr-

Epistemo-
logical

schools

rhonism, apparently developed by medical Skeptics in Alexandria. Beginning with Aenesidemus (1st century BC), this movement, named after Pyrrho, criticized the Academic Skeptics because they claimed to know too much, namely, that nothing could be known and that some things are more probable than others. The Pyrrhonians advanced a series of tropes, or ways of opposing various kinds of knowledge claims, in order to bring about *epochē* (suspense of judgment). The Pyrrhonian attitude is preserved in the writings of one of its last leaders, Sextus Empiricus (2nd or 3rd century AD). In his *Outlines of Pyrrhonism* and *Adversus mathematicos*, Sextus presented the tropes developed by previous Pyrrhonists. The ten attributed to Aenesidemus showed the difficulties to be encountered in ascertaining the truth or reliability of judgments based on sense information, owing to the variability and differences of human and animal perceptions. Other arguments raised difficulties in determining whether there are any reliable criteria or standards—logical, rational, or otherwise—for judging whether anything is true or false. To settle any disagreement, a criterion seems to be required. Any purported criterion, however, would appear to be based on another criterion, thus requiring an infinite regress of criteria, or else it would be based upon itself, which would be circular. Sextus offered arguments to challenge any claims of dogmatic philosophers to know more than what is evident; and in so doing he presented in one form or another practically all of the skeptical arguments that have ever appeared in subsequent philosophy.

Sextus said that his arguments were aimed at leading people to a state of *ataraxia* (unperturbability). People who thought that they could know reality were constantly disturbed and frustrated. If they could be led to suspend judgment, however, they would find peace of mind. In this state of suspension they would neither affirm nor deny the possibility of knowledge but would remain peaceful, still waiting to see what might develop. The Pyrrhonist did not become inactive in this state of suspense but lived undogmatically according to appearances, customs, and natural inclinations.

MEDIEVAL SKEPTICISM

Pyrrhonism ended as a philosophical movement in the late Roman Empire, as religious concerns became paramount. In the Christian Middle Ages the main surviving form of Skepticism was the Academic, described in St. Augustine's *Contra academicos*. Augustine, before his conversion, had found Cicero's views attractive and had overcome them only through revelation. With faith, he could seek understanding. Augustine's account of Skepticism and his answer to it provided the basis for medieval discussions.

In Islāmic Spain, where there was more contact with ancient learning, a form of antirational Skepticism developed among Muslim and Jewish theologians. Al-Ghazālī, an Arab theologian of the 11th and early 12th centuries, and his Jewish contemporary Judah ha-Levi (c. 1075/c. 1085–c. 1141), who was a poet and physician as well as a philosopher, offered skeptical challenges (much like those later employed by the occasionalist Nicolas Malebranche and by David Hume) against the contemporary Aristotelians in order to lead people to accept religious truths in mystical faith. This kind of fideism also appears in the late Middle Ages in the German cardinal and philosopher Nicolaus of Cusa's advocacy of learned ignorance as the way to religious knowledge.

MODERN SKEPTICISM

Modern Skepticism emerged in the 16th century, not from medieval views but from the intellectual crises of the Renaissance and Reformation and from the rediscovery of the Skeptical classics. The voyages of exploration; the humanistic rediscovery of the learning of ancient Greece, Rome, and Palestine; and the new science—all combined to undermine confidence in man's accepted picture of the world. The religious controversy between the Protestants and Catholics raised fundamental epistemological issues about the bases and criteria of religious

knowledge. At the same time the texts of Cicero and Sextus became available again. (Sextus' *Outlines of Pyrrhonism* [*Hypotyposesis*] was published in Latin in 1562, his *Adversus mathematicos* in 1569, and the Greek texts of both in 1621.)

In the Reformation. The fundamental skeptical issues raised by the Reformation appeared in the debate between the outstanding humanist scholar Erasmus and Luther. Erasmus, using Academic skeptical materials, insisted that the issues in dispute could not be resolved, that one should therefore suspend judgment and remain with the church. Luther insisted, on the other hand, that true and certain religious knowledge could and must be gained through conscience. Erasmus' view developed into a Christian Skepticism, accepting traditional Christianity on faith after seeing that no adequate evidence existed. Luther's view, and later that of Calvin, proposed a new criterion—that of inner experience—while the Catholics of the Counter-Reformation employed Pyrrhonian and Academic arguments to undermine the criterion.

Following after Erasmus, another humanist, Giovanni Pico della Mirandola II (nephew of the famous count of the same name) and H.C. Agrippa von Nettesheim, a stormy occult philosopher and physician, employed the skeptical arguments against Scholasticism, Renaissance Naturalism, and many other views to win people to the "true religion." The Catholic scholar Gentian Hervet, in the preface to his 1569 edition of Sextus, saw the Skeptical arguments as the definitive answer to Calvinism and the way to true Christianity.

In the 17th century. The new concern with Skepticism was given a general philosophical formulation by Michel de Montaigne and his cousin Francisco Sanches. Montaigne in *Apology for Raimond Sebond* and Sanches in *Quod nihil scitur*, both written in 1576, explored the human epistemological situation and showed that man's knowledge claims in all areas were extremely dubious. Montaigne recommended living according to nature and custom and accepting whatever God reveals, and Sanches advocated recognizing that nothing can be known and then trying to gain what limited information one can through empirical scientific means.

Montaigne's Skepticism was extremely influential in the early 17th century. His followers, Pierre Charron, J.-P. Camus, La Mothe Le Vayer, and others, further popularized his views. Various French Counter-Reformers used the arguments of Montaigne and Sextus to undermine Calvinism. Montaigne's Skepticism opposed all sorts of disciplines, including the new science, and was coupled with a fideism that many suspected to be insincere.

In the 1620s efforts to refute or mitigate this new Skepticism appeared. A Christian Epicurean, Pierre Gassendi, himself originally a Skeptic, and Marin Mersenne, one of the most influential figures in the intellectual revolution of the times, while retaining epistemological doubts about knowledge of reality yet recognized that science provided useful and important information about the world. The constructive Skepticisms of Gassendi and Mersenne, and later of members of the Royal Society of England like Bishop John Wilkins and Joseph Glanvill, developed the attitude of Sanches into a hypothetical, empirical interpretation of the new science.

René Descartes offered a fundamental refutation of the new Skepticism, contending that, by applying the skeptical method of doubting all beliefs that could possibly be false (due to suffering illusions or being misled by some power), one would discover a truth that is genuinely indubitable, viz., "I think, therefore I am" (*cogito ergo sum*), and that from this truth one could discover the criterion of true knowledge, viz., that whatever is clearly and distinctly conceived is true. Using this criterion, one could then establish: God's existence, that he is not a deceiver, that he guarantees our clear and distinct ideas, and that an external world exists that can be known through mathematical physics. Descartes, starting from Skepticism, claimed to have found a new basis for certitude and for knowledge of reality. Throughout the 17th century Skeptical critics—Mersenne, Gassendi, the re-

Cartesian
Skepticism

viver of Academic philosophy Simon Foucher, and Pierre-Daniel Huet, one of the most learned men of the age—sought to show that Descartes had not succeeded, and that, if he sincerely followed his skeptical method, his new system could only lead to complete Skepticism. They challenged whether the *cogito* proved anything, or whether it was indubitable; whether Descartes' method could be successfully applied, or whether it was certain; and whether any of the knowledge claims of Cartesianism were *really* true. Nicolas Malebranche, the developer of occasionalism, revised the Cartesian system to meet the Skeptical attacks only to find his efforts challenged by the new Skeptical criticisms of Foucher and by the contention of the Jansenist philosopher Antoine Arnauld that Malebranchism led to a most dangerous Pyrrhonism.

Various English philosophers culminating in Locke tried to blunt the force of Skepticism by appealing to common sense and to the "reasonable" man's inability to doubt everything. They admitted that there might not be sufficient evidence to support the knowledge claims extending beyond immediate experience. But this did not actually require that everything be doubted; by using standards of common sense, an adequate basis for many beliefs could be found. Blaise Pascal, who presented the case for Skepticism most forcefully in his *Pensées*, still denied that there can be a complete Skepticism; for nature prevents it. Lacking rational answers to complete Skepticism, man's only recourse lies in turning to God for help in overcoming doubts.

The culmination of 17th-century Skepticism appears in the writings of Pierre Bayle, especially in his monumental *Dictionnaire historique et critique* (1697–1702). Bayle, a superb dialectician, challenged philosophical, scientific, and theological theories, both ancient and modern, showing that they all led to perplexities, paradoxes, and contradictions. He argued that the theories of Descartes, Spinoza, Leibniz, and Malebranche, when skeptically analyzed, cast in doubt all information about the world, even whether a world exists. Bayle skillfully employed Skeptical arguments about such things as sense information, human judgments, logical explanations, and the criteria of knowledge in order to undermine confidence in human intellectual activity in all areas. Bayle suggested that man should abandon rational activity and turn blindly to faith and revelation; he can therefore only follow his conscience without any criterion for determining true faith. Bayle showed that the interpretations of religious knowledge were so implausible that even the most heretical views, like Manichaeism, known for its cosmic dualism of good and evil, and Atheism, made more sense. As a result Bayle's work became "the arsenal of the Enlightenment," and he was regarded as a major enemy of religion.

In the 18th century. Most 18th-century thinkers gave up the quest for metaphysical knowledge after imbibing Bayle's arguments. George Berkeley, an Empiricist and Idealist, fought Skeptical doubts by identifying appearance and reality and offering a spiritualistic metaphysics. He was immediately seen as just another Skeptic since he was denying the world beyond experience.

Bayle's chief 18th-century successor was David Hume. Combining empirical and skeptical arguments, Hume charged that neither inductive nor deductive evidence could establish the truth of any matter of fact. Knowledge could only consist of intuitively obvious matters or demonstrable relations of ideas but not of anything beyond experience; the mind can discover no necessary connections within experience nor any root causes of experience. Beliefs about the world are based not upon reason or evidence nor even upon appeal to the uniformity of nature but only on habit and custom. Beliefs cannot be justified. Belief that there is an external world, a self, a God is common; but there is no adequate evidence for it. Although it is natural to hold these convictions, they are inconsistent and epistemologically dubious. "Philosophy would render us entirely Pyrrhonian, were not Nature too strong for it." The beliefs that a man is forced to hold enable him to describe the world scientifically, but when he tries to justify them he is led to complete Skepticism.

Before he goes mad with doubts, however, Nature brings him back to common sense, to unjustifiable beliefs. Hume's fideism was a natural rather than a religious one; it is only animal faith that provides relief from complete doubt. The religious context of Skepticism from Montaigne to Bayle had been removed, and man was left with only his natural beliefs, which might be meaningless or valueless.

The central themes in Hume's Skeptical analysis—the basis of induction, of causality, knowledge of the external world and the self, proofs of the existence of God—became the key issues of later philosophy. Hume's contemporary Thomas Reid hoped to rebut Hume's Skepticism by exposing it as the logical conclusion of the basic assumptions of modern philosophy from Descartes onward. Such disastrous assumptions should be abandoned for commonsensical principles that have to be believed. As Hume and Kant saw, Reid had not answered Hume's Skepticism but had only sidestepped the issue by appealing to commonsensical living. This provided, however, neither a theoretical basis for beliefs nor a refutation of the arguments that questioned them.

Kant saw that Hume had posed a most fundamental challenge to all human knowledge claims. To answer him, it had to be shown not that knowledge is possible but *how* it is possible. Kant combined a Skepticism toward metaphysical knowledge with the contention that certain universal and necessary conditions are involved in having experience and describing it. In terms of these it is possible to have genuine knowledge about the forms of all possible experience, space and time, and about the categories in which all experience is described. Any effort to apply this beyond all possible experience, however, leads into contradictions and Skepticism. It is not possible to know about things-in-themselves nor about the causes of experience.

Though Kant thought that he had resolved the Skeptical problems, some of his contemporaries saw his philosophy as commencing a new Skeptical era. G.E. Schulze (or Schulze-Aenesidemus) a notable critic of Kantianism, insisted that, on Kant's theory, no one could know any objective truths about anything; he could only know the subjective necessity of his views. The Jewish critic Salomon Maimon contended that, though there are such things as a priori concepts, their application to experience is always problematical, and whether they apply can only be found through experience. Hence, the possibility of knowledge can never be established with certainty. Assured truth on the basis of concepts is possible only of human creations, like mathematical ideas, and it is questionable whether these have any objective truth. The thesis that human creativity is the basis of truth, however, was soon to be developed by Johann G. Fichte, a leading German Idealist, as a new way of transcending Skepticism.

Another Skeptical critic of Kant, J.G. Hamann, saw in Hume's and Kant's work a new basis for fideism. If knowledge of reality cannot be gained by rational means, then one must turn to faith. Based on Hume's efforts, Hamann advanced an antirational Skepticism in an effort to convince Kant to become a fideistic Christian. Hamann's kind of fideism was also developed in France by Catholic opponents of the French Revolution and liberalism—like Joseph de Maistre and Hugues-F.-R. de Lamennais.

In recent and contemporary philosophy. Irrational Skepticism was developed into Existentialism (q.v.) by Søren Kierkegaard in the 19th century. Using traditional Skeptical themes to attack Hegelianism and liberal Christianity, Kierkegaard stressed the need for faith. Only by an unjustified and unjustifiable "leap into faith" could certainty be found—which would then be entirely subjective rather than objective. Modern neo-orthodox and Existentialist theologians have argued that Skepticism highlights man's inability to find any ultimate truth except through faith and commitment. Nonreligious forms of this view have been developed by Existentialist writers like Albert Camus, combining the epistemological Skepticism of Kierkegaard with the religious and value Skepti-

Kant and his critics

Pierre Bayle

David Hume

Existentialism

cism of Nietzsche. The rational and scientific examination of the world shows it to be unintelligible and absurd; and if God is dead, as Nietzsche proclaimed, then the world is ultimately meaningless. But it is necessary to struggle with it. It is thus through action and commitment that one finds whatever personal meaning he can, though it has no objective significance.

Other kinds of Skepticism appear in various forms of recent and contemporary philosophy. The English Idealist F.H. Bradley used classical Skeptical arguments in his *Appearance and Reality: A Metaphysical Essay* to contend that the world could not be understood empirically or materialistically; true knowledge could be reached only by transcending the world of appearance.

George Santayana, an American critical Realist, in *Scepticism and Animal Faith*, presented a naturalistic Skepticism. Any interpretation of immediate or intuited experience is open to question. To make life meaningful, however, men make interpretations by "animal faith," according to biological and social factors. The resulting beliefs, though unjustified and perhaps illusory, enable them to persevere and find the richness of life.

Positivism
and
Analysis

Types of Skepticism also appear in Logical Positivism (see POSITIVISM AND LOGICAL EMPIRICISM) and various forms of linguistic philosophy (see ANALYTIC AND LINGUISTIC PHILOSOPHY). The attack on speculative metaphysics developed by the physicist and early Positivist Ernst Mach, by Bertrand Russell, and by Rudolf Carnap, a leader in the Vienna Circle, where Logical Positivism was nourished, incorporated a Skepticism about the possibility of gaining knowledge beyond experience or logical tautologies. Russell and the important philosopher of science Karl Popper have further stressed the unjustifiability of the principle of induction, and Popper has criticized theories of knowledge based upon empirical verification. A founder of linguistic analysis, Fritz Mauthner, has set forth a Skepticism in which any language is merely relative to its users and thus subjective. Every attempt to tell what is true just leads one back to linguistic formulations, not to objective states of affairs. The result is a complete Skepticism about reality—a reality that cannot even be expressed except in terms of what he called godless mystical contemplation. Mauthner's linguistic Skepticism bears some affinities to the views expressed in Ludwig Wittgenstein's *Tractatus Logico-Philosophicus*. (R.H.P.)

SKEPTICISM IN INDIA

Though the formulations sound very different, similar Skeptical strains also appeared in the history of non-Western thought, especially in India. The *Upaniṣads* themselves, philosophic Scriptures of the later Vedic period, reflected a Skeptical climate of thought; and the Buddha, typically, sidestepped speculative issues, the discussion of which could only delay the business of salvation. The more-or-less orthodox system of Sāṃkhya already had distrusted Scripture and based itself upon perception and its implications.

Others went further. The sect of Ājīvika ("those observing restrictions concerning livelihood") similarly frustrated the progings of metaphysics. Based upon the deterministic doctrines of Gośāla Maskariputra, a contemporary of the Buddha, the Ājīvika denied the efficacy of human action to speed or delay one's salvation; events merely happened as fated until the eon had run its course. Still more extreme were the Cārvākas (also known as Lokāyatas, "the This-Worldly"), who denied not only revelation but also all deductions from sense data. To the Cārvākas, only sense perception counts; hence there is no soul, and mind is merely a gas of the body. The views of these two schools were perennially quoted, but only to be condemned.

The Buddha's willful Agnosticism was continued by the Mādhyamika school of Mahāyāna (the "School of the Middle"), which, particularly in the person of Nāgārjuna (c. 2nd century AD), demolished arguments based on too literal an acceptance of the objective world as real. Nāgārjuna preferred the paradox that objective reality was void (*śūnya*) of significance, but that under Pharmakāya ultimate reality could only be grasped by a synthesis of

objective antitheses. Likewise despairing of any positive statements about what is felt to be real, Dharmakīrti, a Buddhist monk of the 7th century AD, expressed his Skepticism in speaking of man's momentary and ineffable contact with the real, the nature of which is lost when he presses it (as he must) into cognitive relationships.

Akin to the acosmism of the Mādhyamika Buddhists was the nonduality doctrine of Śaṅkarācārya, the great Vedāntin. But, while his views were comparable, they were based upon the very Veda that the Buddha had rejected. His Skepticism was thus fideistic, combining an Agnosticism about the world of common experience with an utter faith in the ultimate reality and purposefulness of the soul, onto which the categories of discursive thought are erroneously, and distortingly, projected.

On a nonphilosophical level Skepticism regarding the apprehension of the world and reality continued through the history of Indian religion. The authority of the learned and the wise was continually questioned and at times derided. The trend has run its course through various devotional and reform movements and is finally reflected in recent attitudes, both on the right and on the left, that are Skeptical of the faiths of imported modernities. (Ed.)

CRITICISM AND EVALUATION

In Western thought Skepticism has raised basic epistemological issues. In view of the varieties of human experience, it has questioned whether it is possible to tell which are veridical. The variations that occur in different perceptions of what is presumed to be one object raise the question of which is the correct view. The occurrence of illusory experiences raises the question of whether it is really possible to distinguish illusions and dreams from reality. The criteria employed can be questioned and require justification. On what basis does one tell whether he has the right criteria? By other criteria? Then, are these correct? On what standards? The attempt to justify criteria seems either to lead to an infinite regress or to just stop arbitrarily. If an attempt is made to justify knowledge claims by starting with first principles, what are these based upon? Can it be established that these principles cannot possibly be false? If so, is the proof itself such that it cannot be questioned? If it is claimed that the principles are self-evident, can one be sure of this, sure that he is not deceived? And can he be sure that he can recognize and apply the principles correctly? Through such questioning, Sceptics have indicated the basic problems that an investigator would have to resolve before he could be certain of possessing knowledge; i.e., information that could not possibly be false.

Critics have contended that Skepticism is both a logically and a humanly untenable view. Any attempt to formulate the position will be self-refuting since it will assert at least some knowledge claims about what is supposed to be dubious. Montaigne suggested that the Sceptics needed a nonassertive language, reflecting the claim of Sextus that the Sceptic does not make assertions but only chronicles his feelings. The strength of Skepticism lies not in whether it can be stated consistently but upon the effects of its arguments on dogmatic philosophers. As Hume said, Skepticism may be self-refuting, but in the process of refuting itself it undermines dogmatism. Skepticism, Sextus said, is like a purge that eliminates itself as well as everything else.

Critics have claimed that anyone who tried to be a complete Sceptic, denying or suspending all judgments about ordinary beliefs, would soon be driven insane. Even Hume thought that the complete Sceptic would have to starve to death and would walk into walls or out of windows. Hume, therefore, separated the doubting activity from natural practical activities in the world. Skeptical philosophizing went on in theory, while believing occurred in practice. Sextus and the contemporary Norwegian Sceptic Arne Naess have said, on the other hand, that Skepticism is a form of mental health. Instead of going mad, the Sceptic—without commitment to fixed positions—can function better than the dogmatist.

Some recent thinkers like A.J. Ayer and John Austin

Criticisms

Buddhist
Skeptici-
sms

have contended that Skepticism is unnecessary. If knowledge is defined in terms of satisfying meaningful criteria, then knowledge is open to all. The Skeptics have raised false problems, because it is, as a matter of fact, possible to tell that some experiences are illusory since we have criteria for distinguishing them from actual events. We do resolve doubts and reach a state of knowledge through various verification procedures, after which doubt is meaningless. Naess, in his book *Scepticismz*, has sought to show, however, that, on the standards offered by Ayer and Austin, one can still ask if knowledge claims may not turn out to be false and hence that Skepticism has still to be overcome.

Evaluation Skepticism throughout history has played a dynamic role in forcing dogmatic philosophers to find better or stronger bases for their views and to find answers to the Skeptical attacks. It has forced a continued re-examination of previous knowledge claims and has stimulated creative thinkers to work out new theories to meet the Skeptical problems. The history of philosophy can be seen, in part, as a struggle with Skepticism. The attacks of the Skeptics also have served as a check on rash speculation; the various forms of modern Skepticism have gradually eroded the metaphysical and theological bases of European thought. Most contemporary thinkers have been sufficiently affected by Skepticism to abandon the search for certain and indubitable foundations of human knowledge. Instead, they have sought ways of living with the unresolved Skeptical problems through various forms of naturalistic, scientific, or religious faiths.

(1957), and *A Treatise of Human Nature*, both ed. by LA. SELBY-BIGGE (1958).

Secondary sources: The standard studies of ancient Skepticism are: EDWYN R. BEVAN, *Stoics and Sceptics* (1959); VICTOR BROCHARD, *Les Sceptiques grecs* (1887); NORMAN MACCOLL, *The Greek Sceptics from Pyrrho to Sextus* (1869); MARY MILLS PATRICK, *The Greek Sceptics* (1929); LEON ROBIN, *Pyrrhon et le scepticisme grec* (1944); and EDUARD ZELLER, *The Stoics, Epicureans and Sceptics*, trans. by O.J. REICHEL (1880). A recent fine study of the epistemological problems involved in ancient Skepticism is CHARLOTTE L. STOUGH, *Greek Skepticism* (1969). See also RAOUL RICHTER, *Der Skeptizismus in der Philosophie* (1904–08); RICHARD H. POPKIN, "Skepticism," *Encyclopedia of Philosophy*, vol. 7, pp. 449–461 (1967), which contains a bibliography on the subject; these examine Skepticism from ancient times to the 19th century. JOHN OWEN, *The Sceptics of the French Renaissance* (1893), is an interesting discussion of Renaissance and 17th-century Skepticism, though not particularly scholarly. DON CAMERON ALLEN, *Doubt's Boundless Sea: Skepticism and Faith in the Renaissance* (1964); and RICHARD H. POPKIN, *The History of Scepticism from Erasmus to Descartes*, rev. ed. (1968), which contains a lengthy bibliography, are studies of Renaissance Skepticism and its impact on philosophy and religion. RICHARD H. POPKIN, "Berkeley and Pyrrhonism," *Review of Metaphysics*, 5:223–246 (1951–52); "David Hume and the Pyrrhonian Controversy," *ibid.*, 6:65–81 (1952–53); "David Hume: His Pyrrhonism and His Critique of Pyrrhonism," *Philosophical Quarterly*, 1:385–407 (1950–51); "The High Road to Pyrrhonism," *American Philosophical*

Quarterly, 2:1–15 (1965); "The Skeptical Crisis and the Rise of Modern Philosophy," *Review of Metaphysics*, 7:132–151, 307–322, 499–510 (1953–54); "The Skeptical Precursors of David Hume," *Philosophy and Phenomenological Research*, 16:61–71 (1955–56); and "Scepticism in the Enlightenment," in T. BESTERMANN (ed.), *Studies on Voltaire and the Eighteenth Century*, 26:1321–1345 (1963), are specialized studies on aspects of Skepticism in relation to modern philosophy. ARNE NÆSS, *Scepticism* (1968), is a most interesting attempt to clarify Skepticism in relation to contemporary thought and to defend it as a viable outlook today.

(R.H.P.)

Skiing

Skiing is a way of moving over snow by the use of a pair of long flat runners, called skis, attached to the shoes or boots. It is practiced for recreational, competitive, or utilitarian purposes. On the level or slight grades, the skier uses a gliding gait, assisted by a ski pole in each hand; downhill, he slides effortlessly over the snow, turning to avoid obstacles, to reduce speed, or to change direction. Ski jumping is usually performed on especially designed inclines of varied size.

Skiers, at first, had to climb to gain heights from which to ski down. In the early 1900s only the mountain railways or aerial cable cars of the Alps were available for uphill transportation of skiers. Since the early 1930s, many new devices have been built for this purpose, including chair lifts, gondola lifts, T-bar and J-stick tramways, platter pulls, and, in the U.S. and Canada, rope tows (especially on small slopes for beginners) and other devices. Such aids greatly promoted the popularity of skiing, for they made possible four or five times as much downhill skiing in a day as when the skier had to climb uphill. The development of snow-making machines permitted the enjoyment of the sport in areas with only marginally adequate snow and during seasons other than winter. In the Scandinavian and eastern European countries, touring and cross-country skiing remained the more popular sports.

Competitive skiing comprises the Nordic, or classic, events (cross-country racing and jumping) and the Alpine, or downhill, events (downhill or straight racing, and slalom and giant slalom racing between series of set gates). The biathlon is a military competition consisting of a cross-country course and rifle target shooting.

The pleasure of downhill skiing lies in the comparatively effortless and speedy manner in which the skier descends a snow-covered slope, controlling the direction of his skis and his speed in accordance with his skill. Cross-country skiing, or ski touring, and ski mountaineering have an appeal similar to that of hiking and mountaineering. The popularity of skiing is attested to by its rapid growth in all parts of the world where there is snow and hilly or mountainous country. Some of the chief attractions of the sport are that there is virtually no limit to the degree of skill that can be acquired, that snow conditions to be coped with are of infinite variety and constantly changing, that no two trails or slopes are the same, and the appeal of the out-of-doors and the scenery.

This article relates the history of skiing, the development of the modern Alpine sport, international competitive skiing, and world organization of the sport, and describes the basic equipment and principles of the basic movements. Only the basic movements are defined in the paragraphs under that title, and no effort is made to describe how to ski. (Most ski books deal with technique: examples are listed in the bibliography.)

History. The oldest skis that have been found, in bogs in Sweden and Finland, are believed to be between 4,000 and 5,000 years old, and a rock carving of two men on skis found near the Arctic Circle in Norway dates from 2000 BC. Unconfirmed 3rd-century-Bc Chinese reports refer to skis being used in the north. It is recorded that the Vikings used skis in the 10th and 11th centuries, and somewhat later the historian Olaus Magnus reported the swiftness with which ski-clad Laplanders pursued game. Skis are also mentioned in Norse mythology, in which Ull (sometimes Skade) was the ski god and Undurridis the ski goddess.

The types and appeal of skiing

The earliest known pictorial representation of skiing, a rock carving from Røa, Norway, dating from 800 BC.

Skis are referred to in continental European literature as early as the 17th century, for instance in a book by the Austrian J.W. von Valvasor, *Die Ehre des Herzogtums Krain* ("The Honour of the Duchy of Carniola"). These were isolated and ephemeral instances and had no historical significance.

Skis were first used for practical purposes rather than for sport—to get from one place to another. Such uses have continued until modern times, especially in Norway, Sweden, Finland, and the eastern European countries.

In 1200 King Sverrir of Norway sent out men on skis to reconnoitre before the battle of Oslo. Ski troops were also used in Sweden as early as 1452. In the 15th, 16th, and 17th centuries, skis were used in warfare in Finland, Norway, Poland, Russia, and Sweden. In 1716, the first ski-equipped troops were organized in Norway. The first skiing manual, written by Capt. Jens Emmahusen of Trondheim, was published in 1733. From 1767, ski competitions were arranged for the troops, with money awarded as prizes.

Ski touring, or cross-country skiing, in the hills and mountains as a sport was a natural development from utilitarian skiing. Ski mountaineering, distinguished by the need to use ropes and ice axes, followed later. The first important expedition in the Alps was the traverse of the main massif of the Bernese Oberland by a party of five Germans headed by Wilhelm Paulcke in 1897. Thereafter, German, French, Austrian, Italian, and British skiers made many first ascents on skis of Alpine peaks and high passes. Among the other ski mountaineers of this early period were Payot of France, F.F. Roget and Marcel Kurz of Switzerland; and, a little later, Count Aldo Bonacossa of Italy and Sir Arnold Lunn of Great Britain.

Development of skiing as a sport. Recreational skiing undoubtedly was engaged in throughout the times when skis were used chiefly for practical purposes. However, up to the mid-1800s, bindings were primitive, consisting only of toestraps, which allowed insufficient control of the skis for jumping or turning. One of the earliest civilian competitions was a cross-country race at Tromsø, Norway, in 1843. A milestone in the competitive sport came about 1860, when Sondre Nordheim, from Mørgedal, Telemark, Norway, first used willow or cane bindings around the heel from each side of the toe strap to fasten the boots to the skis. Nordheim also designed skis with incurving sides, which became the pattern for all modern skis. With this equipment, he evolved the Christiania turn, a graceful, sweeping swing across the fall-line, and the Telemark turn, with the outside ski weighed and leading (for information on turns and other movements see below, *Basic movements*). Competitive skiing also started in California in the 1860s, on straight downhill courses, using skis 12 feet long and only leather toe straps.

The thrills of negotiating occasional small jumps that occurred on many natural downhill runs, where pioneer skiing took place, led the more adventurous to seek out larger and larger jumps and eventually to improve them artificially. The interest in ski jumping grew rapidly. The first big contest was held at Huseby Hill, Oslo, Norway, in 1879, with the king and 10,000 spectators in attendance.

This contest was moved to the Holmenkollen Hill in 1892.

It was the Norwegian jumpers and men who had visited Norway who brought skiing to the Alps of central Europe, where the steep hillsides, mountains, and glaciers required a different technique and more controllable skis than the more rolling terrain of Scandinavia. But a strong influence on the development of interest in Alpine skiing was Fridtjof Nansen's account of his 1888 expedition across Greenland on skis, *Paa Ski Over Grønland*, which was translated into English, French, and German in 1891. Among those inspired by the book was Mathias Zdarsky who became outstanding in the development of a new way of skiing, methods of instruction, and better equipment, and who taught his "Lilienfeld" technique to large classes in Austria.

Other pioneers of this period included Wilhelm Paulcke of Germany and F. Huitfeldt of Norway and, a little later, W.R. Rickmers and Henry Hoek of Germany, Col. Georg Bilgeri of Austria, Col. Christoph Iselin of Switzerland, and Vivian Caulfeild of Great Britain.

In the 20th century skiing became increasingly popular, attracting more and more devotees in Europe and North America. It spread rapidly in Australia and New Zealand in the 1930s, in Chile and Argentina in the 1940s, and in Japan in the 1950s. With the considerable expansion of holiday skiing after World War II, skiers appeared on snow covered slopes around the world, in Yugoslavia and Greece, for example, in the Pyrenees in central Spain and Portugal, in Morocco and Algeria, in the U.S.S.R., in Lebanon, Turkey, and Iran, in the Andes in Argentina and Chile, and in India. The world alpine championships were held in the southern hemisphere for the first time at Portillo, Chile, in 1966. The skiing and other events of the 1972 Olympic Winter Games were held at Sapporo, Japan.

Modern skiing and ski schools. All forms of Alpine skiing progressed during the early 1900s. One outstanding innovator initiated the modern surge in the sport. He was Hannes Schneider of St. Anton, Austria, the outstanding competitor of his time, whose "Arlberg" technique, featuring the crouched position and the stem Christiania, as well as the position of "vorlage," or putting the weight forward, led to the present way of skiing. He started teaching at St. Anton in 1907, and his systematized ski school became the model for those of many other countries. Schneider taught in a methodical progression from snowplow to control speed or stop, through slow snowplow turn, more rapid stem turn, and stem Christiania, to free parallel swing initiated with only a slight quick stem (for descriptions of movements see below *Basic movements*). His school became very popular, and he soon found graded classes and additional instructors necessary. During World War I, he further developed his methods while training Austrian mountain troops.

As more efficient techniques were developed, largely by competition, these also were taught, and attendance at ski schools increased. The first examination for teachers of skiing was held in Austria in 1925. This examination became increasingly exacting over the years, and other countries, including Switzerland, France, Italy, Germany, Canada, and the U.S., adopted similar tests, with certification considered a mark of professional competence. In each of these countries a uniform national system is taught in all or most of the schools, but in some places an eclectic or original method may be used.

Switzerland instituted courses for teachers in the early 1930s, and under the leadership of Christian Rubi the Swiss ski schools promoted a uniform method of instruction. While Schneider's Arlberg ski school put great emphasis on the stem and stem turns as the basis of its technique, the Swiss avoided what they considered excessive attention to these positions, and later the French schools, too, took a more direct route to "parallel" skiing. Émile Allais and Paul Gignoux brought the French theories to the forefront when they challenged the value of teaching the basic stem and body rotation. Ahead of their time were Eugen Matthias, physiologist of the University of Munich, and Giovanni Testa, head of the ski school in St. Moritz, who in the mid-1930s first taught the reverse

Ski touring and mountain eering

Ski jumping

The "Arlberg" technique

The Swiss schools

(or inside) shoulder technique and the technique of turning with knees together. Their book, *Natürliches Skilaufen* (1936), attracted considerable attention, but was not at the time recognized as prophetic of what was to come.

Since World War II, the techniques taught and the sequence of instruction in the ski schools of the various countries have tended to become more similar. In particular, less emphasis is placed on a thorough and almost exclusive grounding in the stemmed turns. Instead, a parallel position of the skis is inculcated, and to make this habitual, early stress is placed on sideslipping, traversing, edge control, and straight running of slopes. The chief differences are between the Austrian system of rhythmic short-swinging (short swings and counterswings across the fall-line; *wedeln*) turns, distinguished by counterrotation and leading with the inside shoulder in turning, as first advocated by Matthias; and the French turning style of *projection circulaire*, in which the shoulders are kept almost square to the direction of movement during a turn.

Among the important factors leading to these developments were the introduction of the steel edge in the 1930s, and the great increase of ski lifts, beginning in the late 1940s. The former facilitated the learning of parallel, narrow-tracked, and precise running and turning. The latter greatly increased the numbers of skiers and multiplied the number of runs each one could make downhill, so that little skiing could be done on virgin snow, and nearly all runs were made on well-packed trails and slopes, thus promoting the development of the short-swinging, with alternate pole-planting, and the *wedeln* techniques.

Organization of the sport. The International Ski Federation (Fédération Internationale de Ski, or FIS) founded in 1924, is the world governing body of the sport. It is composed of the various national ski associations or federations, and these, in turn, are usually composed of individual ski clubs. Two of its chief functions are to set the rules of competition for each branch of the sport, and to sanction the quadrennial world championships and the international calendar comprising all other important events. It also sets the rules of eligibility.

The world's first ski club was the Trysil in Norway, formed in 1861. The first in the United States was organized at Berlin, New Hampshire, in 1872. The Ski Club of Great Britain, founded in 1903, was the sport's first national administrative body. It was superseded by the National Ski Federation of Great Britain (1964). The first intercollegiate ski meet, with Dartmouth, McGill, and Montreal, was held in Quebec, at Shawbridge, in 1914. The first meet between the British Universities Ski Club and the Swiss Academic Ski Club was held in 1927.

The International Association for Ski Instruction (Inter-ski) holds a congress every three years at which teams from the chief skiing countries demonstrate the methods of instruction used by their schools.

Competitive skiing. Downhill races are run on defined courses of a length, steepness, and difficulty appropriate

to the skill and endurance of the entrants. For men's Olympic and world championship events, a vertical descent of between 800 and 1,000 metres is prescribed. The limits for women are 300 metres lower. Courses may be between 2.4 and 5 kilometres long, although some races are considerably longer. Average speed of the winners is usually between 64 and 80 kilometres per hour (40 to 50 miles per hour). Speeds of more than 161 km/hr (100 mph) have been recorded on special short courses.

A slalom course is defined by gates formed by pairs of poles with flags, between which the runner must pass. The course is carefully set to test the skill and judgment of the competitor. For Olympic and world championship races, the men's course must have a vertical descent of between 180 and 220 metres. Fifty-five to 75 gates are required for men, 40 to 60 for women. For less important competitions, courses are shorter and less difficult. Sir Arnold Lunn is credited with initiating the modern slalom in the early 1920s, and with being chiefly responsible for its recognition (and that of the downhill) by the FIS in 1930.

The giant slalom has characteristics of both the downhill and the slalom. The gates are set wider and further apart, the length of the course approaches that of the downhill, and the average speeds achieved are between those of the other two Alpine events. The best Alpine competitors have come from Austria, France, Italy, Switzerland, and, more recently, Canada and the U.S.

The World Cup, inaugurated in 1967, is a competition in which skiers can accumulate points in the three Alpine disciplines in many designated meets during the winter.

Cross-country races are held over rolling terrain. The standard distances in international competition are 15, 30, and 50 km for men, and 10 and 5 km for women. In the relay race, four men each run a 10-km course, and three women a 5-km course. The Vasa race in Sweden is 56 mi (90 km) long.

Jumping competitions are held on carefully graded and prepared hills, classified according to size as 100-m, 80-m, 70-m, etc. The approach, or inrun, usually starts on a scaffold or tower; down this incline the jumper, in a crouched position, accumulates speed until he reaches the takeoff, where he leaps outward, upward, and forward. The best competitors lean far over toward the points of their skis in order to minimize wind resistance and to get an aerodynamic lifting effect to increase the length of their jump. The landing is made on the steep landing hill in a more upright position with the shock of contact taken up by the knees. After the slope levels off, the jumper stops by turning on the outrun. The performance is decided half by the distance covered and half on form, as marked by the judges, who attribute style marks.

The best jumpers and cross-country runners have come largely from the Scandinavian countries, Finland, and eastern Europe, especially from the U.S.S.R., but some also from the Alpine countries.

Basic skiing movements.

and sometimes the giant slalom, events is called the Alpine combined, and the jump and 15 km cross-country together are called the Nordic combined.

The Winter Olympic Games were initiated in 1924 at Chamonix, France, but included only Nordic ski events. The same was true of the St. Moritz, Switzerland (1928), and Lake Placid, New York (1932), Olympics. Alpine events for men and women were introduced at Garmisch-Partenkirchen, Germany, in 1936. World Ski Championships, sanctioned by the FIS, are now held every fourth year, between the Olympics. The first was in 1925, at Johannesbad, Czechoslovakia. The Alpine events were first included in these championships at Murren, Switzerland, in 1931. The oldest international event decided on the results of a downhill and a slalom, is the Arlberg-Kandahar race, first held in 1928, which now rotates between Murren, St. Anton, Chamonix, Sestriere (Italy), and Garmisch, and in 1971 was held in the United States, at Sugarloaf Mountain, Maine. Lunn and Schneider were its founders. Other famous competitions are the Holmenkollen, the world's senior ski meeting, in Norway, the Parsenn Derby and the Lauberhorn in Switzerland, and the Hahnenkamm in Austria.

For a complete record of Winter Olympics winners see ATHLETIC GAMES AND CONTESTS: *Olympic record*. For Nordic and Alpine World Champions, World Cup winners, World Biathlon champions, and progressive world ski-jumping records see SPORTING RECORD in the *Ready Reference and Index*.

The sport of skiing. Basic equipment. The three chief types of skis, downhill (including slalom), jumping, and cross country (racing and touring), have certain characteristics in common. They are pointed, turned up, and usually slightly wider at the front (the tip or shovel) and are squared at the rear (or tail). They are thickest in the midsection under the foot, thinnest just before the ends, and are built with a slight arch, or camber, so as to distribute the skier's weight along the length of the ski. The stiffness of the camber may vary to accord with the use to which the skis are to be put. Over the years skis have been refined in their shape and camber and in precision of stiffness. The running surface, or sole, has been improved to reduce friction and increase durability.

Skis vary in length, the downhill ski for the average adult man being a little less than seven feet (210 centimetres) long, although much shorter skis, slower but more manoeuvrable, are enjoying some vogue, particularly in teaching beginners and novices. Skis were formerly fashioned from one piece of wood, usually hickory, but after the 1930s laminated constructions were also used. After 1950, plastic running surfaces were introduced to increase speed and durability, and skis of metal, usually with a wood or plastic core, became increasingly popular. The downhill ski, which is about three inches (7.6 cm) in width, typically has a shallow groove running longitudinally along the centre of the bottom; this imparts directional stability. In addition, skis have sharp edges of steel along the bottom in order to bite into hard snow or ice.

Skis: types and construction

Jumping skis are longer (about eight feet), wider, thicker, and heavier and ordinarily have three grooves in the bottom and no steel edges. Cross-country skis are narrower and lighter than the downhill skis. They have one groove and often are made of laminated wood. Touring skis have metal edges; cross-country racing skis do not.

For downhill skiing, the skier wears close-fitting, heavy leather or plastic boots with flat and stiff soles in order to exercise precise control over the skis. The boots are firmly attached to the skis by bindings, often with release features, designed to free the skier's foot in case of falls. Many improvements in bindings have been developed. For jumping and cross country a lighter and more flexible boot is used, with a binding that allows the heel to be raised.

For downhill skiing a light pole, or stick, of metal or bamboo, about four feet long, is carried in each hand. For cross-country skiing the pole is typically longer and lighter. These aid the skier in pushing himself along on the level and in climbing. They are also used in maintaining balance when running downhill and to assist in turning. Each pole has a wrist strap at the top and a ring or wheel near the bottom, which prevents the point from sinking too deeply into the snow. Various waxes, depending on temperature and snow conditions, are used on the bottoms of skis to prevent snow from sticking to them and to reduce friction. To aid in climbing, special waxes are used, and sometimes strips of sealskin or plush are strapped or stuck to the bottoms of the skis to prevent backsliding.

Refinements in ski equipment after World War II were accompanied by a great increase in the proficiency of the average recreational or competitive skier. As the parallel (skidded) technique supplanted the earlier stemmed (steered) turns, speed and manoeuvrability were greatly increased.

Basic movements. Brief identifications of the basic skiing movements referred to above and commonly taught in most schools follow. The best way to learn these movements is with a certified instructor.

Formerly the fundamental of instruction, stemmed turns are based on placing one or both skis at an angle to the direction of movement. The chief turning force is the shifting of weight from one ski to the other. The snowplow turn is made from a snowplow, or double stem (skis in a V), position by shifting the weight to one ski and exerting outward-turning pressure with that heel to make a steered turn. The stem turn is made from traversing, with skis parallel, by stemming (angling out) the upper ski and turning as in the snowplow. The stem Christiania is similar except that during the turn the skis are brought parallel and the rest of the turn is skidded with them in this position, while the Christiania is a swing from a slight initial stem that continues across the fall line. A jump turn is executed while in motion by lifting both skis from the snow with the aid of one or both poles, and turning them in the air. The kick turn is a sharp turn made from a stationary position by lifting one ski into a vertical position, letting it drop into the desired direction, and placing the other ski next to it. The ruade is a turn made by lifting the heels of the skis clear of the snow.

Sideslipping is useful on hard-packed trails, and as it also inculcates the parallel ski position and teaches edge control, has become a basic of modern instruction. The skis are skidded sideways by flattening them to disengage the edges and pushing the heels downhill and the skis out from under the body.

Traversing is running downhill and diagonally across the fall line with skis parallel and close together for greater control.

For running downhill in the fall line, the skis are flat, parallel, close together, and equally weighted. The goal is a stable, relaxed position, slightly forward leaning (vorlage), with smooth movements to adjust the skier's centre of gravity to changing conditions of snow and slope. The reverse position (*rücklage*), with the body back and the weight on the heels, was formerly considered a fault, but this position may be preferable with some types of equipment.

Skin, Human

The apparent lack of body hair distinguishes humans at once from all other large land mammals. Regardless of individual or racial differences, the human body seems to be more or less hairless, and it has become fashionable to refer to man as a naked ape, although he is neither naked nor an ape. Certainly, the larger part of human skin is covered with hair so vestigial as to seem absent; yet in certain areas hair grows profusely. These may be referred to as **epigamic areas**, and they have no other useful purpose than that of sexual attraction. Lacking a full coverage of hair, skin has attained adaptive changes in structure that give it strength and resilience. Although skin is the organ with which one is most familiar, man is still hopelessly ignorant about many of its anatomical, physiological, and biochemical properties and with most of its numerous disorders.

THE SKIN AS A WHOLE

The characteristic features of skin change from the time of birth to old age. In infants and children it is velvety, dry, soft, and largely free of wrinkles and blemishes. Children younger than two years sweat poorly and irregularly; their sebaceous glands function minimally. At adolescence, hair grows larger and becomes more pigmented, notably in the scalp, the axillae, the pubic eminence, and on the face of men. Skin pigmentation increases, localized pigmented foci appear mysteriously, and acne lesions

Epigamic
areas

often develop. Hair growth, sweating, and sebaceous secretion begin to blossom in adolescence and reach full bloom in adults. As one ages, anatomical and physiological alterations and exposures to sunlight and wind all leave indelible marks, particularly upon skin not protected by clothing. The dry, wrinkled, flaccid skin of old people has suffered many abuses and is a relic of a fine organ system.

Human skin, more than that of any other mammal, exhibits many gross and subtle topographic differences, for example, those between the palms and the backs of one's hands and fingers. The skin of the eyebrows is thick, coarse, and hairy; that on the eyelids is thin, smooth, and covered with almost invisible hairs. The face is seldom visibly haired on the forehead and cheek bones. It is completely hairless in the vermilion border of the lips, yet coarsely hairy over the chin and jaws of men. The surfaces of the forehead, cheeks, and nose are normally oily, in contrast with the relatively greaseless lower surface of the chin and jaws. The skin of the chest, pubic areas, scalp, axillae, abdomen, soles of the feet, and ends of the fingers differs as much structurally and functionally as it would if the skin in these different areas belonged to different animals.

Man's skin is thicker than that of many other mammals and is thicker on the dorsal than the ventral parts. It is elastic to accommodate size increases and decreases of the body it encases and to accommodate the many subtle movements that characterize the human body. The extent of elasticity is an individual property, largely dictated by regional, racial, and genetic factors; taut in some persons, the skin is easily stretched in others. Skin repairs expertly and with dispatch the perennial minor injuries it suffers and, given an opportunity, repairs major injuries almost equally well.

Since its surface is constantly shedding, it is renewing itself at all times. Its many nerves record all modalities of sensibility of touch, pain, and temperature, and it is therefore the largest sense organ of the body. Finally, the skin is the largest organ of personal identification and sexual attraction, being molded and marked differently in every individual and endowed with numerous subtle and gross epigamic adaptations.

The skin is fashioned in such a way that it attains maximal strength and protection from the environment while remaining delicately in communication with it. Skin achieves maximal strength and pliability by being composed of numbers of layers oriented in such a way that each complements the others structurally and functionally. To allow a communication with the environment, countless nerves, some modified as specialized receptor end organs and others more or less structureless, come as close as possible to the surface layer, and nearly every skin organ is enwrapped by skeins of fine sensory nerves. The distribution of skin nerves supports what is already known from physiology: in most areas the skin is adapted for light-touch sensibility rather than deep pressure.

Human skin is enormously well supplied with blood vessels; it is pervaded with a **tangled**, though apparently orderly, mass of arteries, veins, and capillaries. Such a supply of blood, far in excess of the maximum biological needs of the skin itself, is evidence that the skin is at the service of the blood vascular system, functioning as a cooling device. To aid in this function, sweat glands pour water upon its surface, the evaporation of which absorbs heat from the skin. Sweat glands thus are ancillary devices of the blood vascular system. If the environment is cold and body heat must be conserved, cutaneous blood vessels contract in quick, successive rhythms, allowing only a small amount of blood to flow through them. When the environment is warm, they contract at long intervals, providing a free flow of blood. During muscular exertion, when great quantities of heat generated must be dissipated, blood flow through the skin is maximal. In addition to its control of body temperature, skin also plays a role in the regulation of blood pressure. Much of the flow of blood can be controlled by the opening and closing of certain sphincter-like vessels in the skin. These vessels allow the blood to circulate through the peripheral capillary beds or

to bypass them by being shunted directly from small arteries to veins.

In addition to an overly abundant, complex vascular bed, skin is also riddled by an intricate mesh of lymph vessels. In the more superficial parts of the dermis, minute lymph vessels that appear to terminate in blind sacs are affluents of a superficial lymphatic net that in turn opens into vessels that become progressively larger in the deeper portions of the dermis. The deeper, larger lymph vessels are embedded in the loose connective tissue bed surrounding veins. The walls of lymph vessels are so flabby and collapsed that they often escape notice in specimens prepared for microscopic studies. Their abundance, however, has been demonstrated by the injection of vital dyes inside the dermis and the observation of the clearance of the dye. Since lymph vessels have minimal or no musculature in their walls, the circulation of lymph is sluggish and largely controlled by such extrinsic forces as pressure, skeletal muscle action, massaging, and heat. Any external pressure exerted, even from a fixed dressing, interferes with its flow. Since skin plays a major role in immunological responses of the body, its **lymphatic** drainage is as significant as its blood vascular system.

Skin is an array of different layers, each layer of the stack having its own properties. Although the layers do not display a true orthogonal pattern, they nonetheless make skin comparable to plywood, which has much greater strength than a single board of the same thickness. There are two principal layers; on the surface is the **entirely** cellular epidermis, and beneath it the fibrous dermis. The epidermis is relatively thin and is itself veneered, being composed of four or five variably distinct layers. The dermis is much thicker and composed of two layers. It is the dermis that gives bulk to the skin; leather is tanned dermis.

PARTICULAR ASPECTS OF THE SKIN

The surface of the skin. The intact surface of the skin is pitted by the orifices of sweat glands and hair follicles and is furrowed by intersecting lines that delineate characteristic patterns. Every individual has roughly similar markings on any one part of the body, but the details are unique. The lines are oriented to indicate the general direction of elastic tension. Countless numbers of them, deep and shallow, together with the "pores," give each area of the body a characteristic **topography**; like the deeper furrows and ridges on the palms and soles, they are mostly established before birth. The fine details of each surface of the body are peculiar to each individual. Fingerprints are used as a means of personal identification because they have a high relief, more visible patternings, and can be obtained easily (see below **Dermatoglyphics**).

Not all lines on the surface of the skin are congenital; some are acquired after birth as a result of use or damage. Furrows on the forehead and face, those extending from the corners of the mouth to the wings of the nose, and others are acquired from years of wrinkling the brow or from certain fixed facial expressions such as frequent smiling; these and similar lines represent an accentuation of preexisting congenital lines that become strongly emphasized in old age. As the skin becomes less firm with aging, it also forms wrinkles. Certain occupations leave skin marks, which, depending upon duration and severity, may be transient or permanent.

The ventral surfaces of the hands and feet are etched by distinct alternating ridges and grooves that together comprise dermatoglyphics. The crest of each ridge is pockmarked at spaced intervals by the small, conical depressions of the orifices of sweat glands. The ridges follow variable courses, but their arrangements in specific areas have a consistent structural plan. Though apparently continuous, ridges have many interruptions and irregularities, branching and varying in length. Every small area of surface has ridge details not matched anywhere in the same individual or in any other individual, even in identical twins. This infallible signature makes dermatoglyphics the best-known physical characteristic for personal identification.

The epidermis. The epidermis is thicker on the palms

General structure

and soles than it is anywhere else and is usually thicker on dorsal than on ventral surfaces. Omitting the fine details, it is divisible everywhere into a lower layer of living cells and a superficial layer of compact dead cells. All the cells, living or dead, are attached to one another by a series of specialized surfaces called attachment plaques or **desmosomes**. Thus, instead of being completely fused, the membranes of adjacent cells make zipper-like contacts, with fluid-filled spaces between the contact areas. This structural pattern insures a concatenation of cells to one another so that they cannot be sloughed off easily, and at the same time it also allows nutrient fluids to seep in from the vessels in the dermis. Epidermal cells, which multiply largely at the base in contact with the dermis, gradually ascend to the surface, manufacturing keratin as they go; they finally die in the upper part, forming a horny layer.

The epidermis is an epithelium of variable thickness. It is thickest on friction surfaces and thinnest over the eyelids, the lower parts of the abdomen, and around the external genitalia. Unlike that of most other mammals, it has an intricately sculptured underside and does not lie flat upon the dermis. Seen from the underside, there are straight and branching ridges and valleys, columns and pits, all finely punctuated. The complexity of the underside varies according to topography, and each pattern is characteristic of certain areas. Because of this unevenness, it is al-

most impossible to state the exact thickness of the epidermis. Furthermore, individual differences, sex, and aging have an enormous influence on the structure of the underside. Such labyrinthine patterns give human epidermis two unique advantages: it attains a more intimate connection with the subjacent dermis than if the surface were flat, and its source of dividing cells, the building blocks of the horny layer, is greatly increased.

The two major layers of the epidermis are a viable **malpighian** layer at the bottom, in contact with the dermis, and a dead corneal, or horny, layer on the surface. The cells of the malpighian layer that rest upon the dermis comprise the basal layer. Above the basal cells is a variously stratified prickly cell or "spinous" layer. Its upper cells blend gradually into a granular layer, so called because its cells contain particles of various sizes that stain with basic dyes and are called keratohyaline granules. The granular layer is often several cells deep in normally thick epidermis such as that in the palms and soles. A hyaline, transitional layer one to three cells deep is above the granular layer, interposed between it and the horny layer. In friction surfaces, the backs of the hands, and a few other surfaces, the hyaline layer attains considerable thickness.

Epidermal cells make contact with each other by way of many punctate areas of adhesion. When the epidermis is

Photomicrograph of a vertical section of epidermis from a finger.
William Montagna

dehydrated, its cells remain in contact with one another, but the membrane at the points of adhesion between two adjacent cells is stretched out, giving rise to artifactual structures called "intercellular bridges." Midway between each intercellular bridge, at the actual place of contact, the adjacent cell membranes attain a spindle-shaped swelling, a "desmosome," that has received much attention from electron microscopists. The membranes of the basal cells above the dermis, not being in contact with the membranes of other cells, have half desmosomes, or hemidesmosomes. The cells of the basal layer of the epidermis are columnar or cuboidal, with the long axis usually oriented perpendicularly to the surface. As these cells divide and ascend to the surface, they become progressively larger and of different shapes, oriented horizontally to the surface and increasingly flattened until they reach the dead horny layer, where their appearance becomes scalelike in form.

Reproducibility and differentiation in the epidermis must occur linearly. Cells divide at a constant rate, lest they become depleted with the continual shedding at the surface of the horny layer. Division occurs chiefly in the basal layer, but where the epidermis is very thick, it also occurs a little higher. Cell division in the epidermis is rhythmic and cyclic. It has been estimated that normal human-skin epidermal cells take about 27 days, or roughly one month, to travel from the basal layer to the surface. Under certain pathological conditions (for example, psoriasis), the renewal process is greatly accelerated and may occur in one week or less.

Histologists who are accustomed to dehydrating and embedding skin in paraffin and sectioning it vertically have often dismissed the horny layer as a flimsy structure of no great structural interest. Under the light microscope such preparations show the horny layer as a fragmented, lacy, structureless residue above the granular layer. This debris has little resemblance to the horny layer in living skin; in fresh-frozen sections it is thicker and always compact. The electron microscopist has found that this layer has a precise architecture and that even under minor disturbance its integrity is altered. It can be stripped in individual layers with adhesive tape, or removed intact with vesiculating agents. When intact, the horny layer is a substantial structure of closely bound cells, which, though dead, are well-organized entities. Interposed between external and internal environments, the epidermis is sensitive to changes in both. Having no intrinsic vascular supply, the epidermis is dependent upon the dermis, from which nutritive and other essential substances seep in

through the intercellular spaces to guide its growth and differentiation.

The cells of the epidermis readily adapt to internal and external changes, and they have superlative regenerative powers. Epidermal metabolic activity is geared primarily to the replacement of cells lost on the surface and to the production of highly specific chemical substances that prevent both penetration by noxious substances and the escape of vital substances from within.

The most important mission of the malpighian layer is to form the dead outer covering of the horny layer. This is the final product of epidermal differentiation. The substances manufactured by epidermal cells have been loosely called "keratin." There is confusion as to what is meant by keratin, because a number of substances with distinctly different chemical composition are known by this name. Keratin in the horny layer is a mixture of sulfur-poor fibrous protein surrounded by a sulfur-rich amorphous protein, the two components enclosed in a thickened, cornified plasma membrane. The process of keratinization begins as soon as cells move up from the basal into the spinous layer and when fibrous proteins, microfilaments, begin to form. In their ascension to the surface, cells increase in size and in their content of filaments. In the granular layer proteinous keratohyalin granules are also synthesized, and the cells become replete with both fibrous proteins and granules. In the next stop upward from the granular layer, the granules and most cell organelles become dissipated as a sulfur-rich amorphous substance that stabilizes the horizontal orientation of the filamentous proteins. In the meantime, cell membranes keratinize by becoming a sulfur-rich amorphous protein in their own right. This melange is epidermal keratin. The horny layer also synthesizes lipids, waxes, and sterols, which combine to give it sturdiness and plasticity.

The skin of human beings is variously coloured, with remarkable individual variations occurring even within members of the same race. In addition to the blood in the superficial vessels, the colour of human skin is determined by melanin, a pigment manufactured by special dendritic cells, melanocytes, that reside mostly below or between the basal cells of the epidermis. The number of melanocytes per surface area in any one part of the body is roughly the same within and between races, and the blondest Europeans may have as many melanocytes as the darkest Negro. This means that the quality rather than the quantity of these cells determines the intensity of pigmentation in the skin. When, on exposure to sunlight, the skin becomes tanned, the resident melanocytes have not increased in number; only their activity has increased. Melanocytes are an integral part of the epidermis, having migrated there from the neural crest during embryonic life. These cells can be compared to unicellular glands with long, thin, branching, streamer-like processes that worm their way between the epidermal cells in their immediate vicinity, making up a constellation of epidermal cells around each melanocyte. Melanin is produced inside the cytoplasm and travels to the dendrites. Epidermal cells in contact with the melanin-laden dendrites actually phagocytose the tips of the dendrites. Once inside the epidermal cells, melanin granules tend to move above the nucleus, forming a shroud over it. Such an orientation of melanin suggests that it is there to protect the cells from damaging ultraviolet rays, and experimental evidence in tissue culture has left no doubt that this is the case.

In addition to protecting the skin from ultraviolet light irradiation, epidermal pigmentation forms epigamic markings. The heavy pigmentation of the nipples and areolae of breasts, as well as that in the labia minora, or penis and scrotum, functions solely as a sexual attractant.

In addition to pigment-producing cells in the basal layer, the epidermis also contains branched cells farther up in the spinous layer. These cells of Langerhans have the same shape as melanocytes but form no melanin, and, in spite of much imaginative investigation, no one seems to know what they do.

Still another type of cells, "Merkel cells," is said to be normally resident at the base of the epidermis. Apparently associated with nerves that penetrate the epidermis, Mer-

Pigmentation of skin

Cell division in epidermis

kel cells have been demonstrated well only in the skin of some mammals. There is little doubt that they are also present in human skin, but they have not been shown satisfactorily.

Even in perfectly normal skin, one finds variable numbers of lymphocytes between epidermal cells. There has been much speculation about their significance, but it remains obscure. Actually, lymphocytes are encountered often in all epithelia, and their presence may reflect only their wandering proclivity; once inside the epidermis, they simply die.

The epidermis is a precisely tailored tissue, adapted in every detail to protect the body against its environment. Its architecture, the balance in the rates of the wear and replacement of its cells, the physical and chemical properties of the horny layer, the specific kinds of keratin and lipids that it produces, all cooperate in safeguarding the integrity of the organism against the environment.

The pilary system. Man's body hair has little protective value even in hirsute persons. Eyelashes and eyebrows, the hairs inside the external ears and nostrils, and those around the anogenital orifices have obviously useful functions, and scalp hair is often thick enough to afford some protection. Beard and mustache, and axillary and pubic hair, are embellishments. Other than minimal protection and adornment, the only important biologic role of man's hair is its participation in the sensory mechanism.

All hair follicles are surrounded by sensory nerves, and pressure on the hair shaft is transmitted to these nerves. Other mammals, including subhuman primates, have highly specialized sensitive hair follicles around the eyes, lips, and muzzle. These "tactile" hairs, known as vibrissae or whiskers, are particularly large in nocturnal mammals. The follicles from which they emerge are rich in nerves and are surrounded by a sinus filled with blood. Man is the only animal with no sinus hair follicles; but his hair follicles, particularly those of the face, are well supplied with nerves, and his skin is probably more sensitive than that of any other mammal.

Except for those on the scalp, beard, and mustache, most body hairs grow to a predictable length peculiar to the body area and individual; they are shed periodically and are subsequently replaced by other hairs of the same length. Hairs do not grow continuously; the follicles that produce them have precisely controlled periods of growth and rest. If this were not the case, we would require periodic shearing, as do sheep.

Hairs are manufactured by follicles, tubelike organs attached to the epidermis at the surface and extending through most or all the depth of the skin. The bottom of a follicle is shaped like a scallion, the bulbous part representing the growing end. Follicles grow at an angle to the surface. Two-thirds of the way up on the obtuse angle is a bulge; attached to it are wisps of smooth muscle fibre that on contracting pull the follicle to a more or less perpendicular position. This action also puckers the skin into a mound on the surface, a "goose pimple."

In the centre of the follicle is the hair, with a root extending to the bulbous end. After a period of growth, when the hair has reached its characteristic length, the terminal part of the hair attains a clubbed, rather than a cylindrical, shape. Fibrous rootlets anchor the club to the surrounding tissue of the follicle. While forming the club, the follicle shrivels up, the lower part becoming largely dissipated. A resting follicle can be recognized at once by the clubbed hair, by its short size, and its uniquely different structure.

Follicles remain dormant for variable periods of time. When they become active again, they reconstruct a bulb that manufactures a new hair. As the new hair works its way to the surface, it loosens the club hair from its moorings and causes it to be shed.

Hairs vary in colour, diameter, and contour. The different colours result from variations in amounts, distribution, and types of melanin pigment in them, as well as from variations in surface structure, causing light to be reflected in different ways. Hairs may be coarse or so thin and colorless as to be nearly invisible. Straight hairs are round, while wavy hairs are alternately oval and

round. Very curly and kinky hairs are shaped like twisted ribbons.

Human hair grows about one-third of a millimetre per day. This means that if the colour or shape of a hair is altered as it is formed, several days must elapse before the effect is visible on the surface. Tales of the hair's becoming entirely gray overnight stem from fantasies.

The hair follicles of the scalp differ from the others in their ability to grow sometimes for years without interruption, producing hair of considerable length. It is surprising, therefore, that the human scalp, in which the hair follicles are dense and grow vigorously, should become bald in such large number of individuals. Baldness is not a disease but a systematic involution of hair follicles culminating in organs similar to the primitive embryonic follicles, without necessarily a diminution in absolute numbers. There are about 150,000 hairs on the scalp.

All human beings are, to a degree, bald. Until late in fetal life, the forehead is indistinguishable from the scalp, with no line of demarcation between the two. After the fifth month of gestation, the follicles in the rest of the scalp grow larger, but those of the forehead do not. After birth the hairs on the forehead become even smaller and nearly invisible. The hair line of newborn infants is usually indistinct; the familial pattern of a hair line is established late in childhood, through a process that is identical with that of baldness. When male pattern baldness sets in, in the late 20s or earlier, the follicles affected do exactly the same things as those at the hair line. Involution of hair follicles also takes place elsewhere on the body of infants. Newborn infants are often more hirsute than they are months or even years later. In rare cases of hirsutism, the forehead may be as heavily clothed with hairs as the scalp.

Baldness is a natural tendency of the follicles of the scalp to become very small as individuals become mature and is a secondary sex characteristic.

The sebaceous glands. The sebaceous glands usually grow attached to hair follicles and pour their secretion, sebum, inside the canal of the follicle. Hairs emerging on the surface of the skin are coated with sebum. In a few areas of the body, disproportionately large sebaceous glands are associated with very small hair follicles; in other areas, the glands are altogether free of follicles.

The outstanding structural feature of sebaceous glands is their mode of forming sebum. Undifferentiated glandular cells gradually synthesize and accumulate fat globules in their cytoplasm and become progressively larger and distorted. When they have finally utilized all their vital resources, they die and disintegrate. Sebum is the accumulation of dead, fragmented sebaceous cells and other cellular debris from the pilary canal. The pressure created by sebum in the body of the glands, capillary traction through the ducts, and movements and compression of the skin all aid the glands in pouring their sebum onto the surface.

Scientists who have searched for the specific functions of sebum have had scant success. This semiliquid mixture of bizarre fatty acids, triglycerides, waxes, cholesterol, and cellular detritus does not emulsify readily, is toxic to living tissues, and seems to serve little purpose except as an emollient. Some investigators have dismissed sebum as a useless substance and sebaceous glands as archaic organs that do greater harm than good. Yet man has more and larger glands than most mammals, and there is a specific plan in their distribution: they are largest and most numerous on the face and around the anogenital surfaces. The skin around the nose, mouth, and forehead and over the cheekbones has beds of gigantic glands, the secretion of which keeps these surfaces constantly oily. The sebaceous glands evenly spaced in rows at the border of the eyelids, meibomian glands, are so large that they are easily seen with the naked eye when one everts the eyelids before a mirror. The glands on the genitalia produce copious amounts of smegma.

Only man has rich populations of sebaceous glands on the hairless surfaces of the lips; these glands increase in number and size as individuals mature. The inside of the cheeks also has many large sebaceous glands, and occa-

sionally there are glands even on the gums and tongue. No one knows their significance.

The size and function of sebaceous glands are controlled mostly by androgenic hormones. The glands, large in newborn infants, become smaller during childhood, begin to enlarge in early puberty, and attain full growth in adults. They are larger and more active in men than in women; the level of the total output of sebum, a valid index of their activity, closely parallels the levels of androgenic hormones in individuals. The development of these glands is minimal in eunuchs, but increases when they are treated with androgens.

In spite of our ignorance of its biological significance, sebum is abundantly secreted upon certain specific surfaces of the body; and it cannot be assumed that sebaceous glands, so prominent on the human body, are necessarily archaic.

The sweat glands. The two categories of sweat glands are those called apocrine, which are usually associated with hair follicles, and eccrine, which are not. The two types share practically no biologic properties; they have distinctly different origins, different structures, and different functions.

Most other mammals have numerous apocrine glands on the hairy skin; eccrine glands are usually absent from the hairy skin and limited to friction surfaces. In nonhuman primates there is a tendency for the number of eccrine sweat glands over the body to increase in progressively advanced animals at the same time that the number of apocrine glands becomes reduced. Prosimians have only apocrine glands in the hairy skin; eccrine glands begin to appear in some of the higher forms. The great apes either have equal numbers or have more eccrine than apocrine glands. Man has the most eccrine glands, with apocrine glands restricted to specific areas.

Strictly speaking, apocrine glands have nothing to do with sweating. They appear late in fetal development (5 to 5% months), nearly everywhere on the body, and mostly associated with hair follicles. Most of these rudiments disappear within a few weeks except in the external ear canal, in the axilla, on the nipples of the breasts, around the navel, and on the anogenital surfaces; single glands may be found anywhere. From this, one might speculate that the ancestors of man had apocrine glands widely distributed over the body, and the embryonic rudiments may be reminders of the history of a once widespread organ system. In the areas mentioned above, the glands are large and numerous. In the axilla, they are so large that the coils press upon each other, forming adhesions and cross-shunts of such complexity that the glands are more spongy than tubular. The complex of these large apocrine glands interspersed with an equal number of eccrine sweat glands in the axilla comprises what is known as the axillary organ, one of the most characteristic features of man's skin. Other than man, only chimpanzees and gorillas have axillary organs.

In spite of their large size, apocrine glands secrete only small amounts of a milky, viscid, pale gray, whitish, yellow, or reddish fluid that contributes very little to axillary sweat. If eccrine glands were not there, the axilla would be relatively dry.

Fresh and sterile eccrine and apocrine secretions are fairly odourless. When in contact with bacteria on the surface of the axilla, apocrine sweat is decomposed and emits the characteristic axillary odour. The odour of individual human beings comes mostly from apocrine secretion, with some contribution from sebum. Since the body odours of all other animals have a social or sexual significance, it can be assumed that this is the archetypal purpose of apocrine secretion, even in man.

Apocrine glands are dispensable organs, unnecessary to the biological economy of modern man. They are primarily scent glands that secrete in response to a variety of stressful stimulations. The presence of eccrine sweat in the same areas provides a vehicle in which the viscid, concentrated apocrine secretion is diluted, brought into contact with micro-organisms that decompose it, and distributed over larger surfaces to allow a better aeration and thus a stronger odour.

In most mammals eccrine sweat glands are either absent or limited to the friction surfaces. Eccrine glands are found in the hairy skin of some primates; chimpanzees and gorillas have more eccrine than apocrine glands, and man has 2,000,000 to 5,000,000 of them, with an average distribution of 150 to 340 per square centimetre. They are most numerous on the palms and soles and then, in decreasing order, on the head, trunk, and extremities. Some individuals have more glands than others, but there is no difference between the number in men and in women.

The specific function of sweat glands is to secrete water upon the surface so that it can cool the skin when it evaporates. The purpose of the glands on the palms and soles, however, is to keep these surfaces damp, to prevent flaking or hardening of the horny layer, and thus to maintain tactile sensibility. A dry hand does not grip well and is minimally sensitive. Sweat glands, then, can be divided into those that respond to thermal stimulation, the function of which is thermoregulation, and those that respond to psychic stimuli and keep friction surfaces moist. This makes a clear-cut division between the glands on the hairy surfaces and those on the palms and soles. The axilla, though a hairy surface, has adjacent fields that respond either to thermal or to psychic stimuli but not to both. In addition to thermal and psychic sweating, some individuals sweat on the face and forehead in response to certain chemical substances. The glands on the palms and soles develop at about 3% months of gestation, whereas those on the hairy skin are the last appendages to form, appearing at 5 to 5½ months, when all the other structures are already formed. This dyschrony may represent a fundamental difference in the evolutionary history of the two types of glands. Those on palms and soles, which appear first and are present in all but the hooved mammals, may be more ancient; whereas those glands in the hairy skin, which respond to thermal stimuli, may be more recent organs.

The sweat glands on the hairy skin of subhuman primates probably function subliminally or not at all, although they are structurally similar to those of man. The skin of monkeys and apes remains dry even in a hot environment. Profuse thermal sweating in man, then, seems to be a new function. Eccrine sweat glands respond to a variety of drugs with different properties; they often respond differently in different individuals under nearly identical conditions and sometimes even respond differently in the same individual. Notwithstanding these apparent vagaries in function, eccrine sweat glands are indispensable to man and function perennially though insensibly. Their secretion is controlled by the autonomic nervous system. Sweating is essential for keeping the body from becoming overheated.

Nails. A major characteristic of primates is that their fingers and toes terminate in nails rather than in claws. One can speculate that the development of nails into flattened plates reflects the discontinuation of their use for digging or for defending and attacking. In a broad sense, nails are analogous to hair, having similar composition (keratin) and some basic structural entities. Even the genesis and mode of growth are comparable, but not identical, with those of hair. Although apparently simple structures, nails are formed by complex and still poorly understood structural entities, referred to as nail organs. Unlike hair, nails grow continuously, with no normal periods of rest; if their free edges were protected from wear, they would extend to prodigious lengths, growing in a twisted fashion like a ram's horns. Nails grow about 0.1 mm per day or roughly one-third more slowly than hair. Growth is somewhat slower in winter than in summer and slower in infants and old people than in vigorous young adults. It requires about three months for a whole nail to replace itself. A number of factors can alter normal nail growth, among them age, trauma, poisons, and organic disorders. Habitual nail biting speeds up growth, and certain occupational uses can cause increase in thickness. The nail-forming organ is particularly sensitive to physiologic changes; during stressful periods, prolonged fever, and in response to noxious drugs, nails become cracked, thinner, thicker, furrowed, or otherwise deformed, or they may be

Eccrine
sweat
glands

shed. Such sensitivity of response should make nails relatively good indices of the health of individuals; but because of their ready response to so many internal and external factors, and because changes in them often occur without a known reason, signs of abnormality can be misleading or difficult to interpret. Like hair, the visible part of the nail plate is a dead structure. Defects inflicted upon it by mechanical means that do not disturb the underlying living tissue are eventually cast off at the free border.

Nail root

Nails have a root, buried underneath the skin, a plate that is firmly attached to a nail bed underneath, and a free edge. Depending upon its thickness and the quality of its surface, the nail plate may be pink or whitish; the nail itself is translucent and colourless, allowing the colour of the blood in the superficial capillaries in the nail bed to show through. At its base the nail plate may have a whitish, arched marking called a lunula. Always present on thumb nails, lunulae may be present or absent in the other fingers and are nearly always absent in the little finger. There are variations in different individuals and even between the two hands of the same person; such variations are probably controlled by genetic factors.

The nail itself consists of firmly cemented keratinized cells, flattened horizontally to the surface. Whereas the surface of nail plates appears to be smooth, it is lined by parallel, longitudinal furrows, more strongly etched in some persons than in others and always more prominent in the aged. These markings have some correspondence to the more pronounced grooves and ridges on the undersurface of the plate.

Nails grow from the matrix at the base of the nail root. During the early part of the journey, matrix cells multiply and move forward, synthesizing keratin, underneath the fold of skin (eponychium) at the base of the nail. Once exposed to the surface, the nail is fully formed. The nail plate seems to glide over the nail bed but is firmly attached to it. The entire tissue, nail bed and plate, most likely moves forward as a unit. The nail bed has often been called sterile matrix, since it adds little or nothing to the nail plate. Yet under certain pathologic conditions, it assumes keratinizing activities that result in a variably thickened or deformed nail plate.

Less effective than claws in digging or gouging, the flattened nail is still an excellent adaptation that has added much to the development of manipulative skills. Nails not only protect the tips of fingers but also give them firmness and the ability to pick up or make contact with minute objects. Claws would be useless for such functions.

Summation. The outstanding features of the skin of man are its apparent nakedness and the ability to sweat profusely. Since the only hairs that grow luxuriantly upon his body have no practical value in protecting him from his environment, man's hair is largely ornamental. Baldness is universal and represents another sign of man's advancing nakedness. As man's skin lost its hair cover, it underwent many adaptive changes. The outer horny layer, while remaining thin to allow suppleness, attained remarkable biological ruggedness, protecting the skin from physical and chemical injury and from the invasion of micro-organisms. The skin is employed by the blood vascular system to serve as its major cooling device and as a safety factor to control blood pressure. To better perform its thermoregulatory services, skin has developed eccrine sweat glands, which pour water upon its surface so that it can absorb body heat as it evaporates. Since heat is generated constantly, the glands secrete perennially; when greater amounts of heat are produced by muscle action or a hot environment, sweating becomes profuse. The sweat on the palms and soles functions to keep these surfaces soft, enhancing grip and tactile sensibility. Though apparently identical in structure and function, the glands on the hairy skin and those on the palms and soles have different ontogenetic histories, different central controls, and different functional purposes.

Continuously exposed to trauma, skin has inherent mechanisms that enable it to adapt to new situations and to withstand the onslaught of injurious environmental conditions.

(W.M.)

Skin Diseases

Although the skin is normally and conveniently regarded as a single organ, it is by no means homogeneous over the body, nor even in any single area (see SKIN, HUMAN). The transplantation of a piece of skin from one body site to another, except to the exact position on the opposite side, will make clear that it is out of place. Each skin area has characteristics sufficiently different that they can be recognized visually, although it is not always possible to describe the differences in exact words by scientific measurements.

Each area of skin consists, from the inside out, of a fat layer, a dermis, and an outer covering or epidermis. The dermis contains the special appendages for producing hair and nails, glands, connective tissue, a special arrangement of blood vessels and mechanisms to control blood flow, a specialized lymphatic system, nerve endings to detect a variety of sensations, cells with special functions, and muscle for moving the hairs and skin.

The human epidermis contains two types of melanocyte cells, for producing pigment, and three "races" of epithelial cells. These latter cells operate to form the hair follicle, the sweat duct openings, and the rest of the epidermis.

All of these elements of the skin's structure are blended into a cohesive whole, but disease may affect them individually, severally, or all together.

The skin surface is divided by body part involved into the following main and special areas (it will be noted that there is overlap among them): (1) the trunk and limbs; (2) the chest, abdomen, upper and lower back; (3) the head and neck; (4) the scalp, face, eyelids, ears, front, back, and sides of neck; (5) the genitalia and perianal area; (6) the arm and forearm, the thigh and leg, and buttocks; (7) the front and back, or flexor and extensor, aspects of the limbs; (8) the hands and feet, dorsa, and palms or soles; (9) the main folds or flexures, such as the knee and elbow, sides of the neck, armpits and groins, under the breasts, the natal cleft, and around the umbilicus; (10) other special areas such as the ear canal and the lips.

The range of diseases of human skin is extremely wide. Because skin is visible, many temporary or permanent symptomless changes, which would pass unnoticed in an internal organ, can be observed. The great diversity of skin changes is partly attributable to the differences between human skin and that of animals as a result of evolutionary development, partly because of its complex multiple structure, and partly because the skin can be affected by almost every known pathogenetic process. Moreover, the physical signs of a skin disease may vary in so many different ways that they are often recorded by the observer as different diseases until more is known about their causation.

The diagnosis of skin diseases is determined from the patient's history of his complaint, a detailed examination of the skin lesions, and special investigative procedures. Examination of the skin consists of analyzing the signs of disease in three parameters: first, the distribution of any lesions, noting both the affected and unaffected areas; second, the various individual elements of which each lesion is composed; and third, the pattern

or arrangement (or absence of it) of any lesions on the skin.

SKIN LESIONS

Arrange-
ment of
lesions

The elemental lesions, or individual elements or spots of skin abnormality, may be present in various degrees, in almost any combination, and arranged in numerous different ways. The result is that the number of pictures which skin rashes may present is virtually limitless, no two being identical. They may have a uniform pattern over the affected areas or be distributed at random. Certain configurations are sufficiently characteristic to have diagnostic significance, although not all the lesions will be arranged in the same pattern. Examples of recognizable patterns are: (1) annular (ring-shaped), arcuate (arched), or polycyclic (in many rings); (2) concentric rings; (3) disks and plaques, or flat areas that tend to coalesce; (4) large sheets with ill-defined borders; (5) linear or streaked; (6) retiform (in the shape of a net) and variegated; (7) grouped in clusters; (8) symmetrical or asymmetrical; (9) universal or generalized.

Examination of the lesion. The analysis of a skin rash in this manner produces morphological descriptions and diagnostic nomenclature under which skin diseases have been classified in the past. Knowledge of the anatomy, physiology, biochemistry, and biology of the skin has advanced so much in the past few decades that progress is now being made towards a classification on the basis of pathology and biological changes and the factors responsible for them. With suitable test procedures, it is possible to analyze the cellular and subcellular structure of individual parts of the skin; the functional activity of the separate elements such as production of keratin, the fibrous protein in the outer skin, and cell growth, sweat delivery and absorption, hair growth, pigment production, distribution, and removal, and cutaneous permeability; and also some of the biochemical pathways in the tissues.

The most important procedure, however, is a detailed histological examination of one or more biopsy specimens from the affected areas, in order to observe and attempt to interpret the changes in terms of pathological processes.

Pathological types. The skin is susceptible to all of the types of pathological change that affect other tissues. These include congenital abnormalities, effects of trauma, inflammation, metabolic disorders, neoplasia, and degenerative changes.

In addition, the skin, like other tissues, exhibits many diseases, such as psoriasis and rheumatoid arthritis, that do not readily fit in to any of the above pathological types, though future research may provide more information. Several different concepts of disease have been proposed at various times to explain them, for example, stress, psychosomatic factors, and auto-immunity. However, each of these concepts so far lacks convincing proof.

Congenital
abnormal-
ities

Each of the different components incorporated in the skin may be the site of a congenital and familial, or inherited, abnormality. The aberration may be generalized throughout the skin or localized to a small, large, or multiple area. A localized abnormality, called a nevus (a mole or birthmark, although it need not actually be present at birth), is a congenital abnormality, in structure or function, of cells, tissues, or organs. Such abnormalities are most frequently found in the skin and may serve as distinctive markings on passports or police records. A nevus may remain unchanged throughout life or resolve itself over several years, be slowly progressive, or sometimes give rise to malignant change after a long period of time.

Examples of generalized congenital abnormalities are epidermolysis bullosa and xeroderma pigmentosum. In epidermolysis bullosa, a genetic defect in the adhesion mechanism between the dermis and epidermis permits mild trauma to break the adhesion and allow tissue fluid to flow into the gap and form a blister. Xeroderma pigmentosum involves a genetic defect in the normal enzyme

mechanism for excising and replacing a radiation-damaged segment of the gene chain in the cell nuclei.

The skin is more exposed to trauma than any other tissue. An injury may be physical or chemical, or caused by actinic, or radiant, energy; the damage may be temporary or permanent. Continuous or intermittent trauma may result in skin thickening, such as callosities (abnormal hardnesses), and corns, while more acute trauma—whether physical or chemical—can cause erosions, ulcers, or burns, followed by permanent scarring if the dermis is injured. Less severe chemical injury can lead to inflammation and dermatitis.

Excessive actinic radiation, whether from the sun, X-rays, or other source, will, if acute, cause dilatation of capillaries, along with redness and swelling, followed by scaling, as in sunburn, with subsequent stimulation of the melanocytes to produce suntan. Prolonged exposure to actinic radiation may produce damage to the dermal connective tissue which may be irreversible and later induce skin cancer in the epithelium (see also RADIATION INJURY).

Many skin diseases are manifestations of acute or chronic inflammation. The main causes of such inflammation are (1) infective agents, (2) physical and chemical agents, and (3) immunologic changes. Almost every type of biological agent can infect the skin—viruses, Rickettsia, bacteria, fungi, worms, and arthropods. The discovery of modern antibiotics and chemotherapeutic drugs, and the improvement of public health measures, has greatly reduced the incidence of this type of infection among inhabitants of developed countries. In the developing nations of Africa and Asia, however, infection still accounts for at least 60 percent of all skin diseases.

Inflam-
mation

In contrast, physicochemically induced inflammation is more common in developed and industrialized countries. The principal manifestation is dermatitis, or eczema. (There is no uniform agreement in the use of the words eczema and dermatitis, but there is an increasing tendency among dermatologists to regard them as synonyms.) Dermatitis is a pathological change in the upper dermis and epidermis that can have many different causes. Contact dermatitis is produced by contact of the skin with physical or chemical agents, including drugs, cosmetics, or even clothing, as well as a wide variety of industrial and domestic products.

With the development of modern immunology, many skin diseases of previously unknown cause have been found to be associated with (though not necessarily caused by) immunologic reactions. Some examples are lupus erythematosus, which may also be systemic; pemphigus, with its crops of blisters; dermatomyositis, an inflammation of the skin and the subcutaneous tissues and muscles; and vasculitis, an inflammation of the vessels in the subcutaneous tissues.

The two well-established types of allergic reaction in the skin are urticaria, or skin eruptions, caused by an immunoglobulin antibody circulating in the blood, and allergic contact dermatitis mediated by lymphocytes. Immunologic reactions are also the mechanisms mostly responsible for inflammatory diseases such as erythema multiforme, erythema nodosum, drug-caused eruptions, the rashes of such infectious fevers as measles and scarlet fever, and reactions to such infections as those of tuberculosis, syphilis, and ringworm.

The normal metabolic activities of the human body may be upset when certain internal organs malfunction and thus bring about a variety of diseases. Manifestations of these diseases may show specific and diagnostic changes in the skin. Cells in the skin alone, moreover, may produce abnormal or excessive amounts of metabolic products such as lipid, mucin, and amyloid, causing pathological skin conditions. A dietary deficiency of protein produces the skin and hair changes of a disease known as kwashiorkor; lack of vitamin A causes a dry skin change called phrynodermia; vitamin B deficiency causes dry, fissured lips and sore tongue; while insufficient dietary vitamin C causes hemorrhages in the skin and horniness around the hair follicles (see also VITAMIN; NUTRITION

Metabolic
disorders

AND DIET, HUMAN; NUTRITIONAL DISEASES AND DISORDERS).

Each of the cell types contributing to the structure of the dermis and epidermis may undergo benign or malignant change. At times the distinctions between nevi and benign and malignant growths are ill-defined and difficult to determine.

Aging in the skin is principally a connective tissue change in the dermis that produces the typical signs. The structural arrangement of the fibres is modified, the tissue becomes less elastic, and its mass diminishes. The changes are greatly enhanced by continued exposure to ultraviolet light and hence are most prominent on the sun-exposed skin of such people as farmers, seamen, and those living in sunny, tropical climates. The changes are much less pronounced in Negro and Mongoloid than in Caucasian skin, and, among Caucasians, less in the skin of brunettes than that of blondes.

THE EPIDERMIS

The upper (outer) part of the dermis and the papillae are so intimately related to the epithelium of the epidermis that they can be regarded as a single **dermo-epidermal unit** in disease processes. The dermis controls and influences the growth of the epidermis, so that the source of pathological change in the epidermis is frequently sought in the dermis.

Congenital abnormalities. Since the principal function of the epidermis is to form the horny layer of keratin, lipid, and other components of the outer skin, disease affecting the epidermis is often characterized by a patchy or generalized disturbance of keratinization. Ichthyosis ("like fish skin"), a genetic disorder in which the horny layer develops visible flakes, is thought to be caused by an enzyme "error" in the synthesis of the keratin layer, probably in the formation of its biomolecular arrangement. The condition may, however, be acquired in association with Hodgkin's disease (a malignant lymphosarcoma), or from treatment with a drug, triparanol, which interferes with lipid metabolism. Hyperkeratosis is the formation of excessive keratin. Thick keratin, or callus, is normal on certain sites, such as the heels, but it may be induced (a callosity) by persistent friction or pressure, often as a result of certain occupations or habits. Examples are to be found on the hands of carpenters, shoemakers, upholsterers. A corn is an impacted mass of keratin caused by pressure over a bony point. An increase of keratin may be the result of a genetic abnormality (**keratoderma**) affecting the palms and soles (and, less commonly, other areas) in varied patterns. One type is associated with cancer of the esophagus. Sometimes the whole epidermis over small or large areas is malformed (an epidermal nevus), producing a rough, heaped-up or warty surface.

To cure the condition surgically, the underlying dermis must be excised at the same time. Seborrhic warts (or basal cell papillomas) are the extremely common flesh coloured or brown-to-black pigmented warty lesions that are found especially on the trunk in middle-aged and older people. They are benign proliferations of the basal cell layer of the epidermis, which contains the **melanocytes** and forms a small, cauliflower-like proliferation containing keratin crypts and cysts. They may be regarded as late-developing nevi.

Dandruff. An extremely common disturbance of normal keratinization is dandruff, in which the rate of cell turnover of the epidermis is uneven and may be as high as two or three times normal, in certain places on the scalp. The horny layers in these areas are irregular and distorted, the keratinocytes being malformed or nucleated (separating in large groups). This irregular horny layer provides a milieu in which normal surface bacteria and yeasts multiply considerably. This condition of the scalp is not considered to be **primarily** infectious because reduction of the organisms by appropriate drugs does not cure it.

Infections. Skin surface normally is never sterile. At birth, or soon after, it becomes populated with bacteria, which all but the most stringent measures fail to remove.

The three main resident organisms on the surface are micrococci, diphtheroids, and the acne bacillus. Transient organisms, in a "carrier state" without inducing an infection, are commonly found in many diseases, such as psoriasis or eczema, in which the horny layer is abnormal.

Pathogenic infective agents may penetrate under the horny layer, often through a small break in the skin, and cause inflammation. Staphylococci and streptococci produce impetigo, in which the bacteria are present with pus cells in blisters filled with serous fluid, covered by the horny layer. Streptococci may spread more extensively and deeper through the skin, producing conditions of erysipelas and cellulitis. These are readily cured with appropriate antibiotics.

Many viruses are epidermotropic; they invade epidermal cells, gaining entrance either from outside, via a breach in the horny layer, or from inside, by way of the bloodstream or even the peripheral nerves. The most common ones are the viruses causing warts and **molluscum contagiosum** ("water warts"). Though most frequent on the hands and feet, including the soles (plantar warts), warts may occur anywhere. When the virus invades the nuclei of epidermal cells it stimulates growth so that a small tumour is produced. These may resolve spontaneously or following psychic influences (by hypnosis or "wart charming"), or may have to be removed or destroyed by physical or chemical means. In western Europe, as well as much of the rest of the civilized world, over the past two decades there has been an enormous increase of warts, and no effective drug has been found to cure them, nor has immunization been successful.

Herpes simplex ("fever blisters," "cold sores") and herpes zoster (shingles) are two virus infections that appear as small clusters of vesicles in which the epidermal cells they invade are killed. But the virus is itself then neutralized by an antibody. Examples of other virus infections are orf ("sheep pox"), milkers' nodes, and hand, foot, and mouth disease.

Fungi and yeasts live preferentially in dead material at temperatures lower than blood heat. The keratinous horny layer is ideally suited and many different species of fungi may infect human skin, producing mild or acute inflammation by their secretions, which diffuse through the epidermis. The ecology of human fungal infections throughout the world is constantly changing. In two decades, for example, infection with *Trichophyton rubrum*, a species of ringworm, has spread westward over the Pacific Ocean and United States and eastward over Asia and Europe from China, where it has been endemic for years. But the discovery and use of the antibiotic griseofulvin, one of the few antifungal antibiotics, has greatly diminished the problem. This drug, when given by mouth, is incorporated into the horny layer during the synthesis of keratin.

For about ten years there has been almost a pandemic of yeast infections with *Candida albicans*. Often a commensal, or symbiotic, type of organism that inhabits the mouth, gut, and vagina, is helped to spread on the skin and mucous membranes by medication with broad-spectrum antibiotics, and corticosteroid and antimitotic drugs: anticandida antibiotics **nystatin** and amphotericin. B, however, are available for treatment.

Parasites. The skin surface is constantly exposed to parasites. Some live on or in the skin (scabies and lice), while most merely feed on it. In scabies ("the itch") the female mite (*Sarcoptes scabiei hominis*) burrows into the horny layer to lay eggs. Most of the itching and rash of scabies is due to an allergic reaction to the mite or its products. An attack does not confer immunity, and large epidemics appear in cycles of about 20 years. Pubic and head lice (*Pthirus pubis* and *Pediculus humanus capitis*) have crablike claws by which they cling to the large hairs and lay their eggs (nits) on them. Body lice (*Pediculus humanus corporis*) live and lay their eggs on woollen clothing. All of these parasites feed by puncturing the skin and sucking blood; the inflammatory papules and excoriations follow this traumatic puncture. Various parasitic worms, especially in tropical countries, may penetrate and live in the skin or pass on through to infest

Herpes infections

Abnormalities of the keratin

other organs. There are numerous other parasites including bedbugs, fleas, mosquitoes, and ticks, which feed on human blood and cause itchy papules when inflammatory agents in their saliva are injected into the skin. They may also be vectors for organisms producing localized skin infections, such as leishmaniasis, or systemic diseases, such as malaria and typhus. There are many effective parasitocidal drugs available for prophylaxis and treatment.

Psoriasis, eczema, and lichen planus. Three important diseases of the dermo-epidermal layer are psoriads, eczema, and lichen planus. Usually, but not always, clinically and histologically distinctive, they do not appear to have a single precise cause but seem to be of multifactorial origin, resulting from an interplay of genetic, environmental, and internal factors. They pursue a fluctuating course, are subject to relapses, are completely reversible and responsive to potent corticosteroid drugs.

Psoriasis

Psoriasis, an ancient disease (probably the biblical leprosy), is a genetic disorder inherited as a dominant trait with incomplete penetrance (it does not always affect individuals who possess the gene). One to two percent of the population in Britain, for example, carry the gene. It may affect any or every part of the skin, the favourite sites being the extensor aspect of the knees and elbows, the scalp and the trunk. The eruption of lesions may be precipitated by physical trauma such as a scratch or wound, streptococcal throat infections, and, on occasion, psychic trauma. It is rare in early childhood and attains peaks of onset in the second and fifth decades of life.

The two distinctive features of its pathology are an increased epidermopoiesis, or epidermal cell turnover (three to four times the normal), and the immigration of polymorphonuclear leukocytes (white blood cells) into the upper layers of the epidermis, forming micro-abscesses and visible pustules if large enough. The capillaries in the dermal papillae are tortuous. The process can be reversed simply by the use of cytotoxic agents, but the mechanisms by which it is controlled or triggered in the first place remain obscure. The disease is usually benefited by sunlight, being worse in winter than summer, and less common on the face and exposed parts, but how ultraviolet light exerts this action is not yet known.

Dermatitis and eczema

As previously mentioned, the terms dermatitis and eczema are increasingly recognized as synonymous. They refer to a pathological change that can be induced in any person's skin and may be precipitated by a variety of causes including trauma, chemical agents, infections, and disorders of metabolism and circulation. Dermatitis is a major skin disease in highly developed countries but almost unknown among the Eskimo of Alaska. Distinctive features of the condition are capillary dilatation and release of fluid, which penetrates between the damaged prickle cells of the epidermis, and swelling and destruction of the epidermal cells to form small vesicles. Normal keratinization is disrupted, so that the horny layer is malformed and allows the leakage of the fluid onto the surface.

Cases of dermatitis are normally classified according to the pattern or arrangement of the disease over the skin surface, apart from contact dermatitis, which occurs at any site where the responsible agent comes into contact. About two-thirds of dermatitis cases can be categorized into contact, atopic, seborrheic, discoid, and varicose patterns. The atopic (from the Greek: "different, strange") pattern is a genetic disorder, inherited as an incomplete dominant (see also ALLERGY AND ANAPHYLACTIC SHOCK). It is frequently associated with asthma, hay fever, and food allergies, all of which, but not the dermatitis, are found in individuals whose serum contains the special immunoglobulin IgE. These people also show physiological abnormalities of their cutaneous vessels and sweat apparatus, and a small number of them develop a type of cataract of the lens in the eye.

Contact dermatitis is the only pattern that can readily be produced experimentally. One type (irritant) results from a direct toxic or damaging action on the epidermal cells by substances such as alkalis, detergents, oils, and solvents; the other type (allergic) occurs only if the indi-

vidual has been sensitized by a previous exposure and has acquired a special cell-mediated immunologic sensitivity to the particular substance (allergen). To induce contact sensitivity such substances, and there are a wide range of them, must form an irreversible covalent bond with a homologous protein or polypeptide. Lymphocytes and macrophage cells in the skin, intact cutaneous lymphatic vessels, and lymph nodes are other essential components in the process. When the contact allergen encounters specifically sensitized lymphocytes in the skin, the changes of dermatitis result. The pharmacodynamic mediators of the reaction are possibly a protein and a prostaglandin hormone, but this is not yet proved. Contact dermatitis is of great importance as a cause of occupational illness and in many countries such industrial dermatitis accounts for more than half the claims for compensation. The common allergens responsible include many metals (nickel, chromium, cobalt, and beryllium), aniline, paraphenylenediamine, and related chemicals containing an amino group in the *para* position on a benzene ring, many drugs and therapeutic substances, additives used in the manufacture of rubber, and synthetic resins, as well as a wide range of natural products, including flowers, shrubs, ivies, balsams and other trees, and turpentine (see also POISONOUS ANIMALS AND PLANTS).

Lichen planus is a common skin disease in Europe, the United States, and West Africa. It is characterized by purplish, flat-topped, angulated papules, arranged singly, in sheets or in rings. It produces similar changes in most of the mucous membranes, in the mouth, and on the genitalia. It is characterized histologically by necrosis of the basal cell layer of the epidermis and a dense, inflammatory infiltrate around it. The only known causes, albeit of only a small percentage of the patients affected, are certain drugs and contact with some colour-film developer chemicals. The usual drugs responsible are organic gold and arsenic salts, atabrine, and amphenazole. During World War II many servicemen developed an especially severe form of lichen planus as a result of taking a daily tablet of atabrine for malarial prophylaxis. The mechanism is almost certainly immunologic, since a further small dose induces a rapid relapse, but there is no evidence that such a mechanism is operative in all individuals affected with lichen planus.

Lichen planus

Cancer. All grades of skin cancer are found among Caucasians living in sunny climates. The principal types are intraepidermal, or cancer in *situ*; basal-cell epithelioma (rodent ulcer); and squamous cell epithelioma. There may be racial differences (basal-cell cancer is rare in the Japanese), and there is sometimes a strong genetic predisposition to its development, as in the mendelian dominant basal-cell nevus syndrome, or the recessive *xeroderma pigmentosum*. Chronic exposure to inorganic arsenic, in the form of medicine, paints, sheep dip, and pesticides, or accidental exposure, causes cancer of both the skin and internal organs. Exposure of the skin to coal tar and its derivatives, or to many mineral oils widely used in the engineering industry, produces grades of skin cancer from "tar warts" to malignant and fatal epitheliomas. Apart from the head and hands and arms, the male genitalia can be affected (scrotal cancer) by oil soaking through the clothing. The minimal period of exposure required is about ten years.

Pigmentation and melanocytes. The pigment-cell system, consisting of basal- and high-level melanocytes of the epidermis, shows only three common types of disease — variations in the production of pigment, nevus proliferation, and malignant growth.

Pigment production by melanocyte cells is a complex biological process. The copper-containing, metallo-enzyme-tyrosinase system is influenced not only by metabolic and hormonal changes in the body but also by local disease in the skin, especially inflammation. The normal stimulus to the enzyme is ultraviolet light of wavelengths 290 to 315 nanometres (billionths of a metre), producing suntan. The response is greatly increased by the ingestion or local application of a group of chemicals called psoralens, which are found in many plant products and are now made synthetically.

Pigment production

Inflammatory diseases in the skin, such as eczema, psoriasis, lichen planus, and infections, as well as trauma to the epidermis, will often induce a temporary increase or decrease of pigmentation. The general control of melanocyte function is by the melanocyte-stimulating hormone secreted by the pituitary gland, and skin-lightening factor (melatonin) secreted by the pineal gland. Diseases of these and other endocrine glands (*e.g.*, Addison's disease and thyrotoxicosis) cause increased or decreased pigmentation by disturbing the normal balance of these hormones. Protein, and therefore tyrosine, deficiency (as in kwashiorkor) or appropriate enzyme deficiency (as in phenylketonuria) will cause decreased melanin formation.

Vitiligo. Loss of pigmentation occurs in vitiligo (leukoderma). This is a common familial disease and is a serious social and cosmetic disability, most particularly in the more pigmented peoples of Asia and Africa. Circumscribed depigmented patches appear and in some cases become confluent over large areas of the body or even universal. The melanocytes lose the capacity to make melanin, but the nature of the cell damage is not known. In some patients the melanocytes can be stimulated to produce pigment again by exposure to ultraviolet light after topical application or internal administration of 8-methoxy psoralen.

Depigmentation

Depigmentation similar to vitiligo can be produced by inhibiting the tyrosinase system with substances such as hydroquinones, 4-isopropylcatechol and p-tertiary butylphenol. Hence, Caucasians can be made as black as Negroes by injections of a melanocyte-stimulating hormone, and Negroes can be made as white as albinos with hydroquinone; but there are hazards associated with such procedures.

Proliferation of melanocytes to form a mole, a melanocyte nevus, is extremely common. They may be flat (macular) or raised (papular), large or small, and all shades of colour from that of normal skin to jet black. They are normally only of cosmetic interest, but their importance is that uncontrolled growth of melanocytes constitutes a malignant melanoma, one of the most dangerous tumours known.

Melanocytes are sometimes found producing melanin pigment in the deeper layers of the dermis. A patch of such cells is normal in Mongoloid babies at birth but much less frequently found in other races. It is called a Mongolian spot or blue nevus. The black melanin pigment appears blue through the skin, in the same way that a tattoo with carbon black looks blue. There is a particular optical relationship between collagen and the pigment that leads to a subtractive colour mixing in the light reflected from the dermis.

Melanin pigment shed by melanocytes or extravascular blood pigment (hemosiderin) or pigment injected by tattoo is engulfed by tissue macrophages or histiocytes, although some may persist free in the dermal tissue. Some of the pigments used by tattooists, in addition to carbon, are insoluble compounds of cobalt, cadmium, and chromium. Occasionally the tattooed person may develop an allergic reaction to one of these metals.

THE DERMIS

The collagen, or elastic fibres of the dermis, may be congenitally malformed and constitute a connective tissue nevus; such nevi are especially associated with a more serious genetic disease called tuberous sclerosis or epiloia, with epilepsy from brain lesions and small papular lesions on the face (adenoma sebaceum). Over-elasticity of the skin, capillary fragility, "double joints," and other genetic abnormalities of the biomolecular organization of this tissue are seen in various conditions called *cutis laxa*, pseudoxanthoma elasticum, and the Ehlers-Danlos syndrome.

Although the dermis may be affected by many types of acute inflammation, the most important type is chronic granulomatous inflammation. A granuloma is formed in the dermis by masses of large epithelioid or histiocytic cells, and often giant multinucleate cells, with varying admixtures of lymphocytes and other inflammatory cells.

Chronic granulomatous inflammation

Granulomas with the histiocytes lined up around the edge are particularly seen in granuloma annulare, a condition that appears as small, beaded papulonodular rings, especially on backs of the hands and fingers. It is frequent in children and often resolves spontaneously. In adults it may be much more widespread and associated with diabetes mellitus. A similar granulomatous change in which the histiocytes contain large quantities of fat is found in xanthoma lipoidica, which appears as papular, and later atrophic, plaques on the shins, usually in individuals with diabetes mellitus. A third variety of palisaded granuloma comprises the large dermal rheumatoid nodules, mostly over bony prominences, in patients with rheumatoid arthritis.

Granulomas without palisading of the histiocytes may be produced as a reaction to any foreign body or abnormal material in the dermis but are more often caused by allergy or hypersensitivity to infective or chemical agents. Some of the diseases in which these reactions appear are tuberculosis, syphilis, leprosy, deep mycoses, leishmaniasis, lymphogranuloma, and sarcoid. They are also seen as a result of sensitization to such chemical substances as beryllium and zirconium, or of sensitization by colloidal silica.

Injury and inflammation may result in scarring—fibrosis of the connective tissue fibres. It can involve excessive production of fibrous tissue that may be temporary (hypertrophic scar or "proud flesh") or long lasting, as a keloid.

After about age 20 the dermal connective tissue undergoes changes in its fibre configuration, making it less extensible. This change is progressive and accompanied by atrophy as senescence progresses. Similar alterations are produced by corticosteroid drugs and sometimes, to a lesser degree, by increased secretions of certain adrenal hormones during puberty and pregnancy, as a result of which any severe stretching of the skin causes small breaks in the fibres seen as purplish streaks ("striae atrophicae") on the hips, abdomen, back, and axillary folds. The changes are usually not reversible.

The connective tissue of the dermis is affected in important and related diseases—lupus erythematosus, scleroderma, and dermatomyositis. Each of these diseases has its principal manifestations in the skin, although each affects internal organs as well, and it is the progressive involvement of the internal organs that may prove fatal. Scleroderma ("hard skin") is more frequently seen as localized patches of indurated, waxy skin, harmless, and resolving spontaneously. Lupus erythematosus also occurs more often as fixed red, scaly patches with much dilatation of the blood vessels, especially over the face, and may resolve spontaneously, or with treatment, over several years. But the systemic forms of scleroderma, lupus erythematosus, and dermatomyositis are serious diseases with a mortality rate of about 50 percent. All three occur more frequently in women than in men. Scleroderma is associated with Raynaud's disease—arterial spasm in the fingers, which go white and anaesthetic ("dead fingers") in response to cold. Dermatomyositis mainly involves the skin and muscles, and in such patients over age 40, more than half are found to have some form of internal cancer.

Connective tissue diseases

Pathologically, the main changes in these diseases are in the dermis and the blood vessels. In scleroderma, the fibres are normal, but the ground substance is thickened so that the dermis appears to be expanded in depth and homogenized. In lupus erythematosus the upper dermis is edematous—*i.e.*, contains much extracellular fluid—and has a thickened basement membrane, while the basal cells of the epidermis may degenerate and die. In dermatomyositis the edema fluid contains mucin, the chief constituent of mucus. In all three there is varying infiltration of lymphocytic cells accompanied by damage to small blood vessels.

These three diseases, once grouped together as so-called collagen or connective tissue disease, are now regarded as autoimmune diseases. The affected individuals are found to have various types of auto-antibodies in their blood, the most important being the antinuclear factor.

Metabolic disorders

Metabolic disorders may result in the deposition of excess materials in the dermis and cause visible disease. Uric acid salts are deposited in gout, calcium salts in calcinosis, lipids in xanthomatosis, an abnormal protein in amyloidosis, mucin in myxedema, and porphyrins in porphyria. The appearances of the skin are usually sufficiently characteristic to be diagnostic.

One manifestation of the presence of excess porphyrins (as a result of abnormal metabolism in the bone marrow or the liver) is abnormal sensitivity to ultraviolet light, which causes small blisters on the skin. The wavelength responsible is 400 nanometre, the peak absorption band for porphyrin. Photosensitivity of the skin has become more common in recent years. Apart from porphyria and certain idiopathic (*i.e.*, of unknown cause) light-provoked rashes, the most important causative agents are photosensitizing drugs, such as sulfonamides (antibacterial), phenothiazines (psychotropic), thiazides (diuretics), sulfonyl ureas (hypoglycemic), halogenated salicylanilides (germicidal), and nalidixic acid (urinary antiseptic). After exposure to ultraviolet light, patients taking these drugs may develop redness, swelling, or blisters on the exposed parts.

The blood vessels. Dermal blood vessels are involved in many skin diseases. They can be malformed in various ways, producing hemangiomas or vascular nevi. They control temperature by dilatation and contraction, but this control may be disturbed in patients with Raynaud's disease (episodic spasm of digital arteries) and chilblains.

The dermal vessels will dilate and may release plasma, white blood cells, or red cells in response to inflammation from any cause—physical, chemical, or immunological. The vessel walls themselves may be damaged in a disease process. Vasodilatation and edema with inflammatory cells is found in erythemas of many types such as rosacea on the face, erythema nodosum and erythema multiforme on the limbs, urticaria, purpura, and vasculitis. The individual areas are usually small, making up a rash of scattered macules, papules, or nodules. Many of the infectious fevers, such as scarlatina, measles, and secondary syphilis, are of this type. But many widespread red, scaly rashes have no precisely identifiable cause, although they produce recognizable patterns, such as pityriasis rosea (reddish branny scales) or annular erythemas (red or pink rings).

The hair and pilo-sebaceous follicles. The hair follicles with their sebaceous glands are special invaginations of the epidermis and dermis, so that the formation of hair is similar to that of the horny layer. Although the epidermis grows and produces a horny layer continuously, each hair follicle has a cyclical growth pattern. A scalp hair grows for about three years and then the follicle rests for about three months before producing a new hair. This hair cycle may be interfered with by many types of local disturbance such as trauma, inflammation, or vascular insufficiency; and by general factors such as nutritional deficiencies, excesses of certain types of radiation, some drugs, major internal diseases, prolonged high fever, and metabolic changes. Severe infective illnesses like typhoid frequently cause the hair to involute and rest for about three months, after which it rapidly falls out as the new hairs start to grow. The commonest drugs to cause a diffuse hair loss are anticoagulants and antimetabolic agents used for the treatment of malignant disease and after transplantation surgery.

The process of production of hair by a follicle is complicated, and there are a wide variety of genetic disorders in any one of which one facet may be faulty, resulting in a sometimes, but not always, remediable hair abnormality. Examples are beaded hair (monilethrix), ringed hair (pili annulati), and twisted hair (pili torti).

There are different types of hair follicles over the body surface producing variations from the fine and almost invisible lanugo (downy) hair to the large coarse scalp, pubic, and male beard hair. The two main factors that influence the type of hair are genetic and hormonal. Androgen production at puberty produces both a change from straight to V-shaped in the forehead hairline in boys, as well as the development of coarse beard, axil-

lary, pubic, and body hair. The common type of male-pattern baldness (alopecia) on the scalp may start at any time after puberty as recession at the temples and thinning over the crown. It is produced by the male hormone, testosterone, acting on genetically predisposed follicles. The follicles are not destroyed but gradually regress to the stage of those producing small lanugo hairs.

Patches of hair loss are due to localized disease affecting the hair follicles. The commonest in alopecia areata, in which the hair roots are the site of inflammation, but ringworm infections, by proliferating in the hair shaft, cause the hair to break off and fall out. These changes are normally reversible, but the hair roots may be permanently damaged and scarred by some skin diseases such as lichen planus, lupus erythematosus, and scleroderma and by excessive X-irradiation. One of the most important diseases of the hair and sebaceous gland units (the pilosebaceous follicles) is acne vulgaris. The clinical signs are blackheads (comedones), papules, pustules, cysts, and scars, together with excessive oiliness of the skin (seborrhea). The effects are produced in both boys and girls by androgenic hormones (produced in the testes and adrenal glands at puberty) acting on susceptible follicles in the so-called acne areas—the face, chest, and back. How the effect is produced on the follicle is not precisely known. The sebaceous gland enlarges and the follicle wall becomes damaged and its opening blocked. Once occluded, the gland and follicle keratinize to form a horny cyst. If anaerobic organisms (principally the acne bacilli—*Corynebacterium* or *Propionibacterium acnes*) are trapped in the cyst, they metabolize the sebum to produce irritant fatty acids. These acids cause inflammation and abscesses, which eventually resolve and may leave scars. The most valuable forms of treatment are ultraviolet light, desquating local applications, and the systemic administration of tetracycline antibiotics.

It is possible for similar changes to be brought on in pilosebaceous follicles on any area of skin by contact with bromides and iodides, mineral oils, tar and pitch, chlorinated naphthalenes and chlorodiphenyls, as a result of either external or systemic exposure.

Sweat glands. The eccrine sweat glands (*i.e.*, exocrine sweat glands as opposed to the apocrine, in which the secretions are concentrated at the free end of the cell and thrown off with that part of the cell) are under the control of the autonomic nervous system and produce sweat as a result of three types of stimuli. First, there is a normal low-grade secretion by all the glands of "insensible" perspiration amounting to about half a litre (about a pint) per day. Second, there is thermal sweating, in which a rise of temperature will induce all the glands to increase secreting. Third, emotional stimuli produce increased secretion from the glands on the forehead, palms and soles, in the armpits and around the anogenital area. Inability to secrete adequate sweat (anhidrosis) is usually a congenital abnormality. Hyperhidrosis is the abnormal excessive secretion of sweat, usually on the palms and soles and in the axillae.

Prickly heat (miliaria) results from the occlusion of the sweat pore openings as a result of maceration and blockage in a hot, humid climate. The gland continues to secrete and the pressure may rupture the sweat duct at its junction with the epidermis, resulting in spillage of sweat into the epidermis with consequent inflammation.

Nails. A nail is formed by an invagination of the skin, similar to that forming a hair follicle. The specialized area of dermis and epidermis produces a type of hard keratin with a higher proportion of sulfur-containing amino acids.

Like the rest of the skin or the hair follicle, the nail matrix may be congenitally abnormal and produce many varieties of malformed nails, as for example pachyonychia congenita (thickened nails). The matrix may also be the site of trauma and produce a deformed nail; the damage may be temporary or permanent.

The most common causes of diseased nails are chronic paronychia—an inflammation resulting from loss of the thin cuticle from exposure to water and alkalis—fungus infections, trauma, psoriasis, impaired circulation, and

Acne vulgaris

Temporary hair loss

Chronic paronychia

dermatitis. Chronic paronychia is an occupational hazard of dishwashers, barmaids, and vegetable preparers. When the cuticle is lost, water, bacteria, and yeasts seep under the nail fold and cause inflammation.

Fungi can infiltrate the nail plate itself and disrupt its structure, causing variable degrees of deformity, but generally resulting in thickening and crumbling of the plate. Psoriasis frequently affects the nails. The most common change is a thimble-like pitting on the surface, but separation of the plate from the nail bed (onycholysis) and thickening are also seen.

Any disease of the skin, such as dermatitis, lichen **planus**, or psoriasis and chilblains, and other forms of interference with the blood supply, may also affect the nail matrix and produce irregular growth of the nails.

Quite apart from specific diseases, variations from the normal pattern are frequently seen—white patches, splitting of the tips, brittleness, ridging, curvature, and other minor abnormalities too numerous to mention.

Slang

Difficult to define, slang consists basically of unconventional words or phrases that express either something new or something old in a new way. It is **flippant**, **rt**, **indecorous**; it may be indecent or obscene. Its **colourful** metaphors are **generally** directed at respectability, and it is this succinct, sometimes witty, frequently impertinent social criticism that gives slang its characteristic flavour. Slang, then, includes not just words but words used in a special way in a certain social context. The origin of the word slang itself is obscure; it first appeared in print around 1800, applied to the speech of disreputable and criminal classes in London. The term, however, was probably used much earlier. Other related types of non-standard word usage include cant and jargon, synonyms for vague and high-sounding or technical and esoteric language not immediately intelligible to the uninitiate. In England, the term cant still indicates the specialized speech of criminals, which, in the United States, is more often called argot. The term dialect refers to language characteristic of a certain geographic area or social class.

The development of slang. Slang emanates from conflicts in values, sometimes superficial, often fundamental. When an individual applies language in a new way to express hostility, ridicule, or contempt, often with sharp wit, he may be creating slang, but the new expression will perish unless it is picked up by others. If the speaker is a member of a group that finds that his creation projects the emotional reaction of its members toward an idea, person, or social institution, the expression will gain currency according to the unanimity of attitude within the group. A new slang term is usually widely used in a subculture before it appears in the dominant culture. Thus slang—e.g., "sucker," "honkey," "shave-tail," "jerk"—expresses the attitudes, not always derogatory, of one group or class toward the values of another. Slang sometimes stems from within the group, satirizing or burlesquing its own values, behaviour, and attitudes; e.g., "shot-gun wedding," "cake eater," "greasy spoon." Slang, then, is produced largely by social forces rather than by an individual speaker or writer who, single-handed (like Horace Walpole, who coined "serendipity" more than 200 years ago), creates and establishes a word in the lan-

guage. This is one reason why it is difficult to **determine** the origin of slang terms.

Creators of slang. Civilized society tends to divide into a dominant culture and various subcultures that flourish within the dominant framework. The subcultures show specialized linguistic phenomena, varying widely in form and content, that depend on the nature of the groups and their relation to each other and to the dominant culture. The shock value of slang stems largely from the verbal transfer of the values of a subculture to diametrically opposed values in the dominant culture. Names such as fuzz, pig, fink, bull, and dick for policemen were not created by officers of the law. (The humorous "dickless Tracy," however, meaning a policewoman, was coined by male policemen.)

Occupational groups are legion, and while in most respects they identify with the dominant culture, there is just enough social and linguistic hostility to maintain group solidarity. Terms such as scab, strike-breaker, **company-man**, and goon were highly charged words in the era in which labour began to organize in the United States; they are not used lightly even today, though they have been taken into the standard language.

In addition to occupational and professional groups, there are many other types of subcultures that supply slang. These include sexual deviants, narcotic addicts, ghetto groups, institutional populations, agricultural sub-societies, political organizations, the armed forces, Gypsies, and sports groups of many varieties. Some of the most fruitful sources of slang are the subcultures of professional criminals who have migrated to the New World since the 16th century. Old-time thieves still humorously refer to themselves as **FFV—First Families of Virginia**.

In criminal subcultures, pressure applied by the dominant culture intensifies the internal forces already at work, and the argot forming there emphasizes the values, attitudes, and techniques of the subculture. Criminal groups seem to evolve about this specialized argot, and both the subculture and its slang expressions proliferate in response to internal and external pressures.

Sources. Most subcultures tend to draw words and phrases from the contiguous language (rather than creating many new words) and to give these established terms new and special meanings; some borrowings from foreign languages, including the American Indian tongues, are traditional. The more learned occupations or professions like medicine, law, psychology, sociology, engineering, and electronics tend to create true neologisms, often based on Greek or Latin roots, but these are not major sources for slang, though nurses and medical students adapt some medical terminology to their slang, and air force personnel and some other branches of the armed services borrow freely from engineering and electronics.

Linguistic processes forming slang. The processes by which words become slang are the same as those by which other words in the language change their form or meaning or both. Some of these are the employment of metaphor, simile, folk etymology, distortion of sounds in words, generalization, specialization, clipping, the use of acronyms, elevation and degeneration, metonymy, synecdoche, hyperbole, borrowings from foreign languages, and the play of euphemism against taboo. The English word trip is an example of a term that has undergone both specialization and generalization. It first became specialized to mean a psychedelic experience resulting from the drug LSD. Subsequently, it generalized again to mean any experience on any drug, and beyond that to any type of "kicks" from anything. Clipping is exemplified by the use of "grass" from "laughing grass," a term for marijuana. "Funky," once a very low term for body odour, has undergone elevation among jazz buffs to signify "the best"; "fanny," on the other hand, once simply a girl's name, is currently a degenerated term that refers to the buttocks (in England, it has further degenerated into a taboo word for the female genitalia). There is also some actual coinage of slang terms.

Characteristics of slang. Psychologically, most good slang harks back to the stage in human culture when animism was a worldwide religion. At that time, it was

The specialized languages of sub-cultures

Primitive
origins
of slang

believed that all objects had two aspects, one external and objective that could be perceived by the senses, the other imperceptible (except to gifted individuals) but identical with what we today would call the "real" object. Human survival depended upon the manipulation of all "real" aspects of life—hunting, reproduction, warfare, weapons, design of habitations, nature of clothing or decoration, etc.—through control or influence upon the animus, or imperceptible phase of reality. This influence was exerted through many aspects of sympathetic magic, one of the most potent being the use of language. Words, therefore, had great power, because they evoked the things to which they referred.

Civilized cultures and their languages retain many remnants of animism, largely on the unconscious level. In Western languages, the metaphor owes its power to echoes of sympathetic magic, and slang utilizes certain attributes of the metaphor to evoke images too close for comfort to "reality." For example, to refer to a woman as a "broad" is automatically to increase her girth in an area in which she may fancy herself as being thin. Her reaction may, thus, be one of anger and resentment, if she happens to live in a society in which slim hips are considered essential to feminine beauty. Slang, then, owes much of its power to shock to the superimposition of images that are incongruous with images (or values) of others, usually members of the dominant culture. Slang is most popular when its imagery develops incongruity bordering on social satire. Every slang word, however, has its own history and reasons for popularity. When conditions change, the term may change in meaning, be adopted into the standard language, or continue to be used as slang within certain enclaves of the population. Nothing is flatter than dead slang. In 1910, for instance, "Oh you kid" and "23-skiddoo" were quite stylish phrases in the U.S. but they have gone with the hobble skirt. Children, however, unaware of anachronisms, often revive old slang under a barrage of older movies rerun on television.

Some slang becomes respectable when it loses its edge; "spunk," "fizzle," "spent," "hit the spot," "jazz," "funky," and "p.o.d." once thought to be too indecent for feminine ears, are now family words. Other slang survives for centuries, like "bones" for dice (Chaucer), "beat it" for run away (Shakespeare), "duds" for clothes, and "booze" for liquor (Dekker). These words must have been uttered as slang long before appearing in print, and they have remained slang ever since. Normally, slang has both a high birth and death rate in the dominant culture, and excessive use tends to dull the lustre of even the most colourful and descriptive words and phrases. The rate of turnover in slang words is undoubtedly encouraged by the mass media, and a term must be increasingly effective to survive.

While many slang words introduce new concepts, some of the most effective slang provides new expressions—fresh, satirical, shocking—for established concepts, often very respectable ones. Sound is sometimes used as a basis for this type of slang, as, for example, in various phonetic distortions (e.g., pig Latin terms). It is also used in rhyming slang, which employs a fortunate combination of both sound and imagery. Thus, gloves are "turtledoves" (the gloved hands suggesting a pair of billing doves), a girl is a "twist and twirl" (the movement suggesting a girl walking), and an insulting imitation of flatus, produced by blowing air between the tip of the protruded tongue and the upper lip, is the "raspberry," cut back from "raspberry tart." Most slang, however, depends upon incongruity of imagery, conveyed by the lively connotations of a novel term applied to an established concept. Slang is not all of equal quality, a considerable body of it reflecting a simple need to find new terms for common ones, such as the hands, feet, head, and other parts of the body. Food, drink, and sex also involve extensive slang vocabulary. Strained or synthetically invented slang lacks verve, as can be seen in the desperate efforts of some sportswriters to avoid mentioning the word baseball—e.g., a batter does not hit a baseball but rather "swats the horsehide," "plasters the pill," "hefts the old apple over the fence," and so on.

Transience
and
persistence

The most effective slang operates on a more sophisticated level and often tells something about the thing named, the person using the term, and the social matrix against which it is used. Pungency may increase when full understanding of the term depends on a little inside information or knowledge of a term already in use, often on the slang side itself. For example, the term Vatican roulette (for the rhythm system of birth control) would have little impact if the expression Russian roulette were not already in wide usage.

Diffusion of slang. Slang invades the dominant culture as it seeps out of various subcultures. Some words fall dead or lie dormant in the dominant culture for long periods. Others vividly express an idea already latent in the dominant culture and these are immediately picked up and used. Before the advent of mass media, such terms invaded the dominant culture slowly and were transmitted largely by word of mouth. Thus a term like snafu, its shocking power softened with the explanation "situation normal, all fouled up," worked its way gradually from the military in World War II by word of mouth (because the media largely shunned it) into respectable circles. Today, however, a sportscaster, news reporter, or comedian may introduce a lively new word already used by an *ingroup* into millions of homes simultaneously, giving it almost instant currency. For example, the term uptight was first used largely by criminal narcotic addicts to indicate the onset of withdrawal distress when drugs are denied. Later, because of intense journalistic interest in the drug scene, it became widely used in the dominant culture to mean anxiety or tension unrelated to drug use. It kept its form but changed its meaning slightly.

Other terms may change their form or both form and meaning, like "one for the book" (anything unusual or unbelievable). Sportswriters in the U.S. borrowed this term around 1920 from the occupational language of then legal bookmakers, who lined up at racetracks in the morning ("the morning line" is still figuratively used on every sports page) to take bets on the afternoon races. Newly arrived bookmakers went to the end of the line, and any bettor requesting unusually long odds was motioned down the line with the phrase, "That's one for the end book." The general public dropped the "end" as meaningless, but old-time gamblers still retain it. Slang spreads through many other channels, such as popular songs, which, for the initiate, are often rich in double entendre.

When subcultures are structurally tight, little of their language leaks out. Thus the Mafia, in more than a half-century of powerful criminal activity in America, has contributed little slang. When subcultures weaken, contacts with the dominant culture multiply, diffusion occurs, and their language appears widely as slang. Criminal narcotic addicts, for example, had a tight subculture and a highly secret argot in the 1940s; now their terms are used freely by middle class teen-agers, even those with no real knowledge of drugs.

Uses of slang. Slang is used for many purposes, but generally it expresses a certain emotional attitude; the same term may express diametrically opposed attitudes when used by different people. Many slang terms are primarily derogatory, though they may also be ambivalent when used in intimacy or affection. Some crystallize or bolster the self-image or promote identification with a class or *ingroup*. Others flatter objects, institutions, or persons but may be used by different people for the opposite effect. "Jesus freak," originally used as ridicule, was adopted as a title by certain street evangelists. Slang sometimes insults or shocks when used directly; some terms *euphemize* a sensitive concept, though obvious or excessive euphemism may break the taboo more effectively than a less decorous term. Some slang words are essential because there are no words in the standard language expressing exactly the same meaning; e.g., "freakout," "barn-storm," "rubberneck," and the noun "creep." At the other extreme, multitudes of words, vague in meaning, are used simply as fads.

There are many other uses to which slang is put, according to the individual and his place in society. Since most

emotional
attitudes

slang is used on the spoken level, by persons who probably are unaware that it is slang, the choice of terms naturally follows a multiplicity of unconscious thought patterns. When used by writers, slang is much more consciously and carefully chosen to achieve a specific effect. Writers, however, seldom invent slang.

It has been claimed that slang is created by ingenious individuals to freshen the language, to vitalize it, to make the language more pungent and picturesque, to increase the store of terse and striking words, or to provide a vocabulary for new shades of meaning. Most of the originators and purveyors of slang, however, are probably not conscious of these noble purposes and do not seem overly concerned about what happens to their language.

Attitudes towards slang. With the rise of naturalistic writing demanding realism, slang began to creep into English literature even though the schools waged warfare against it, the pulpit thundered against it, and many women who aspired to gentility and refinement banished it from the home. It flourished underground, however, in such male sanctuaries as lodges, poolrooms, barbershops, and saloons.

By 1925 a whole new generation of U.S. and European naturalistic writers was in revolt against the Victorian restraints that had caused even Mark Twain to complain, and today any writer may use slang freely, especially in fiction and drama. It has become an indispensable tool in the hands of master satirists, humorists, and journalists. Slang is now socially acceptable, not just because it is slang but because, when used with skill and discrimination, it adds a new and exciting dimension to language. At the same time, it is being seriously studied by linguists and other social scientists as a revealing index to the culture that produces and uses it.

Slang in English-speaking areas. In looking at slang in the English-speaking world, authorities see not only a strong historical tradition for the production and use of slang but also conditions fertile for its continued growth. There are, for example, strong dominant cultures within which there have been powerful vertical movements of people into the middle class; large blocks of foreign immigrants, along with a multitude of the subcultures mentioned earlier; and, most important, channels of communication with foreign cultures and subcultures and an established language that has long proved its ability to absorb and utilize slang. There is, furthermore, a solid literary tradition hospitable to slang, some terms tending to become part of the literary language.

England. England may indeed be the mother of slang wherever English is spoken, not only because of centuries of production but also because of the wide distribution of Englishmen throughout the world. Today, however, British slang is distinctive and tends to be insular. It has absorbed much lively material from Irish, Scottish, and Welsh speech forms, as well as foreign terms from the more recent immigration of Asians, Africans, and West Indians. Some of these expressions were well established abroad during the colonial period. Within the present generation there has been a large-scale invasion of American slang (decried by some Britishers), largely derived from criminal sources. Perhaps the leading domestic source is the colourful speech of the Cockneys of London.

More recently developed British subcultures, not far removed from that of the Cockneys, and hostile to either the Establishment or to other nonconformist subcultures or both, are the Mods, Teddy-boys, Rockers, and Suedeheads, or Skinheads. In addition, drug addiction increased dramatically in the 1960s, with a concentration in younger age groups. Each of these subcultures has developed its own special characteristics, particularly its life-style, and language; some of their expressions may flavour British slang in the future.

Australia. In Australia, still a frontier country, slang is in lively production. Because it was heavily settled by transported convicts until 1868, it still preserves many terms from 18th- and 19th-century British criminal usage, especially rhyming slang, which may be somewhat archaic in Britain today. There are also many adaptations

of words from native aboriginal languages, together with earthy metaphors originated by the sundowners, swagmen, and drovers in the bush, the Australian versions of hoboes, itinerant workers, and cattle and sheep drivers. The larrikins who constitute the city street gangs also contribute a steady stream of urban slang to a language that is, perhaps, about to reach its literary maturity.

Canada and the United States. Canada and the United States share a great body of common slang, though there are differences. Canada, for instance, still has close ties with England, and much more British slang finds its way, both via print and the spoken word, into Canada than into the United States. Further, Canada is a bilingual country and more French slang filters into Canadian English than into British English; this French is different in nature from continental French and its slang vocabulary is little known or used in France. There are also more terms of Indian and Eskimo origin than appear in slang in the United States. In addition, large blocks of only partially assimilated immigrants from Scandinavia and central Europe, as well as from Scotland, England, and Ireland, still exist. Sizable urban enclaves in the areas of Vancouver, the Toronto-Detroit-Buffalo triangle, and Montreal have both occupational and criminal subcultures feeding slang into the dominant culture. For many reasons, native slang does not have the currency in journalism and literature that it enjoys in the United States.

Slang in European languages. Several other European languages that, during the past, have contributed considerably to British and especially to American slang have well-developed slang systems of their own.

Spanish. Spain, with a long picaresque tradition in both life and literature, absorbed much argot from criminal subcultures into the printed language beginning in the 16th century. Cervantes, like Shakespeare, knew slang and used it well. This slang, along with the subcultures producing it, spread to the New World and proliferated through all Spanish settlements, with usage in each country developing along somewhat different lines. Modern continental Spanish slang is heavily indebted to the large indigenous Gypsy population. England was influenced most by continental Spanish, the United States by Caribbean, and especially Mexican, slang. Today, while Mexican slang contains some archaic Spanish terms, it is heavily dominated by *caló* (a semicriminal argot) and contains many aboriginal words, creations based on American English, and terms originated by the Pachucos, Mexican-American youths along the Mexican border. This is the Spanish slang, along with that of Cuban and Puerto Rican enclaves in many American cities, that most influences American usage today. Frequently it is clipped or anglicized so that it is not readily recognized as Spanish, as in the case of "pot" (marijuana, itself a *caló* word) from *potiguaya*, in turn cut back from *potacín de guaya* (a strong intoxicant made of ripe cannabis seedpods soaked in wine or brandy).

French. French has a long tradition of slang production. There are, for example, criminal subcultures in Marseille that probably date back to the days of Roman colonialism. Slang today is as popular with literary men as it is with the man in the street. Recent immigration from Algeria has coloured French slang heavily. As in most other European cultures, the Gypsies continue to contribute to slang. Under the policing of the French Academy, backed during the 1960s by General DeGaulle, there was an official campaign, largely unsuccessful, to bar American slang from the French language. While French formerly contributed some words to American slang, and even more to British slang, it adds little today.

Italian. The Italians, especially urban Italians, are major makers of slang for home consumption. Sicily, however, has contributed the secret argot of the Mafia, which exists both in Italy and in the United States but remains largely secret in both countries, though Italian police have attempted to study it. Italians borrow freely from the slang terms of other European languages and, since World War II, from American slang, which is still popular in Italy though officially deplored.

Romanian. Romania, once a Roman prison colony,

Slang in literature

Mexican slang

Preservation of British terms in Australian slang

has a rich slang heritage, particularly from the Gypsies, who are numerous. In addition, Romania's policy of giving Gypsies work permits and gradually incorporating them into the dominant culture promises to encourage a wider infusion of Romany terms into the standard language. From the Balkans to Scandinavia, older Gypsy terms have heavily infiltrated criminal argots and general slang.

German. In German, where *Hochdeutsch* (High German) dominates the standard language, slang has little recognition in literature, though many colourful idioms exist in the several regional dialects, and among males of the dominant culture there is an *arschloch-humor* (anal humour), which is primarily scatological and remains on a spoken level. Yiddish, on the other hand, is rich in colourful metaphor and, in larger cities like Hamburg and Berlin, established a place for itself in theatrical and literary usage before World War I. Although German proper has contributed little to slang in other languages, Yiddish, with its roots in Middle High German, has put many terms into international circulation. German scholars have given close attention to the collection and analysis of older traditional nonstandard language usage under the categories of *Gaunersprache* and *Rotwelsch*, which are criminal argots; in fact, Martin Luther gave Europe one of its first German compilations of the language of Gypsies, fake friars, wandering Jews, and rogues in the preface of the *Liber Vagatorum* (1528; "Book of Vagabonds").

(D.W.M.)

BIBLIOGRAPHY. The transiency of most slang makes compiling a bibliography difficult. Otherwise undistinguished fiction may show certain varieties with high comprehension and sensitivity; almost any Sunday newspaper supplement may have a casual report on the usage of some currently newsworthy subculture; many studies, such as the PETER TAMONY series, *Americanisms: Content and Continuum*, 2 vol. (1969), may be known only to the professional scholar.

The most comprehensive critical bibliography is provided by DAVID W. MAURER in his updating of H.L. MENCKEN, *The American Language*, 4th ed. abridged, ch. 11 (1963); useful also are the quarterly bibliographies in *American Speech*.

For English, *Slang and Its Analogues*, 7 vol. (1890-1904, reprinted in 3 vol., 1970), by JOHN S. FARMER and WILLIAM ERNEST HENLEY, is still the most comprehensive work. More contemporary but less careful are various works by ERIC PARTRIDGE, notably *A Dictionary of Slang and Unconventional English*, 7th ed. rev. (1970), and *A Dictionary of the Underworld*, 3rd ed. (1968). FRANCIS GROSE, *A Classical Dictionary of the Vulgar Tongue* (1785; ed. with notes by PARTRIDGE, 1931, reprinted 1968), is an historical landmark; more specialized is JULIAN FRANKLYN, *Dictionary of Rhyming Slang*, 2nd ed. (1975). For American slang the only dictionary of consequence is that of HAROLD W. WENTWORTH and STUART BERG FLEXNER (eds.), *Dictionary of American Slang*, 2nd supplemented ed. (1975). More specialized are ROBERT S. GOLD, *A Jazz Lexicon* (1964, reissued 1980); DON B. WILMETH, *The Language of American Popular Entertainment* (1981); and HYMAN E. GOLDIN, FRANK O'LEARY, and MORRIS LIPSUS (eds.), *Dictionary of American Underworld Lingo* (1950). DAVID W. MAURER has provided many studies of specialized argots, as in *The Big Con* (1940), *The Argot of the Racetrack* (1951), *Whiz Mob* (1955), and, with VICTOR H. VOGEL, *Narcotics and Narcotic Addiction*, 4th ed. (1973). For Canadian slang, see MARK M. ORKIN, *Speaking Canadian English* (1970); and WALTER S. AVIS, *A Bibliography of Writings on Canadian English 1857-1965* (1965); for that of Australia and New Zealand, see SIDNEY J. BAKER, *The Australian Language* (1945, reissued 1978), *The Drum: Australian Character and Slang* (1960), and *New Zealand Slang* (1941); and G.W. TURNER, *The English Language in Australia and New Zealand*, 2nd ed. (1972).

Comprehensive treatments of slang in other languages are even rarer than those in English. For French, see GEORGE SANDRY and MARCEL CARRERE, *Dictionnaire de l'argot moderne* (1953); and FRANÇOIS CARADEC, *Dictionnaire du français argotique et populaire* (1977). Less comprehensive is CARLA PEKELIS, *A Dictionary of Colorful Italian Idioms* (1965). Depending on their orientation, most introductions to linguistics or to modern English have some discussion of the origin and significance of slang.

(S.B.F./R.McD.)

Slavery, Serfdom, and Forced Labour

The feature common to all forms of servitude surveyed in this article is the social sanction that permits one person

or group to compel the involuntary labour of another person or group. In all cases the bonded individual—whether slave, serf, indentured servant, or otherwise—is obliged to perform personal service for his lord or master under conditions that make him socially inferior and are restrictive of his freedom of action.

Certain forms of service, actually or allegedly involuntary, are not included within the range of this article. Military conscription, including impressment, is excluded because it rests on the age-old principle that every able-bodied citizen owes military service, however socially unequal the method of his selection. Metaphorical or extended uses of the term slave are also avoided. The expression wage slave, for instance, was used by Marxists in reference to labourers under capitalism and by U.S. slaveholders in the antebellum South to refer to Northern industrial labourers. Advocates of democracy have sometimes attributed slavery to citizens of totalitarian states.

The article is divided into the following sections:

- I. Forms of involuntary servitude
 - Slavery
 - Contract labour
 - Serfdom
 - Corvée, or statute, labour
- II. Slavery in antiquity
 - The ancient Near East
 - Greece and Rome
- III. Servitude in ancient India and China
 - Slavery and the caste system in India
 - Slavery and peasant serfdom in China
 - The peasantry in Japan
- IV. Servitude in Muslim lands and Europe
 - The persistence of slavery
 - European serfdom
- V. Early modern plantation slavery
 - Introduction and development of slavery in the New World
 - Antislavery movements in the Western Hemisphere
- VI. Forced labour in the late 19th and the 20th centuries
 - Early international efforts to suppress slavery and forced labour
 - Forced labour in modern states
 - The United Nations and the ILO

I. Forms of involuntary servitude

SLAVERY

A slave is one who is owned by another and deprived of most or all rights and freedoms, hence the term chattel slave, denoting personal property at law. The slave is dependent on the whim of the owner, who may generally force him to any service and, at least in principle, may usually even dispose of his life. The term slavery, however, does embrace differing degrees of social status. Slaves in ancient Rome, for instance, could be educated and often could acquire property and the means of buying their freedom. Black slaves in the antebellum South, on the other hand, were expressly forbidden by law to receive an education or acquire property and thus could rarely attain on their own the means to buy their freedom. Very possibly the most extreme form of slavery was represented by the *Sklavenarbeiter*, or slave labourers, of Nazi Germany—Jews, Slavs, and other conquered peoples who, unlike most slaves, were often not even cared for as valued capital. As one survivor reported,

We were not slaves; our status was much lower. True, we were deprived of freedom and became a piece of property which our masters put to work. But here the similarity with any known form of slavery ends, for we were a completely expendable piece of property... The equipment in the shop was well maintained. It was operated with care, oiled, greased and allowed to rest; its longevity was protected. We, on the other hand, were like a piece of sandpaper which, rubbed once or twice, becomes useless and is thrown away to be burned with the waste.

(W. Manchester, *The Arms of Krupp*, Little, Brown, 1968, p. 522)

Origins of slavery. Explanations of the origins of slavery are necessarily speculative, constituting post hoc rationalizations. It would seem, however, that, through the hunting and food-gathering stages of civilization, slavery probably was unknown; the hunter or food gatherer sim-

of
slavery

Effects of
pastoral-
ism and
agriculture

ply would have had no use for a slave, who would have been **more** of a burden than an asset for his master, as he would have been an additional mouth to feed. This reasoning seems to be supported by the fact that such hunters' societies as have survived into historical times, as for example those of most of the American Indians and of the Australian aborigines, do not seem ever to have practiced slavery.

In any event slavery as an institution definitely made its appearance when tribes reached the pastoral, as distinct from the hunter, stage. Even then it was modest as far as the number of slaves was concerned because the care of flocks required only a few hands. Furthermore, life was simple and there was little difference between the condition of a slave and that of the wives, sons, or daughters of his master, who were also subject to the latter's absolute authority.

The exploitation of slave labour increased at the agricultural stage. But as long as agriculture retained the character of a subsistence economy, slavery continued to bear on the whole the "patriarchal," or "domestic," character of the pastoral period.

Expansion of slavery. The real change in the character of slavery, as well as its expansion, came as a result of the change from a subsistence to a market economy. When large tracts of land fell into the hands of a relatively few wealthy landowners, and only one or a few staple products were cultivated, it was generally profitable to employ the labour of slaves working in large gangs. Under these conditions the slaves became an anonymous multitude, and their treatment was quite different and much harsher than when they still were considered members of their master's household. Examples of this type of "praedial," or "plantation," slavery existed in ancient Greece and Rome and in New World plantation economies.

In the cities slaves were used not only in the domestic service of the master and his family in all kinds of capacities and exploited for the satisfaction of the master's lust or of his artistic tastes but also for work in mining, industry, commerce, and the like. Slave girls staffed the brothels and filled the harems of the ancient world. At times there also were slave policemen and slave warriors. Among the latter, some achieved great power and sometimes took the place of their masters and even founded dynasties. Such cases, of course, were exceptional, and usually slaves were treated as an inferior class or caste.

Sources of slaves. It would seem that individuals were reduced into slavery mainly by capture or force; as punishment for some offense; by birth from slave parents; by sale for nonpayment of debt; or by sale by parents, guardians, or chieftains.

Undoubtedly, capture is the most ancient source of slaves. And once the need for slave labour increased, expeditions were undertaken with the specific view of capturing human beings to reduce them into slavery. Thus slave raiding and kidnapping became the major means of supply. They were practiced in antiquity as well as in modern times—until the end of the 19th century and perhaps even later.

Punishment for crime is also an ancient source of slaves. When society took the right to punish for crime into its own hands, criminals usually became publicly rather than privately owned slaves, as in the case of condemned criminals sentenced to the galleys. Although slavery of this kind seems to have disappeared, a certain analogy to it may be found in penal servitude and perhaps also in forced or compulsory labour employed by some colonial powers and imposed by certain governments upon political opponents.

A third source of slaves—birth—was the consequence of the acceptance of the idea that the slave was the property of his master. Consequently, the child born of slave parents belonged to their owner; however, birth has been a less important source of slaves than one would imagine: in particular, under the conditions of mass slavery such as those that prevailed on the Roman latifundia, and later on American plantations, there were usually a far greater number of men than women among the slaves. Furthermore, it was often more profitable to buy grown-up slaves

than to wait until children reached an age where they could be put to work.

Another major source of slaves was sale. This needs some explanation. Insofar as slaves were considered as objects of property, they were subject to sale—and the main purpose of slave raiding was to supply the slave market. In these cases, sale is not considered as the source of slavery, as the individuals concerned already were slaves (by capture or kidnapping, birth, sentence, or prior sale).

In many societies, however, it has been possible for a free individual to sell a person under his authority—a wife or concubine, a child or grandchild, or a ward—into slavery for money or other consideration; or a tribal chieftain might sell individuals, families, or groups under his jurisdiction or sanction their forced removal by traders. Although the sale of persons into chattel slavery has been virtually eliminated, it must be stressed that practices leading to similar results frequently have outlived legal prohibitions. One such practice has been the sham adoption of children, especially girls, of extremely poor households by wealthier people who pay a certain price to the natural parent and thereafter exploit the child. Such practices were widespread even in the 20th century in China and other countries of Southeast Asia, where they were known under the Chinese name of *mui tsai* ("little sister") and also in certain regions of South America, where the "adopted" child was frequently of Indian origin.

Sham
adoption

CONTRACT LABOUR

Closely related to slavery resulting from sale was the practice of contract labour, in which an individual surrendered his freedom to quit his work or his master, usually for a specified period. His entry into service may have been voluntary, as in the case of indentured servants who gained some financial advantage (such as transportation costs to a new land), or it may have been involuntary, as in the case of debtors enslaved for nonpayment of debts or criminals whose sentences have been commuted to indentured servitude. During the period of subjection, in any event, the individual's labour had at least one of the features of slavery in that he was not free to leave and was subject to coercive measures if he tried.

Debt bondage. In a considerable number of civilizations, an insolvent debtor either became his creditor's slave or could be sold by the latter to a third person. Usually the condition arose from a pledge by a debtor of his personal services, or those of a person under his control, as security for a loan. The main feature of such an arrangement is that the value of services furnished is not applied toward the liquidation of the debt. Consequently the individual pledged has practically no hope ever to escape his servile condition. And, as it is not unusual in such cases that the debt remains due after the death of the original debtor, thereby devolving on his next of kin, the servile station may become hereditary. Despite measures taken to put an end to servitude for debt, it has survived in many regions even in the second half of the 20th century. It occurs mainly in underdeveloped agricultural countries, but even economically more advanced countries have not been entirely exempt from it. In agricultural communities it often happens that the lender of money or credit is at the same time a wealthy local landlord, while the debtors are the impoverished farmers. In more industrialized communities, the moneylender either directly exploits the debtor's labour for his own profit or hires him out to some third party.

"Temporary" debt
slavery

Colonial indenture. In colonial times, indentured servitude was a form of contract labour; in the middle and later 19th century, Chinese and Indian labourers, commonly called coolies, moved great distances under contractual arrangements. Deception, kidnapping, and coercion were widely used as means of obtaining control of defenseless persons, usually unskilled and poorly educated adult males.

North American indentured labour began with the founding of the colonies and existed concurrently with free labour and slavery until the American Revolution. Its subjects were males and females of western European and

North
American
indentured
servants

Effects of
market
economy
and
urbanism

Slavery as
punishment

mainly British origin. The terms of indenture were harsh to favourable, depending upon the strength of the individual's position and the preferences of his master. The harshest terms and the longest indentures were imposed upon criminals whose death sentences (often for political offenses and numerous crimes now regarded as misdemeanours) were commutable upon entry into colonial indentures.

At the other extreme, those able to negotiate the terms of indenture were able to obtain contracts generally patterned after English apprenticeship customs and were usually free after five to seven years of service. Colonial laws gave some protection to the indentured servant but also sanctioned and enforced performance of the contract whether oral or written.

The indenture of Chinese and Indians also was associated with colonial developments but occurred later, following the abolition of slavery in areas other than the American colonies. Indian emigrant labourers were brought into British, French, and Dutch African colonies and also into Ceylon, Malaya, and the Caribbean. Chinese labourers served in many of these areas and also in Peru, Western Samoa, New Zealand, and Hawaii. The Chinese, Japanese, and Hindustani workers who came to California in the latter 19th century were commonly regarded as coolies, but they were mainly free immigrants, some of whom had completed or escaped from indenture contracts. Their numbers included those who remigrated from the sugar plantations of Hawaii. Although Asian indenture was not free of kidnap, decoy, and fraud, it was basically a noncompulsory system to the extent that the governments of China and India were able to protect the interests of their nationals by legislation and negotiation. Poverty in the home country was the foundation of Asiatic indenture. In contrast, American colonial indenture, though founded partly on poverty, was also fed by a harsh penal code characterized by political and religious intolerance.

Peonage. A form of contract labour commonly associated with deception or circumvention is peonage. Early in the history of Mexico, the conquerors worked out a plan by which the poor, especially the Indians, could be forced to do the work of the planters and mine operators. The word peon became synonymous with the English word labourer, but it later was restricted in its meaning to those labourers who were compelled to serve their creditors to pay debts that by contract they had pledged themselves to pay in labour. For example, although the Thirteenth Amendment to the U.S. Constitution and congressional legislation prohibited any such involuntary servitude in the United States, the former slave-holding states devised certain legislation, following emancipation, to make labour compulsory. Under these state laws, employers deceived ignorant men by inducing them to sign contracts for labour in payment of debts and deceived those who might have to pay fines imposed by the courts to sign other similar contracts. In rural districts far removed from the populous centres, the chain-gang system of forced labour, under the pretense of farming out the services of penal offenders, resulted in great injustice. The practice of leasing **short-term** prisoners, both white and black, to managers of labour camps was continued in a few of the Southern states.

SERFDOM

According to customary legal distinctions, slaves were chattel to be treated at will, whereas serfs, though bound to a lord, were attached to a hereditary plot of land, liable only for certain dues and services and by right protected from being maimed or killed. In fact, however, serfs almost everywhere very often could be bought and sold without land and frequently were subject to almost unlimited discipline from their masters. In any case, the vast majority of serfs were peasants. This means that they obtained their subsistence from a plot of land. This, rather than their place in public law, was the essential feature differentiating serfs from slaves. The slave was an instrument of production owned by a master who provided him with food and clothing. The serf provided his own food and clothing from his own productive effort. Under for-

tunate circumstances he could produce more than his own subsistence requirements and accumulate reserves of his own. He was, however, a dependent peasant; this meant that a substantial proportion of the surplus product of his holding was taken by his overlord. Alternatively, or additionally, the lord used the serf's labour for the cultivation of the portion of his land that was not held by tenants. The payment of rent in money, in kind, or in labour was not, however, the only or even the essential sign of the serf's dependence, for rents are paid by freemen as well as by serfs. The essential additional mark of serfdom was lack of freedom of movement of the peasant family and restrictions on the free disposal of its property. When the peasant could leave his holding, and if necessary his village, without obtaining a lord's permission, he was no longer a serf.

CORVÉE, OR STATUTE LABOUR

Although the term **corvée** applied originally to the regular work that both serfs and freedmen owed a lord, it later became synonymous with statute labour, a specified amount of labour on public projects required by law. The **corvée** was revived when money payment did not provide sufficient labour for public projects. This might occur when public revenues were low, when there was a shortage of labour, or when the available labour did not customarily seek outside employment. It was revived in France in 1726 for road work and was finally abolished during the French Revolution. In England and Scotland statute labour on roads was used from the 16th through the 19th centuries, by which time the turnpike system had begun to take over the main roads. Compulsory labour in Africa was instituted by Europeans to overcome the African's alleged resistance to leaving the village to work for wages. In French West Africa, for example, the **corvée** was applied until 1946; all able-bodied African males were obliged to work about 15 days a year on public works. In the Peoples Republic of China today, civilians may be drafted to spend a certain number of days (usually ten) a year on road work, repairing dikes, and so forth.

The basic distinction between the **corvée** and ordinary forced labour is that the **corvée** is a general and periodic short-term obligation; forced labour is usually prescribed for a long or indefinite period as a method of discipline or discrimination on a highly selective basis.

II. Slavery in antiquity

THE ANCIENT NEAR EAST

Sources of slaves. Warfare was the earliest source of slaves in the ancient Near East and always remained a relatively important one. Originally captives seem to have been slaughtered; later, women and then men were spared to serve their captors: the Sumerian word for slave woman means literally "woman from a foreign land" and appears at an earlier date than that for a man slave. Some prisoners passed into private possession, but most of them became the property of the kings (in Egypt all captives belonged in the first instance to Pharaoh), who either kept them or dedicated them to service in temples. The numbers of royal (state) and temple slaves thus created often grew considerably. They were the only large aggregations of slaves in preclassical times; and, except perhaps in late Assyrian times, there seems to have been no equivalent of the great private slave households of Roman times.

The supply of slaves by war was supplemented by purchase, usually from among neighbouring peoples. "House born" slaves, however, enjoyed a slightly higher social status, and masters often supplied their slaves with "wives" or "husbands" in order to obtain them. An important source of slaves lay within the native population itself. At least from the 3rd dynasty of Ur in Babylonia (c. 2100 BC), and no doubt earlier, and from the Old Kingdom in Egypt (c. 2686–c. 2160 BC) self-sale or the sale of children in order to pay debts was widespread. Unlike the ordinary form of slavery, debt slavery was recognized as a social evil that should be held in check.

Many Babylonian kings, notably in the Old Babylonian period (c. 1800–1600 BC), issued decrees liberating debt

slaves

slaves and abolishing public and private debt. The Hebrew sabbatical year (the seventh) in which Israelite debt slaves were to go free was paralleled in the Code of Hammurabi by which such persons were to be released upon completing three years' work for their creditor. It is not known how far and for how long these laws were observed, though Jeremiah castigates their evasion (Jer. 34:8–17). Poor Jews were forced to sell their children into slavery to pay their taxes after returning from the Babylonian Captivity (Neh. 5:1–5).

Slaves,
freemen,
and
freedmen

Status of slaves. Slaves and freemen were not often or strictly divided racially or culturally as they have been in more recent slave societies. Moreover, between slave and freeman there existed a variety of *semifree* classes dependent on king or temple, and even free citizens were commonly liable to labour service (*corvée*). Nevertheless a slave was not a human being before the law but a "head" like an animal. He seems to have enjoyed no protection from his master, and if he was injured by someone else, the case was considered as one of damage to his master's property. Hebrew law provided that if a master beat his slave to death and the victim lingered on for a day or two, the master went unpunished "for the slave is his money" (Ex. 21:20–21). In the circumstances, runaways were numerous, and in Babylonia the laws of Hammurabi prescribed death for harbouring a fugitive; other societies, notably among the Hebrews, were more lenient. Probably most masters found that it paid to treat slaves reasonably well, and sometimes inducements were held out to them, such as the privilege of retaining small gratuities or the prospect of ultimate liberation. Manumission (freedom) was often granted on condition that the freedman (who was frequently adopted) should support his ex-master during his lifetime; any failure to do so led to re-enslavement. The freedman thus was in an intermediate position between slavery and complete freedom; he might be required to remain for life or a definite time with, or perform some special duty or service for, his former master or a person named by him, and his failure or refusal to do so would subject him to being again reduced to slavery.

The capacity of slaves to carry on business on their master's behalf was recognized, under rigid safeguards, in Babylonian times. By the Neo-Babylonian period (c. 620 BC), slaves carrying on business—as merchants, bankers, artisans, tenant farmers—and living on their own were commoner; some of them even owned slaves of their own. Any property acquired by a slave, however, remained legally the possession of his master, the slave making a payment for the privilege of engaging in business.

Slave
occupa-
tions

Economic importance. Slaves were to be found in almost every field of work in preclassical antiquity, but in the absence of reliable statistics it is impossible to estimate the total economic importance of slave labour.

Most privately owned slaves in cities were domestics; in the country they worked alongside their masters in the fields. They seem never to have presented a threat to the existence of free tenant farmers, though true slave farmers existed on large estates in the Assyrian Empire, and could be bought and sold either with the land they worked or separately. This was probably exceptional, because of the conditions of the period. Slaves seem to have been rarer in skilled trades and professions, though slave apprentices are mentioned, especially in Neo-Babylonian times, in contracts concluded between their owners and master craftsmen. Skilled workmen were also to be found among the temple slaves but were probably exceptional there also. In general, craftsmen were freemen. It seems certain, therefore, that any threat to the economic conditions of free persons by slaves was confined to the unskilled, and it can only have been acute in times of an overabundant supply of labour, but to judge from the retention of unpopular forced-labour service, a shortage of labour was much commoner.

GREECE AND ROME

Slaves are mentioned in the Homeric poems, which probably reflect the conditions of the early 1st millennium BC, and they play a prominent role in the legal code of Justinian

(AD 527–565). During these 15 centuries, slavery was an accepted institution, never seriously challenged. In the 5th and 4th centuries BC, it is true, some philosophers questioned slavery like all other fundamental human institutions, such as the state and the family. As Plato was not much interested in the problem, we know little of the debate, but it appears from Aristotle that some philosophers declared that slavery was contrary to nature and therefore unjust. Aristotle himself took an opposite view. According to him, many—indeed the majority—of the human race lacked those higher qualities of the soul that were necessary for freedom. Slavery was not only good for the master, who was provided with living instruments, but for the slave, who received guidance that he was incapable of providing for himself. Aristotle admitted that in practice men free by nature were enslaved "by accident," and natural slaves were allowed to be free; but although the institution was not always properly used, it was fundamentally natural and good. Later philosophical schools, like the Cynics and Stoics, who preached the brotherhood of man, held that slavery was contrary to nature, but they did not suggest its abolition. Freedom and slavery, like all material concerns, were, they taught, matters of indifference. To Christians there were neither bondmen nor freemen in Christ, but in this world they counselled masters to be kind to their slaves and slaves to be obedient to their masters. The doctrine of the Roman law was summed up by Justinian in the sentence, quoted from the 2nd-century lawyer Florentinus: "Slavery is an institution of the *jus gentium* (law of nations), whereby a man is, contrary to nature, subjected to the ownership of another." No other legal institution is expressly admitted to be contrary to natural law, but after this formal acknowledgment of philosophical theory, the Roman lawyers formulated the practical rules governing slavery without demur.

Sources of Greek and Roman slaves. The sources of slaves were many and varied. In primitive Athens and Rome, insolvent debtors might be enslaved by their creditors. This was forbidden by Solon at Athens in the 6th century BC and in the late 4th century BC in Rome, but the rule probably prevailed longer in many communities. With the extension of Roman law to the whole empire, slavery for debt ceased to be legal. In Greece, children exposed and abandoned by their parents became the slaves of those who reared them. Roman law varied on this point until Justinian in the 6th century declared that all exposed infants were free. Poor parents also sometimes sold their children. This was prohibited by Roman law but was nevertheless not uncommon, especially under the later empire; the sale of newborn infants was legally recognized by Constantine the Great. A freeman might, under Roman law, allow himself to be sold into slavery and could not reclaim his freedom if he was over 20 and had received a part of the price paid for him. A few offenses were punished both in Greece and Rome by sale into slavery, and under the empire a common penalty for crimes among the lower orders was slavery in the state mines and quarries.

The principal sources of slaves, however, were war, piracy and kidnapping, breeding, and import from barbarian lands. Victors in war always possessed, and frequently exercised, the right of selling captives. With the establishment of the principate (27 BC) conditions changed, however. Under Augustus there were still wars of conquest and many thousands of barbarian prisoners were enslaved, but thereafter large-scale wars were rare. Peace reigned within the empire, piracy and brigandage were effectively suppressed and, without these two major sources, slaves could be imported only from beyond the Rhine, the Danube, and the Euphrates. In these circumstances, slaves became scarcer and their price rose. Breeding in these circumstances became necessary and profitable.

Economic importance. There were few activities that were not common to freemen and slaves. The latter were, of course, excluded from political life and only citizens could hold magistracies (public office). Slaves were, moreover, excluded from military and naval service; only in mo-

Subordination as the mark of servility

ments of extreme crisis were slaves enrolled in the armed forces, being freed for the purpose. Domestic service, however, was reserved for slaves; it is almost unknown in classical antiquity to find a freeman as a personal servant. It is often stated on the basis of statements in Plato, Aristotle, and Cicero that the Greeks and Romans regarded manual work, with the exception of agriculture, as degrading for freemen and only fit for slaves. The great majority of Athenian citizens, however, either were peasants, craftsmen, or labourers and felt no shame in the fact; they worked even in the mines. But while the hardest manual labour was tolerated, any employment that involved being subject to another man's orders was considered servile and degrading, even if the work was managerial and not manual. This attitude seems to have been widespread in the Greek and Roman world, and it had far-reaching effects on the economy.

It meant in the first place that slaves (or freedmen) were normally employed in secretarial and managerial posts. In 4th-century Athens, bank managers were often slaves or freedmen of the bank owners. Within the sphere of agriculture the bailiff, who was directly responsible to his owner, was normally a slave, even though the estate was worked by free tenants and free casual labour. In the early principate in Rome a curious anomaly arose. The emperor's principal secretaries and accountants, who were slaves or freedmen, inevitably became politically influential and important and came to do the work of secretaries of state and ministers of finance. This situation caused great bitterness among the senatorial aristocracy, but it was only after a century that the problem was solved, when the offices of the imperial household came to be regarded as public rather than as domestic posts and became acceptable to members of the equestrian order, though not to senators.

Secondly, it was virtually impossible for any industrial enterprise to expand beyond the scope of a household business without the use of slave labour. A freeman would accept casual jobs, usually on a contract basis, but he was generally unwilling to submit himself to regular work under a master's orders. A craftsman might employ members of his family and perhaps apprentices, but if he wished to expand his business he had to buy slaves. Except when slaves were very cheap, this meant a heavy and risky capital outlay, and as a result industry tended to be on a small scale, unless conditions were exceptionally favourable, as in mining.

Apex of Roman slavery

Slavery reached its high-water mark in Rome in the 2nd and 1st centuries BC. Not only were slaves very abundant and cheap, owing to the prevalence of wars and piracy, but the Roman upper classes were immensely wealthy and were building up huge estates (*latifundia*). The result was the introduction of agricultural slavery on a vast scale. The peasantry were progressively expropriated, and their lands either cultivated by slave gangs or converted into ranches manned by slave herdsmen. This is the only period of antiquity in which large-scale revolts occurred, in Sicily in 135–132 and 104–100 BC and the rising of Spartacus in Italy in 73–71 BC, and the difficulty with which these revolts were suppressed proves the large numbers involved. Slaves were also employed on a vast scale in the mines; there are said to have been as many as 40,000 in the silver mines of New Carthage in Spain.

In the later empire, despite the fall in the price of slaves, there developed hereditary groups of agricultural slaves who could not legally be sold apart from the land; their status in law and practice more and more resembled that of free tenants, who on their side were being converted into serfs and were bound to a given piece of land. Convicts were used in certain state quarries, but miners were, in general, freemen. The chief innovation of the age was the establishment by Diocletian, in the 3rd century, of state weaving and dyeing factories manned by slaves; but by the 4th century these slaves had become hereditary groups whose status differed little from that of freemen.

Social conditions. It is obviously impossible to generalize on the condition of slaves in classical antiquity. All slaves were liable to the arbitrary cruelty of their masters; their only legal remedy was to escape to a sanctuary and

demand to be sold to another master. Antoninus Pius (AD 138–161) ruled that the killing of a slave by his master was homicide, but Constantine (306–337) absolved the master if the slave died as a result of flogging. In practice there were great differences between various categories of slaves. In the mines slaves often were ruthlessly worked to death, and the chained gangs on the land were brutally treated. On the other hand, a private secretary or a nurse might be treated as one of the family, and a craftsman in charge of a workshop or a sea captain in command of a ship enjoyed de facto most of the rights of a freeman. Miners and agricultural slaves had little hope of freedom, while domestic servants could reasonably hope to be manumitted, and craftsmen and shopkeepers had a fair chance of buying their freedom.

The fact that slavery was universally accepted as a normal social institution made relations between slaves and masters easier. Slavery was regarded as a misfortune but not as a wrong, and slaves felt no resentment against their masters unless they were ill-treated. There was, moreover, no distinction of race or colour between slaves and freemen. In classical Greece most slaves were barbarians, but there were many Greek slaves (although no Greek was a slave in his own city) and free barbarians, and there was no marked racial or cultural cleavage between the Greeks and the neighbouring barbarian peoples. In the Roman Empire slaves were, for the most part, from the same stock as the provincials. Nor was there any marked distinction in the kind of work done by freemen and slaves. There were slaves in the professions and skilled trades and free manual workers. Slaves were not distinguishable by dress or any outward mark from free persons in the same walk of life, and the intermarriage between slave and free, though legally null, was not uncommon in the lower ranks of society. A manumitted slave did not in Greek cities become a citizen, citizenship being a strictly hereditary privilege, but he ranked like any other resident alien. In Roman law he became a citizen if manumitted in proper legal form, though he did not enjoy full civic rights, being ineligible to serve in the army or to hold public office or become a city councillor. (Ed.)

Legal rights of freedmen

III. Servitude in ancient India and China

SLAVERY AND THE CASTE SYSTEM IN INDIA

India's oldest legal treatise, called the Laws of Manu (variously dated between the 2nd century BC and 2nd century AD), contains articles apparently dating back to the 12th century BC and identifying six types of servants: the captive taken under a flag or in a battle; the domestic who enters someone's service for maintenance; the serf born of a woman slave in the master's home; the man who has been bought or won; one inherited in an estate; the one who is a slave as punishment for not being able to pay a fine. Any one of these enslaved persons could attain freedom, however, under the following conditions: (1) the enslaved war prisoner could attain freedom if he left in his place a slave who could perform the duties his master had charged him with; (2) the person condemned to slavery for debts could be freed if he paid his master what was owed him; (3) a slave saving his master's life was considered free before the law and deserving of a reward. But in all these cases of liberation, the tacit consent of the master was necessary for the slave to exercise his right to be free.

The Code of Manu

More abundant than slavery was serfdom. Within the rigid classification of social classes in ancient India, the Sūdra caste was obliged to serve the Kṣatriya, or warrior, caste, the Brahmins, or priests, and the Vaiśyas, or farmers, cattle raisers, and merchants. There is an unbreakable barrier, however, separating these castes from the inferior Sūdra caste, the descendants of the primitive indigenous people who lived in serfdom. Below this there was yet a final class, the lowest and unworthy and without a social category, made up of the pariahs, who lived by begging. The separation that the pariahs were obliged to maintain was rigorous, not only in terms of caste but also in terms of their daily lives, because pariahs were positively forbidden to approach a person in a higher caste; even when begging alms, they had to maintain a certain distance.

Castes in India

Even the servile Siidra despised the pariah, although the former lived forever afraid of and subject to the other classes.

Not even from an economic standpoint did the Śūdra find the opportunity for a door to open the way toward his betterment. In those times it was not a person's economic wealth that gave him his social rank but rather his social and racial level; and thus one of Manu's laws says: "Although able, a Śūdra must not acquire excess riches, since when a Siidra acquires a fortune, he vexes the Brāhman with his insolence." The barrier separating the servile castes took on extreme cruelty in some laws:

A man of low caste who dares to contest a man of a higher caste must be branded below the hip and exiled. If he raises a hand or a stick to a superior, the hand shall be cut off; and if in a moment of rage he kicks him, that foot shall then be cut off. Should he inflict injuries upon a man of a higher caste, a hot dagger shall be put into his mouth.

The legal condition of the Śūdra left him only death as a means of improving his condition.

SLAVERY AND PEASANT SERFDOM IN CHINA

The sale and purchase of slaves did not exist in China as a formal business, although there were in fact enslaved serfs and also men or women who became slaves for the following reasons: (1) impoverished persons could surrender themselves to slavery in order to avoid dying of starvation; (2) criminals committing high treason could be made into slaves in public service or at the royal palace; (3) the children of these condemned ones could be castrated and used as overseers and eunuch slaves in the harems; (4) adulterous women, expelled from the home, often had no other recourse but to offer themselves as slaves; (5) debtors sliding into insolvency could be taken into slavery by creditors. This practice was in existence from the most primitive times and continued in China until the 16th century.

In China, extreme serfdom generally made slavery unnecessary. The landowner did not need the purchase of men for labour, because the serfs, theoretically free but in practice subject to the most cruel serfdom, worked as slaves. The Chinese landholders obtained all of the serfs they needed and in fact more than necessary, since the great fecundity of the peasant couples kept them in good supply. The rural serfs paid their tribute in labour; they worked the lord's lands, while some women helped to pay tribute by weaving silk.

In the social history of the Chinese Empire, the various dynasties that succeeded each other for millennia are usually distinguished by some predominant cultural characteristic, but there is an inalterable parallelism in all of the epochs with respect to serfdom. From the Shang dynasty, when history and legend unite (2nd millennium BC), there is evidence of an industrious agricultural people working servilely on the lands of the lords. In the Chou dynasty (1122–221 BC), when feudalism was organized by means of a tributary system, the rural population was oppressed by great vigilance in the collection of tribute; and the farmer lived practically dedicating his life to the lord, who required his oppressive share whether the harvest was good or bad, and drove the serf into extreme poverty. During times of famine (caused by poor harvests or wars between the lords), the parents either abandoned their children with the hope that fortune would save them from starvation or they would offer them as slaves to a lord who would feed them. The Chou dynasty was the epoch of the great philosophers, Confucius, Mencius, and Lao-tzu. According to Lao-tzu, it was necessary to return to the natural life, to the simplicity of primitive work, in which each family depended upon its efforts with the land and fed only themselves and did not enrich the lords. Confucius, on the contrary, less a philosopher than a moralist, partisan of order at any cost, espoused education as the means of attaining progress for the lower social classes. These were times of rivalries between the lords, until one of them, Ch'in Shih Huang-ti, brought to an end the feudal anarchy of the Chou dynasty and founded the absolute monarchy of the Ch'in dynasty (221–206 BC), which scorned the philosophers and the words of the

texts, imposed a harsh militarism, and completed the most gigantic effort of an enslaved populace: the Great Wall of China. But the workers who performed this forced labour were farmers who knew that the Great Wall would defend the country from the frequent incursions of the Tartars, who put them in danger of being enslaved or being robbed. The following dynasty, the Han (206 BC–AD 220), was a return to intellectualism, which implemented the standards of Confucius and his followers; then Buddhism infiltrated into China from India and, in spreading humanitarian ideas, influenced behaviour toward the worker and tended to soften the oppression of the serfs. Nevertheless, with all of the luxury, culture, and refinement of the imperial court, which reached its maximum splendour with the T'ang dynasty (AD 618–907), the misery of the people and their enslavement grew.

Tenant farmers and agricultural labourers who worked on the large private estates continued to be free in theory but were in practice at the mercy of the landowners. They could be bought and sold; they could be arbitrarily punished; they had virtually no rights before the law. This form of landlordism and tenant farming continued from these early times up until the modern period.

THE PEASANTRY IN JAPAN

By the 8th century AD Japan had been greatly influenced by Buddhist ideas and views of life emphasizing mercy and tolerance, but the Buddhist foundations of Japanese life were apparently insufficient to free the slaves and serfs characteristic of the landed economy. The manor, or *shōen* in Japan, remained one of the major features of social organization. It contained the lord and his retinue and at least three types of labourers: the "free workers," who were only nominally free, for without land of their own they were really immobile; the serfs who went with the land (and whose condition was remarkably similar to the serfs of medieval Europe); and the land and household slaves.

In the centuries that followed, however, so much new land was put under cultivation that the great landowners found it difficult to find additional slave labourers or serfs and thus had to rely more and more on the services of freemen or runaway serfs, who themselves were showing a new kind of enterprise and occupying new plots of land. The general effect of the labour shortage was to improve the treatment of slaves and serfs and thus gradually to reduce the old distinctions between free and unfree. The general effect of the occupation of new plots of land was to encourage the development of individual enterprise and a sense of devotion to one's own land in Japan. All this was to shape strongly the character and status of the Japanese peasant into modern times. (L.Bo.)

IV. Servitude in Muslim lands and Europe

THE PERSISTENCE OF SLAVERY

The Muslim world. Slavery continued under the Eastern Roman and Byzantine Empire, and the appearance of Islām gave a new character or direction to the institution. Muhammad found slavery well established in Arabia when he began to preach the new religion in the first years of the 7th century. His attitude toward it as revealed in the Qur'ān (Koran) was similar to that of the Christian churches: he did not condemn slavery but taught that slaves should be treated with humanity and that the liberation of a slave was a pious and meritorious act.

But the appearance of Islam was followed by wars of conquest that covered vast areas in Asia, northern Africa, and eastern and southern Europe. After the Arabs came other Muslim invaders, including the Ottoman Turks. All these wars led to the capture of numerous prisoners, often reduced to slavery, although usually the civilian population was left free on condition of paying taxes to the conquerors. During the Crusades, Christians also enslaved many of their Muslim prisoners. This brought about a considerable increase in the slave traffic, not only in Muslim lands but in Christian Europe as well. Even the church's strenuous efforts to prevent the sale of Christians by Christians were not always successful: Hanseatic, Venetian, and Genoese slave traders bought Syrians,

Serfdom
in China

The
Qur'anic
view

Muslim-
Christian
reprisals

Serbians, Bulgarians, Armenians, and others from the Turks and resold them elsewhere. The fall of Constantinople in 1453 was followed by a marked increase of sales. Another source of slavery in Muslim lands was the capture of seamen and passengers in the Mediterranean by buccaneers operating from North Africa. "Slave charities" were established in England and other European countries to redeem these Christian prisoners, and diplomatic efforts were made to curb the Muslim slave trade. Muslim slavers also raided territories in various parts of black Africa or purchased slaves from African chieftains.

It must be noted, however, that slavery in Muslim countries, which continued for centuries and survived legally, or at least in custom, in a few of them, has always been very different from that which existed in Rome and in the Americas after their colonization by Europeans. Gang slavery for work in the fields or in industry and mining was almost unknown in the Islamic world. Most of the slaves were employed in wealthy households for domestic service and were well treated, in accordance with the prescriptions of the Qur'ān. The one really cruel Muslim institution was that of the eunuchs, which involved emasculation. Women slaves in harems became their masters' concubines or even legitimate wives. Furthermore, Muslim society was not usually race or colour conscious. Liberated slaves of whatever origin were readily absorbed as equal members of the community, and examples of slaves or former slaves reaching the highest positions were numerous. Perhaps the most famous example of all is the case of the Mamlūk slave dynasty, which ruled Egypt for more than two and a half centuries (1250–1517), during which period one slave ruler succeeded another in the same way as normally a son succeeds his father.

Spain and Portugal. In Spain and Portugal, slavery continued to exist, not only through the period of Arabic, or Moorish, dominance but also after their reconquest by the Christians in the 15th century. Naturally, the defeated Muslims were the first to be reduced into slavery. But soon the Portuguese set out to import slaves from Africa as well. The first black slaves were imported in 1444 by Portuguese captains of Prince Henry the Navigator, who had obtained them as ransom in exchange for Moorish prisoners. Later, the Portuguese engaged directly in the slave trade and established factories (trading posts) for that purpose on the coast of Guinea.

Black slaves were imported in ever-increasing numbers into southern Portugal and neighbouring regions of Spain, where Seville became an important slave market. These regions had greatly suffered from wars between Christians and Muslims, and their populations had been largely depleted. Imported Africans were employed not only for service in wealthy households but also for work in the fields and for a variety of tasks in the cities, especially as stevedores in the harbours. Because the Portuguese, and to a lesser degree also Spaniards, as a result of the many conquests, had little race or colour consciousness, the various elements of the population mixed relatively freely and ultimately merged.

EUROPEAN SERFDOM

Origins of serfdom. One of the sources of the servile population of medieval Europe was the body of slaves of the late Roman Empire and of the barbarian states that succeeded the empire. As early as the 2nd century AD, the slackening of production for the market caused changes in estate management. Large estates that had been worked by slave gangs housed and fed by the estate owner were divided into peasant holdings, some of which were granted to the slaves, who, however, were not necessarily freed. In some cases enfranchisements did put the former slave on a level with free members of society, but for the most part even the freedman continued to be under the protection of his former master and owed him loyalty and services.

The bulk of the peasants of the late empire and early Middle Ages were neither slaves nor freedmen but coloni. These coloni might have taken up holdings granted by a proprietor or they might have surrendered their own

lands to him in return for protection, receiving back their land as a dependent tenement. This surrender and reissue of land frequently accompanied the act by which a person commended himself to a great man and swore fealty to him, though the act of commendation did not necessarily involve any land transaction. It was made in order to obtain protection (especially in the empire) from the state tax gatherer and (especially in the disorders of the early Middle Ages) from invaders and oppressive neighbours. Whatever the origin of the coloni, a problem concerning them, which was as old as the Roman Empire, was to prevent them from leaving their land. The solution was to bind them to their holdings. This was done, probably originally for fiscal reasons, by the emperor Constantine in AD 332. But it was so useful to the landlords that by the 6th century it was still firmly established, and coloni, though legally free, were treated as an inferior element in society.

A significant element of the new servile condition was the labour services owed on the landlord's own (demesne) land. In theory, these labour services were no more symptoms of servile tenure than other forms of rent or service. But in practice the exaction of labour services required the exercise by the landlord's agents of labour discipline. This was recognized as one of the clearest signs of a man's personal subjection.

In the 9th and 10th centuries, the serfs, in the strict sense of the word, those who in fact were called servi, were mainly those descended from the former slave population, though many on the big estates who were not called servi (e.g., the coloni) had conditions of life that were virtually servile. In the next three centuries, economic and political conditions in Europe changed considerably. Population increased; commerce and industry developed; towns grew up; and, both within the old territories of the Carolingian Empire and in sparsely occupied Slavonic lands east of the Elbe, forests and marshes were opened up for cultivation. Politically there was, first of all, a disintegration of the old forms of authority, both central and local and, from the 12th century, a reconstitution of feudal monarchies, duchies, and counties. Statistical evidence about serfdom during this period is scanty, but by the 13th century it is clear that there was an immense increase in the number of dependent peasants, whether in the territories of present-day France, England, or western Germany. It has been shown that this increase in the numbers of peasants whose social and economic condition was virtually equivalent to servility did not occur, as was once believed, as a result of the spread of the legal status of the Carolingian servi to the coloni, freedmen, and other categories of dependent peasants on the big estates.

Social conditions and statuses. The servi were considered to be personally subjected to one master "to the very bones." Their condition was hereditary, usually through the mother. They had no legal rights in the public courts. They could not normally enter the clerical order. The only way in which their servile status could be ended was by an act of enfranchisement or manumission by their master. Since these serfs constituted a hereditary caste, the only way in which their numbers grew over the centuries was by natural increase. This was offset by manumissions and by escape. By the middle of the 13th century, the serfs in the stricter juridical sense of the word were relatively no more numerous than four centuries earlier. The increase was in the numbers of dependent peasants whose status was socially, if not juridically, servile. They were servile because lords at all levels in the feudal hierarchy were strengthening their rights (or seizing rights) of private jurisdiction through the right of command, bannum, exercised not merely over their tenants but over all inhabitants within their area of jurisdiction. Even the juridically free tenants had no redress against the lord who had appropriated for himself a jurisdiction that had once been public.

In the case of both types of lordship, whether personal or real or in many instances a mixture of both, there were three principal obligations shared by serfs and by other dependent peasants. The first obligation was the payment to the lord of a head payment, or capitagium (French cheuage). This was common to serfs, to enfranchised

Labour services owed by the serf

Obligations of the serf to the lord

Black slavery in Portugal

Coloni

men, to those who had commended themselves to a religious overlord, and to other dependent peasants. It was not a heavy payment, but it was the sign that the payer accepted his dependence on the lord. Next was the obligation (*forismaritagium*) to obtain the lord's permission for marriage outside the social group or outside the lord's domain. This was particularly important in the case of juridical serfs, for if a male serf married a free woman, the offspring followed the mother's condition. But in the case of both juridical serfs and dependents, marriage outside the domain was (apart from flight) the most serious threat to the lord's future supply of tenants and labourers. The third principal obligation was that of surrendering part of the peasant inheritance to the lord at the death of the servile or subject tenant. This *mainmorte* of the serf was the whole or a substantial part of the inheritance, where there were no direct heirs to succeed. If there were direct heirs, the lord would allow the inheritance to go to them, so that they could continue production and pay rent. Subject peasants who were not juridical serfs had a modified obligation, that of paying the best beast or chattel, but this was paid whether the direct heirs succeeded or not. These were the three most common symbols of dependence; other symbols included the payment of an arbitrary tallage, a seigneurial tax, which was a burden shared by juridical serfs and subject peasants alike.

This necessarily simplified description of serfdom, and peasant dependence between the 9th and 13th centuries must be tempered with the recognition that from region to region there were varying degrees of dependence and of servile obligations.

Decline of serfdom in the west. As early as the end of the 13th century, the French monarchy, largely for fiscal reasons, began a policy of individual manumission of serfs on crown lands. Perhaps the most significant early initiatives, however, came from the heads of the Italian communes, which were among the most powerful rulers of the peninsula. Their motives were mixed and included the wish to weaken the power of the landowning nobility, to increase the number of free taxpayers to the commune, and to increase the urban labour force. These real motives were covered by moralizing. The enfranchisement of serfs by Bologna in 1256–57 was attributed to the realization that slavery was the consequence of the fall of man, that man's natural condition is freedom, and that Bologna was the home of freedom.

By the 14th century, economic conditions in western Europe were favourable to the replacement of the servile by the free peasant tenant. The growth of the power of central and regional governments permitted the enforcement of peasant-landlord contracts (as in *métayage*, or stock and land-lease contracts) without the need for peasant servility. The final abandonment of labour services on demesnes removed the need for the direct exercise of labour discipline. The drastic population decline after 1350, as a result of the Black Death, altered the land-to-labour ratio in favour of tenants. And, not least, peasant risings, which were endemic in England, France, Italy, and Spain in the 14th and 15th centuries, culminating in the German Peasant War of the early 16th century, also forced more favourable terms of peasant tenure. Although the new peasants were not necessarily better off economically than their servile forebears, their status in society conformed to their economic position rather than to the legal classification of their holdings or their persons.

Prolonged serfdom in eastern Europe. This favourable evolution was not shared by the peasants of eastern Europe. In the later Middle Ages, peasant status from eastern Germany to Muscovy deteriorated sharply; a second serfdom began that was prolonged well into modern times, in Russia until 1861. Peasant conditions in eastern European countries before the 14th century do not seem to have been worse than those of the west. In some ways they were better, for in eastern Germany, Poland, Bohemia, Moravia, and Hungary the colonization of forest land had led to the establishment of many free-peasant communities. But a combination of political and economic circumstances reversed these developments.

Eastern Europe from the Baltic to the Balkans in the 14th and 15th centuries suffered wars even more devastating than those of western Europe. These not only diminished the peasant population and increased the area of uncultivated land, as in the west, but also increased the power of the nobility at the expense of central governments. In eastern Germany, Prussia, Poland, and Russia this development coincided with an increased demand for grain from western Europe. To profit from this demand, landlords took back peasant holdings, expanded their own cultivation, and made heavy demands for peasant labour services. Not until the end of the 18th century were the peasants of the Austro-Hungarian Empire freed from a serfdom that was defined by the Emperor Joseph II himself as the absence of freedom of movement, of freedom of marriage, and of the right to learn a profession according to one's choice. Not until Alexander II's Emancipation ukase of 1861 were the serfs of Russia similarly given personal freedom, together with allotments of land.

V. Early modern plantation slavery

INTRODUCTION AND DEVELOPMENT OF SLAVERY IN THE NEW WORLD

Exploitation of Indian labour. The Spanish conquistadors in the New World first endeavoured to use the native Indian population as labour. In this connection it may be observed that although slavery was not a general institution in the Americas before the arrival of Europeans, it certainly existed in some regions, and particularly in parts of Central America. For example, Cortés left a description of the great marketplace, at Tlalotelco near Tenochtitlán (present Mexico City), and of the large number of male and female slaves brought there "for sale as the Portuguese bring Negroes from Guinea." The Spaniards themselves shipped a number of captured Indians to the home country, either as presents for the sovereigns or for sale. In America, however, Indians were generally subjected by the Spaniards to institutions more reminiscent of serfdom, such as *repartimiento* or *encomienda*, and were more often exploited in hard agricultural work than in outright slavery. Only in the mines was the situation different; there labour was more akin to outright slavery.

Whatever the case, difficulties arose. First, Indians proved to be less docile than had been thought and sometimes rebelled or more often disappeared in the surrounding forests. Second, they often lacked physical vigour and succumbed in large numbers to diseases brought over from Europe. In addition, their employers found themselves at odds with the Roman Catholic missionaries. The missionaries' main preoccupation was the evangelization of the pagan population, and consequently they wanted it to be treated gently. The Spanish king Ferdinand II, the Catholic, adopted a solution midway between the desires of the settlers for abundant and cheap labour and the much more lenient attitude of missionaries; Indians could be forced to work but only under certain prescribed conditions, including humane treatment and the payment of a remuneration. But the last prescriptions of the edict often were disregarded.

Even the subsequent introduction of black slaves from Africa did not put an end to the exploitation of Indians, and both forms of servitude existed side by side. In the Spanish possessions on the mainland, the servitude of Indians was prevalent; from it evolved peonage. Certain remnants of this condition survived as late as the second half of the 20th century, thus outliving the abolition of chattel slavery. On the other hand, in the Caribbean island colonies—not only of the Spaniards but also of the British, French, Dutch, and Danes—the aboriginal Indian population suffered total extinction in the course of time.

The importation of African slaves. The harsh treatment of Indian slaves eventually prompted Bartolomé de Las Casas, Roman Catholic bishop of Chiapas, to approach the new Spanish king, Charles I, with the proposal that each Spanish settler should be permitted to bring over a certain number of black African slaves. In 1517 this idea was accepted, although in somewhat modified form, and a Spanish nobleman was granted, by letters patent, a license to import each year a specified number of Africans into Hispaniola on

Emancipation in the Italian communes

Deterrence to Indian slavery

the condition of paying duties to the royal treasury. Soon thousands of blacks were brought, not only into Hispaniola but also into the other islands of the Caribbean and later to the mainland. There black slavery prevailed and, with the development of sugar plantations, assumed colossal proportions beginning at the end of the 17th century. Thus a measure of mercy conceived for the protection of Indian natives became the origin of one of the cruelest institutions of all time—black plantation slavery.

Similar events occurred in Brazil, after the coast of that country fell under Portuguese domination. Indian aborigines were directly enslaved in large numbers with perhaps even more inhumanity than in Spanish possessions. When sugar, and later coffee, plantations developed on the vast *latifundia*, however, the Portuguese adopted the same solution as the Spaniards and imported blacks as slaves in ever-increasing numbers.

In the North American English possessions, perhaps the striking fact is that black slavery as a systematic institution appeared relatively late: the first shipload of slaves arrived, almost by chance, in Virginia in 1619 and in a Dutch, and not a British, ship. At first slavery developed extremely slowly, and in Virginia in 1681 there were still only 2,000 black slaves as against 6,000 indentured labourers of European origin. It was only after intensive cultivation of tobacco developed, and a little later also of rice, that slavery took root in the colony, so that the number of slaves reached 59,000 in 1714. From then on, it increased steadily, mainly through new arrivals, reaching 263,000 in 1754. But a few years later the increase slowed down, and at the time of the American Revolution it even seemed that slavery might gradually disappear. The reason was that tobacco rapidly exhausted the land on which it was grown, so that it had to be used for other crops, by far less profitable. It was only with the introduction of cotton, and particularly after the invention of the cotton gin in 1793, that the trend was once again reversed and the number of slaves increased steadily until it reached the census figure of 4,441,830 on the eve of the Civil War in 1860.

Thus, the development of the institution of slavery in Central and South America and, later, in parts of North America was intimately connected with the growth of the plantation economy. Black slaves also worked in the mines, as *stevedores* in the ports, and in other heavy work: served as domestic servants of all kinds; and were trained in various trades. But it was after the development of sugar, tobacco, and cotton plantations that the slave trade between the west coast of Africa and the Americas reached enormous proportions, becoming the most lucrative trade of the time and constituting a considerable proportion of traffic as a whole.

Growth of the triangular slave trade. The English became the most important importers of slaves, although the French, the Dutch, and others also took part in the commerce, to supply their own colonies or the larger and richer Spanish possessions. On the other hand, the Portuguese reserved the monopoly of traffic to Brazil to their nationals.

This trade was usually triangular. Ships set out first from a home port, such as Liverpool or Bristol in the case of the British, for the Atlantic coast of Africa. They carried liquor, firearms, cotton goods, and various trinkets that were exchanged for slaves brought from the African hinterland to one of the numerous factories established along what became known as the Slave Coast (Gulf of Guinea). Then came the so-called middle voyage from Africa toward the West Indies or one of the colonies or countries on the American continents: this leg of the trip was the slave trade proper. Although usually shortened by favourable winds, it represented a true torture for the involuntary passengers. They were closely packed in the hull to save space and often chained in order to avoid rebellion or to prevent them from jumping into the sea. Even by standards of the time, food was inadequate and water scarce. There was no proper ventilation, nor were sanitary installations provided. It has been calculated that at least 20 percent of all the blacks transported did not survive the voyage. Once they arrived at their destination, survivors

were either directly delivered to their prospective employers or more often kept in stockades to await a purchaser. The ship then undertook the third and last leg of the voyage—homeward—loaded with the various staples produced on the American plantations. One of the chief items of the trade was molasses, from which rum was distilled and used for the purchase of more slaves on the next trip.

Treatment of slaves. Policies regarding the treatment of slaves varied widely among the colonies. By way of generalization, it may perhaps be said that slaves fared better in colonies of Catholic and Latin nations than in those of Protestant countries. One reason for this is that the link between the mother country and its dependencies was much closer for the first group than for the second. Consequently, the metropolitan authorities, through their agents, tried to exercise at least a minimum of control over planters. These countries, namely, Spain, Portugal, and France, promulgated detailed laws concerning the treatment of slaves, of which the most famous is the French *Code Noir* (Black Code) put into force by King Louis XIV in 1685. This compilation contained a number of relatively mild prescriptions, which were, however, often disregarded. Even more liberal was the Spanish Slave Code promulgated in 1789. In the British possessions, on the other hand, white settlers often were granted self-government. Consequently they were free to promulgate regulations as they saw fit. These often were extremely stringent, as in the case of the Barbados Code, imitated in Virginia and elsewhere. Beginning with the last years of the 17th century, however, under the impact of the anti-slavery movement both at home and in certain American colonies, improvements were sometimes introduced in the British dependencies.

Another factor affecting the situation of black slaves in the colonies of Roman Catholic nations was the interest taken in their lot by the clergy. One partial expression of this influence was the enactment of already mentioned codes by metropolitan authorities. But the Roman Catholic clergy also tried to exert authority upon slaveowners on the spot. For example, the clergy encouraged church marriages for slaves and opposed the separation of families. On the other hand, the Anglican clergy did not seem to show similar interests in the slaves, and in many British possessions and U.S. states the law expressly prohibited legally binding slave marriages. But here too the situation in some cases changed under the influence of the Quakers and of certain Protestant dissidents.

A third difference came as a result of the attitude of the peoples themselves. As already noted, the Portuguese and Spaniards had relatively far less race or colour prejudice. Mating between white men and black women was a common phenomenon in all colonies. The rule everywhere was that the child inherited its mother's condition and consequently was born a slave. It was customary, however, in Roman Catholic lands for the master to grant manumission to his child and sometimes also to the mother. Manumission was also frequently granted for long and devoted services of a domestic slave, in particular to nurses who had looked after the master's children. As a result, for example, in Haiti under French domination, a class of free and relatively well-to-do mulattoes gradually emerged. In Brazil, where toleration toward the half-castes and even full blacks was much more in evidence, a number of free persons of African descent had reached positions of eminence even before the liberation that came in 1888; this, in turn, fostered still more the spirit of nondiscrimination and had its effect on the condition of slaves, particularly those in direct contact with their masters. It would be excessive to say that in Anglo-Saxon territories, including the Southern United States, similar situations never occurred. But there the colour line was drawn once and for all, and a person having a small strain of African blood was a "Negro," whether slave or free. In addition, some of the colonial statutes prohibited manumission or made it extremely difficult.

What is certain is that the condition of slaves in all countries depended greatly upon their position and the tasks they had to perform. Those in domestic service were usually a kind of privileged elite, although here again

there were many gradations depending upon the nature of the job, the character of the master, and personal qualities of the slave himself. The next category was that of slaves exercising various trades. The third—and most numerous—included the slaves working on plantations. Here were the worst excesses, particularly if the estate was large and the absentee landowner had to rely on an agent who hired supervisors. Nonetheless, in order to maintain a balanced picture, one must always remember that published accounts usually dealt with either the best or the worst examples. Probably on the whole the situation of slaves was not much worse than that of indentured labourers brought over from Europe. At times it might have been even better because the master had reason to take care of his slave, who represented capital, whereas he had no similar incentive in regard to the labourer. But, of course, the condition of the slave was permanent and even hereditary, whereas an indentured man retained important rights under colonial laws and became free at the expiration of his contract. Furthermore, the condition of slavery itself was degrading. This was keenly felt by many blacks, particularly those who had been brought over from Africa and sold into slavery; a person born into slavery was more likely to accept his condition with resignation. But rebellion was an ever-present threat, and uprisings occurred from time to time in various parts of the slave world—in Brazil and Haiti (which thus gained its independence from France), for example, and also in the British possessions. Nor was the danger absent in some of the Southern U.S. states, although the Civil War proved that it had been greatly exaggerated: during the entire period Southern slaves showed a surprising passivity and toward the end some of them were even called upon to serve in the forces of the Confederacy.

ANTISLAVERY MOVEMENTS IN THE WESTERN HEMISPHERE

Altogether probably more than 15,000,000 blacks were transported to the Western Hemisphere, and before 1800 far more African slaves than English or European colonists crossed the Atlantic—mostly to the West Indies and South America. But despite its inhumanity and size, the slave system aroused little protest until the 18th century. Rational thinkers of the Enlightenment then began to criticize it for its violation of the rights of man, and pietistic or evangelical religious groups condemned it for its unchristian and brutal qualities. In Britain and America, the Quakers, who began their criticism in 1671, were the first significant opponents of slavery, and the dynamics of the antislavery movement were largely religious throughout. Consequently, the leaders were always more concerned with ending the sin of slavery than with finding a constructive social policy for the slaves. In France, where the *Société des Amis des Noirs* ("Society of the Friends of the Blacks") was founded in 1788, the rational factor was stronger than the evangelical.

By the late 18th century, moral disapproval of slavery was widespread, and antislavery reformers gained a number of deceptively easy victories. In Britain, Granville Sharp, working almost alone, secured a decision in the *Somerset* case (1772) that West Indian planters could not hold slaves in England, since slavery was contrary to English law. In America, leading figures of the revolutionary period, such as Thomas Jefferson and Benjamin Franklin, condemned slavery. Between 1777 and 1804 all of the states north of Maryland abolished it—some by gradual, others by immediate action. Meanwhile, in the South, numerous and vigorous antislavery societies enjoyed considerable success in persuading owners to manumit their slaves voluntarily.

These victories, however, had little effect upon the centres of slavery, the great plantations of the Deep South, the West Indies, and South America. The antislavery movement, therefore, slowly turned to the problem of slavery in these areas, and as it did so, it passed through three major phases.

Efforts to outlaw the slave trade. The first phase involved British and American efforts to prohibit the importation of African slaves into the British colonies and the United States. English Quakers began actively to cam-

paign for such a prohibition in 1783. In 1787 the Abolition Society, consisting mostly of Quakers, was formed. Under William Wilberforce, who led the movement in Parliament, and Thomas Clarkson, who devoted many years to the tireless collection of evidence concerning the evils of the trade, the antislavery forces waged an unremitting contest against powerful opposition. The trade to the British colonies was finally abolished in 1807.

Meanwhile, in the United States, the Constitutional Convention in 1787 had considered placing in the constitution a prohibition of the trade, but, in order to conciliate Southern interests that opposed immediate action, the convention agreed to a provision that congress might prohibit the trade after 20 years. Accordingly, in 1807 the United States also prohibited it.

Efforts toward abolition (emancipation). Antislavery men had hoped that when the supply of new slaves was stopped, slavery itself would gradually wither away. But this did not follow, and in its second phase abolitionism concentrated upon the emancipation of populations already in slavery. Most of the Spanish possessions in America abolished slavery when they won independence in the first quarter of the 19th century. (Slavery, though, continued in countries such as Cuba and Puerto Rico, which remained under Spanish rule.) In Britain antislavery leaders organized the Anti-Slavery Society in 1823, made Thomas Fowell Buxton their parliamentary leader in place of the aging Wilberforce and, after another prolonged and dramatic contest, finally succeeded in 1833 in passing a law to free all slaves in the British colonies after a 5- to 7-year period of apprenticeship, with compensation to their owners. In 1848 France also abolished slavery in its West Indian colonies. This was France's second attempt, for the French revolutionists in 1794 had proclaimed emancipation, but the internal struggle over this question in Haiti had led to bloody and violent uprisings. During a vain attempt to restore French control of the island, Napoleon re-established slavery (1802), and it continued in other French colonies until 1848.

The British abolition movement had a deep influence in the United States. As the cotton economy developed, slavery gained new vigour and the South began to defend slavery in positive terms. Discouraged by these developments and disappointed by the limited results of their appeals to gradualism and persuasion and their attempts to colonize free Negroes in Liberia, U.S. antislavery men turned, about 1830, to a more militant policy. Denouncing all slaveholders, they demanded immediate abolition by law. In this aggressive program the most conspicuous and most extreme leader was William Lloyd Garrison, editor of the *Liberator* (1831) and founder of the American Anti-Slavery Society (1833). But Garrison's actual following was small, and it is quite possible that a greater influence was exercised by the burning evangelist Theodore Dwight Weld, who, with his "Seventy Apostles," carried the gospel of antislavery to pulpits throughout the North. Also, the activity of free Negroes, of whom Frederick Douglass was the most important, is not to be underestimated.

U.S. abolitionism laboured under the handicap that it threatened the harmony of North and South in the Union and it ran counter to the constitution, which left the question of slavery to the individual states. Therefore the Northern public remained unwilling to adopt abolitionist policy and distrustful of abolitionist extremism, as illustrated by John Brown's raid at Harpers Ferry (1859). Even when convinced of the evil of slavery as they were by Harriet Beecher Stowe's *Uncle Tom's Cabin* (1852), most Northerners rejected abolitionism. But they were prepared to resist the spread of slavery into new territories. The election of Abraham Lincoln as president on this issue in 1860 led to the secession of the Southern states and to the Civil War (1861–65). The war, in turn, led Lincoln, who had never been an abolitionist, to emancipate the slaves in areas in rebellion (1863) and led further to the freeing of all other slaves by the Thirteenth Amendment to the Constitution in 1865.

Efforts to stop slave smuggling. Meanwhile, the third phase of the abolition movement had already begun, as

Britain took the lead in efforts to break up the remaining slave trade. All leading countries, by this time, had enacted laws against the trade, but smuggling was extensive and open. In fact, the closing of U.S. and British markets had merely deflected the trade to Cuba, Brazil, and elsewhere, and as late as 1850 more than 50,000 slaves a year were being transported. A new organization, the British and Foreign Anti-Slavery Society, was therefore formed in 1839 under the leadership of Joseph Sturge. While this society kept up a public agitation, the British government sought to obtain international agreements to stop the trade by means of an effective naval patrol, but the profitability of the trade and jealousy of British naval power both stood in the way. In 1862, however, the United States signed a treaty conceding the right of search, which was necessary for effective enforcement. After this treaty, the slave trade was quickly reduced to a trickle. Later, the worldwide reaction against slavery led to abolition in Cuba, between 1880 and 1886, and in Brazil, between 1883 and 1888.

The system of African slavery as a Western phenomenon, after shaping the destiny of three continents and dominating the history of three centuries, had largely ceased to exist.

VI. Forced labour in the late 19th and the 20th centuries

EARLY INTERNATIONAL EFFORTS TO SUPPRESS SLAVERY AND FORCED LABOUR

Pre-World War I agreements. In the second half of the 19th century, the exploration of Africa revealed all the horrors of slave raiding and of the traffic in human beings that was going on completely unchecked in a vast territory covering the basins of the Nile and the Congo and the region of the great African lakes. Slave caravans fanned out from the interior to the shores of the Mediterranean, the Red Sea, the Persian Gulf, and the Indian Ocean. Some of the slaves brought there were sold for local employment, but most were sent farther, usually in small native craft, to Turkey, Arabia, Iran, and other eastern countries.

The occupation, at least nominally, of the newly explored African lands by European powers offered an opportunity to strike at the root of the evil. The new authorities, particularly the British, worked to halt the overland traffic and slave raiding. An international diplomatic conference at Berlin in 1885, called for the purpose of delimiting the spheres of influence in the Congo Basin, presented the first opportunity for the coordination of the action already undertaken by individual European administrations. The General Act of Berlin, which applied only to the so-called Conventional Basin of the Congo, required all of the powers concerned "to strive for the suppression of slavery and especially of the Negro slave trade."

The Second Brussels Conference of 1890, however, was a far more important event. Its outcome was the General Act of Brussels, which for a quarter of a century constituted the fundamental charter of international efforts to suppress slavery. One of the important facts about the General Act of Brussels was the number of its signatories: in addition to all the major European powers and the United States, Turkey, Persia (Iran), and Zanzibar were parties thereto. The participation of the last three countries was particularly significant because at the time they still recognized the institution of slavery. But perhaps the major feature of the General Act was the broadness of the subjects covered by its provisions. These included recommendations for taking various measures of vigilance in countries of origin and transit, such as the establishment of permanent military posts and the use of patrols for stopping slave raiding and the conveyance of slaves by land. These acts, and some others connected with them, were to be treated as criminal offenses. Other provisions dealt with measures to be taken for the welfare of liberated or fugitive slaves and their repatriation.

The League of Nations and the International Labour Organisation. The outbreak of World War I in 1914 brought to a standstill the international efforts inaugurated

by the General Act of Brussels. At the close of the war, the principal Allied Powers (Belgium, the British Empire, France, Italy, Japan, Portugal, and the United States) thus signed a new convention at Saint-Germain-en-Laye on September 10, 1919, designed to revive the "endeavour to secure the complete suppression of slavery in all its forms and of the slave trade by land and sea."

The Saint-Germain Convention coincided with the creation of the League of Nations, which took up the general problem of slavery in 1920. In 1924 the League set up a Temporary Slavery Commission of experts to collect information on slavery proper (including so-called domestic slavery), slave raiding and the slave trade, and also on such other institutions and practices as serfdom; purchase of girls as brides; sham adoption of children to exploit their work; various forms of indenture, or reducing to servitude, of persons for debt or for other reasons; and systems of compulsory labour, both public and private. The commission recommended the conclusion of an international convention covering all these matters.

When the League of Nations Assembly adopted the International Slavery Convention in 1926, however, it created ambiguity as to its scope. It decided not to include the subject of forced or compulsory labour, which it referred for further study and action to the International Labour Organisation. As a consequence, the ILO produced the Convention of 1930 "outlawing" the use of forced labour, defined as "all work or service which is exacted from any person under the menace of any penalty and for which the said person has not offered himself voluntarily." It excluded from the category of forced labour compulsory military service and, later, national service required of conscientious objectors, normal civic obligations and "minor communal services," prison labour performed "under the supervision and control of a public authority," and work in the case of force *majeure*. This term relates to work exacted "in the event of war or of a calamity or threatened calamity, such as fire, flood, famine, earthquake, violent epidemic or epizootic diseases, invasion by animal, insect, or vegetable pests, and in general any circumstance that would endanger the existence or well being of the whole or part of the population."

In specific terms, perhaps the League's most successful efforts were to suppress slavery, through the mandate system, in the former Ottoman territories and German colonies. The League also succeeded in bringing around the two nations then most notoriously associated with slavery: Ethiopia was denied entry into the League until it had undertaken a definite program of eliminating slavery (despite the later Italian seizure of Ethiopia, the country lived up to this undertaking and abolished slavery in 1942 upon recovering its independence), and Liberia availed itself of the League's financial and technical assistance to do away with intertribal slavery and some other forms of servitude, including forced labour.

FORCED LABOUR IN MODERN STATES

A number of 20th-century states have resorted to forced labour for economic and political reasons. Persons either suspected of opposition to the regime or considered racially or nationally unfit have been summarily arrested and placed under long or indefinite terms of confinement in concentration camps, remote labour colonies, or industrial camps. There the inmates have been forced to labour, usually under dire conditions. Those unable to work have often died from starvation (or been exterminated outright), and those who have not starved have frequently died from overwork. Although such forced-labour punishment has been established in various forms under many regimes, both totalitarian and colonial, it has been used most extensively in Nazi Germany and the Soviet Union. Millions of persons have been confined, punished, and exploited in concentration camps and labour colonies.

Nazi slave labour. In Nazi Germany, concentration camps (*Konzentrationslager*) were first established for the confinement of opponents of the Nazi Party, mostly leaders of the Communist and Social Democratic parties. But political opposition soon was enlarged to include others,

particularly such persecuted minorities as the Jews. In the anti-Jewish pogrom of 1939, 20,000 Jews were taken into "protective custody" and sent to the concentration camps. By 1939 six major camps had been established: Dachau, Sachsenhausen, Buchenwald, Mauthausen, Flossenbürg, and Ravensbrück.

The outbreak of World War II created a tremendous demand for labour in Germany, and Nazi authorities turned to the concentration camp population to augment the labour supply. From 1940 to 1942 nine new camps were established: Auschwitz, Neuengamme, Gusen, Natzweiler, Gross Rosen, Lublin, Niederhagen, Stutthof, and Arbeitsdorf. Thousands of forced labourers from countries occupied by Germany were placed in concentration camps and auxiliary labour camps.

By the end of September 1944 there had been put to work in the Third Reich some 2,000,000 prisoners of war (the majority Russians and Ukrainians) and some 7,500,000 foreign civilian men, women, and children—Poles, Russians, Ukrainians, French, Belgians, Dutch, Danes, Norwegians, Luxembourgers, Czechs, Slovaks, Hungarians, Yugoslavians, Greeks, Italians, and Algerians. Although some of the non-Jewish civilians from western Europe arrived initially as "volunteers" (*Freiwillige*), subsequently to be turned into slave labourers (*Sklavenarbeiter*), almost all of the millions were rounded up by force, transported to Germany in boxcars, and put to work in factories, mines, and fields under conditions that were degrading and brutal. Housing was so deplorable, rations were so meagre, and work was so excessive that few persons could survive long internment. Crematoriums were established in some camps to dispose of the bodies of the dead. Toward the end of the war, when food and fuel supplies became exhausted, thousands died of starvation and disease. The Allied forces found the quick and the dead lying side by side in the barracks. Camp after camp presented a scene of horror.

From 1942 to 1943, the highly efficient organizer of Nazi war production and economy, including the provision of labour, was Albert Speer, who was subsequently sentenced at Nuremberg in 1946 to 20 years' imprisonment. The slave labour program itself was under the subordinate charge of Fritz Sauckel, as deputy general for labour allocation (*Generalbevollmächtigter für den Arbeitseinsatz*). Sauckel was hanged at Nuremberg in 1946.

Corrective labour camps of the Soviet Union. During the first years of the Soviet regime, the Cheka (All-Russian Extraordinary Commission for Repression of Counterrevolution and Sabotage) was the primary repressive instrumentality of the state. The Cheka was given the power to exile persons to concentration camps without judicial trial. It was replaced in 1922 by the OGPU (United Government Political Administration). At that time there were 23 concentration camps in various locations in the U.S.S.R.

Although its powers were not absolute, the OGPU could arrest and send to concentration camps, without trial, persons accused of political offenses, such as espionage and counter-revolution, as well as those accused of certain criminal offenses, such as looting and illegal border crossing. In 1923 the OGPU established a concentration camp on Solovetski Island in the White Sea in which prisoners were first used extensively for forced labour. Thereafter, the Soviet concentration camp system became a gigantic organization for the exploitation of inmates through work.

The OGPU established many corrective labour camps in northern U.S.S.R. and Siberia, especially during the first five-year plan, 1928–32, when thousands of rich peasants (*kulaks*) were driven from their farms under the collectivization program. The inmates of the camps in northern U.S.S.R. were used principally in the lumbering and fishing industries and on large public-works projects, such as the construction of the White Sea–Baltic Sea canal. The inmates of the Siberian camps were used principally in lumbering and mining. In 1932 the OGPU set up corrective labour camps for gold mining in the Arctic tundra along the Kolyma River in far eastern Siberia.

The OGPU was replaced by the NKVD (People's Com-

missariat of Internal Affairs) in 1934. Thereafter the corrective labour-camp system was administered by the NKVD, which had its own paramilitary force. The Stalinist purges of 1937–38 brought additional thousands of political "unreliables" into the camps. By 1939, a vast system of concentration camps, utilized primarily for forced labour, existed across the northern reaches of European Russia and Siberia. These camps were said to be essentially institutions of slavery. Inmates were housed in rough barracks and were inadequately clothed for the severe Arctic climate. The standard rations of bread and soup were scarcely adequate to maintain life. Camp commandants were credited with the amount of work produced against the amount of food consumed. As a consequence, the prisoners were driven to, and often beyond, the limits of human endurance.

The occupation of eastern Poland in 1939 and the incorporation of the Baltic states into the Soviet Union in 1940 led to incarceration in concentration camps of large numbers of non-Soviet citizens from those areas. Following the outbreak of war with Germany in 1941, the camps received prisoners of war and Soviet nationals accused of collaboration with the enemy. After the war, Soviet soldiers who had allowed themselves to be captured were sent to the camps. The powers of the NKVD were transferred to the MVD (Ministry of Internal Affairs) in 1946 and then, in turn, to the KGB (Soviet State Security Service) in 1954. Under the MVD and KGB corrective labour camps continued to serve as primary instruments not only of political control but also of the economic structure until the mid-1950s. After a worldwide survey of forced labour conducted in 1953 by the UN ad hoc Committee of Three had exposed certain conditions in the Soviet Union, the severer features of the Soviet labour system apparently were mitigated (even though the Soviet bloc had boycotted the committee's work). Soviet sources indicate that about one-third of the corrective labour camps were converted, in 1956, to the relatively milder corrective labour colonies, following a series of rebellions and strikes between 1953 and 1955.

THE UNITED NATIONS AND THE ILO

The United Nations and human rights. After the conclusion of World War II, when the United Nations organization replaced the League, the question of combatting slavery in its different forms came once again to the fore. The General Assembly, at its third session (1948), adopted the Universal Declaration of Human Rights, which in article 4 states that "1. No one shall be held in slavery or servitude; slavery and the slave trade shall be prohibited in all their forms."

Following the fourth session of the General Assembly, in 1949, an ad hoc committee of four members was set up "to survey the field of slavery and other institutions or customs resembling slavery." This body, in 1951, presented a report to the Economic and Social Council outlining a program for action. The basic ideas were that the League of Nations' 1926 Slavery Convention, binding 45 states, should be maintained in operation and brought into the framework of the UN, which, however, should also prepare a new international instrument to make sure that not only chattel slavery but also other institutions and practices already studied by the League of Nations, and servitude of women resulting from marriage practices, should be brought to an end. In addition, mindful of another experience of the former League, the Ad Hoc Committee recommended the creation of a Standing Committee of Experts to supervise the application of both the old and the new conventions.

Continued existence of slavery and other forms of servitude. The UN implemented the first recommendation in 1953 by executing a protocol transferring to its secretary general the powers and duties of the League's Secretariat in regard to the 1926 Slavery Convention. The conclusion of a supplementary convention was implemented in 1956, after a number of further studies, summarized in a report presented in 1955 by Hans Engen of Norway. In his introduction he pointed out that he endeavoured "to extract . . . only those statements which, in his

The Stalinist purges

Conditions in concentration camps

Universal Declaration of Human Rights

view, would assist the [Economic and Social] Council in surveying the extent to which slavery, and practices resembling slavery, exist in the world today." He stated, however, that the documentation was in some respects incomplete and unverified. It must also be added that a number of governments concerned either denied the information in the report, stated that it was inaccurate or out-of-date, or indicated measures had been taken to combat the objectionable practices reported. The material in the report on the continued existence of slavery (including "domestic slavery") and the slave trade concerned a number of countries in the Arabian Peninsula. Mention also was made of a few countries in Southeast Asia, Africa, and South America. The material on serfdom concerned mainly countries in Asia, although certain regions in Africa and Central America also were mentioned. The material related to "traditional forms of unpaid or underpaid personal services exacted by landowners and other employers of labour, or their agents" concerned a number of South and Central American countries, certain regions in Africa, in East and Southeast Asia, and in the north of the Arabian Peninsula. The material related to debt bondage, including pledging and pawning of third persons as security for debt, concerned a number of countries in East and Southeast Asia, in the north of the Arabian Peninsula, in various parts of Africa, and in Latin America. The material related to the exploitation of children, notably under the guise of adoption, concerned various countries of East and Southeast Asia, South America, and Africa. The material related to the "purchase" of wives and the "inheritance" of widows concerned mainly territories in Africa, northern Australasia, South America, and Asia.

The Supplementary Convention on the Abolition of Slavery, the Slave Trade, and Institutions and Practices Similar to Slavery (1956) retained the 1926 definition of slavery but supplemented it with a description of the various institutions and practices similar to slavery, referred to above, in respect to which all of the signatory states agreed to "take all practicable and necessary legislative and other measures to bring about progressively and as soon as possible [their] complete abolition or abandonment."

Further efforts of the International Labour Organisation. Another significant postwar attack on forced labour was the ILO's convention number 105, adopted in 1957 and, by the early 1960s, ratified by 91 member states and made applicable to 52 nonmetropolitan territories. The convention condemned the use of forced labour (1) as a means of political coercion or education or as a punishment for holding or expressing political views, or views ideologically opposed to the established social, political or economic system; (2) as a method of mobilizing or using labour for purposes of economic development; (3) as a means of labour discipline; (4) as punishment for having participated in strikes; (5) as a means of racial, social, national, or religious discrimination. Of the Communist bloc countries, only Poland had ratified the 1957 convention by the early 1960s.

The 1962 review by the ILO upon the operation of the convention observed that, despite various improvements, forms of forced labour "are still rife in many countries." Countries were cited in which "the expression of political opinions which do not conform to those held by the organization in power (or at least in one case on certain fundamental questions) is prohibited by various legal provisions which entail forced labour, contrary to the convention." These countries were South Africa, Spain, the U.S.S.R., and the United Arab Republic. In another group of countries—Burma, China, Republic of the Congo, Fiji, Kenya, Liberia, Northern and Southern Rhodesia (later Zambia and Rhodesia), Portugal (overseas provinces), Ruanda-Urundi (later Rwanda and Burundi), the Solomon Islands, Sudan, and Swaziland—the law "expressly provided for the possibility" of compulsory labour in normal times on public works. The ILO declared that such requirements should be terminated.

Another section of the report pointed out that a group of countries—principally nonmetropolitan areas but including Denmark and India—provided in legislation for

forced labour in public works in ways that unduly widened the concept of work for "minor communal services." In such cases work was permitted that was only indirectly of benefit to "the members of the community" from which the labour is exacted or that "is for the benefit of more than the village community." Clearly there remained adequate scope for detailed debate in each case on the problem of borderline instances of alleged forced labour.

In general, the ILO has strongly emphasized the need to develop competent forms of labour inspection in order to reduce the possibility of undetected forced labour.

(Ed.)

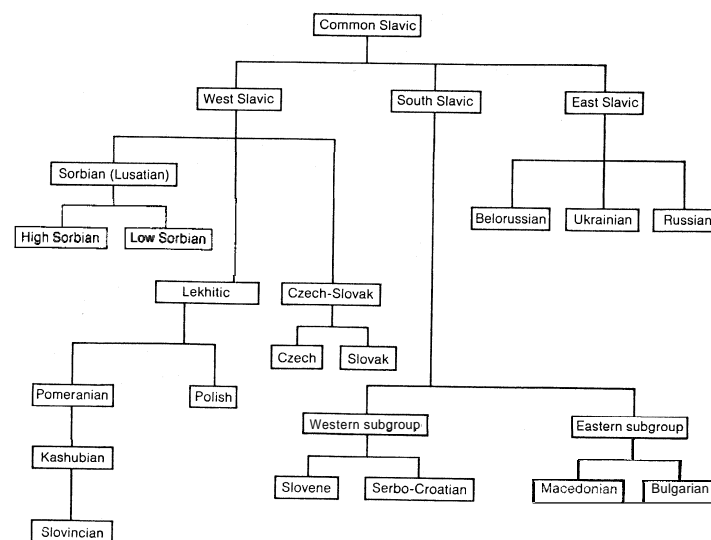

Slavic Languages

The Slavic, or Slavonic, languages, constituting a separate branch of the Indo-European language family, are closer to the Baltic languages than to any other Indo-European subgroup, but they share certain linguistic innovations with the other eastern Indo-European languages (such as Indo-Iranian and Armenian) as well. From their original area situated between the Oder and the Dnepr rivers, the Slavic languages have spread to the territory of the Balkans (Bulgarian, Serbo-Croatian), central Europe (Czech and Slovak), eastern Europe (Polish, Ukrainian, Russian), and the northern parts of Asia (Russian). The number of native speakers for the entire branch is about 260,000,000. In addition, Russian is used as a second language by most inhabitants of the Soviet Union. Some of the Slavic languages have been used by writers of worldwide significance (e.g., Russian, Polish, Czech) and the Church Slavonic language is an important means of communication within the Eastern Orthodox Church.

LANGUAGES OF THE FAMILY

The Slavic language group is divided schematically into three branches: South Slavic, with two subgroups—Serbo-Croatian-Slovene and Bulgarian-Macedonian; West Slavic, with three subgroups—Czech-Slovak, Sorbian, and Lekhitic (Polish and related tongues); and East Slavic comprising Russian, Ukrainian, and Belorussian.

Three branches of Slavic

In the spoken Slavic dialects (as opposed to the sharply differentiated literary languages) the linguistic frontiers are not always apparent. There are several transitional dialects and mixed forms of speech that connect the different languages, with the exception of the area where the South Slavs are separated from the other Slavs by the non-Slavic Romanians, Hungarians, and German-speaking Austrians. But even in this latter domain, some vestiges of the old dialectal continuity (between Slovene and Serbo-Croatian, on the one hand, and Czech and Slovak, on the other) that was later interrupted can be traced; the same traces of the old links are seen in comparing Bulgarian and Russian dialects. Thus the traditional schematic division of the Slavic group into three separate branches is not to be taken as the real model of historical development. It would be more realistic to represent the historical development as a process in which tendencies to differentiate and to reintegrate the cognate dialects have been continuously at work, bringing about the remarkable degree of uniformity in the different dialects. Still it would be an exaggeration to suppose that communication between any two Slavs is possible without any linguistic complications. The myriad differences between the dialects and languages in phonological and phonetic realization as well as in the spheres of semantics and morphology may cause misunderstandings even in the simplest of conversations; and the difficulties are greater in the language of belles lettres, even in the case of closely connected languages. For a Slav to master effectively a second Slavic language demands time and work.

South Slavic. Bulgarian is spoken by almost 8,000,000 people in Bulgaria and adjacent areas of other Balkan countries and the Soviet Union. There are two major groups of Bulgarian dialects: an Eastern one that became the basis of the literary language in the middle of the 19th century and a Western one that influenced the literary language. Bulgarian texts prepared before the 16th century were written mostly in an archaic language that preserved some features of Old Bulgarian (10th to 11th centuries) and Middle Bulgarian (beginning in the 12th century).

Although the vocabulary and grammar of the early texts written in the Old Church Slavonic language include some Old Bulgarian features, the language was nevertheless based originally on a Macedonian dialect. Old Church Slavonic was the first Slavic language to be put

down in written form, by SS. Cyril and Methodius. The modern Macedonian language, spoken by more than 1,000,000 people in Yugoslavia and Greece, was the last Slavic language to attain a standard literary form; during World War II, its central dialects of Prilep and Veles were elevated to this status. The Central Macedonian dialect is closer to Bulgarian, while the Northern dialect shares some features with the Serbo-Croatian language. Modern Macedonian dialects may be considered as links between the Eastern (Bulgarian) subgroup of South Slavic and the Western (Serbo-Croatian) subgroup.

The Western subgroup of South Slavic includes the dialects of Serbo-Croatian, among them those of the Prizren-Timok group, which are close to some North Macedonian and West Bulgarian dialects. The literary Serbo-Croatian language was formed in the first half of the 19th century on the basis of the Shtokavian dialects that extend over the greater part of the Serbo-Croatian territory in Yugoslavia. These dialects are called Shtokavian because they use the form *Jto* (shto) for the interrogative pronoun "what?". They are distinguished from the Chakavian dialects of western Croatia, Istria, the coast of Dalmatia (where a literature in that dialect developed in the 15th century), and of some islands in the Adriatic; in those areas *ča* (cha) is the form for "what?". A third main group of Serbo-Croatian dialects, spoken in northwestern Croatia, uses *kaj* rather than *Jto* or *ča* and is therefore called Kajkavian. In all, more than 15,000,000 people speak Serbo-Croatian.

The Slovene language is spoken by almost 2,000,000 persons in the Socialist Republic of Slovenia in federal Yugoslavia and in the adjacent areas of Italy and Austria. It has some features in common with the Kajkavian dialects of Croatia and includes many dialects with great variations between them. In Slovene (particularly its Western and Northwestern dialects) some traces can be found of old links with the West Slavic languages (Czech and Slovak).

West Slavic. To the West Slavic branch belong Polish and some remnants of other Lekhitic languages (Kashubian and its archaic variant Slovincian), Low and High Sorbian (also called Lusatian or Wendish), Czech, and Slovak. Approximately 40,000,000 people speak Polish in Poland, in some regions of Czechoslovakia and the Soviet Union, and in the United States and Canada. The main Polish dialects are Great Polish (in the northwest), Little Polish (in the southeast), Silesian, and Mazovian. The last dialect shares some features with Kashubian. There are about 200,000 native speakers of Kashubian remaining in Poland on the left bank of the Lower Vistula River. Slovincian belongs to the Northern group of Kashubian dialects, which is distinguished from a Southern group. Kashubian dialects (including Slovincian) are considered to be the remnants of a Pomeranian subgroup that belonged to the Lekhitic group. Lekhitic also included Polabian, which was spoken up to the 17th and 18th centuries by the Slavic population of the Elbe (Labe) River region. (At that time a dictionary and some phrases in the language were written down.)

The Polabian language bordered the Sorbian dialects, which are still spoken by about 120,000 inhabitants of Lower Lusatia and Upper Lusatia in East Germany. There are three main groups of Sorbian dialects: High Sorbian (Upper Sorbian), one of whose dialects in the area of Bautzen (Budyšin) is the basis of the literary language; Low Sorbian (or Lower Sorbian); and East Sorbian, the remnants of which are spoken in the area of Muskau (Mużakow).

Czech is spoken by over 9,000,000 people in the western part of Czechoslovakia (Bohemia, Moravia, and Silesia); its dialects are divided into Bohemian, Moravian, and Silesian groups. The literary language is based on the Central Bohemian dialect of Prague. The Slovak literary language was formed on the basis of a Central Slovak dialect in the middle of the 19th century. Western Slovak dialects are close to Moravian and differ from the Central and the Eastern dialects, which have features in common with Polish and Ukrainian. More than 4,000,000 people speak Slovak; they are located mostly in Slovakia.

East Slavic. Russian, Ukrainian, and Belorussian (White-Russian) comprise the East Slavic language group. Russian is the native language of about 130,000,000 people and is widely used by many others in the Soviet Union and in some other eastern European countries. Its main dialects are divided into a Northern Great Russian group, a Southern Great Russian group, and a transitional Central group.

Ukrainian dialects are classified into Northern, South-eastern, Southwestern, and Carpathian divisions (the last group having features in common with Slovak); the literary language is based on the Kiev-Poltava dialect. More than 41,000,000 people speak Ukrainian in the Soviet Ukraine, and there are more than 500,000 Ukrainian speakers in Canada and the United States.

More than 9,000,000 people speak Belorussian in the Belorussian Soviet Socialist Republic. Its main dialectal groups are Northwestern Belorussian, some features of which may be explained by contact with Polish, and Northeastern Belorussian. The dialect of Minsk, which served as a basis for the literary language, lay on the border between these two groups.

HISTORICAL SURVEY

The Slavic protolanguage. Each branch of Slavic originally developed from a dialect of Proto-Slavic, the ancestral parent language of the group, which in turn developed from an earlier language that was also the antecedent of the Proto-Baltic language. Both Slavic and Baltic share with the eastern Indo-European languages (called satem languages) the same change of Indo-European palatalized *k* and *g* sounds (consonants modified by bringing the front of the tongue up to or toward the hard palate) into spirants of the *s* and *z* type (e.g., in Proto-Slavic **ssto* "hundred" contrasts with Latin *centum*, etc.). The Slavic and Baltic branches are distinguished by such innovations as: (1) the change of the old Indo-European syllabic *r*, *n*, and *m* (which functioned as vowels) to *ir*, *ur*, and related variants; (2) the same patterns of stress in nouns and verbs; and (3) the same reshuffling of the verbal system to produce two forms of the past tense in *-ā* and *-ē*.

Some scholars believe that, after the common Indo-European area had been divided into different dialect zones (approximately after the 3rd millennium BC), a protodialect developed in the Baltic and Slavic areas that had many features peculiar to only these two branches of Indo-European. At the same time this protodialect was connected with certain western Indo-European protodialects called Old European that are identified as the source of a number of river names. The ancient Baltic and Slavic names of rivers (hydronyms), such as the Russian Oka, are of the same type as those found in the central European area. The dialects of the Slavic protolanguage spoken near the Carpathian Mountains in the upper Vistula area may have been part of the intermediate zone situated between the western Indo-European dialects (Germanic, Celtic, Italic, and so on) and the eastern Indo-European ones; in addition to Baltic and Slavic in the north, this intermediate zone included the Indo-European languages of the Balkans (Illyrian, Thracian, Phrygian). The domain of the Proto-Balto-Slavic dialect may have been situated to the east of the Germanic and other Old European dialects, to the north of Ancient Balkanic (including Illyrian), and to the west of Tocharian. The exact geographical borders of the Balto-Slavic domain appear impossible to determine, but they may well have been located in eastern Europe around present-day Lithuania and to the east and south of it. The later diffusion of Slavic languages southward into the Carpathian region may represent the spread of one of the dialects of this Old Baltic domain. The oldest Slavic protolanguage may be described as the result of the historical transformation of the Baltic protolanguage (but not vice-versa).

Until the middle of the 1st millennium AD, the Slavs were known to other people as the inhabitants of the vast territories between the Dnepr and the Vistula. In the 6th century AD the Slavs expanded to the Elbe (Labe)

Slavic

Distribution of the Slavic languages in Europe.

River and the Adriatic Sea and across the Danube River to the Peloponnese. In that period, according to the oldest references of Greek and Latin sources about the Slavs, they were already divided into several groups. The Slavic language, however, was uniform in its phonological and grammatical structure, with important dialectal variations occurring only in the vocabulary. The main phonological difference between the oldest pattern common to Baltic and Slavic and the later one that characterized Slavic alone was that in Slavic all syllables became open (*i.e.*, a syllable could end only in a vowel). Thus, all consonants at the end of a syllable were lost. This led to a reshuffling of most of the inflectional endings.

The next period in Slavic linguistic history began with the loss of the reduced vowels, called yers (*jeri*), that resulted from Indo-European short *ĩ* and *ũ*; this loss caused a wide-ranging change in many words and forms. Although this process was common to all the Slavic dialects, which were still connected with each other at that period, it took place slowly and at different rates in

different dialects, beginning in the 10th to the 12th century and expanding from the southwest to the northeast. After the loss of the yers, which gave different results in different dialectal groups (see Table 3), the uniformity of the Slavic language area began to disappear, and separate branches and languages emerged. An important clue to the date of the dissolution of Slavic unity is the separate development in different Slavic dialects of the name of the emperor Charlemagne (742–814). This name must have entered into Slavic in the postulated form **korljъ* ("Karl") before the dissolution took place. Subsequently the proper name became the generic term for "king." The segment *-or-* in the postulated form appears differently in the modern Slavic languages—compare Bulgarian *kral*, Serbo-Croatian *kralj*, Slovene *králj* (*i.e.*, South Slavic *-ra-*), Russian *korol* (*i.e.*, East Slavic *-oro-*), Czech *král*, Polish *król*.

Emergence and early development of the Slavic languages. The separate development of South Slavic was caused by a break in the links between the Balkan and

Disruption
between
South
Slavic
and West
Slavic
groups

the West Slavic groups that resulted from the settling of the Magyars in Hungary during the 10th century and from the Germanization of the Slavic regions of Bavaria and Austria. Some features common to Slovak and Slovene may possibly have developed before the West-South break. The eastward expansion of dialects of Balkan Romanian (a Romance language) led to a break in the connection between the South and the East Slavic groups around the 11th–12th centuries. The history of the Balkan Slavs was closely connected with Byzantium, in contrast to that of the Lekhitic and Sorbian subgroups of the Western Slavs, which was connected with west European culture.

An effort on the part of the Slavs to counteract the influence of the Western Christian Church (which was associated with the German Empire) was the motive behind the introduction of the Old Church Slavonic language into the liturgy in Great Moravia, the first Slavic national state. Founded in the 9th century, Great Moravia united different groups speaking West Slavic dialects. In 863 its prince, Rostislav, invited St. Cyril (Constantine) and his brother St. Methodius to create a national church with a language and writing of its own. Prior to that time some Christian texts in Moravia had been translated into Slavic from Latin (and partly perhaps from Old High German); these have been preserved only in later copies.

The second period in the history of the Old Church Slavonic language (893–1081) occurred in the Bulgarian kingdoms of Symeon (893–927) and Peter (927–969) and in the kingdom of Samuel (997–1014), and was connected with the literary activity of many Bulgarian scholars who translated numerous Greek texts into Slavic and also produced a small number of original works. In the writings of the period of Symeon and Peter, Western (Macedonian) features were substituted for Eastern Bulgarian ones.

Reflection
of Old
Church
Slavonic
variants
in various
manu-
scripts

Development of the individual Slavic languages. Both the Western (Macedonian) and Eastern (Bulgarian) variants (recensions) of the Old Church Slavonic language are preserved in manuscripts of the 11th century, while the East Slavic (Russian) variant is reflected in the oldest dated Old Church Slavonic manuscript, Ostromir's *Evangelium* (1056), and in many later texts. The Moravian variant must be reconstructed on the basis of some later texts (such as the Kiev fragments of the beginning of the 11th century) dating from after the break with the Great Moravian tradition. In some documents of the 10th and 11th centuries, the Bohemian variant (sharing some West Slavic peculiarities with Moravian) has been preserved. Several features are common to the Moravian and Bohemian varieties of the Old Church Slavonic language, to the Slovene (Pannonian) variant reflected in the Freising fragments (late 10th century), and to the Croatian Old Church Slavonic tradition that is attested from the 12th century, as well as to the Serbian tradition. All these variants of the Old Church Slavonic language have some peculiarities that are to be explained as the result of the interaction of the original system with that of a local dialect. At about 1000 all Slavic languages were so close to one another that such interaction was possible.

From these local variants of the Old Church Slavonic language that are preserved in the manuscripts of the 10th to the 12th centuries, one should distinguish the later local Church Slavonic languages (Russian, with its different variants; Middle Bulgarian; Serbian, which was replaced by the Russian variant in Serbia in the 18th century; Croatian; and the Romanian variant of Church Slavonic, which was used as a literary and church language of Romania from the 14th to the 18th centuries). From the linguistic point of view, these later Church Slavonic literary languages differ from the earlier varieties in their systems of vowels; the early nasalized vowels were replaced by different later reflexes, and the reduced vowels (*yers*), with the exception of those followed by a syllable containing another *yer*, were generally lost. These changes in the sound pattern were accompanied by changes in vocabulary that were the result of cultural factors.

After the schism between the Eastern (Orthodox) and

Western (Roman) Christian churches in the 11th century and the beginning of the Crusades, the Church Slavonic language fell out of use in all West Slavic countries and in the western part of the Balkan Slavic region. The only exception was the renaissance of Croatian Church Slavonic in the 13th century. At the end of the same century, the first Czech verses in the local dialect were written; they were the precursors of the rich poetic literature in the Old Czech language that appeared in the 14th century. The early Czech literary language was marked by the influence of Latin, which had replaced the Bohemian variety of Old Church Slavonic as a literary language.

In the earliest period of its development, the Polish literary language was modelled on the Czech pattern. After the Christianization of Poland, Latin (and later German) loanwords entered the Polish language in their Czech form. The Czech influence is seen in the Polish literary language until the 16th century (the "Golden Age"), when Renaissance tendencies resulted in the creation of texts that had aesthetic merit and were at the same time stylistically close to everyday speech. Later on the Polish literary language was enriched by cross-fertilization with Ukrainian and Belorussian.

In the 16th century in Dalmatia, a rich poetic literature in Croatian was created by poets who were influenced by the Italian Renaissance and who also wrote in Italian and Latin. A Slovene translation of the Bible was published in 1575–84 and Kashubian and Sorbian religious texts were also produced during this period. The comparatively early rise of the West Slavic (and western South Slavic) languages as separate literary vehicles was related to religious and political factors that resulted in the decline of the western variants of the Church Slavonic language.

In contrast, the continuing use of Bulgarian Church Slavonic and different variants of Russian Church Slavonic made it difficult to construct literary languages for Bulgarian and Russian based on everyday speech. Bulgarian texts were written in Bulgarian Church Slavonic until the 16th century. After that the language of the so-called Damaskinar (Damascene) literature was developed, closer to the popular speech; its development, however, was hampered under Turkish rule. Most of the Old East Slavic (Old Russian) literary texts were written in a mixture of Russian Church Slavonic and the Old Russian vernacular language; only a few documents, particularly some parts of the chronicles (annals), are written entirely in Old Russian. The proportion of South Slavic (Church Slavonic) and East Slavic (Old Russian) elements in each text is different depending on its stylistic peculiarities.

In the middle of the 17th century, the old Great Russian variant of the Church Slavonic language in the official Russian Orthodox Church was replaced by a new variant taken from the southwestern East Slavic tradition, a form that incorporated some Ukrainian and Belorussian elements. This development was connected with a split in the Orthodox Russian Church; the Old Believers, who split off from the main body of the church, continued to use the archaic Great Russian variant, while Patriarch Nikon's new variant, based on the southwestern tradition, was adopted by the official church and is used in it to this day. Because the Ukrainian tradition includes many West Slavic elements, this reform, which occurred after the incorporation of the Ukraine into the Russian Empire, was a step in the direction of the Westernization of the Russian language that took place soon after Peter the Great began his attempts to reconstruct and Westernize the whole Russian way of life.

In the 18th and 19th centuries, many waves of loanwords from different Western languages entered the Russian language. While some of the syntactic structures earlier had been formed on Germanic and Latin patterns, many western European semantic characteristics penetrated into the Russian language as a result of the intensive French–Russian bilingualism of the Russian upper classes at the end of the 18th and the beginning of the 19th century. The great Russian literature of the 19th and the early 20th century (up until Tolstoy's death in 1910) created a literary language close to everyday speech,

Linguistic
results of
religious
schism

especially to that of the villages. In the official style of Russian, however, Church Slavonic elements still dominate, as can be seen even in general newspaper articles.

The concept of a language that would unite all the Slavs has remained in the back of the Slavic consciousness, not as a real aim but rather as an important symbol. The most interesting attempt to unite different chronological and local Slavic strata was carried out by the Serbian Romantic writer Vuk Stefanović Karadžić. In modern literature one might cite the experiments at unification of Velemir Khlebnikov, a Russian futurist writer, and of the Polish poet Julian Tuwim, who created a Polish–Russian symphony of sounds in some of his poems.

Standardization of the modern Slavic languages.

Among the Slavic languages that attained their standard literary form at a later stage in Slavic history than those mentioned above is Ukrainian. It was used in some literary texts in the late 18th century and in turn influenced the language of Gogol, one of the greatest Russian writers of the 19th century, to the extent that the language of some parts of Gogol's early texts may be described as a mixed Russian–Ukrainian dialect. In the 19th century and especially in the first decades of the 20th century, a number of great poets wrote in Ukrainian. The movement toward national liberation led to the introduction of many neologisms into the language, which persisted even after some attempts were made toward the artificial unification of the East Slavic area. After World War I, the Belorussian language became a standard language in the Belorussian Soviet Socialist Republic.

Since World Wars I and II, all of the Slavic languages have acquired the status of either the main language of an independent state (e.g., Bulgarian and Polish) or the language of an autonomous part of a state (e.g., Russian, Ukrainian, and Belorussian in the Soviet Union; Serbo-Croatian, Slovene, and Macedonian in Yugoslavia; Czech and Slovak in Czechoslovakia). Only the minor languages are exceptions: Kashubian is used officially only in some cultural performances, and Low and High Sorbian are now taught in schools in East Germany. The extent of dialectal variation in the different languages ranges from a very great degree in Slovene to a much smaller degree in some areas of such languages as Polish and Russian. Radio and other mass media have been among the main influences leading to linguistic consolidation. Languages like Polish, Czech, and Russian, which have served as a basis for great literatures, have become models for others that are only now being put to literary use (although for such languages as Kashubian and, to some degree, for High and Low Sorbian, the folk literature remains much more important as a model than individual literary works and translations of past centuries).

LINGUISTIC CHARACTERISTICS

A number of distinguishing characteristics set off the Slavic languages from other Indo-European subgroups. On the whole, Slavic auxiliary words tend to be unstressed and to be incorporated into a single phonetic group or phrase with autonomous stressed words. Inflection (i.e., the use of endings, prefixes, and vowel alternations) has persisted as the main method of differentiating grammatical meanings, although to a lesser degree in the nouns than in the verbs because many functions of the noun case endings may also be expressed by prepositions. Verbal categories have retained their complex archaic character. The movable stress pattern common to most South and East Slavic languages has had a profound influence on versification in these languages.

Many linguistic devices found both in the oral tradition and in individual literary works of the different Slavic languages may be traced to common ancestral forms. An exuberant use of diminutives and metaphoric figures marks the Slavic oral tradition. It seems possible to reconstruct a common Proto-Slavic model of the universe as seen through linguistic expression. The main feature of such a model is the recurrence of binary (two-way) contrasts, as is evidenced by such cue words as *bogъ* "god" from "a portion allotted by the gods" and *ne-bogъ* "not having its portion, having bad fortune." Such pairing of

opposites bears a striking resemblance to the ancient Iranian dualistic view of the world, a view that evidently influenced the Slavs to a degree not yet fully appreciated.

As compared with the common Indo-European scheme, the pre-Slavic cultural linguistic heritage seems in some degree simpler, evidently as a result of the loss of direct contact with the Southern civilizations that served as a pattern for pre-Indo-European culture. Later developments were caused largely by western European and Greek (particularly Byzantine Christian) influences and by contacts with eastern cultures, which led to innovations in the vocabularies of the East Slavic and South Slavic languages. In some instances, whole series of designations for objects were borrowed into Russian and other East Slavic languages from eastern sources.

All Slavic languages are synthetic, expressing grammatical meaning through the use of affixes (suffixes and, in verbal forms, also prefixes), vowel alternations partly inherited from Indo-European, and consonant alternations resulting from linguistic processes peculiar to Slavic alone. Although analytical methods of expressing grammatical meanings (through prepositions and other "empty" grammatical words) are present in older strata of the language, they are used to the exclusion of all other means only in the case system of Modern Bulgarian and Macedonian. The tendency toward analytic expression is noticeable in contemporary everyday Russian speech, but the drift of the Slavic languages in this direction (as in the development of the western European languages) has been held back by the stabilization of the language resulting from mass communication and education.

Phonological characteristics. The Slavic systems of distinctive sounds are rich in consonants, particularly in spirants and affricates. This is especially true in comparison with the protolanguage and with other Indo-European languages. The affricates (which are consonant sounds begun as stops, with complete stoppage of the breathstream, and released as fricatives, with incomplete stoppage) have resulted historically from a succession of different processes of palatalization that have occurred in Slavic and are one of the most characteristic features of Slavic phonology. Palatalization is the process whereby the pronunciation of an originally nonpalatal sound is changed to a palatal sound by touching the hard palate with the tongue; it is also the process whereby a nonpalatal sound is modified by simultaneously moving the tongue up to or toward the hard palate. Originally, palatalization was connected with the adaptation of a consonant to the following vowel within a syllable, specifically, with the adaptation of a consonant to a following front vowel. This adaptation gave rise to "soft" (palatalized) syllables, composed of palatalized consonants followed by front vowels. The *j* sound, as *y* in English "year" (from older nonsyllabic Indo-European *i*), tended to palatalize the preceding consonant either by merging with it or by giving rise to consonant groups such as *bl'* from *bj* (by). As palatalized stop consonants (for instance *k'*, *g'*, *t'*, *d'*) became increasingly differentiated from the corresponding nonpalatalized series (*k*, *g*, *t*, *d*), the palatalized stops tended to develop further into affricates (with the subsequent development of voiced affricates into spirants). Thus palatalized *k'* before the ancient front vowels developed into the affricate *č* (as *ch* in English "church"), and palatalized *g'* in the same environment changed to *3* (as *j* in "judge"), which became the spirant sound *ž* (as *z* in "azure") in all Slavic languages. Before front vowels resulting from ancient diphthongs, palatalized *k'* changed to a *ts* sound, written as *c* (e.g., Old Church Slavonic *cěna* "price," Serbo-Croatian *cijéna*, Russian *cena*, cognate to Lithuanian *káina*), and *g'* changed to a *dz* sound, which later changed to *z* (Old Church Slavonic [*d*] *zelo* "very," Old Czech *zielo*, Belorussian *do žěla*, cognate to Lithuanian *gailas*). The sounds *t'* (from *tj*) and *d'* (from *dj*) changed, respectively, into different stops, affricates, and spirants according to special rules in the separate Slavic dialects (see Table 1).

These processes of assibilation of the palatalized velar (*k'*, *g'*) and dental (*t'*, *d'*) sounds happened repeatedly in the history of the individual Slavic languages. Palataliza-

tion (softness) as a distinctive feature of most consonant sounds has been preserved in East Slavic; for example, in Modern Russian palatalized (or soft) *t'*, *d'*, *s'*, *z'* contrast with nonpalatalized (or hard) *t*, *d*, *s*, *z*. (The contrast between the palatalized *k'* and the hard *k* is just now in the process of development.) Some West Slavic languages also have this palatalized–nonpalatalized contrast, while others do not. Czech, Slovak, and Serbo-Croatian, which have the usual three sets of labial, dental, and velar consonants inherited from the proto-language, have developed a special, additional series of palatal stops. In all of the Slavic languages, voiced stop consonants (pronounced with vibrating vocal cords) contrast with voiceless stop consonants (pronounced without vibrating vocal cords).

The tendency to increase the number of different spirants (nonstops) is connected with the processes of palatalization. In the Ukrainian and the Southern Russian dialects and in Belorussian, Czech, Slovak, High Sorbian, and some Slovene dialects there also developed a voiced velar spirant sound, corresponding to the voiceless velar spirant of the Proto-Slavic language. The nasal vowels *ę* and *o* that had developed in Proto-Slavic from older combinations of vowels with nasal consonants (still retained in Baltic) have been preserved only in some Lekhitic languages and in some South Slavic dialects, especially those of Slovene (see Table 2). The vowel systems are especially rich in those Slavic languages that have preserved prosodic differences in pitch (tone) and quantity (length)—Serbo-Croatian, Slovene, and Northern Kashubian. The reshaping of the Slavic vowel systems is in large measure a result of the loss of the yers, which had different effects in different dialects (see Table 3).

Table 2: Development of Proto-Slavic Nasal Vowels Compared with Baltic

English translation	Lithuanian	Serbo-Croatian	Polish	Russian
"I spin"	sprendžiū	predem	przędę	pryadu
"snipe, woodcock"	slanka	Sljuka	ślōnka	sluka (obs.)
"soft"	minkštas	mek	miękki	myagky
"wise"	maiidras	mudar	mądry	mudry

Prosodic differences in vowel quantity have been preserved in Czech and Slovak, in which new vowels developed as a result of contraction. A fixed stress accent is found in the West Slavic languages as well as the Western and Central Macedonian dialects, in contrast to Proto-Slavic, Serbo-Croatian, Slovene, Bulgarian, and the East Slavic languages. In Czech and Slovak, as well as in Sorbian and Southern Kashubian, stress is fixed on the first syllable of the word, but in Polish, Eastern Slovak, and Southern Macedonian, it falls on the next to the last syllable of the word, while in Western Macedonian it falls on the third syllable from the end. The Slavic languages

with a nonfixed placement of stress reflect the Proto-Slavic (and Indo-European) distinction between two types of noun and verb paradigms: (1) the paradigm with movable stress in which the stress (indicated here by ') falls on the root in some forms and on the inflectional ending in others (e.g., "head" in Russian is *golová* in the nominative case and *gólovu* in the accusative, these forms derive from Proto-Slavic **golvá*, **gólvo* [an asterisk indicates an unattested, reconstructed form]) and (2) the paradigm in which the stress is fixed on the stem (e.g., "willow" in Russian is *iva* in the nominative case, *ivu* in the accusative, from **íva*, **ívō*).

Grammatical characteristics. Most Slavic languages reflect the old Proto-Slavic pattern of seven case forms (nominative, genitive, dative, accusative, locative, instrumental, vocative), which occurred in both the singular and the plural. In the dual number the cases that were semantically closest to each other were represented by a single form (nominative–accusative, instrumental–dative, genitive–locative). The dual number is preserved today only in the westernmost area (i.e., in Slovene and Sorbian) and in the archaic Slovenian language. The trend toward the modern, more analytical type of construction using prepositions and away from the synthetic type using case endings exclusively (as in Proto-Slavic and the archaic Slavic languages), is evident in the gradual elimination of the use of the dative and locative forms without prepositions. The end result of this development is seen in Bulgarian and Macedonian, in which noun declension has almost completely disappeared and has been replaced by syntactic combinations using prepositions. In the other South Slavic languages and in the western part of the West Slavic area (Sorbian and Czech), the same tendency to lose some of the distinctions between cases may be seen, but to a lesser degree. In the other West Slavic languages and in East Slavic, on the other hand, the old system of cases has been preserved in spite of the large number of loanwords and other neologisms that have no case distinctions at all (e.g., borrowed Russian nouns like *kino* "cinema," or acronyms ending in a vowel like Rayono "district people education department").

The declension of pronouns has been preserved in all Slavic languages. The old combinations of adjectives with pronouns gave rise to the definite forms of adjectives. These forms still contrast with the indefinite forms in South Slavic, but in the other languages the indefinite forms have either been gradually lost or else have been preserved only to serve a special function, that of predicate noun. In Bulgarian and Macedonian, as well as in some northern East Slavic dialects, an article is used, placed after the noun (e.g., in Macedonian, *knigata* "book-the"). The noun may be combined with either an article, as in the above example, or with a deictic (pointing) pronominal element—e.g., in Macedonian, *kniga-va* "this book here," or *kniga-na* "that book there." In addition to three noun genders (masculine, feminine,

The seven case forms

Table 3: Results of Loss of Yers

neuter), many Slavic languages distinguish animate and inanimate noun forms of some cases; and in some West Slavic languages, Ukrainian, and Bulgarian, personal and nonpersonal noun forms are differentiated.

Verb
tenses

In the modern Slavic languages the verb is inflected to show present and past tenses. In the early history of the individual Slavic languages, however, a distinction was made between the aorist (originally differentiated as to voice, as in Baltic and Greek) and the imperfect; this distinction is still preserved in modern South Slavic (with the exception of Slovene) and Sorbian. (The aorist is a verb form indicating the occurrence of an action without reference to its completion, repetition, or duration; the imperfect is a verb tense designating a continuing state or an uncompleted action, especially in the past.) Slavic has almost no traces of the Indo-European old perfect tense, but, from combinations with the verbal noun in -l, new perfect forms were created that were differentiated from the pluperfects. Later these perfect forms came to be used as past tense forms in different Slavic languages. The most striking feature of the Slavic verb is the existence of paired stems to express the perfective (completed) and imperfective (uncompleted) aspects of the same verb—e.g., Russian *dat'* "to give" (i.e., "to complete the process of giving"), *davat'* "to be in the process of giving."

The present tense form of a perfective verb may be used to express future meaning, which can also be indicated by other means. In most South Slavic languages it is expressed by combinations (originally syntactic) with the verb "to want." The eastern South Slavic languages, Bulgarian and Macedonian, have lost the infinitive forms of the verb as a result of the influence of non-Slavic Balkan languages. These same Slavic languages have developed verb forms to differentiate between an action witnessed by the speaker and one not witnessed (hence only reported) by him.

A striking feature of Slavic syntax is the widespread use of possessive adjectives (e.g., Russian *bozheskaya milost* "the mercy belonging to God") instead of the genitive case of the noun (*milost boga* "the mercy of God"). Word order in the Slavic languages is characterized by a gradual shift of the verb toward the medial position; originally the initial position was more characteristic. Other important features of Slavic syntax are related to this medial positioning of the verb and the consequent occurrence of the verb before the object. For example, grammatical elements are often placed before nouns; today they follow nouns only in some set phrases like Old Church Slavonic *boga radi* "for God's sake," with *radi* following the noun *boga* "God's."

Originally the verb occupied the initial position, which throws light on the origin of the reflexive verbal forms; these may be traced to the Proto-Slavic combination of the verb with a reflexive pronoun that occurred immediately after the verb and was pronounced as part of one accentual unit with the verb. Words other than pronouns that occurred immediately after verbs were also pronounced as a unit with them (these called enclitics).

The rules for the shift of the stress in syntactic combinations with enclitics were identical for verbs and nouns. Depending on the intonation of the word preceding the enclitic, the stress could be shifted either to the enclitic (as in Bulgarian *zimŭs* "this winter") or to the proclitic or preceding unstressed particle or word (as *na* in Serbo-Croatian *ná brijeg* and Russian *ná bereg* "on the shore").

Vocabulary. The original vocabulary of general terms common to Baltic and Slavic is still retained in most of the Slavic languages. In prehistoric times Proto-Slavic borrowed a number of important social and religious terms from Iranian (e.g., *bogŭ* "God," *mirŭ* "peace"). Later, special terms were borrowed by East Slavic and South Slavic from different eastern languages (especially Turkish) as a result of the political domination of the Tatars in Russia and of the Turks in the Balkan area. After the Renaissance, loanwords were taken from classical and western European languages (especially German and French) into all of the Slavic languages. Church Slavonic

in its different variants remained the main source of innovations in vocabulary in East Slavic and in some South Slavic languages. The Slavic languages make extensive use of prefixes and suffixes to derive new words and thereby enrich the vocabulary; e.g., Russian *čern-y* "black," *c'ern-i-t'* "to blacken," *o-čern-i-t'* "to slander." Several prefixes may be combined to modify the meaning of a verb (e.g., Ukrainian *po-na-vi-pisuvati*, in which three prefixes are added to the verb "to write" to convey the meaning "to write out copiously"; Bulgarian *is-po-razboleyase*, in which the added prefixes intensify the meaning "to develop an illness"). Many derivational suffixes are common to most Slavic languages—e.g., the very productive suffix *-stvo* (as in Russian *khristian-stvo* "Christianity," Ukrainian *pobratim-stvo* "fraternity," Polish *glup-stvo* "foolishness, trifle," Macedonian *golenz-stvo* "high status, arrogance"). The archaic type of derivation by compounding, inherited from Indo-European, was particularly productive in Church Slavonic under the stimulus of Greek. Compounding remains one of the methods of creating new terms, especially technical terms (e.g., Russian *vodokhranilishe* "reservoir" from *voda* "water" and *khranilishche* "depository"), but is far less important than affixation. Some Slavic languages typical-

ly derive new words by means of a condensed suffixing (e.g., Czech *železnice* "railroad," from *železo* "iron" combined with a noun-forming suffix; *hledisko* "point of view," from *hled* "look" combined with a noun-forming suffix), while others tend to use phraseological combinations of words (e.g., Russian *vodokhranilishche*, or the adjective *železnodorožny* "railroad," from *zeleznaya doroga* "iron road" combined with an adjective-forming suffix).

Writing systems. The first writing system used for Slavic was the Glagolitic system invented by St. Cyril. Quite original in pattern, it reflected accurately the sound system of the Macedonian dialect. The forms of its letters can be traced to several different alphabets, mainly Greek and Semitic ones. Glagolitic was widely used in the first three centuries of Slavic literature but was gradually replaced by the Cyrillic alphabet, created in the 10th century and still used to write all the East Slavic languages, Bulgarian, Macedonian, and Serbian.

Other Slavic languages use the Latin (roman) alphabet. To render the specific distinctive sounds of a Slavic language, either Latin letters are combined or diacritic signs are used (e.g., Polish *sz* for the *sh* sound in "ship," Czech *č* for the *ch* sound in "church"). An orthographic system devised by the Czech religious reformer Jan Hus was adopted into different West Slavic systems of writing, including Czech, Slovak, and Sorbian. Polish spelling was patterned after the Czech spelling of the 14th century. Most of the Slavic writing systems are closely related to the sound patterns of the individual languages and are constructed either to symbolize the distinctive sounds of the language or to render the same morphemes by the same groups of letters despite differences in pronunciation in various forms. Modern Russian spelling reflects a morpheme-based principle.

BIBLIOGRAPHY. ROMAN JAKOBSON, *Slavic Languages*, 2nd ed. (1955), is the best short structural sketch. A useful general survey is REINHOLD TRAUTMANN, *Die slavische Völker und Sprachen* (1947). The comparative grammar is described in the following works: ANTOINE MEILLET, *Le Slave commun*, 2nd ed. rev. (1934), the best introduction to Proto-Slavic from the point of view of Indo-European; VACLAV VONDRÁK, *Vergleichende slavische Grammatik*, 2 vol. (1924–28), rich in material; JOSEPP J. MIKKOLA, *Urslavische Grammatik*, 3 vol. (1913–50), condensed, but not quite up-to-date now. The general drift of the languages is seen in RAJKO NAHTIGAL, *Slovanski jeziki*, 2nd ed. (1952). A traditional approach to the history of the phonemic systems is exemplified in САМУИЛ БОРИСОВИЧ ВЕРНИШТЕЙН, *Очерк сравнительной грамматики славянских языков*, vol. 1 (1961); ANDRÉ VAILLANT, *Grammaire comparée des langues slaves*,

Щ	щ	Щ	щ	sht	Ger. still
Ъ	ъ		ъ*	û	above
	ь		ь		‡‡
Ю	ю	Ю	ю	yu	youth‡
Я	я	Я	я	ya	yard‡

*û can occur initially in only a few words. †When transliterated, this is represented by an apostrophe. In modern orthography ' is used medially and finally for the y consonant before o and is pronounced yonder. ‡When ya, yu, and 'o are preceded by consonants they are themselves pronounced like a, u, and o, respectively, but cause the preceding consonant to be palatalized. The softening is less great in Bulgarian than it is in Russian.

vol. 1 (1950); and PEETER ARUMAA, *Urslavische grammatik*, vol. 1 (1964); recent developments in the diachronic phonology are summarized in ROMAN JAKOBSON, *Selected Writings*, 2nd ed., 6 vol. (1971–); FRANTISEK MARES, *The Origin of the Slavic Phonological System and Its Development Up to the End of Slavic Language Unity* (1965); GEORGE SHEVELOV, *A Prehistory of Slavic* (1964); CHRISTIAN S. STANG, *Slavonic Accentuation* (1957); and NICHOLAS VAN WILK, *Les Langues slaves, de l'unité à la pluralité*, 2nd ed. rev. (1956). The dialectal differentiation of Proto-Slavic from the point of view of comparative phonology is analyzed in ANTONI FURDAL, *Rozpad języka prasłowiańskiego w świetle rozwoju głosowego* (1961); and HENRIK BIRNBAUM, "The Dialects of Common Slavic," in HENRIK BIRNBAUM and JAAN PUVEL (eds.), *Ancient Indo-European Dialects* (1966). The problem of the original territory and migrations of the speakers of Proto-Slavic is discussed in the light of linguistic and archaeological evidence in the following works: TADEUSZ LEHR-SPLAWINSKI, *O pochodzeniu i praojczyźnie Słowian* (1964), a brilliant survey using archaeological data; KAZIMIERZ MOSZYŃSKI, *Pierwotny zasięg języka prasłowiańskiego* (1957), employs a strictly linguistic approach, and is hardly convincing; K.H. MENGES, *An Outline of the Early History and Migrations of the Slavs* (1953), cites important Oriental sources; MARIJA GIMBUTAS, *The Slavs* (1971), provides an archaeological and linguistic survey of Slavic migrations to Central Europe and the Balkan Peninsula; and S.H. CROSS, *Slavic Civilization Through the Ages* (1948, reprinted 1963), provides some general information. The only reliable Common Slavic etymological dictionary remains the unfinished work of ERICH BERNEKER, *Slavisches etymologisches Wörterbuch*,

2nd ed., vol. 1 (1924). Of essential value for proof of the close links between Slavic and Baltic is REINHOLD TRAUTMANN, *Baltisch-Slavisches Wörterbuch* (1923); the study of verbal forms is presented in CHRISTIAN S. STANG, *Das slavische und baltische Verbum* (1942); and H. KOLLN, *Oppositions of Voice in Greek, Slavic and Baltic* (1969). For the accentual pattern of Slavic as compared to Baltic, see especially ВЛАДИСЛАВ МАРКОВИЧ ИЛИЧ-СВИТЫЧ, *Именная акцентуация в балтийской и славянском* (1963). The only English textbook introduction to concrete data on each language remains R.G.A. DE BRAY, *Guide to the Slavonic Languages*, rev. ed. (1969).

(V.V.I.)

Slavic Religion

Slavic religion as a term is taken here to include only the relevant beliefs and practices of the ancient Slavic peoples of eastern Europe. Slavs are usually subdivided into East Slavs (Russians, Ukrainians, and Belorussians), West Slavs (Poles, Czechs, Slovaks, and Lusatians), and South Slavs (Serbs, Croats, Slovenes, Macedonians, and Bulgars).

In antiquity the Slavs were perhaps the most numerous branch of the Indo-European family of peoples. The very late date at which they came into the light of recorded history (even their name does not appear before the 6th century AD) and the scarcity of relics of their culture make serious study of them a difficult task. Sources of information about their religious beliefs are all late and by Christian hands.

SLAVIC WORLD VIEW

Since *patria potestas*—i.e., paternal power in the form of absolute authority—was absent from their family structure and monarchical government from their civil society, the Slavs' pantheon of deities was without a centre or a hierarchy of divinities. As in Baltic religions each supernatural being was active in its own particular sphere without contact with other deities. Although contacts with the Indo-European world are evident (as found, for example, in the concepts of a celestial god and a god of lightning), the Slavic religious atmosphere was substantially different from that of other Indo-European peoples.

Socially the Slavs were organized as exogamous clans (based on marriages outside blood relationship) or, more properly, as sibs (related by blood) since marriage did not cancel membership in the clan of one's birth—a type of organization unique among Indo-European peoples. The elected chief did not have executive powers. The world had been created, in the Slavic view, once and for all, and no new law ought to modify the way of life transmitted by their ancestors. Since the social group was not homogeneous, validity and executive power were attributed only to decisions taken unanimously in an assembly, and the deliberations in each instance concerned only the question of conformity to tradition. Ancient Slavic civilization was one of the most conservative known on earth.

According to a primitive Slavic belief, a forest spirit, *leshy*, regulates and assigns prey to hunters. Its food-distributing function may be related to an archaic divinity. Though in early times the *leshy* was the protector of wild animals, in later ages it became the protector of flocks and herds. In early 20th-century Russia, if a cow or a herdsman did not come back from pasture, the spirit was offered bran and eggs to obtain their return.

Equally ancient is the belief in a tree spirit that enters buildings through the trunks of trees used in their construction. Every structure is thus inhabited by its particular spirit: the *domovoy* in the house, the *ovinnik* in the drying-house, the *gumenik* in the storehouse, and so on. The belief that either harmful or beneficial spirits dwell in the posts and beams of houses is still alive in Bosnia, Slovenia, and the Poznań area. Old trees with fences around them are objects of veneration in Serbia and Russia and among the Slavs on the Elbe River. In 19th-century Russia a chicken was slaughtered in the drying house as a sacrifice to the *ovinnik*. This vegetal spirit is also present in the sheaf of grain kept in the "sacred corner" of the dwelling under the icon and venerated along with

it, and also in noncultivated plant species that are kept in the house for propitiation or protection, such as branches of the birch tree and bunches of thistle. Such practices evidence the preagrarian origin of these beliefs. Similar to the *leshy* are the field spirit (*polevoy*), and, perhaps, the water spirit (*vodyanoy*). Akin to the *domovoy* are the spirits of the auxiliary buildings of the homestead.

MYTHOLOGY

Cosmogony. A myth known to all Slavs tells how God ordered a handful of sand to be brought up from the bottom of the sea and created the land from it. Usually, it is the Devil who brings up the sand; in only one case, in Slovenia, is it God himself. This myth is diffused throughout practically all of Eurasia and is found in ancient India as well.

A 12th-century German missionary, Helmold, left a record of his surprise in encountering among the Slavs on the Baltic a belief in a single heavenly God, who ignored the affairs of this world, having delegated the governance of it to certain spirits begotten by him. This is the only instance in which the sources allude to a hierarchy of divinities, but its centre is empty. The divinity mentioned by Helmold is a *deus otiosus*; i.e., an inactive god, unique in the mythology of the Indo-European peoples. Such a deity is, however, also found among the Volga Finns, the Ugrians, and the Uralians.

Principal divine beings. Common to this Eurasian area is another divinity, called by Helmold and in the *Knytlinga* saga (a Danish legend that recounts the conquest of Arkona through the efforts of King Valdemar I of Denmark against the pagan and pirate Slavs) Zerneboch (or Chernobog), the Black God, and Tiarnoglofi, the Black Head (Mind or Brain). The Black God survives in numerous Slavic curses and in a White God, whose aid is sought to obtain protection or mercy in Bulgaria, Serbia, and Pomerania. This religious dualism of white and black gods is common to practically all the peoples of Eurasia.

The Kiev *Chronicle* (also called the *Chronicle of Nestor*)—a 12th- to 13th-century account of events and life in the Kievan state—enumerates seven Russian pagan divinities: Perun, Volos, Khors, Dazhbog, Stribog, Simargl, and Mokosh. A Russian glossary to the Greek writer John Malalas' (6th century) Byzantine *Chronicle* mentions a Svarog, apparently the son of Dazhbog. Of all these figures only two, Perun and Svarog, are at all likely to have been common to all the Slavs. In Polish, *piorun*, the lightning, is derived from the name of Perun, and not vice versa. In the province of Wielkopolska the expression *do pierona*—meaning "go to the devil"—has been recorded. In the expression, *pieron/piorun* is no longer the lightning but the being who launches it. The curse is considered to be so strong that little boys in school will refuse to read it. Uncertain or indirect traces of Perun are also encountered among the Carpathians and in Slovenia and Serbia. The lightning-wielding Perun cannot be considered the supreme god of the Slavs but is rather a spirit to whom was given the governance of the lightning.

In Estonia the prophet Elijah is considered to be the successor to Ukko, the ancient spirit of lightning. Similarly, the prophet Elijah replaces Elwa in Georgia and Zeus in Greece. It is therefore probable that, among the Slavs also, Elijah is to be considered a successor of Perun. According to a popular Serbian tradition, God gave the lightning to Elijah when he decided to retire from governing the world. The Serbian story agrees with Helmold's description of the distribution of offices by an inactive God. Elijah is a severe and peevish saint. It is rare that his feast day passes without some ill fortune. Fires—even spontaneous combustion—are blamed on him.

A similar complex may be seen if the Slavic Perun is equated with Perkūnas, the lightning deity of the Lithuanians. In Latvia, creatures with black fur or plumage were sacrificed to Perkun, as they were to the fire god Agni in ancient India. Such deities are therefore generic deities of fire, not specifically celestial and even less to be regarded as supreme. Scholarly efforts to place Perun at

Helmold's
deus
otiosus

Varieties
of
spirits

the centre of Slavic religion and to create around him a pantheon of deities of the Greco-Roman type cannot yield appreciable results. Russian sources treat Svarog, present as Zuarasici among the Liutici of Rethra (an ancient locality in eastern Germany), as a god of the drying-house fire. But the Belorussians of Chernigov, when lighting the drying-house fire, invoke Perun and not Svarog, as if Svarog (apparently from *svar*, "litigation" or "dispute," perhaps referring to the friction between the pieces of wood used to produce ignition) were an appellation of Pemn.

Folk conceptions. In a series of Belorussian songs a divine figure enters the homes of the peasants in four forms in order to bring them abundance. These forms are: *bog* (God); *sporysh*, anciently an edible herb, today a stalk of grain with two ears, a symbol of abundance; *ray* (paradise); and *dobro* (the good). The word *bog* is an Indo-Iranian word signifying riches, abundance, and good fortune. *Sporysh* symbolizes the same concept. In Iranian *ray* has a similar meaning, which it probably also had in Slavic languages before it acquired the Christian meaning of paradise. *Bog*, meaning "riches," connotes grain. The same concept is also present in Mordvinian *pa* and *riz*—where their provenance is certainly Iranian. Among the Mordvins, Paz, like the Slavic Bog, enters into the homes bringing abundance. The adoption of the foreign word *bog* probably displaced from the Slavic languages the Indo-European name of the celestial God, Deivos (Ancient Indian Deva, Latin Deus, Old High German Ziu, etc.), which Lithuanian, on the other hand, has conserved as Diēvas.

Worship of
celestial
bodies

Among the heavenly bodies the only object of Slavic veneration was the moon. The name of the moon is of masculine gender in Slavic languages (Russian *mesyats*; compare Latin *mensis*). The word for sun (Russian *solntse*), on the other hand, is a neuter diminutive that may derive from an ancient feminine form. In many Russian folk songs a verb having the sun as its subject is put in the feminine form, and the sun is almost always thought of as a bride or a maiden.

It is to the moon that recourse is had to obtain abundance and health. The moon is saluted with round dances and is prayed to for the health of children. During lunar eclipses, weapons are discharged at the monsters who are said to be devouring the moon, and weeping and wailing express the sharing of the moon's sufferings. In Serbia the people have always envisioned the moon as a human being. Such appellations as father and grandfather are customarily applied to the moon in Russian, Serbo-Croatian, and Bulgarian folk songs. At Risano (modern day Risan, Yugoslavia) in the days of Vuk Karadžić (1787–1864)—the father of modern Serbian literature—it was said of a baby four months old that he had four grandfathers. In Bulgaria the old people teach small children to call the moon Dedo Bozhe, Dedo Gospod (uncle God, uncle Lord). Ukrainian peasants in the Carpathians openly affirm that the moon is their god and that no other being could fulfill such functions if they were to be deprived of the moon. In two Great Russian supplications the sickle moon is invoked as "Adam"—the final phase of a fully developed moon worship in which the moon becomes the progenitor of the human family.

PRACTICES, CULTS, AND INSTITUTIONS

Places of worship. Though the idols of which the Russian chronicles speak appear to have been erected out-of-doors, the German chronicles provide detailed descriptions of enclosed sacred places and temples among the Baltic Slavs. Such enclosures were walled and did not differ from profane fortifications—areas usually of triangular shape at the confluence of two rivers, fortified with earthwork and palisades, especially on the access side. The fortifications intended for religious purposes contained wooden structures including a cell for the statue of a god, also made of wood and sometimes covered in metal. These representations, all anthropomorphic, very often had supernumerary bodily parts: seven arms, three or five heads (Triglavus, Suantevitus, and Porenutius). The temples were in the custody of priests, who enjoyed

prestige and authority even in the eyes of the chiefs and received tribute and shares of military booty. Human sacrifices, including eviscerations, decapitations, and trepanning, had a propitiatory role in securing abundance and victory. One enclosure might contain up to four temples; those at Stettin (Polish Szczecin), in northwest Poland, were erected in close proximity to each other. They were visited annually by the whole population of the surrounding district, who brought with them oxen and sheep destined to be butchered. The boiled meat of the animals was distributed to all the participants without regard to sex or age. Dances and plays, sometimes humorous, enlivened the festival.

Temple
ceremonies

Communal banquets and related practices. The custom of communal banquets has been preserved into modern times in Russia in the *bratchina* (from *brat*, "brother"), in the *mol'ba* ("entreaty" or "supplication"), and in the *kanun* (short religious service); in the Serbian *slava* ("glorification"); and in the *sobor* ("assembly") and *kurban* ("victim, prey") of Bulgaria. Formerly, communal banquets were also held by the Poles and the Polabs (Elbe Slavs) of Hannover. In Russia the love feasts are dedicated to the memory of a deceased person or to the patron saint of the village, in Serbia to the protecting saint from whom the *rod* or *pleme* ("clan") took its name. Scholars no longer have any doubts of the pagan nature of these banquets. The Serbian *slava* is clearly dedicated to a saint held to be the founder of the clan. These saints are patrons or founders, and are all men who have died. When the Serbs celebrate the *slava* of the prophet Elijah or of the archangel Michael they do not set out the "dead man's plate" (the *koljivo*, boiled wheat), because Elijah and Michael are not dead. In certain localities in Serbia even the women given in marriage to another clan, the so-called *odive*, have to be present at the *slava*. They return with their children (according to the ancient matrilineal conception of the offspring), but not with their husbands who belong to another clan and celebrate another *slava*. More akin to the ancient pagan feasts of the Baltic is the Serbian *seoska slava* or *slava* of the village in which the whole population of the place takes part and they consume in common the flesh of the victims prepared in the open air. Such feasts are votive. In Russia sometimes the animals (or their flesh) are first brought into the church and incensed. Even at the beginning of the 20th century there were small villages in Russia where cattle were butchered only on the occasion of these festivities, three or four times a year. The *Homily of Opatoviz* (attributed to Herman, bishop of Prague) of the 10th–11th centuries emphatically condemns the love feasts as well as the veneration of statues and Slavic worship of the dead and veneration of saints as if they were gods. As in the Christian Era the saints entered the line of ancestors, so perhaps in pagan antiquity, ancient divinities (Perun, Svarog) were taken over as tribal progenitors. The Slavs did not record genealogies (exogamous societies have no need of them), and the founders of their clans were mainly legendary. The social unit sought to assure for itself the favour of powerful figures of the past, even of more than one, representing them in several forms on the same pillar or giving to their statues supernumerary bodily parts that would express their superhuman powers. A hollow bronze idol, probably ancient Russian, was found at Ryazan (U.S.S.R.). The idol has four faces with a fifth face on its breast.

The eastern Finns and the Ugrians venerated their dead in the same way, similarly representing them as polycephalic (multiple-headed), and also held communal banquets in their honour. Wooden buildings (the so-called *continae*) in which the faithful Baltic Slavs used to assemble for amusement, to deliberate, or to cook food have been observed in the 20th century among the Votyak, the Cheremis, and the Mordvins, but especially among the Votyak. Such wooden buildings also existed sparsely in Slavic territory in the 19th century, in Russia, particularly in the Ukraine, as well as here and there among the South Slavs.

If it is supposed that, as among the Finns and the Ugrians, each clan venerated its own divine ancestor in a

separate building, this would explain why many sacred enclosures would contain more than one contina—three at Carentia (the island of Garz at the mouth of the Oder River) and four at Stettin.

The system of idolatry of the Baltic area was essentially manistic (pertaining to worship of ancestors). It is not irrelevant that until the 19th century there survived here and there throughout the Danubian–Balkan region the custom of reopening graves three, five, or seven years after interment, taking out the bones of the corpses, washing them, wrapping them in new linen, and reintering them. Detailed descriptions of this procedure have come particularly from Macedonia and Slovenia. Among East and West Slavs only faint echoes of the custom of a second interment survive in folk songs. In the former gubemiya (administrative subdivision) of Vladimir, east of Moscow, as late as 1914, when a grave was to be dug, a piece of cloth was taken along with which to wrap the bones of any earlier corpse that might be unearthed in the process of digging. Such corpses would then be reinterred with the newly deceased. In protohistoric times the tumuli (mounds) of the mortuaries of the Krivichi, a populous tribe of the East Slavs of the northwest, the so-called long *kurgans* (burial mounds), contained cinerary urns buried in the tumulus together and all at one time. Such a practice could occur only as the consequence of collective and simultaneous cremation. There must, therefore, have existed a periodic cremation season or date, as for the opening of the tombs in Macedonia and as has been verified elsewhere in comparing the South Asian areas of second interment, in preparation for which the corpses are temporarily exhumed. The cremations by the Krivichi are of exhumed bones. In the Volga region today the Mordvins still burn the disinterred bones of the dead in the flames of a "living fire" ignited by friction.

Considering the religious past of the Slavs, it is not surprising that manism was strong enough to epitomize and overwhelm all or practically all of their religious views. The seasonal festivals of the Slavs turn out to be almost entirely dedicated to the dead, very often without the participants realizing it, as in the case of the *Koljada* (Latin *Kalendae*)—the annual visit made by the spirits of the dead, under the disguise of beggars, to all the houses in the village. It is possible that the bones of the disinterred were kept for a long period inside the dwellings, as is still sometimes done in the Tyrol of Austria, and that the sacred corner—now occupied by the icon—was the place where they were kept.

The spirits of the departed are not only venerated but also feared, especially the spirits of those who were prematurely deprived of life and its joys. It is believed that such spirits are greedy for the good things thus lost and that they make attempts to return to life—to the peril of the living. They are the prematurely dead, the so-called unclean dead. Particularly feared are maidens who died before marriage and are believed to be addicted to the kidnapping of bridegrooms and babies. One annual festival in particular, the *Semik* (seventh Thursday after Easter) was dedicated to the expulsion of these spirits. They are called *rusalki* in Russia, *vile* or *samovile* in Serbo-Croatia and Bulgaria.

The dead person who does not decompose in the grave becomes a vampire, a word and concept of Slavic origin. To save the living from a vampire's evil deeds, it is necessary to plant a stake in the grave so that it passes through the heart of the corpse or else to exhume the corpse and bum it. Since the classes of unclean dead are believed to have been constantly increasing (in Macedonia, for example, it is believed that all those born in the three months between Christmas and Lady Day are unclean), it will be seen that all of the dead—once objects of veneration and piety—will at some point be in danger of rancor, fear, and eventual disregard. A Christian clergy that has lent its presence at the exhumation and destruction of vampires has thereby contributed unwittingly to the preservation of this last phase of Slavic paganism into modern times.

There are other rites associated with second interment of which the Slavs have forgotten the purpose, such as the

cemetery pyres—fires lit on top of the tombs—or the assiduous watering of graves. In Polynesia and South America where second interment is practiced, these same acts have the purpose of fostering decomposition of the corpses in order to hasten exhumation.

Numerous other ritual acts are performed by the Slavs, for the most part related to this complex of beliefs. In 19th-century Russia, if a man encountered the procession of naked women who were plowing a furrow around the village at night in order to protect it from an epidemic, he was inevitably killed. It was a chthonic (underworld) being to which, in those same times, human sacrifices were offered in Russia (more rarely in Poland and Bulgaria), since the victims were often buried alive. In most cases they were either voluntary victims or chosen by lot from among the devotees. Since such acts were punished by the law of the state, the sacrifices were performed in secrecy and are difficult to document.

BIBLIOGRAPHY. The sources for Slavic paganism were collected by C.H. MEYER, *Fontes historiae religionis slavicae* (1931); and reproduced in the appendix of the Italian translation of A. BRUCKNER, *Mitologia slava* (1923; pub. orig. in Polish, 1918). Brückner's work and the more recent work by V. PISANI, "Il paganesimo balto-slavo," in *Storia delle religioni*, ed by P. TACCHI VENTURI, pp. 587–632 (1934), represent the two most valiant attempts to furnish an Indo-European interpretation of Slavic paganism. For the critical side of the problem these two works remain indispensable. For the archaeological aspects, see C. SCHUCHHARDT, *Arkona, Rethra, Vineta* (1926). HELMOLDUS, "Chronica Slavorum" may be found in *Monumenta Germaniae historica*, vol. 21 of the series "Scriptorum" (1869). In the same series are the texts of the other German chroniclers and biographers. Descriptive exposition of the whole is in L. NIEBERLE, *Slovanské starožitnosti* (1911); and in B.O. UNBEGAUN, "La Religion des anciens Slaves," in A. GRENIER, *Les Religions étrusque et romaine . . .*, pp. 389–445 (1948). An attempt to find in the folklore traces of a more ancient mythology was made by W.R.S. RALSTON, in *The Songs of the Russian People, As Illustrative of Slavonic Mythology and Russian Social Life* (1872). A collection of materials and interesting suggestions in the same field is found in V.J. MANSIKKA, *Die religion der Ostslaven* (1922). For ethnography, see D. ZELENIN, *Russische (ostslavische) Volkskunde* (1927); K. MOSZYNSKI, *Kultura ludowa Słowian*, 3 vol. (1930–39); E. SCHNEEWEIS, *Grundriss des Volksglaubens und Volksbrauchs der Serbokroaten* (1935); P. CARA-MAN, *Obrzęd koledowania u Słowian i u Rumundw* (1933); and P. BOGATYREV, *Actes magiques, rites et croyances en Russie Subcarpathique* (1929). See also J. MACHAL, "Slavic Mythology," in *The Mythology of All Races* (1918).

(E.G.)

Sleep

Sleep is a normal, easily reversible, recurrent, and spontaneous state of decreased and less efficient responsiveness to external stimulation. The state contrasts with that of wakefulness, in which there is an enhanced potential for sensitivity and an efficient responsiveness to external stimuli. The sleep–wakefulness alternation is the most striking manifestation in higher vertebrates of the more general phenomenon of periodicity in the activity or responsiveness of living tissue (see PERIODICITY, BIOLOGICAL). There is no single, perfectly reliable criterion of sleep. Sleep is defined by the convergence of observations satisfying several different motor, sensory, and physiological criteria. Occasionally, one or more of these criteria may be absent during sleep or present during wakefulness, but even in such cases there usually is little difficulty in achieving agreement among observers in the identification of the two behavioral states.

THE NATURE OF SLEEP

Sleep usually requires the presence of flaccid or relaxed skeletal muscles and the absence of the overt, goal-directed behaviour of which the waking organism is capable. Part of the recurring fascination with sleep talking and sleepwalking stems from their apparent violation of this latter criterion. Were these phenomena continuous, rather than intermittent, during a behavioral state, it is indeed questionable whether the designation "sleep" would continue to be appropriate. The characteristic posture associated with sleep in man and in many but not all

Motor and sensory criteria used in defining sleep

The custom of second interment

The belief in vampires

animals is that of horizontal repose. The relaxation of the skeletal muscles in this posture and its implication of a more passive role toward the environment are symptomatic of the reduced behavioral repertoire of sleep.

Indicative of the decreased sensitivity of the human sleeper to his external environment are the typical closed eyelids (or the functional blindness associated with sleep while the eyes are open) and the presleep rituals that include seeking surroundings characterized by reduced or monotonous levels of sensory stimulation. Three additional criteria, reversibility, recurrence, and spontaneity, distinguish the insensitivity of sleep from that of other states. Compared to that of hibernation or coma, the insensitivity of sleep is more easily reversible; *i.e.*, sleep may be defined in terms of the possibility of "waking up." Although the occurrence of sleep is not perfectly regular under all conditions, it is at least partially predictable from a knowledge of the duration of prior sleep periods and of the intervals between periods of sleep; and, although the onset of sleep may be facilitated by a variety of environmental or chemical means, sleep states are not thought of as being absolutely dependent upon such manipulations.

In experimental studies, both with subhuman vertebrates and with man, sleep also has been defined in terms of physiological variables generally associated with recurring periods of inactivity identified behaviourally as sleep. For example, the typical presence of certain electroencephalogram (EEG) patterns (brain patterns of electrical activity as recorded in tracings) with behavioral sleep has led to the designation of such patterns as "signs" of sleep. Conversely, in the absence of such signs (as, for example, in a hypnotic trance) it is felt that true sleep is absent. Such signs as are now employed, however, are not invariably discriminating of the behavioural states of sleep and wakefulness. Advances in the technology of animal experimentation have made it possible to extend the physiological approach from externally measurable manifestations of sleep such as the EEG to the underlying neural (nerve) mechanisms presumably responsible for such manifestations. As a result, it may finally become possible to identify structures or functions that are invariably related to behavioral sleep and to trace the evolution of sleep through comparative anatomical and physiological studies of structures found to be critical in the maintenance of sleep behaviour in the higher vertebrates.

In addition to the behavioral and physiological criteria already mentioned, subjective experience (in the case of the self) and verbal reports of such experience (in the case of others) are used at the human level to define sleep. Upon being alerted, one may feel or say, "I was asleep just then," and such judgments ordinarily are accepted as evidence for identifying a prearousal state as sleep, but such subjective evidence can be at variance with behavioristic classifications of sleep.

More generally, problems in defining sleep arise when evidence for one or more of the several criteria of sleep is lacking or when the evidence generated by available criteria is inconsistent. Do subhuman species sleep? Other mammalian species whose EEG and other physiological correlates are akin to those observed in human sleep demonstrate recurring, spontaneous, and reversible periods of inactivity and decreased critical reactivity. There is general acceptance of the designation of such states as sleep. As one descends the evolutionary scale below the birds and reptiles, however, and such criteria are successively less well satisfied, the unequivocal identification of sleep becomes more difficult. Bullfrogs (*Rana catesbeiana*), for example, seem not to fulfill sensory threshold criteria of sleep during resting states. Tree frogs (genus *Hyla*), on the other hand, show diminished sensitivity as they move from a state of behavioral activity to one of rest. Yet the EEGs of the alert rest of the bullfrog and the sleeplike rest of the tree frog are the same. There are parallel problems in defining sleep at different stages in the development of a single individual. At full-term birth in the human being, for instance, a convergence of non-subjective criteria clearly seems to justify the identifica-

tion of periods of sleep, but it is more difficult to justify the attribution of sleep to the human fetus.

Problems in defining sleep may arise from the effects of artificial manipulation. For example, the EEG patterns commonly used as signs of sleep can be induced in an otherwise waking organism by the administration of certain drugs. Sometimes, also, there is conflicting evidence: a person who is "awakened" from a spontaneously assumed state of immobility with all the EEG criteria of sleep may claim that he had been awake prior to this event. In such troublesome cases, and more generally, it is becoming common to qualify attributions of sleep with the criteria upon which such attributions rest—*e.g.*, "behavioral sleep," "physiological sleep," or "self-described sleep." Such terminology accurately reflects both the multiplicity of criteria available for the identification of sleep and the possibility that these criteria may not always agree with one another.

DEVELOPMENTAL PATTERNS OF SLEEP AND WAKEFULNESS

How much sleep does a person need? While the physiological bases of the need for sleep remain conjectural, rendering definitive answers to this question impossible, much evidence has been gathered on how much sleep people do in fact obtain. Perhaps the most important conclusion to be drawn from this evidence is that there is great variability among individuals in total sleep time. For adults, anything between six and nine hours of sleep as a nightly average is not unusual, and 7½ hours probably best expresses the norm. Such norms, of course, inevitably vary with the criteria of sleep employed. The most precise and reliable figures on sleep time, including those cited here, come from studies in sleep laboratories, where EEG criteria are employed.

Age consistently has been associated with the varying amount, quality, and patterning of electrophysiologically defined sleep. The newborn infant may spend an average of about 16 hours of each 24-hour period in sleep, although there is wide variability among individual babies. During the first year of life, total sleep time drops sharply; by two years of age, it may range from 9 to 12 hours. Decreases to approximately six hours have been observed among the elderly.

As will be elaborated below, EEG sleep studies have indicated that sleep can be considered to consist of several different stages. Developmental changes in the relative proportion of sleep time spent in these sleep stages are as striking as age-related changes in total sleep time. For example, the newborn infant may spend 50 percent of total sleep time in a stage of EEG sleep that is accompanied by intermittent bursts of rapid eye movements (REMS, indicative of a type of sleep that in some respects bears more resemblance to wakefulness than to other forms of sleep; it is discussed later in this article), while the comparable figure for adults is approximately 25 percent, and for the aged is less than 20 percent. There is also a decline with age of EEG stage 4 (deep slumber).

Sleep patterning consists of (1) the temporal spacing of sleep and wakefulness within a 24-hour period and (2) the ordering of different sleep stages within a given sleep period. In both senses, there are major developmental changes in the patterning of sleep. In alternations between sleep and wakefulness, there is a developmental shift from polyphasic sleep to monophasic sleep (*i.e.*, from intermittent to uninterrupted sleep). At birth, there may be five or six periods of sleep per day alternating with a like number of waking periods. With the dropping of nocturnal feedings in infancy, and of morning and afternoon naps in childhood, there is an increasing tendency to the concentration of sleep in one long nocturnal period (see Figure 1). The trend to monophasic sleep probably reflects some blend of the effects of maturing and of pressures from a culture geared to daytime activity and nocturnal rest. Among the elderly there may be a partial return to the polyphasic sleep pattern of infancy and early childhood, namely, more frequent daytime napping and less extensive periods of nocturnal sleep. Significant developmental effects also have been observed in spacing of stages within sleep. In the adult, REM sleep

Length of
time spent
in sleep

Problems
in
defining
sleep

Aspects of
sleep
patterning

rarely occurs at sleep onset, while, in newborn infants, sleep-onset REM sleep is typical.

It would be difficult to overestimate the significance of the various age-related changes in sleep behaviour for a general theory of sleep. In the search for the functional significance of sleep or of particular stages of sleep, the shifts in sleep variables can be linked with variations in waking developmental needs, in the total capacities of the individual, and in environmental demands. It has been suggested, for instance, that the high frequency and pre-emptory character of REM sleep in the newborn infant may reflect a need for stimulation from within to permit orderly maturation of the central nervous system (CNS).

From E.J. Murray, *Sleep, Dreams and Arousal*, p. 297 (1965): Appleton-Century-Crofts

Figure 1: Alternations of sleep and wakefulness at specified ages. The shading indicates periods of sleep.

Another interpretation of age-related changes in REM sleep stresses its possible role in processing new information, the rate of acquisition for which is assumed to be relatively high in childhood but reduced in old age. As these views illustrate, developmental changes in the electrophysiology of sleep are germane not only to sleep but also to the role of CNS development in behavioral adaptation.

PSYCHOPHYSIOLOGICAL VARIATIONS IN SLEEP

That there are different kinds of sleep has long been recognized. In everyday discourse there is talk of "good" sleep or "poor" sleep, of "light" sleep and "deep" sleep; yet, only in the second half of the 20th century have scientists paid much attention to qualitative variations within sleep. Sleep was formerly conceptualized by scientists as a unitary state of passive recuperation. Revolutionary changes have occurred in scientific thinking about sleep, the most important of which has been increased sensitivity to its heterogeneity.

This revolution may be traced back to the discovery of sleep characterized by rapid eye movements (REM sleep), first reported by the physiologists Eugene Aserinsky and Nathaniel Kleitman in 1953. REM sleep proved to have characteristics quite at variance with the prevailing model of sleep as recuperative deactivation of the central nervous system. Various central and autonomic nervous system measurements seemed to show that the REM stage of sleep is more nearly like activated wakefulness than it is like other sleep. It now has become conventional to consider REM ("paradoxical") and non-REM (NREM or "orthodox") sleep as qualitatively different. Thus the earlier assumption that sleep is a unitary and passive state has yielded to the viewpoint that there are two different kinds of sleep, a relatively deactivated NREM phase and an activated REM phase.

Non-rapid eye movement sleep. NREM sleep itself is conventionally subdivided into several different stages on the basis of EEG criteria. Stage 1 is observed at sleep onset or after momentary arousals during the night and is defined as a low-voltage mixed-frequency EEG tracing with a considerable representation of theta-wave (four to seven hertz, or cycles per second) activity. Stage 2 is a relatively low-voltage EEG tracing characterized by intermittent, short sequences of waves of 12–14 hertz ("sleep

spindles") and by formations called K-complexes, bi-phasic wave forms that can be induced by external stimulation, as by a sound, but that also occur spontaneously during sleep. Stages 3 and 4 consist of relatively high-voltage (over 50-microvolt) EEG tracings with a predominance of delta-wave (one to two hertz) activity; the distinction between the two stages is based on an arbitrary criterion of amount of delta-wave activity, with greater amounts classified as stage 4. Unlike the basic distinction between NREM and REM, differences among NREM sleep stages generally are regarded as quantitative rather than qualitative.

The EEG patterns of NREM sleep, particularly of stages 3 and 4 (tracings of slower frequency and higher amplitude), are those associated in other circumstances with decreased vigilance. Furthermore, after the transition from wakefulness to NREM sleep, most functions of the autonomic nervous system decrease their rate of activity and their moment-to-moment variability. Thus, NREM sleep is the kind of seemingly restful state that appears capable of supporting the recuperative functions assigned to sleep. There are, in fact, several lines of evidence suggesting such functions for NREM stage 4: (1) increases in such sleep, in both man and laboratory animals, have been observed after physical exercise; (2) the concentration of such sleep in the early portion of the sleep period (*i.e.*, immediately after wakeful states of activity) in human beings; and (3) the relatively high priority that such sleep has, among human beings, in "recovery" sleep following abnormally extended periods of wakefulness.

Rapid eye movement sleep. REM sleep is a state of diffuse bodily activation. Its EEG patterns (tracings of faster frequency and lower amplitude than in NREM stages 2–4) are at least superficially similar to those of wakefulness. Most autonomic variables exhibit relatively high rates of activity and variability during REM sleep; for example, there are higher heart and respiration rates and more short-term variability in these rates than in NREM sleep, increased blood pressure, and, in males, full or partial penile erection. In addition, REM sleep is accompanied by a relatively high rate of gross body motility, periodic twitching of the muscles of the face and extremities, relatively high levels of oxygen consumption by the brain, increased cerebral blood flow, and higher brain temperature. An even more impressive demonstration of the activation of REM sleep is to be found in the firing rates of individual cerebral neurons, or nerve cells, in experimental animals: during REM sleep such rates exceed those of NREM sleep and often equal or surpass those of wakefulness. Another distinguishing feature of REM sleep, of course, is the intermittent appearance of bursts of the rapid eye movements, whence the term is derived.

For both man and animals, REM sleep now is defined by the concurrence of three events: low-voltage, mixed-frequency EEG; intermittent REMs; and suppressed tonus of the muscles of the facial region (*i.e.*, suppression of the continuous slight tension otherwise normally present). This decrease in muscle tonus and a similarly observed suppression of spinal reflexes are indicative of heightened motor inhibition during REM sleep. Animal studies have identified the locus ceruleus, in the pons, as the probable source of this inhibition. (The pons is in the brain stem directly above the medulla oblongata; the locus ceruleus borders on the brain cavity known as the fourth ventricle.) When this structure is surgically destroyed in experimental animals, they periodically engage in active, apparently goal-directed behaviour during REM sleep, although they still show the unresponsivity to external stimulation characteristic of the stage. It has been suggested that such behaviour may be the acting out of the hallucinations of a dream.

An important theoretical distinction is that between REM sleep phenomena that are continuous and those that are intermittent. Tonic (continuous) characteristics of REM sleep include the low-voltage EEG and the suppressed muscle tonus; intermittent events in REM sleep include the REMs themselves and, as observed in the cat, spikelike electrical activity in those parts of the brain concerned with vision and in other parts of the cerebral cortex. The

The three events defining REM sleep

Stages of NREM sleep

various intermittent events of REM sleep tend to occur together, and it seems to be these moments of intermittent activation that are responsible for much of the difference between REM sleep and NREM sleep. The spiking mentioned is observed occasionally in NREM sleep, an occurrence that has been interpreted by some theorists as suggesting that REM sleep is not qualitatively unique in its capacity to support intermittent activation and that between NREM and REM sleep the differences may be less striking than the differences in eye movement and in EEG have indicated.

Sequences of NREM and REM sleep. The usual temporal progression of the two kinds of sleep in the adult human is for a period of approximately 70–90 minutes of NREM sleep (the stages being ordered 1–2–3–4–3–2) to precede the first period of REM sleep, which may last from approximately 5 to 15 minutes. NREM–REM cycles of roughly equivalent total duration then recur through the night, with the REM portion lengthening somewhat, and the NREM portion shrinking correspondingly, as sleep continues. Approximately 25 percent of total accumulated sleep will be spent in REM sleep and 75 percent in NREM sleep. Most of the latter will be EEG stage 2. The high proportion of stage 2 NREM sleep is attributable to the loss of stages 3 and 4 in the NREM portion of the NREM–REM cycles after the first two or three (see Figure 2).

Figure 2: Nocturnal sleep pattern in young adults. Note the absence of stage 4 and the decreased length of NREM periods during the latter part of the night and the short first REM period.

Light and deep sleep. Which of the various NREM stages is light sleep and which deep sleep? The criteria used to establish sleep depth are the same as those used to distinguish sleep from wakefulness. In terms of motor behaviour, motility decreases (depth increases) from stages 1 through 4. By criteria of sensory responsivity, thresholds generally increase (sleep deepens) from stages 1 through 4. By most physiological criteria, NREM stages 3 and 4 are particularly deactivated (deep). Thus, gradations within NREM sleep do seem fairly consistent, with a continuum extending from the "lightest" stage 1 to the "deepest" stage 4.

Relative to NREM sleep, is REM sleep light or deep? The answer here seems to be that by some criteria REM sleep is light and by others it is deep. For example, in terms of muscle tone, which is at its lowest point during sleep in REM sleep, it is deep. In terms of its relatively high rates of intermittent fine and gross body motility, REM sleep would have to be considered light. Arousal thresholds during REM sleep are variable, apparently as a function of the meaningfulness of the stimulus (and of the possibility of its incorporation into an ongoing dream sequence). With a meaningful stimulus (e.g., one which cannot be ignored with impunity), the capacity for responsivity can be demonstrated to be roughly equivalent to that of "light" NREM sleep (stages 1 and 2). With a stimulus having no particular significance to the sleeper, thresholds can be rather high. The discrepancy between these two conditions suggests an active shutting out of irrelevant stimuli during REM sleep. By most physiological criteria related to the autonomic and central nervous systems, REM sleep clearly is more like wakefulness than like NREM sleep, but drugs that cause arousal in wakefulness, such as amphetamine, suppress REM sleep. In terms of subjective response, recently awakened sleepers often de-

scribe REM sleep as having been "deep" and NREM sleep as having been "light." The subjectively felt depth of REM sleep may reflect the immersion of the sleeper in the vivid dream experiences of this stage.

Thus, as was true in defining sleep itself, there are difficulties in achieving unequivocal definitions of sleep depth. Several different criteria may be employed, and they are not always in agreement. REM sleep is particularly difficult to classify along any continuum of sleep depth. The current tendency is to consider it a unique state, sharing properties of both light and deep sleep. The fact that selective deprivation of REM sleep (elaborated below) results in a selective increase in such sleep on recovery nights is consistent with this view of REM sleep as unique.

Autonomic variables. Some autonomic physiological variables have a characteristic pattern relating their activity to cumulative sleep time, without respect to whether it is REM or NREM sleep. These variables are viewed by some authorities as incidental rather than essential features of the state of sleep, which is conceived in terms of the central nervous system. Such variables presumably reflect constant or slowly changing features of both kinds of sleep, such as the cumulative effects of immobility and of relaxation of skeletal muscles on metabolic processes. Body temperature, for example, drops during the early hours of sleep, reaching a low point after five or six hours, then rises toward the morning awakening.

Behavioral variables. Behaviorally, it has been shown that already established motor responses can be evoked in all stages of sleep, but it has proved much more difficult to demonstrate that new responses can be acquired during sleep. When EEG criteria of sleep are employed, it appears that "sleep learning" of verbal material takes place only to the degree that the person being tested is partially awake during the presentation of the stimuli. Another line of behavioral study is the observation of spontaneously occurring integrated behaviour patterns, such as walking and talking during sleep. In keeping with the idea of a heightened tonic (continuous) motor inhibition during REM sleep, but contrary to the idea that such behaviour is an acting out of especially vivid dream experiences or a substitute for them, sleep talking occurs primarily in NREM sleep and sleepwalking exclusively in NREM sleep. Talking in one's sleep is particularly characteristic of lighter NREM sleep (stage 2), while sleepwalking is initiated from deeper NREM sleep (stage 4). Episodes of NREM sleepwalking generally do not seem to be associated with any remembered dreams, nor is NREM sleep talking consistently associated with reported dreams of appropriate content.

Dreaming. Aserinsky and Kleitman suggested that REMs are related to the visual imagery of ongoing dream experiences. They found that persons awakened during REM periods were able to recall vivid visual dreams, while NREM awakenings were associated with little or no dream recall. Subsequent research has established that rapid eye movements in sleep are indeed associated with vivid visual dreaming (85 percent or so of REM-sleep arousals in young adults producing reported dreams) but also has demonstrated that NREM sleep also can be associated with memorable mental activity. While NREM mental activity generally is not as dreamlike (i.e., visual, dramatic, bizarre, emotional) as is typical REM-sleep dreaming, it has at least some features in common with REM dreams, particularly mental activity during NREM stage 1 at the onset of sleep. Some reports from this latter stage are of vivid, visual, hallucinated dramatic episodes indistinguishable from typical REM reports. Thus the physiological distinction between REM and NREM sleep is not always paralleled by accompanying differences in mental activity during sleep, and REM sleep is not the only stage of sleep capable of supporting vivid dream activity. The dreams associated with REM sleep, however, seem most likely to be spontaneously recalled, and it is probably REM dreams that have given rise to dream theories and that are most widely employed today in psychotherapeutic practice. It once was believed that the REMs of this stage are in point-for-point correspondence with visual

Sleep learning; sleepwalking, sleep talking

Problems of defining depth in REM sleep

Recall of REM sleep dreams

imagery, with a dream of watching a tennis match, for instance, associated with a REM sequence of right-left-right-left. The evidence for such a correspondence now seems equivocal. An alternative proposal is that the REMs are not specific responses of the visual system to ongoing mental activity but rather are part of a much more diffusely organized system of intermittent activation that also happens to include vivid moments of dreaming. The most important contributions to studies on dreams that psychophysiological research on sleep has made have been the demonstrations of much more dreaming (four or five separate, lengthy periods of REM sleep, totalling as much as two hours), and of many more different kinds of dreaming (*e.g.*, reports of everyday thinking sometimes elicited on awakenings from NREM) during sleep than previously had been recognized. As yet, psychophysiological dream studies have not had a marked impact on either clinical dream theory or clinical dream practice, perhaps because they have focussed on physiological concomitants of manifest dream content rather than on unconscious determinants of such content.

EFFECTS OF SLEEP DEPRIVATION

Types of
sleep
depriva-
tion

One time-honoured approach to determining the function of an organ or process is to deprive an organism of the organ or process. In the case of sleep, the deprivation approach to function has been applied, both experimentally and naturalistically, to sleep as a unitary state (general sleep deprivation), and, experimentally only, to particular kinds of sleep (selective sleep deprivation). General sleep deprivation may be either total (*e.g.*, a person has had no sleep at all for a period of days) or partial (*e.g.*, over a period a person obtains only three or four hours of sleep per night). The method of general deprivation studies is enforced wakefulness. Selective deprivation has been reported for two stages of sleep: stage 4 of NREM sleep and REM sleep. Both typically occur after the appearance of other sleep stages, REM sleep after all four NREM stages and stage 4 after the lighter NREM stages. The general idea of selective deprivation studies is to allow the sleeper to have natural sleep until the point at which he enters the stage to be deprived and then to prevent the stage, either by experimental awakening or by other manipulations such as application of a mildly noxious stimulus or prior administration of a drug known to suppress it. The hope is that total sleep time will not be altered but that increased occurrence of some other stage will substitute for the loss of the one selectively eliminated.

General sleep deprivation. On a three-hour sleep schedule, partial deprivation does not reproduce, in miniaturized form, the same relative distribution of sleep patterns achieved in a seven- or eight-hour sleep period. Some increase is observed in absolute amounts of REM sleep during the three-hour sleep period as compared to the first three hours of normal sleep, and there also is a significant increase in the amount of stage 4 of NREM sleep. Lighter NREM sleep (*e.g.*, stage 2) seems to have a particularly low priority under partial sleep deprivation. Although the REM sleep percentage increases somewhat under partial deprivation, the person is still far from achieving his usual quota in absolute minutes of sleep time. On uninterrupted recovery nights following the termination of the deprivation, there is more REM sleep than there was before the deprivation. This change is viewed as a compensatory "rebound" of REM sleep such that at least some of the quota is made up. Most if not all of the nightly quota of stage 4 of NREM sleep can be achieved on a three-hour nightly schedule. Because partial deprivation on a three-hour nightly regimen also tends to be selective deprivation (the person receives most of his quota of stage 4 NREM sleep but relatively little of his quota of stage REM), the behavioral effects of such deprivation may be relevant to the question of the adaptive functions served by REM sleep. One study has reported no effects from deprivation of REM sleep on the capacity for performance on a perceptual discrimination task but decreased motivation. When a schedule of partial deprivation began to interfere with the routine accumulation of stage 4 (*i.e.*, less than three hours of sleep per night), on

the other hand, the capacity for performance seemed to be adversely affected.

In view of several obvious practical considerations, many general deprivation studies have used animals rather than human beings as experimental subjects. Waking effects routinely observed in these studies have been of deteriorated physiological functioning, sometimes including actual tissue damage. The pattern of findings, however, has been variable from study to study and even from animal to animal within a given study, so that it is difficult to draw any clear conclusions. There is some suggestion that age is related to sensitivity to the effects of deprivation, younger organisms proving more capable of withstanding the stress than mature ones.

Among human subjects, the champion nonsleeper apparently was a 17-year-old student who voluntarily undertook a 264-hour sleep deprivation experiment. Effects noted during the deprivation period included irritability, blurred vision, slurring of speech, memory lapses, and confusion concerning his identity. No long-term (*i.e.*, postrecovery) effects were observed on either his personality or his intellect. More generally, although brief hallucinations and easily controlled episodes of bizarre behaviour have been observed after five to ten days of continuous sleep deprivation, these symptoms do not occur in most subjects and thus offer little support to the hypothesis that sleep loss induces psychosis. In any event, these symptoms rarely persist beyond the period of sleep that follows the period of deprivation. When inappropriate behaviour does persist, it generally seems to be in persons known to have a tendency toward such behaviour. Generally, upon investigation, injury to the nervous system has not been discovered in persons who have been deprived of sleep for many days. This negative result must be understood in the context of the limited duration of these studies and should not be interpreted as indicating that sleep loss is either safe or desirable. The short-term effects observed with the student mentioned are typical and are of the sort that, in the absence of the continuous monitoring his vigil received, might well have endangered his health and safety.

Other commonly observed behavioural effects during total sleep deprivation include fatigue, inability to concentrate, and visual or tactile illusions and hallucinations. These effects generally become intensified with increased loss of sleep, but they also wax and wane in a cyclic fashion in line with 24-hour fluctuations in EEG alpha-wave (8–12 hertz) phenomena and with body temperature, becoming most acute in the early morning hours. Changes in intellectual performance during moderate sleep loss can, to a certain extent, be compensated for by increased effort and motivation. In general, tasks that are work paced (the subject must respond at a particular instant of time not of his own choice) tend to be affected more adversely than tasks that are self-paced. Errors of omission are common with the former kind of task and are thought to be associated with "microsleep" — momentary lapses into sleep. Changes in body chemistry and in workings of the autonomic nervous system sometimes have been noted during deprivation, but it has proved difficult to establish either consistent patterning in such effects or whether they should be attributed to sleep loss per se or to the stress or other incidental features of the deprivation manipulation. In general, involuntary bodily functions seem relatively more impervious to effects of short-term deprivation than are adaptive, or voluntary, ones. The length of the first recovery sleep session for the student mentioned above, following his 264 hours of wakefulness, was slightly less than 15 hours. His sleep demonstrated increased amounts of both stage 4 NREM and stage REM sleep. After shorter periods of sleep loss, the tendency is for stage 4 compensation to occur first (during the first recovery session), and REM-sleep compensation later (during the second recovery session).

Selective sleep deprivation. Studies of selective sleep deprivation have confirmed the attribution of need for both stage 4 NREM and REM sleep, because an increasing number of experimental arousals is required each night to suppress both stage 4 and REM sleep on successive nights

Effects
of total
sleep
depriva-
tion

Effects of
selective
sleep
depriva-
tion

of deprivation, and because both show a clear rebound effect following deprivation. Rebound from stage 4 NREM-sleep deprivation occurs only on the night following termination of the deprivation regardless of the length of the deprivation, whereas the duration of the rebound effect following REM-sleep deprivation is related to the length of the prior deprivation. Little is known as yet of the consequences of stage 4 deprivation.

Particular interest has attached to the selective deprivation of REM sleep, partly because of its unique and somewhat puzzling properties as an activated state of sleep and partly because of the association of this stage with vivid dreaming. REM-sleep-deprivation studies once were considered also to be "dream-deprivation" studies. This psychological view of REM sleep deprivation has become less pervasive since the experimental demonstration of the occurrence of dreaming during NREM sleep stages, and because, contrary to the Freudian position that the dream is an essential safety valve for the release of emotional tensions, it has become evident that REM-sleep deprivation is not psychologically disruptive. REM-sleep-deprivation studies have focussed more upon the presumed functions of the REM state than upon those of the vivid dreams that accompany it. The evidence from these studies has proved to be partially supportive of a number of different theoretical positions concerning REM sleep. Some animal studies have reported deleterious effects of REM-sleep deprivation on learning or other cognitive tasks (*i.e.*, tasks concerned with thinking, remembering, perceiving, and the like), in line with the view that cognitive processing may be one function of REM sleep. Other animal studies have shown heightened levels of sexuality and aggressiveness after a period of deprivation, suggesting a drive-regulative function for REM sleep. Other observations suggest increased sensitivity of the central nervous system to auditory stimuli and to electroconvulsive shock following deprivation, as might have been predicted from the theory that REM sleep somehow serves to maintain CNS integrity.

Effects of
REM sleep
deprivation

Although there is a need for REM sleep, apparently it is not absolute. Animals have been deprived of REM sleep for as long as two months without showing behavioural or physiological evidence of injury. Several problems arise in connection with the methods of most REM-sleep-deprivation studies. Controls for factors such as stress, sleep interruption, and total sleep time are difficult to manage. Thus it is unclear whether observed effects of REM-sleep deprivation are the result of REM-sleep loss or the result of such factors as stress and general sleep loss. It also is unclear whether it is the loss of continuous REM sleep or of the intermittent events that accompany it that is crucial in REM-sleep deprivation. Preliminary research indicates the latter, suggesting that REM-deprivation studies are more relevant to the function of separate intermittent events occurring in sleep than to the function of the continuous REM sleep.

PATHOLOGICAL ASPECTS

It is important, at the outset, to emphasize that, as dramatic and reliable as the various stages of sleep are, their functions or relationships to waking performance, mood, or health still are largely unknown. Thus, association of a sleep abnormality with a certain stage of sleep (either in the sense that an abnormal event occurs during a certain stage or in the sense that an abnormal condition is associated with an increase or decrease in the proportion of total sleep time spent in that stage) is difficult to interpret when the function or necessity of that stage is uncertain. The pathology of sleep includes: (1) primary disturbances of sleep-wakefulness mechanisms, such as seem to characterize encephalitis lethargica ("sleeping sickness"), narcolepsy (irresistible brief episodes of sleep), and hypersomnia (sleep attacks of lesser urgency but greater duration than those of narcolepsy); (2) minor episodes occurring during sleep, such as bedwetting and nightmares; (3) medical disorders such as duodenal ulcer whose symptoms are accentuated during sleep; and (4) sleep symptoms of the major psychiatric disorders.

Primary disturbances. Epidemic lethargic encephalitis is produced by viral infections of sleep-wakefulness

mechanisms in the hypothalamus, a structure at the upper end of the brainstem. The disease often passes through several stages: fever and delirium; hypsomnia (loss of sleep); and hypersomnia (excessive sleep), sometimes bordering on a coma. Inversions of 24-hour sleep-wakefulness patterns also are commonly observed, as are disturbances in eye movements.

Narcolepsy, like encephalitis, is thought to involve specific abnormal functioning of subcortical sleep regulatory centres. Some persons who experience attacks of narcolepsy also have one or more of the following auxiliary symptoms: cataplexy, a sudden loss of muscle tone often precipitated by an emotional response such as laughter or startle and sometimes so dramatic as to cause the patient to fall down; hypnagogic (sleep onset) and hypnopompic (awakening) visual hallucinations of a dreamlike sort; and hypnagogic or hypnopompic sleep paralysis, in which the patient is unable to move voluntary muscles (except respiratory muscles) for a period ranging from several seconds to several minutes. When narcolepsy includes one or more of the accessory symptoms, some of the sleep attacks consist of periods of REM at onset of sleep. This precocious triggering of REM sleep (which occurs in adults generally only after 70–90 minutes of NREM sleep) may indicate that the accessory symptoms are dissociated aspects of REM sleep; *i.e.*, the cataplexy and the paralysis represent the active motor inhibition of REM sleep and the hallucinations represent the dream experience of REM sleep. In the narcoleptic patient without the accessory symptoms, the narcoleptic attacks usually consist of NREM sleep. Thus, narcolepsy may involve either REM or NREM sleep, and it is thought that both forms of narcolepsy probably involve a failure of wakefulness mechanisms to inhibit sleep mechanisms.

Hypersomnia may involve either excessive daytime sleep and drowsiness or a nocturnal sleep period of greater than normal duration, but does not include sleep-onset REM periods. One reported concomitant of hypersomnia, the failure of heart rate to decrease during sleep, suggests that hypersomniac sleep may not be as restful per unit of time as is normal sleep. In its primary form, hypersomnia is probably hereditary in origin (as is also narcolepsy) and is thought to involve some disruption of the functioning of hypothalamic sleep centres. Narcolepsy and hypersomnia are not characterized by grossly abnormal EEG sleep patterns. The abnormality seems to involve a failure in "turn on" and "turn off" mechanisms regulating sleep, rather than in the sleep process itself. Both narcoleptic and hypersomniac symptoms can be managed by administration of drugs. Several forms of hypersomnia are periodic rather than chronic. One very rare disorder of periodically excessive sleep, the *Kleine-Levin syndrome*, is characterized by periods of two to four weeks of excessive sleep in association with a ravenous appetite and psychotic-like behaviour during the few waking hours. The "*Pickwickian syndrome*" (in reference to the fat boy, Joe, in Dickens' *Pickwick Papers*), another form of periodically excessive sleep, is associated with obesity and respiratory insufficiency.

Hypsomnia (this word, meaning "too little sleep," is chosen in preference to "insomnia," or "lack of sleep," because some sleep invariably is present) is less clearly understood than the conditions already mentioned. It has been demonstrated that, by physiological criteria, self-described poor sleepers generally sleep much better than they imagine. Their sleep, however, does show signs of disturbance: frequent body movement, enhanced levels of autonomic functioning, and reduced levels of stage REM. Although hypsomnia in a particular situation is common and without pathological import, chronic hypsomnia may be related to psychological disturbance. Hypsomnia conventionally is treated by administration of drugs, but often with substances (*e.g.*, barbiturates) that are potentially addicting and otherwise dangerous when used over long periods.

Minor episodes. Among the minor episodes sometimes considered abnormal in sleep are: somniloquy (sleep talking) and somnambulism (sleepwalking), enuresis (bed-wetting), bruxism (tooth grinding), snoring, and

Hyper-
somnia;
hypo-
somnia

Sleep
talking;
sleep-
walking;
bed-
wetting;
tooth
grinding

nightmares. Sleep talking seems more often to consist of inarticulate mumbblings than of extended, meaningful utterances. It occurs at least occasionally for many people, and at this level cannot be considered pathological. Sleepwalking is not uncommon in children, but its continuity into adulthood is considered suggestive of persistent immaturity of the central nervous system. Enuresis may be a secondary symptom of a variety of organic conditions or, more frequently, a primary disorder in its own right. In the latter case, it seems to involve some immaturity in neural control of bladder muscles. While mainly a disorder of early childhood, enuresis persists into adulthood for a small number of persons. Treatment generally has been directed either toward sensitizing the sleeper to bladder distention, so that he will awaken and urinate according to appropriate social norms, or toward increasing bladder capacity, so that sleep can be sustained without bed-wetting episodes. Primary enuresis does not seem to be an abnormality of sleep, sleep cycles of bed-wetting and of normal children being roughly the same. Tooth grinding is not consistently associated with any particular stage of sleep, nor does it appreciably affect overall sleep patterning; it, too, seems to be an abnormality in rather than of sleep. Rhythmic snoring can occur throughout sleep, although it probably is most prevalent in the NREM stages. It indicates the partial muscular relaxation of sleep, and its occasional occurrence is not considered abnormal.

Varieties
of
nightmare

A variety of frightening experiences associated with sleep have, at one time or another, been called nightmares. As not all such phenomena have proved to be identical in their associations with sleep stages or with other variables, several distinctions need to be made among them. Incubus, the classical nightmare of adult years, consists of arousal from stage 4 NREM sleep with a sense of heaviness over the chest, with diffuse anxiety, but with little or no dream recall. Night terrors (pavov *nocturnus*) are disorders of early childhood. Delta-wave NREM sleep suddenly is interrupted with a scream, the child may sit up in apparent terror, and he is incoherent and inconsolable. After a period of minutes, he returns to sleep, often without ever having been fully alert or awake. Dream recall generally is absent, and the entire episode may be forgotten in the morning. Anxiety dreams most often seem associated with spontaneous arousals from REM sleep. There is remembrance of a dream whose content is in keeping with the disturbed awakening. While their persistent recurrence probably indicates waking psychological disturbance or stress caused by a difficult situation, anxiety dreams occur occasionally in many otherwise healthy persons.

Disorders accentuated during sleep. A variety of medical symptoms may be accentuated by the conditions of sleep. Attacks of angina (spasmodic, choking pain), for example, apparently can be augmented by the activation of the autonomic nervous system in REM sleep; the same is true of gastric acid secretions in persons who have duodenal ulcer. NREM sleep, on the other hand, can increase the likelihood of certain kinds of epileptic discharge.

The resemblance of dream consciousness to waking psychotic experience often has been noted, and the psychotic has been considered a "waking dreamer." Thus it has been theorized that waking psychotic symptoms may be generated by a spontaneous, or REM-sleep-deprivation-induced, shift of REM phenomena from sleep to the waking state. Many authorities also have suggested that in depression not caused by external factors, hypsomnia, a prominent feature of the state, may be a causal factor. While these ideas are intriguing, and have received much systematic study, the evidence at present is inconclusive. Symptomatically, schizophrenic persons have shown neither the exacerbation of psychotic symptoms under experimental REM-sleep deprivation nor the consistent or large deviations from normal EEG sleep patterning that would seem to be required by the hypothesis that sleep mechanisms play some critical role in bringing on psychotic episodes. Depressed persons do sleep less and often have a lower percentage of REM sleep than normal persons and do obtain little delta-wave NREM sleep, but it is

not clear whether these sleep symptoms indicate a fundamental involvement of sleep mechanisms in the causation of depressive states.

DRUGS AND SLEEP

Various chemical substances long have been employed to induce or prolong sleep, but there have been few controlled, double-blind (neither the physician who evaluates the results nor the patient knows whether the latter has received drug or placebo—an inert substitute) studies of alleged hypnotics (sleep-inducing drugs) in which sleep has been assessed by physiological measurement; and the mechanisms of sleep themselves are only now beginning to be isolated. The little research that has been done makes it clear that the manner in which a drug affects sleep can be extremely complex, with different effects sometimes attributable to different dosages of the same substance and with different effects sometimes observed for short-term and long-term administration of the same substance.

Many pharmacological agents tend to reduce the absolute amount and relative proportion of sleep spent in REM sleep. In this sense, REM sleep has been called a fragile state. Specifically, most effective hypnotics, particularly the barbiturates (*e.g.*, pentobarbital, secobarbital), decrease both total REM time and the proportion of sleep spent in REM sleep, with enhanced amounts of NREM sleep. Amphetamine, an analeptic (stimulant), decreases REM sleep. Many tranquilizers also slightly reduce REM sleep. There is evidence that the withdrawal symptoms of persons taken off addictive drugs of any variety (*e.g.*, barbiturates, amphetamines, narcotics) are accompanied by relatively high percentages of REM sleep. It has been suggested that the drugs in question are REM-sleep deprivors, that the elevated periods spent in REM sleep on withdrawal represent REM-sleep rebound, that the withdrawal syndrome may be functionally related to high pressure for REM sleep, and that the vivid, unpleasant dreams associated with REM-sleep rebound may be responsible for patients' return to the use of the REM-sleep-depriving agents. Caffeine seems to have little effect on normal sleep patterning, but the effects of alcohol are variable: the short-term effect is to reduce the time spent in REM sleep, but, with continued administration, there may be a REM-sleep rebound. Not all drug effects are on REM sleep; some of the more recently developed tranquilizers and hypnotics have been found to reduce stage 4 sleep.

Much interest has attached to the search for hypnotic substances that are not REM-sleep deprivors; *i.e.*, that induce or prolong sleep without altering natural sleep patterns. While some such hypnotics have been found, they most often either have adverse side effects or have not been fully evaluated. Theoretically, the most interesting substances are those few that have been found to increase REM sleep. In certain dosage ranges and under certain conditions, such an effect has been noted for reserpine, a tranquilizer, and for D-lysergic acid diethylamide (LSD), a hallucinogen. Both substances have important interactions with neurohumors (serotonin and norepinephrine—substances formed in nerve cells), and their effects may offer clues to the mechanisms underlying REM sleep.

THEORIES OF SLEEP

Two kinds of sleep theory of contemporary interest may be distinguished. One begins with the peripheral physiology of sleep and relates it to underlying neural (nervous-system) or biochemical mechanisms. Such theories most often rely on experiments with animals by means of drugs or surgery. Alternatively, sleep theories may start with behavioral observations of sleep and may attempt to specify the functions of such a state of lethargy and insensitivity from an evolutionary or adaptive point of view. The question here is not so much how we sleep, or even why we sleep, but what good it does.

Mechanistic theories. Historically, mechanistic theories of sleep have focussed on a succession of organs or structures in a manner reflective of the degree of access different civilizations have had to the inner workings of the human body. Thus the relatively perceptible pro-

Drugs that
reduce
REM sleep

cesses of circulation, digestion, and secretion played large roles in the theories of classical antiquity, and modern theories have been concerned with the central nervous system, particularly the brain, although various peripheral factors in the induction of sleep are not ruled out. Proposals that blood composition, metabolic changes, or internal secretions regulate sleep are necessarily incomplete to the extent that they ignore the contributions of environment and intent to the onset of sleep. It also is noted that in two-headed human monsters one "twin" may seem asleep while the other is awake, despite their sharing circulatory system.

Neural theories. Among neural theories of sleep, there are certain issues that each must face. Is the sleep-wakefulness alternation to be considered a property of individual neurons (nerve cells), making unnecessary the postulation of specific regulative centres, or is it to be assumed that there are some aggregations of neurons that play a dominant role in sleep induction and maintenance? The Russian physiologist Ivan Petrovich Pavlov adopted the former position, proposing that sleep is the result of irradiating inhibition among cortical and sub-cortical neurons (nerve cells in the outer brain layer and in the brain layers beneath the cortex). Micro-electrode studies, on the other hand, have revealed high rates of discharge during sleep from many neurons in the motor and visual areas of the cortex, and thus it seems that, as compared with wakefulness, sleep must consist of a different organization of cortical activity rather than some general, overall decline.

Another issue has been whether there is a waking centre, fluctuations in whose level of functioning are responsible for various degrees of wakefulness and sleep, or whether the induction of sleep requires another centre, actively antagonistic to the waking centre. Early speculation favoured the passive view of sleep. A *cerveau isolé* preparation, an animal in which a surgical incision high in the midbrain has separated the cerebral hemispheres from sensory input, demonstrated chronic somnolence. It has been reasoned that a similar cutting off of sensory input, functional rather than structural, must characterize natural states of sleep. Other supporting observations for the stimulus-deficiency theory of sleep included presleep rituals, such as turning out the lights, regulating stimulus input, and the facilitation of sleep induction by muscular relaxation and fatigue. With the discovery of the ascending reticular activating system (ARAS, a network of nerves in the brainstem), it was found that it is not the sensory nerves themselves that maintain cortical arousal but rather the ARAS, which projects impulses diffusely to the cortex from the brainstem. Presumably sleep would result from interference with the active functioning of the ARAS. Injuries to the ARAS were, in fact, found to produce sleep. Sleep thus seemed passive, in the sense that it was the absence of something (ARAS support of sensory impulses) characteristic of wakefulness.

Theory has tended to depart from this belief and to move toward conceiving of sleep as an actively produced state. Two kinds of observation primarily have been responsible for the shift. First, earlier studies showing that sleep can be induced directly by electrical stimulation of certain areas in the hypothalamus have been confirmed and extended to other areas in the brain. Second, the discovery of REM sleep has been even more significant in leading theorists to consider the possibility of actively produced sleep. REM sleep, by its very active nature, defies description as a passive state. As is noted below, REM sleep can be eliminated in experimental animals by the surgical destruction of a group of nerve cells in the pons, the active function of which appears to be necessary for REM sleep. It thus is difficult to imagine that the various manifestations of REM sleep reflect merely the deactivation of wakefulness mechanisms.

The REM-NREM-sleep dichotomy poses a third issue for the theories of sleep mechanisms, or at least for those that accept the idea of sleep as an active phenomenon. Does one hypnogenic (sleep-causing) system serve both kinds of sleep, or are there two antagonistic sleep systems, one for REM sleep and one for NREM sleep? Opinion is sharply

divided. One group of theorists states that there must be two sleep systems. It is noted that NREM sleep is not affected by injuries to the pontine **tegmentum** (the posterior part of the pons) but that REM sleep is abolished and that NREM sleep is suppressed in animals whose brainstem has been severed at the midpoint of the pons, suggesting that an NREM-sleep centre behind this section no longer is capable of suppressing the effect of the ARAS. It is further observed that the neurohumor serotonin is localized in the brainstem regions presumed to be responsible for NREM sleep; that destruction of serotonin-containing nerve cells in the brainstem may produce insomnia; that, in some species, reductions of serotonin by chemical interference with its production produces an amount of sleep loss correlated with the reduction of serotonin; that administration of a serotonin precursor (a substance from which serotonin is formed) after interference with production of serotonin produces a sleeplike state and that artificially induced increases in brain serotonin increase NREM sleep; that the neurohumor norepinephrine is localized in the brainstem regions presumed to be responsible for REM sleep; and that substances interfering with the synthesis of norepinephrine suppress REM sleep. Other theorists have proposed that REM and NREM sleep are served by a common hypnogenic system. Chemical stimulation of certain brain structures, assumed to constitute a hypnogenic system, has been found capable of inducing both stages of sleep. It also is argued that different varieties of sleep should require different mechanisms no more than do different varieties of wakefulness (e.g., alertness, relaxation).

Functional theories. Functional theories stress the recuperative and adaptive value of sleep. Sleep arises most unequivocally in animals (birds and mammals) that maintain a constant body temperature and that can be active at a wide range of environmental temperatures. In such forms, increased metabolic requirements may find partial compensation in periodic decreases in body temperature and metabolic rate (i.e., during NREM sleep). Thus, the parallel evolution of temperature regulation and NREM sleep has suggested to some authorities that NREM sleep may best be viewed as a regulatory mechanism conserving energy expenditure in species whose metabolic requirements are otherwise high. As a solution to the problem of susceptibility to predation that comes with the torpor of sleep, it has been suggested that the periodic reactivation of the organism during sleep better prepares it for fight or flight, and that the possibility of enhanced processing of significant environmental stimuli during REM sleep may even reduce the need for sudden confrontation with danger. Other functional theorists agree that NREM sleep may be a state of "bodily repair," while suggesting that REM sleep is one of "brain repair" or restitution, a period, for example, of increased cerebral protein synthesis or of "reprogramming" the brain so that information achieved in wakeful functioning is most efficiently assimilated. In their specification of functions and provision of evidence for such functions, such theories are necessarily vague and incomplete. The function of stage 2 NREM sleep is still quite unclear, for example. Such sleep is present in only rudimentary form in sub-primate species, yet consumes approximately half of human sleep time. Comparative, physiological, and experimental evidence is yet unavailable to suggest why so much human sleep is spent in this stage.

BIBLIOGRAPHY. The standard reference on the physiology of sleep is N. KLEITMAN, *Sleep and Wakefulness*, rev. ed. (1963). The more recent physiological literature is summarized in A. KALES (ed.), *Sleep: Physiology and Pathology: A Symposium* (1969). The behavioral approach to sleep is exemplified by E.J. MURRAY, *Sleep, Dreams, and Arousal* (1965). Sound, well-written popularizations are G.G. LUCE and J. SEGAL, *Sleep* (1966), and *Insomnia: The Guide for Troubled Sleepers* (1969).

Slime Mold

Science fiction did not invent the slime molds, but it has borrowed from them in using the idea of sheets of liquid,

Varieties of Myxomycete fruiting bodies.

Arthur L. Cohen

flowing cytoplasm engulfing and dissolving every living thing they touch. What fiction can only imagine, nature has produced, and only their small size and dependence on coolness, moisture, and darkness has kept the slime molds from ordinary observation, for they are common enough.

Coolness, moisture, and darkness are found in the soil and in logs, twigs, and leaves decaying on the forest floor; there also are found the slime molds. An old log turned over—preferably a few days after a warm summer rain—may reveal on its underside a white or yellowish fan of almost liquid consistency, a sheet of slowly flowing living substance. The drier upper side of the log may be covered with what look like pinhead-sized toadstools that, when touched, give off clouds of dust-fine spores. The creeping, feeding fan—the plasmodium, or vegetative phase, of a slime mold—has the characteristics of a primitive animal called an amoeba. The reproductive stage—the fruiting body, or sporangium, with its dusty spores—has the characteristics of a lower plant, a mold.

The preceding account is an abbreviated, general description of one group of slime molds, the Myxomycetes, which includes the largest, most abundant, and best known of the slime molds. The Myxomycetes have a plasmodial stage and definite fruiting bodies—they are the true slime molds. Other slime molds, mostly not all closely related to the Myxomycetes, include the Acrasieae, the Plasmodiophoreae, the Labyrinthulales, and the Protosteliales. The Acrasiales are forms in which individual amoebas aggregate without fusing to form a multicellular fruiting structure—they are the simple slime molds, or cellular slime molds. The Plasmodiophorales, also called the endoparasitic slime molds, are root parasites of higher plants; they have a plasmodial stage but lack definite fruiting bodies. The Labyrinthulales—the

net slime molds—are largely marine organisms consisting of spindle-shaped cells that glide within a network of slime tubes (the net plasmodium). The Protosteliales are near-microscopic organisms that show some affinities with the Myxomycetes.

The economic importance of the Myxomycetes is negligible. The ashy-gray sporangia of *Physarum cinereum* sometimes develop overnight in large patches on well-watered lawns. These grayish crusts with their sooty spores, which appear so dramatically, do no harm, however, and soon disappear.

The vast majority of Plasmodiophorales are rather benign parasites of plants of no economic importance, but *Plasmodiophora brassicae*, clubroot of cabbage, is the single most serious disease of cabbages and other members of the mustard family. *Spongospora subterranea*, a parasite of potatoes, while usually unimportant, may at times have disastrous effects on the crops.

The Acrasiales and Protosteliales have no known economic importance and, unlike true fungi and bacteria, are apparently only minor participants in the great material cycles of nature, such as the decomposition of organic matter into its basic chemicals, carbon dioxide and water.

THE MYXOMYCETES (TRUE SLIME MOLDS)

The Myxomycetes include approximately 60 genera containing about 500 species. They are divided into two subclasses, the Exosporeae and the Endosporeae. In the Exosporeae the spores are apparently borne externally instead of within a sporangium, but studies have indicated that each "spore" is itself a much reduced sporangium, containing the genuine spore within. The Endosporeae contains only one genus, *Ceratiomyxa*, with about three species.

The Endosporeae have the spores obviously borne with-

Economic
importance

in a sporangium. The majority of slime molds with surface-crawling plasmodia belong to the Endosporeae in the order Physarales, a group distinguished by dark spores and the presence of calcium carbonate (lime) at least in the sporangium wall (peridium). The most thoroughly studied slime mold genera—*Physarum*, *Didymium*, and *Fuligo*—are all members of the Physarales, which is sometimes also known as the Calcareae.

The sporangium. Although some Myxomycetes (e.g., *Didymium*) form fruiting structures (sporangia) from plasmodia that creep over the surface of wood and leaves, others, such as the common and beautiful *Stemonitis*, form the fruits from plasmodia buried within the decaying wood. There is no indication that a log or tree stump is inhabited until drops of creamy liquid appear on the surface—as if the dead wood were perspiring living protoplasm. This is the first sign that the plasmodium, whose strands are spread throughout the porous wood, is finishing its days as an active, growing, feeding network. These droplets coalesce and grow, expanding to a thick cushion that eventually becomes a column, perhaps half an inch wide and an inch high. A purplish tinge, gradually darkening to black, spreads over the column as it begins to take shape as a bundle of cylinders, each supported by the stalk it has formed. The bundle, now almost black, dries out, and each sporangium, densely filled with dark spores, separates from its neighbours. The tenuous wall enclosing the sporangium, the peridium, disintegrates on drying. A touch of the hand or a puff of wind is all that is required to disperse the spores. Finally, only the delicate skeletons of the sporangia are left; each consists of a stalk with an intricate network of branches, the capillitium, which held the spores. This whole feathery tuft of sporangia, resting on a silvery sheet of dried slime, the hypothallus, forms and fulfills its mission of reproduction within a day.

The startling transformation of a shapeless, ever-changing plasmodium into an intricately organized fruiting structure is the very remarkable feature of the Myxomycetes.

The capillitium

of different species is formed variously, but a composite picture of its formation is as follows. Within the mass of cytoplasm enclosed by the peridium, lines appear that later become chains of clear droplets, or vacuoles. The vacuoles coalesce to form hollow tubes whose walls become coated with dense material. Some capillitia are what the name implies, fine hairlike processes. Some have the walls beautifully sculptured with spirals and cogs, as in the genera *Trichia*, *Hemitrichia*, and *Arcyria*, in which, on drying, the capillitium expands into a fluffy mass, scattering the spores as it does so. In others, the capillitium is permeated with lime.

Not all plasmodia are stalked. Some plasmodia break up into sessile droplets that invest themselves with a sporangial wall and complete their development without ever rising on a stalk. In those with fruiting structures known as plasmodiocarps, the plasmodium hardly breaks up at all, but the profound interior change of liquid cytoplasm to dusty spores still occurs. The largest sporangia are aethalia, compound sporangia composed of individual sporangia incompletely separated from each other. In the genera *Fuligo* and *Brefeldia*, they form great cushiony masses, those of *B. maxima* sometimes reaching a foot in length. The massed compound sporangia (aethalia) may range from the easily delineated individual

sporangia of *Tubifera* through the tortuous interwoven structures of *Fuligo* (plasmodiocarps) to the spherical fruit of *Lycogala*, in which individual sporangia are so reduced and mutually joined that the sphere is practically a single entity.

The remarkable genus *Ceratiomyxa* represents another extreme, for each sporangium contains only one spore. Thus the crowded fruiting structures of this genus, which cover well-decayed logs like miniature coral reefs, are not sporangia but the tremendously developed hypothallus. The sporangia are the powdery microscopic structures on the surface, each containing one spore.

Arthur L. Cohen

Ceratiomyxa fruiting structures.

(Top) Two forms of *Ceratiomyxa* growing together: spongelike *C. porioides* and branched *C. fruticulosa*. It has been argued these may be different environmental forms of same species. This photograph does not indicate this since there is no intergrade. (Bottom) Young colonies of *fruticulosa* with young brown fruiting bodies of another Myxomycete among them. The yellow form is uncommon; it turns white upon complete maturity.

Spores and swarm cells. The spores are formed in the sporangium by successive furrowing, or cleavage, of the cytoplasm; the furrows redivide the mass until each unit contains one nucleus. Each block rounds up, becomes surrounded by a dense spore wall, and shrinks away from its fellows as it dries. The spores of Myxomycetes may vary slightly in shape from oval to round and in size from four to 15 microns (0.004 to 0.015 millimetre, or about 0.0002 to 0.0006 inch) in diameter. The colour may be black, gray, brown, brilliant red, yellow, or—rarely—white (except in *Ceratiomyxa*, which usually has white spores). The spore surface is often covered with ridges or spines.

If the spores are placed in water, they swell, and, in a half hour to a week, depending on species and on such factors as the age of the specimen, the spore wall either splits open or a pore forms, from which a minute, naked mass of cytoplasm emerges. This globule, the swarm cell,

The
myx-
amoeba

shoots out a whiplike process, a flagellum, becomes pear-shaped and, with the flagellum lashing in front of it, swims away. Two flagella are usually present, but the second flagellum is short, inactive, and rarely seen. The swarm cell may suddenly come to rest on any surface, put forth pseudopods—lobes of living substance—and creep along. In this stage, called a myxamoeba, it can feed as any amoeba does, by engulfing bacteria. If the flagella are entirely retracted, the myxamoeba is practically indistinguishable from any of the many species of small amoebas in the soil. It may put forth its flagella and suddenly take off; the myxamoeba transforms again into a swimmer.

Structural details of *Didymium iridis*.

(Top left) Section of mature sporangium showing (A) stalk, (B) columella (projection of stalk into spore head), (C) peridium, (D) few strands of capillitium in mass of spores, (E) spores. (Top right) Phase photomicrograph of living amoebae. (Bottom left) Phase photomicrograph of live swimming swarm cell showing flagellum. (Bottom right) Electron micrograph of swarm cell in transition between amoeboid and flagellate phases showing (F) flagellum, (S) second flagellum, (P) pseudopodia.

The myxamoeba or its transform, the flagellated swarm cell, is a gamete (sex cell). The fusion of two such cells and the fusion of their nuclei is the fundamental sexual act in reproduction of Myxomycetes, as it is in other organisms.

The plasmodium. Growth anti appearance. The fusion of the two gametes, whether flagellate or amoeboid, and the subsequent fusion of their nuclei, initiates the plasmodial phase. The flagella are permanently retracted and the amoeboid zygote (fertilized cell) begins to grow. Instead of following the pattern found in most other organisms, in which the cell divides after the nucleus has duplicated itself, in the slime molds only the nuclei divide repeatedly, first in complete synchrony and then in synchronous waves, as the ever-growing plasmodium becomes larger. As the plasmodium flows over the damp undersurface of logs or through the rotting wood itself, over leaves, or through the soil, it feeds on bacteria, molds, and sometimes large fungi, leaving the undigested remains behind as dark imprints of its own shape.

On a smooth surface a vigorous plasmodium generally takes the form of a fan with trailing veins, creeping in the direction of the broadly curved front edge. Microscopically, the fan looks like a broad river delta, with a network of channels in which the cytoplasm streams now slowly, now so rapidly that the particles are but blurred streaks. These channels gradually separate into distinct veins from front to rear. The internal streaming is not all in one direction. In any vein or channel, the cytoplasm slows, pauses, and then often reverses direction. Gener-

ally, a little more flows toward the front than flows back, so that the plasmodium moves in a pulsating fashion, advancing steadily like an incoming tide on a beach.

The description above is that of the "classical" or phaneroplasmodium, but other types have been observed. They are the protoplasmodium, a minute, sluggishly amoeboid form, without distinct veins, each plasmodium giving rise to one sporangium (e.g., *Echinostelium minutum*); and the aphanoplasmodium, a colourless mass consisting of fine veins forming a network or sometimes lying parallel to each other, but the whole structure lacking the fan structure described above. Almost invisible, it is, nevertheless, of fairly frequent occurrence (e.g., *Stemonitis*, *Comatricha*, *Lamproderma*).

Cytoplasmic movement. If the plasmodium is moved about or cut, flow ceases and the cytoplasm sets, forming a gel. Then hesitantly but with increasing vigour, flow resumes. If a strand of a vigorous plasmodium is cut, a drop of the liquid interior substance oozes out and usually immediately sets to a gel. This droplet, if gently detached and placed on a clean surface, may, in a few hours, become a minute plasmodium.

Although many cells show this streaming of the liquid living substance, only the myxomycete plasmodium shows it on such a grand scale. The theory has long been that the streaming results from contraction of the walls, which squeeze the inner liquid plasm from one part to another. In apparent confirmation of this muscular action of the more solid parts, there has been isolated from the cytoplasm of *Physarum polycephalum* a protein called myxomyosin, which resembles in its properties myosin, the contractile protein of muscle. The myxomycete plasmodium thus resembles in many aspects a primitive muscle but with this difference: the muscle cell has a constant array of longitudinal fibres, but the plasmodium unceasingly dismantles and reconstructs its array of contractile fibres.

Microscopic structure and chemical composition. The cytoplasm of the Myxomycetes resembles that of other cells in having internal structures such as nuclei, mitochondria, and vacuoles (see CELL AND CELL DIVISION), and, in the plasmodium stage, it resembles the cytoplasm of amoebas. The major difference is the giant size—one plasmodial cell membrane encompasses dozens to millions of nuclei and other subcellular structures. Like amoebas, the plasmodium puts forth microscopic extensions, or pseudopods; engulfs food in digestive vacuoles; and discards waste in excretory vacuoles, which burst like blisters at the surface. Also like amoebas, the thin layer of cytoplasm just beneath the cell membrane, particularly at the advancing edge, is colourless and glassy, lacking the innumerable organelles and particles of the interior.

The nuclei are characteristically small and usually have one prominent nucleolus, a small body with the nucleus. Nuclear division in the Myxomycetes is remarkable in being of two types. In the plasmodium and spores, it is of the so-called primitive type, in which the nuclear membrane remains intact during division. In swarm cells and myxamoebas it is of the more common and presumably more advanced type in which the nuclear membrane disintegrates and a new membrane forms around each daughter nucleus.

Characteristic of the plasmodium is an external layer of slime clothing the entire active mass. Being unceasingly secreted, it is unceasingly left behind the creeping plasmodium as a network of collapsed tubules. The slime of several species of *Physarum* is a glycoprotein (a combination of sugars and protein) similar to many other lubricant secretions, such as mucus and saliva. The sugar component in all cases so far investigated is known as galactose.

Plasmodia may be colourless, red, white, buff, maroon; most frequently yellow or orange; and rarely blue, black, or green. Colour may be influenced by age, diet, and growth conditions. The basic colour is often shaded by the colour of the growth medium or particles picked up. The pigment is contained in granules in the colourless ground substance; but on the death of the plasmodium, it

Arthur L. Cohen

dissolves in water and stains the surrounding medium—a sure sign in laboratory cultures that at least a portion of the plasmodium has been killed. Numerous studies have not yet determined the chemical nature of the pigments.

Sexual processes. Over 100 years ago it was thought that plasmodia were formed by several swarm cells or myxamoebas coming together and fusing nonsexually. Fusion between swarmers (flagellated swarm cells or myxamoebas), however, has been shown to be sexual, and the zygote formed initiates the young diploid (having two sets of chromosomes per nucleus) plasmodium. Nevertheless, although nuclear fusion occurs, its location in the life cycle has been placed by various researchers anywhere from the fusion of the swarmers to the transformation of the plasmodium into sporangia. Nuclei in plasmodia of the same species and strain are now known to be haploid (with one chromosome set), diploid, or polyploid (having more than two chromosome sets). All nuclei of one plasmodium have uniform ploidy.

Reduction divisions (gamete formation) occur somewhere in the sporangial phase, either in the formation of the spores or in the spores themselves. There is general agreement, however, that the fully developed spore is a meiospore—its nucleus or nuclei are the immediate products of meiosis, reduction division that produces nuclei with one set of chromosomes each.

Individuality and self-recognition. The plasmodium is not an individual in the full sense. Although it behaves as a unit, it can be cut into small pieces that may either fuse together again or grow into new plasmodia. The nature of the plasmodium was shown by a classical experiment in the late 19th century. A plasmodium, gorged with debris and food particles, was placed on moist cotton. It strained itself through the fibres, leaving the debris behind, and reconstituted itself, thoroughly scoured, on the other side of the barrier.

The plasmodia of *Fuligo septica*, usually lemon yellow when found in nature, may become white under certain laboratory conditions and remain yellow under others. Yellow and white plasmodia from the same parent no longer fuse when brought into contact, but each can

merge with a plasmodium of its own colour. The same interesting phenomenon has been observed in other species. Plasmodia or "incompatible" strains of the same species will not fuse. As in higher forms, fusion or rejection is controlled by "incompatibility genes." Genetic compatibility, however, does not explain the failure of fusion of plasmodia of the same source.

The sclerotium. If a plasmodium is rapidly dried, it becomes a dull, lifeless, horny mass. But given some time to dry, perhaps 24 hours, it contracts, becomes somewhat waxy, and usually retains its colour, having thereby transformed into a sclerotium. The sclerotium is composed of many cells, each containing a number of nuclei, with each cell separated from its neighbours by very thin walls. If the sclerotium is moistened, the walls dissolve within a few hours, and what earlier resembled a splash of dry, orange paint resumes activity. The sclerotium is a resistant resting stage that ensures survival during times of environmental stress. Plasmodia that form sclerotia, for example, easily may be filed away in envelopes for a year or more and come alive again when dampened.

Habitat and geographical occurrence. The majority of Myxomycetes are inhabitants of the temperate zones and are typically active—in creeping about as plasmodia or in fruit formation—in warm, moist weather of spring or early summer; nevertheless, active plasmodia of some species may be found any time the temperature has remained above freezing for a few days, and some forms are typically alpine, the new fruits developing on sodden branches and leaves at the snow line.

Surprisingly few forms are exclusively tropical, the best known being *Alwisia bombarda*, although some, such as species of *Didymium*, extend well into the tropics.

Geographically the Myxomycetes recognize no boundaries. Species that are common in one region are generally found in any similar habitat and climate.

Stemonitis, *Lycogala*, *Reticularia*, *Ceratiomyxa*, and a host of other genera are practically always found on wood. Many of the lime-bearing types—such as species of *Physarum*, *Didymium*, and *Badhamia*—are found on leaves and straw. *Physarum cinereum* typically lives in

Germinating sclerotium of *Badhamia utricularis*, photographed over nine-hour period. (Left) Dormant orange sclerotium on piece of absorbent paper placed in moist petri dish; within four hours it has absorbed water and begun to show activity. (Centre) One hour later fully active plasmodium has begun to spread out from paper. (Right) After four more hours bulk of plasmodium has left paper and formed typical veined plasmodial fan.

Arthur L. Cohen

the soil, and sometimes its gray fruits cover lawns overnight. Only *Fuligo septica* can throw up its formless yellow or brown or white aethalia (massed structureless sporangia) anywhere—on a tree trunk six feet (about two metres) above ground, in the crack of a concrete pavement, on desert sand, and, as once recorded, on a whale's skull set to bleach on the grounds of the British Museum of Natural History.

Environmental responses. In general, surface-growing, pigmented plasmodia require light to form sporangia. Nonpigmented forms do not, but other conditions may be necessary; for example, at least some strains of *Didymium iridis* invariably fruit in the laboratory when they exhaust their food supply. In all forms studied there seems to be a point beyond which the plasmodium is committed to form sporangia, and, although no sign may be visible, the plasmodium—or even a minute fragment too small to form a good sporangium—will attempt to fruit, even if the fragment literally dies in the attempt. Profound and complex changes, particularly in the quantity of enzymes (biological catalysts) concerned with respiration, occur naturally during the fruiting process.

Spore germination

Some myxomycete spores, such as those of *Reticularia lycoperdon*, germinate very readily; any suspension of spores will show swarm cells, sometimes within 30 minutes, and will achieve nearly 100 percent germination in about four hours. Many others take several days, and some, such as those of *Tubifera ferruginosa*, very rarely germinate in the laboratory. An aging phenomenon seems to be effective for some species, since spores that germinate hardly at all when freshly collected produce

swarmers or myxamoebas in high percentage after several months of rest or following alternate wetting and drying.

Swarm cells and myxamoebas respond to nonlethal unfavourable conditions, such as drying or a stale growth medium, by forming thin-walled microcysts (sporelike resting bodies) that may germinate again with the return of an appropriate environment.

Plasmodia have approximately the same environmental preferences as do spores during germination—a slightly acid growth medium (pH6) and an optimum temperature of about 27° C (81° F). In general, however, they prefer a film of moisture rather than total immersion in water. Neither plasmodia nor swarm cells can withstand high concentration of decay products or other metabolic substances. Although plasmodia feed on yeasts, molds, and bacteria, they are easily stifled if conditions are such that the food supply outgrows the plasmodium.

Oriented responses are well known in plasmodia. They will, for example, usually creep off a stale growth medium to a fresh one. They will move away from light except when preparing to fruit, in which case they seek the nearest exposed region by moving toward lighted areas. A plasmodium will also creep upstream against gently flowing water.

Nutrition. A number of slime molds can thrive on laboratory media that contain either killed bacteria or yeasts or extracts prepared from them. Such a medium is not completely known chemically. The continuous growth of one strain of *Physarum polycephalum* plasmodia on a completely known growth medium has, however, been accomplished. The medium contained nearly 40

Life cycle of a true Myxornycete.

constituents including minerals, amino acids, and vitamins. The majority of Myxomycetes, however, have not been successfully cultivated in the laboratory. The cultivation of a few forms is extremely simple, and these have become favourite study and research organisms. *Physarum polycephalum*, the most rapidly growing form known, can be purchased from biological supply houses. It forms gigantic plasmodia in a few days and may be kept on a moist paper towel sprinkled with oatmeal. This species has probably been used more than all other forms for studies involving cytoplasmic streaming, nutrition, and biochemistry. *Didymium iridis* forms smaller plasmodia, but, since it can be reliably carried through its cycle from spore to spore, it is much used for genetic studies and for detailed cytological investigations.

THE PLASMODIOPHORALES (ENDOPARASITIC SLIME MOLDS)

As the only known parasitic group of slime molds, the Plasmodiophorales are also the only economically important ones. The frequently devastating disease, club root of cabbage, caused by *Plasmodiophora brassicae*, has been known since classical times. *Plasmodiophora* causes monstrous deformities of the roots of cabbage and other members of the mustard family. By interference with the functions of the roots, the plants are stunted and frequently die. Because the mustard family includes, besides cabbage, such important vegetables as cauliflower, brussels sprouts, turnips, radishes, and kale, the disease and its causative organism have been extensively studied.

No member of the Plasmodiophoreae has been carried indisputably through its life cycle in the laboratory, and its subterranean habitat makes observation difficult. A generalized life cycle can be constructed by putting together the pieces that have been observed. Upon decay of the parasitized tissue, spores are released into the soil and produce swarm cells with two anterior flagella. Swarm cells may transform into myxamoebas, which penetrate root hairs and there grow into primary plasmodia. The primary plasmodia produce a second crop of swarm cells that now serve as gametes. These fuse and infect the body of the root by growing into a massive plasmodium and stimulating the characteristic tumourlike growth of the parasitized cells. The plasmodia divide into spores, which are released on the death of the host tissues. The spores can survive in fields for many years, so that after an infestation has occurred, it is very difficult to eradicate.

PROTISTELIALES

If the dead leaves and stems of grasses and weeds are kept damp in a rather cool room for a week or so, their surfaces bear microscopic transparent stalks, each topped by a glassy spore. These minute organisms, barely discernible at about 0.01 inch in height, can be mistaken for any of the innumerable small molds that grow on dead

plant tissues. They are, however, members of the order Protisteliales that are like the other slime molds in masquerading as genuine fungi.

In general, a myxamoeba of the genus *Protostelium* transforms into a spore by secreting a stalk on which it is elevated. The spore (or cyst) rapidly reverts to an amoeba again when wetted under favourable conditions. But in *Schizoplasmodium*, another genus in the Protisteliales, a very small plasmodium transforms into a **multinucleate** spore that germinates to form another plasmodium. In *Cavostelium*, flagellate swimmers are formed bearing one or more anterior flagella. In none of the Protisteliales has true sexual fusion ever been observed. Since no more cells come out of the germinating spore or cyst than went into them, the stalked spore is a resting stage rather than a reproductive one. True reproduction occurs by division of amoebas or plasmodia.

Schizoplasmodium cavostelioides has ballistospores—spores that are shot off by formation and explosion of a gas bubble formed within the outer membrane of the spore. Although several true fungi have ballistospores, such jet propulsion is otherwise unknown among slime molds.

The Protisteliales are literally everywhere, provided there is vegetation and a reasonable amount of moisture. Although a few have been recovered from rotten wood and manure, the favourite location seems to be on the dead stalks, shrivelled flowers, and withered leaves of standing plants. In the laboratory they are rather easily grown on yeasts and bacteria when these in turn are growing on an impoverished medium to prevent excessive growth. Undoubtedly future search will discover more than the present approximately six genera and one dozen species.

Proto-
stelid
habitats

THE ACRASIALES (CELLULAR SLIME MOLDS)

The cellular slime molds are remarkable organisms. *Dictyostelium mucoroides*, for example, looks very much like a common mold, a mass of spores set on a slender stalk, but its basic structure and mode of formation are completely different from that of any mold, in fact, different from that of any other group of organisms known.

In a suitable habitat the spore germinates, and from the split spore case emerges a small amoeba. Each amoeba feeds by engulfing bacteria before it divides. The amoebas greatly increase in numbers under proper conditions and then begin to converge. Until this time of aggregation, they are virtually indistinguishable from the many other amoebas that swarm in the soil.

If a plate of growth medium (agar), very dilute in nutrients, is streaked with suitable bacteria, such as the ordinary *Escherichia coli* and a few of the spores of *D. mucoroides* are placed on the plate, the spores germinate, each yielding a very small amoeba. These amoebas feed on the bacteria and divide again until the plate is practically devoid of bacteria, the amoebas forming almost a complete covering. The amoebas then begin to congregate, climbing up on each other as they form a little mound. The centre pile becomes a hemisphere with a nipple, similar in appearance to half a lemon set on end, and, in its interior, a sheath forms around a core of amoebas each of which fills with a fluid, swells, secretes stiff cell walls, and dies, becoming in structure and function a central stalk. This cylinder of sacrificed amoebas forms the stalk on which the remaining amoebas climb. The stalk becomes narrower until finally it is a chain of single cells; the survivors of the ascension transform into oval spores, held in a drop of mucus.

Dictyostelium discoideum has one further stage in the welding of separate living entities into one composite organism. When the myxamoebas have aggregated to the conical stage with the little nipple at the top, the whole pyramid falls over on its side, and, with the nipple raised and leading the way, the "slug" moves over the surface toward the light before continuing further development.

Other cellular slime molds also have a migration stage. After aggregation some species of *Dictyostelium* and *Polysphondylium* form slugs that crawl along the surface, more or less intermittently, forming a horizontal stalk.

Sequence from aggregation state to fruiting stage in *Dictyostelium discoideum* (Top left) Entire aggregate (Top centre) Highly magnified section of stream (Top right) View from above of slug-shaped, migrating pseudoplasmodium. (Bottom) Culmination stages over approximately nine hours.

(Top left, centre, right) D.R. Francis (bottom) J.T. Banner

Later they culminate by building a vertical single or branched stalk on which the spore balls form. But in these forms, stalk formation and migration loosely overlap; only in *Dictyostelium mucoroides* are they sharply distinct.

There are several different genera and species of Acrasiales, which differ strikingly in colour and shape. If the amoebas of the different forms are mixed, each sort separates itself and forms its own fruiting structures. If aggregation has started, and the early aggregations, say, of the purple, branched *Polysphondylium violaceum* and of the white, single-stalked *Dictyostelium discoideum* are mixed, the amoebas again sort themselves out and build their own pure sporangia. But if the aggregations have continued almost to the point of differentiation, sorting out no longer occurs; instead, hybrid fruiting structures are produced. But when the spores from these germinate, each produces amoebas after its own kind; the "mixed decks" thus unshuffle themselves.

There has been debate on sexual reproduction in the Acrasiales. What some biologists called sexual fusion of amoebas, others called cannibalism. The preponderant evidence now favours a completely asexual mode of life.

The Acrasiales resemble the Myxomycetes and Protozoa in being phagotrophic; *i.e.*, they feed on small particles by engulfing them. The diet is bacterial, and they are very easily grown in culture on bacteria washed to remove injurious metabolic products or on bacteria growing on a medium so weak that toxic metabolites do not accumulate significantly.

The Acrasiales, first thought to be inhabitants of dung, are now known, with a few possible exceptions, to be inhabitants of the soil. Collection methods indicate that they are common, being numerous in species and numbers in forest soil, but they also occur in garden, lawn, and field soils.

Unlike the Myxomycetes, the Acrasiales consist of relatively few forms. The vast majority isolated from soil are species of either the genus *Dictyostelium* or the closely related *Polysphondylium*.

There are a few genera, such as *Guttulina* and *Guttulinopsis*, that fruit on the dung of various animals. In these, separation into stalk and spore head is highly imperfect, the spore cells and stalk cells shading into each other.

By excluding some doubtful and imperfectly known

forms, the Acrasiales may be divided into two groups or families containing six genera and about a dozen species (see below *Annotated classification*).

ORGANISMS RESEMBLING SLIME MOLDS

Since the late 19th century a number of organisms have been assigned to the slime molds largely on the basis of a plasmodial or apparently plasmodial stage. Many have not been seen since the original descriptions. A notable exception is the genus *Labyrinthula*. Formerly considered very rare, it is now recognized to be the cause of an extremely destructive disease of eel grass. *Labyrinthula* forms a net plasmodium, an open network that can creep about as a unit. Close examination has shown that this is not a plasmodium, but a colony consisting of often closely packed, spindle-shaped individual cells that glide within tubes of secreted slime. The net plasmodium is thus more like an elastic subway system than a true plasmodium. While flagellate swarm cells have been reported for several species and heaps of cysts or spores for another, too little is known of the life cycle to place these organisms with any certainty. Modern authorities tend to exclude them from the slime molds.

A unique group of organisms, the Myxobacteria, form thin, spreading amoeboid colonies consisting of bacteria-like cells embedded in a slimy sheet. The whole colony can act as a unit, very much as does the acrasian aggregation stage in building a fruiting structure, in some cases forming simple spheres, in other cases complicated treelike forms. All evidence, however, points to the Myxobacteria being either true bacteria or closely related to them and, hence, distinct from any slime mold.

The Myxobacteria

CLASSIFICATION

Distinguishing taxonomic features. The various orders, families, genera, and species of the Myxomycetes are distinguished from each other by the characteristics of the fruiting structures. In rough order of importance these are spore colour; presence and type of a capillitium (fibres or tubes, usually hairlike, within the sporangium); presence and location of lime in the sporangium; and the dimensions and surface structures of the fruits, capillitium, and spores. Identification to family and sometimes to genus can usually be made by the naked eye, although separation of many genera requires at least

Effects of mixing pseudo-plasmodia

a hand lens. Specific identification usually requires a high-powered microscope, careful observation, and shrewd guessing.

The other slime-mold groups are not necessarily closely related to the Myxomycetes, but they do resemble them in being primitive amoeba-like colonial organisms at some stage in their life cycle. They also produce fungus-like fruiting structures (except for the Plasmodiophorales), as do the Myxomycetes.

Annotated classification. The slime molds are not presented in the following classification to show relationships, but to emphasize differences between the classes. Botanical nomenclature is used, although zoological nomenclature could be used with equal justification. In the following classification, the portion on the Myxomycetes is based largely on that of Martin and Alexopoulos (1969).

DIVISION MYXOMYCOPHYTA (MYCETOZOA)

Primitive eucaryotic (having true nuclei) organisms resembling both protozoa (me-celled animals) and fungi, having a vegetative (active, growing, feeding) phase consisting of individual amoeboid cells (myxamoebas) or of a multinucleate amoeboid mass or sheet (plasmodium); at length, by transformation of the plasmodium or by congregation and transformation of the myxamoebas, forming usually fungus-like fruiting structures bearing one to many spores. Some have flagellated cells (swarm cells) at one stage of the life cycle. Sexual fusion of myxamoebas or swarm cells known in some.

Class hlyxomycetes (True Slime Molds)

Vegetative phase a plasmodium; fruiting structure a sporangium containing 1 to many spores. Each spore on germination producing 1 or more myxamoebas that may transform into flagellated swarm cells, which in turn often revert back to the amoeboid stage. Swarm cells usually with 2 flagella, one longer and projecting anteriorly for swimming, the other usually short, inactive, and folded closely back against the cell surface; hence infrequently observed. Cosmopolitan terrestrial forms, usually found in decaying plant material.

Subclass Ceratiomyxozycetidae (Exosporeae)

Spores borne singly and externally on sporophores (fingers, ridges, or flat sheets of jelly-like material which dries down at maturity). On germination spores produce a 4-nucleate amoeboid body with the nuclei soon dividing, and the mass splitting into 8 swarm cells. Possibly each so-called spore actually a reduced sporangium, the sporangial wall closely adherent to the contained single spore.

Order Ceratiomyxales. The only order, it has the characteristics of the subclass.

Family Ceratiomyxaceae. The only family. One genus (*Ceratiomyxa*) with 3 species.

Subclass Myxogastromycetidae (Endosporae, Myxogastres)

Spores few to many, borne within a definite fruiting structure (sporangium) with a more or less persistent sporangial wall (peridium). A capillitium (system of simple or branching fibres or tubes) may permeate the spore mass. The sporangium may contain a columella (an axis), which, according to species, may range from a spherical mass to a tapering rod, attached to the base of the sporangium; in stalked forms it is an actual or apparent continuation of the stalk. Sporangia may be distinct and sessile (sitting on the substrate) or stalked; or more or less imperfectly distinct from each other in the form of plasmodiocarps (strands of the plasmodia that secrete a peridium, and form spores internally without breaking up into individual sporangia), or aethalia (compound fruiting bodies consisting either of tightly interwoven plasmodiocarps or of closely compacted and more or less fused sporangia with reduced or lost individuality at maturity). Aethalia may have a pseudocapillitium (individual sporangial walls reduced to fibres, shreds, or perforated ragged plates) along with or replacing the true capillitium. Fruiting structures at maturity may rest on a hypothallus (a thin sheet of dried gelatinous material derived from the mucoid covering of the plasmodium). Spores germinate to produce 1 or more myxamoebas, which in some cases immediately divide, and become transitionally to persistently flagellate. Approximately 60 genera and 500 species.

Order Liceales. Spore mass brownish yellow to dark brown or black, or gray to pinkish gray, occasionally (in *Cribraria* and *Dictydium*) dark purple. Capillitium absent, but aethalia may have pseudocapillitium formed from reduced sporangial walls.

Family Liceaceae. Spore mass varying from yellowish brown to black. Fructifications sessile, stalked, or of small plasmodiocarps. One genus (*Licea*) with 19 species.

Family Reticulariaceae. Spore mass light brown (rarely yellow), rust-coloured, olive brown, or dark brown. Individual sporangia closely compacted together or more commonly partly or completely fused into an aethalium. Pseudocapillitium frequently present. Four genera (*Tubifera*, *Dictydiaethalium*, *Lycogala*, and *Reticularia*) with about 20 species.

Family *Cribrariaceae*. Spores tawny to dark brown, in some species of *Cribraria* and *Dictydium* dark purple or brownish-purple. Sporangia usually stalked. Dictydine granules (dense, usually dark microscopic granules) characteristic of the family found in peridium, stalk, and sometimes on the spores. Three genera (*Lindbladia*, *Cribraria*, and *Dictydium*) with about 30 species.

Order *Echinosteliales*. Spore mass white, gray-yellow, pink, or brown; spores nearly smooth but with characteristic circular plates on the surface. Sporangia separate, minute, stalked; usually less than 0.5 millimetre in height, light coloured. Capillitium, if present, ranging from few threads to well-developed net, columella present or absent. Sporangia develop from minute protoplasmodia, each giving rise to a single sporangium.

Family *Echinosteliaceae*. One family with the characteristics of the order. One genus (*Echinostelium*) with 5 species, including the smallest known myxomycete, *E. roseum*.

Order *Trichiiales*. Spore mass usually bright coloured: yellow, orange, various shades of red, maroon, sometimes gray. Sporangia stalked, sessile, plasmodiocarpous or united into aethalia. Capillitium always present, often ornamented with spirals, bands, or spines. Columella never present.

Family *Dianemaceae*. Capillitium of solid threads, surface smooth or with reduced ornamentation; capillitium never forming a net. Sporangia usually minute, usually sessile or plasmodiocarpous. Four genera (*Listerella*, *Dianema*, *Calomyxa*, and *Minakatella*) with 9 species.

Family *Trichiaceae*. Capillitium obviously tubular (except solid or nearly solid in *Prototrichia*), with often prominent sculpturing or ornamentation in the form of rings, spines, or spirals. Capillitium frequently netlike or consisting of a tangled mass of short threads. Sporangia stalked, sessile, plasmodiocarpous, or occasionally united into aethalia. In the major genera sporangia and spore mass often bright coloured: yellow, orange, red, maroon. Ten genera (the most important and largest are *Arcyria*, *Trichia*, *Hemitrichia*, and *Perichaena*) with about 60 species.

Order *Stemonitales*. Spore mass dark, ranging from dark rust to deep brown, black, and purplish black. Lime absent from peridium and capillitium in all species, but present in hypothallus, and stalk (when present) of *Diachea* and *Leptoderma*, and in columella of *Diachea*. Capillitium often much branched, of dark threads. Peridium usually thin, frequently vanishing at maturity. Sporangia distinct or united into an aethalium. The genus *Stemonitis* includes some of the largest and most beautiful of myxomycete sporangia.

Family *Stemonitaceae*. With the characteristics of the order. Fifteen genera (the most important are *Stemonitis*, *Comatricha*, *Lamproderma*, and *Diachea*) and about 90 species.

Order *Physarales*. Spore mass dark brown to black or purplish black. Lime always present in peridium, sometimes in capillitium, and usually in stalk if present. Sporangia of all forms; stalked, sessile, plasmodiocarpous, or united into aethalia. These are the most widely distributed of Myxomycetes and occupy the most diverse habitats.

Family *Physaraceae*. Capillitium in the form of lime-impregnated tubes or collapsed tubes with limy nodes. Lime granules always amorphous. Eight genera (the largest and most common being *Physarum*, *Badhamia*, and *Fuligo*) with about 140 species. The genus *Physarum*, with over 100 species, accounts for about 20 percent of all known Myxomycetes.

Family *Didymiaceae*. Capillitium nonlimy, usually of slender threads. Peridium with lime forming an eggshell-like crust, or in distinct pegs, or in needle-like crystals. Six genera (the largest are *Didymium* and *Diderma*) with about 70 species.

Class Plasmodiophoromycetes (Plasmodiophorida) (Endoparasitic Slime Molds)

Vegetative stage a plasmodium living parasitically within the cells and tissues of higher and lower plants; at length forming spores in clusters of defined shape or in amorphous masses, but not within sporangia. Spores liberated on disintegration of host cells. Myxamoebas and anteriorly biflagellate swarm cells formed; thus resembling Myxomycetes, though possibly not related. Sexual cycle not confirmed.

Order *Plasmodiophorales*. The only order, it has the characteristics of the class.

Family *Plasmodiophoraceae*. The only family. Nine genera and about 35 species. *Plasmodiophora* and *Spongospora* are the most important genera.

Class *Protosteliidae* (*Protostelia*)

Minute stalked forms, each stalk bearing one to few spores,

but apparently without sporangial walls. Myxamoebas known in all, anteriorly biflagellated or monoflagellated swarm cells in some. Vegetative stage a uninucleate amoeba or plurinucleate minute plasmodium. The Protostelia have been recognized as a group only since 1966, and as methods for their isolation, recognition, and study are developed, it may be expected that more genera and species will be added.

Order Protosteliales. The only order, it has the characteristics of the class.

Family Cavosteliaceae. Flagellated cells present. One genus (*Cavostelium*) with 2 species.

Family Protosteliaceae. Flagellated cells absent. Five genera (the best known are *Protostelium* and *Schizoplasmodium*) with about a dozen species.

Class Acrasieae (Cellular Slime Molds)

Vegetative phase consists of individual myxamoebas, which later aggregate into a pseudoplasmodium (plasmodium-like mass but with individual cells retaining their identity), which then forms a fruiting structure, the cells more or less differentiating into stalk and spore cells. Flagellated stage apparently nonexistent; sexual fusion debatable.

Order Acrasiales. The only order, it has the characteristics of the class.

Family Guttulinaceae. Myxamoebas with few, blunt (lobose) pseudopodia. Spore mass on a more or less ill-defined stalk; spores and stalk cells intergrading. Three genera (*Guttulina*, *Guttulinopsis*, and *Acrasis*) with about 10 species.

Family Dictyosteliaceae. Myxamoebas with numerous fine needle-like (filose) pseudopodia. Stalk sharply distinct from spore mass. Four genera (*Dictyostelium*, *Polysphondylium*, *Coenonia*, and *Acytostelium*) with about 10 species.

Groups Resembling Slime Molds

Often included in discussions of slime molds, and at times classified with them, these organisms are now considered unrelated to any of the above groups. They are included here for completeness.

Order Labyrinthulales (Net Slime Molds). Marine, terrestrial, or freshwater parasites or saprobes (organisms obtaining food from dead organic matter) with spindle-shaped cells that congregate in networks of mucous filaments or tubes. Sexual reproduction not confirmed. Fruiting bodies absent. Swarm cells, where known, have 2 flagella inserted at the side, one of which bears fine, lateral, filamentous processes (tinsel flagellum); hence completely unlike swarm cells in the slime molds. The order includes the genus *Labyrinthula*, and 3 other doubtful genera, with about a dozen species.

Order Myxobacteriales (Slime Bacteria). Rod-shaped bacterial cells often held together as a slowly moving pseudoplasmodium in a common mucous sheet. Fruiting structures consist of clumps of aggregated cells forming globular masses, ridges, or branched tree-like structures. Eleven genera with about 60 species. *Myxococcus* and *Chondromyces* are the largest genera.

Critical Appraisal. The slime molds are opsimorphic organisms, which means that they have in common a clear distinction in time between growth in terms of increase in mass or of cell number and development. The active stages are amoeboid, whether as single cells, as in the Acrasiales and some Protosteliales, or as a true plasmodium, as in some Myxomycetes and a few Protosteliales. Otherwise, the active stages are quite different, and the term slime mold is more a convenient, if misleading, designation than a term inferring relationship. In their possession of true plasmodial stages, swarm cells with two flagella at the anterior end, the Myxomycetes and Plasmodiophorales seem to be related. The Plasmodiophorales could be considered Myxomycetes adapted for a parasitic life. The Protosteliales may themselves be a heterogeneous group. Relationships would be easier to define if all of them had plasmodial and flagellate swarm-cell stages. But some form neither, and those that form plasmodia do not have flagellated swarmers.

The Acrasiales were first associated with the Myxomycetes by accident, because it was thought that the aggregation stage was a true plasmodium. But they lack both any flagellated stage and any convincing evidence of sexuality; in addition, the aggregated individuals are distinct. The fruiting structure of the Acrasiales is a cellular stalk on which the spores are borne. The fruiting structure of the Myxomycetes is a secreted noncellular envelope in which the spores are contained. Small soil amoebas closely resembling acrasian myxamoebas are very common, and, in the laboratory, they often form

veritable pavements of closely packed cells and tend to form heaps of cysts. It is not too great a step from these amorphous heaps to the structures of the more differentiated Acrasiales.

Though the myxomycete fruits superficially resemble those of higher fungi, the fact that all structural parts of the fruit are dead secretions rather than the more or less interwoven cellular filaments so characteristic of true molds and mushrooms remove them from the true fungi.

BIBLIOGRAPHY

General works and systematic treatises: C.J. ALEXOPOULOS, *Introductory Mycology*, 2nd ed. (1962), a survey of fungi including a brief discussion on the life histories, classification, and relationships of several groups of slime molds; J.T. BONNER, *The Cellular Slime Molds*, 2nd ed. rev. (1967), a well-written, easily understood book, illustrated with clear diagrams and excellent photographs, containing all important information on the Acrasieae up to the year of publication; A.L. COHEN, "The 'Late Formers'—Changing Concepts of the Opsimorphs (*Myxomycetes*, *Acrasieae*, *Myxobacteria*)" *Arch. Mikrobiol.*, 59:59–71 (1967), a review of the slime molds and other organisms in which development comes after increase in size ("opsimorphs"); W. CROWDER, "Marvels of Mycetozoa," *Natn. Geogr. Mag.*, 49:421–443 (1926), a popular account of the Myxomycetes illustrated with coloured plates of unexcelled beauty; M. DWORKIN, "Biology of the Myxobacteria," *A. Rev. Microbiol.*, 20:75–106 (1966), the only complete review of the Myxobacteria, necessarily somewhat technical and condensed; J.F. PETERSON, "The Fruiting Myxobacteria: Their Properties, Distribution, and Isolation," *J. Appl. Bact.*, 32:5–12 (1969), a review of the systematics and distribution of the fruiting Myxobacteria with explicit directions for isolating and cultivating them; W.D. GRAY and C.J. ALEXOPOULOS, *Biology of the Myxomycetes* (1968), a thorough review of the Myxomycetes, treating all aspects except classification; J.S. KARLING, *The Plasmodiophorales*, 2nd rev. ed. (1968), a very thorough but highly technical account of the Plasmodiophorales including doubtful forms; A. LISTER, *A Monograph of the Mycetozoa*, 3rd ed. (1925), an excellent handbook of myxomycete taxonomy, well illustrated in colour and monotone; T.H. MACBRIDE and G.W. MARTIN, *The Myxomycetes* (1934), although particularly stressing the North American forms, this volume covers the Myxomycetes of the world; G.W. MARTIN and C.J. ALEXOPOULOS, *The Myxomycetes* (1969), chiefly a taxonomic survey of the Myxomycetes, including a thorough condensed review of slime mold biology, illustrated with coloured plates; L.S. OLIVE, "The Protostelida: A New Order of the Mycetozoa," *Mycologia*, 59:1–29 (1967), a comprehensive treatment of this small group with a discussion of their affinities; "The Mycetozoa: A Revised Classification," *Bot. Rev.*, 36:59–89 (1970), a critical discussion of the relationships of all the slime molds, with formal keys to the different groups; K.S. POKORNY, "Labyrinthula," *J. Protozool.*, 14:697–708 (1967), a brief and not overly technical survey of the genus *Labyrinthula* and its relatives, treating nutrition, development, and relationships.

Special works: J.T. BONNER, "Differentiation in Social Amoebae," *Scient. Am.*, 201:152–162 (1959), a very lucid semipopular account of cellular differentiation in the Acrasieae as they go through their remarkable life cycle; H.R. HENNEY and T. LYNCH, "Growth of *Physarum flavicomum* and *Physarum rigidum* in Chemically Defined Minimal Media," *J. Bacteriol.*, 99:531–534 (1969), a technical paper containing full references to previous similar work; L.S. OLIVE and C. STOIANOVITCH, "Monograph of the Genus *Protostelium*," *Am. J. Bot.*, 56:979–988 (1969), a brief, somewhat technical description of all the species of *Protostelium* known up to 1969.

Works on the collection, care, and simple cultivation of slime molds: The following references give directions for the isolation of Acrasieae, the collection of myxomycete fruits and plasmodia, and the cultivation of various slime molds. Methods are those that may be done in the home and with ordinary biology classroom equipment. A.L. COHEN, "The Isolation and Culture of Opsimorphic Organisms. I. (A.L.C.)

Sluter, Claus

The works of Claus Sluter (c. 1340/50–1406), one of the masters of early Netherlandish sculpture, infuse realism with spirituality and monumental grandeur. His influence was extensive among both painters and sculptors of 15th-century northern Europe. Born in the mid-14th century, he is known through his works rather than accounts of his person. He is thought to be the Claes de Slutere van Herlam (Haarlem) listed in the records of the stonemason's guild in Brussels about 1379. The sculptured consoles—brackets that support cornices or ornaments—that projected from Brussels Town Hall, now in the Musée Communal, are thought to show if not his hand at least his guiding spirit. From ducal archives he is known to have entered in 1385 the service of Philip the Bold, at the Burgundian capital of Dijon. Philip, duke of Burgundy, was ruler of the Netherlands and regent of France in the last decades of the century. He founded the Carthusian monastery of Champmol at Dijon in 1383 and made its chapel a dynastic mausoleum adorned with sculpture by Sluter.

Lauros—Giraudon

"Moses" from the "Well of Moses," marble sculpture by Claus Sluter, 1395–1404/5. In Chartreuse de Champmol, Dijon, France. Figures are life-size.

All of the surviving sculpture known to be by Sluter was made for Philip. Two compositions are still at the site of Champmol: the figures, on the central pillar that divided the portal of the chapel, showing the Duke and Duchess presented by their patron saints John the Baptist and Catherine to the Virgin and Child and the famous "Well of Moses" in the cloister, the remains of a wellhead that had been surmounted by a group showing the Calvary of Christ (the head and torso fragment of Christ is in the Archaeological Museum, Dijon). The other extant work is the Duke's own tomb, which once stood in the chapel at Champmol but is now reassembled in the Dijon museum.

The archives in Dijon provide some information on Sluter's life and sculptural commissions. In 1389 he succeeded Jean de Marville as chief sculptor to the Duke, replacing Marville's assistants with sculptors from Brussels. In that year he began carving the portal sculptures, which had been planned as early as 1386. He replaced the portal's damaged central canopy and by 1391 had completed the statues of the Virgin and Child and the two

saints. By 1393 the statue of the Duchess was completed, and it is presumed that the Duke's statue also was finished by then. In 1392 he bought alabaster in Paris, and in the following year he inspected work at Mehun-sur-Yèvre by André Beauneveu, talented sculptor to the greatest art patron of the period, Philip's extravagant brother, Jean, duc de Berry. In 1395 Sluter travelled in the Low Countries, going to Dinant for marble and to Malines. That same year he began the Calvary group for the cloister and in 1396 brought to Dijon his nephew Claus de Werve and more sculptors from Brussels to assist in his numerous ducal commissions. The architectural portion of the Duke's tomb had been completed by 1389, but only two mourning figures of the sculptural composition were ready when the Duke died in 1404; three weeks earlier, Sluter, to ensure the peace of his soul and body and for shelter and protection in his old age, purchased—in modern terms—a retirement plan at the abbey of Saint-Etienne, Dijon. It seems, however, he never availed himself of that retreat before his own death in 1406. Philip's son, Duke John the Fearless, contracted in 1404 for the completion of his father's tomb within four years; but Sluter's nephew did not finish it until 1410, and he used it as the model for Duke John's own tomb. (Many of the mourning figures around the base are copies of what must be Sluter's work, though the problem of establishing his exact contribution is difficult because the two tombs were disassembled in the French Revolution and extensively restored from 1818 to 1823.)

Sluter, an innovator in art, moved beyond prevailing French taste for graceful figures, delicate and elegant movement, and fluid falls of drapery. In his handling of mass, he also moved beyond the concern with expressive volumes visible in Beauneveu's sculpture. The grandeur of Sluter's monumental, naturalistic forms can only be paralleled in Flemish painting—by the van Eycks and Robert Campin—or in Italian sculpture—by Jacopo della Quercia and Donatello—several decades later.

The portal of the Champmol chapel is now somewhat damaged (the Virgin's sceptre is missing, as are the angels, once the object of the child's gaze, holding symbols of the Passion). This work, though begun by Marville, must have been redesigned by Sluter, who set the figures strongly before an architecture with which they seem intentionally not closely aligned, the doorway becoming a background for the adoring couple of Duke Philip and his wife. This transforms traditional portal design into a pictorial form in which architecture has become a foil, the framework for a figured triptych. Projecting canopies and jutting corbels carved with figures, deep undercuttings and swirling draperies aid Sluter's dynamic naturalism. This is a weighty, massive art of dominantly large, balanced forms.

The six-sided "Well of Moses," now lacking its crowning Calvary group, which made the whole a symbol of the "fountain of life," presents six life-sized prophets holding books, scrolls, or both. The figures, beginning with Moses, proceed counterclockwise to David, Jeremiah, Zechariah, Daniel, and Isaiah (the first three were in place by 1402). The French art historian Émile Mâle (1862–1954) popularized the discovery that their scrolls contain the prophetic passages the figures spoke in a medieval mystery play, *The Trial of Christ*, foretelling the death of Christ for the redemption of mankind. Six angels at the corners of the cornice mourn the event at one time depicted above. Moses was placed directly below the face of Christ, and the location of Zechariah, father of John the Baptist, was at Jesus' back, as befits a precursor. Zechariah looks down sadly as youthful Daniel vigorously points to his prophecy. On the other side of Daniel, and serving to balance Daniel's passionate temperament, is the calm reflective Isaiah. This juxtaposition reveals Sluter's use of alternating naturalistic balances. The head and torso fragment of Christ from the Calvary (now at the Musée Archéologique, Dijon) reveal a power and intensity of restrained expression that conveys overwhelming grandeur. Suffering and resignation are mingled, a result of the way the brow is knitted, though the lower part of the face, narrow and emaciated, is calm and without mus-

"Well of Moses"

cular stress. The "Well of Moses" was originally painted in several colours by Jean Malouel, painter to the duke, and gilded by Hermann of Cologne (the figure of Jeremiah even wore copper spectacles for which there exists a payment record of 1403). The figures of the composition dominate the architectural framework but also reinforce the feeling of support the structure provides through their largeness of movement.

Sluter's latest preserved work, the tomb of Philip the Bold, now in the Musée de Dijon, France, was first commissioned from Jean de Marville, who is responsible only for the arcaded gallery below the sepulchral slab of black marble from Dinant. Forty figures, each about 16 inches high and either designed or executed by Sluter, made up the mourning procession. Not all the figures are still in position at the tomb; three are lost, three are in the Cleveland Museum of Art, and one is in a French private collection. They served as models for Sluter's nephew, Claus de Werve, Juan de la Huerta, and other artists for sculptured tombs in France and beyond its borders. Sluter did not invent the mourning procession nor did he design the setting. But he conceived of the figures as *pleurants* (weepers), of whom no two are alike; some are openly expressing their sorrow, others are containing their grief, but all are robed in heavy wool garments that occasionally veil a bowed head and face to convey a hidden mourning. The voluminous draperies continue to suggest the sense of large movement visible in such a figure as the Moses of the wellhead. The figures for the tomb are a culmination of Sluter's awareness of natural forms and individual expression, the supreme realization in sculpture of the volatility of his age that was so quick to respond to opposite moods, to weep as strongly as it laughed, that in one moment contemplated with gloom this sinful world and in the next moment delighted in the variety of nature. Spiritualist and naturalist in one, Sluter epitomized in sculpture the growing awareness of an individualized nature with discoverable laws and an enduring grandeur.

MAJOR WORKS

The known extant works of Sluter were constructed for the Chartreuse de Champmol (Dijon, France), which was destroyed in 1792. The only works of Sluter remaining there are parts of the portal of the Chapel (1385–93), and the remains of the "Puits de Moïse," or "Well of Moses" (1395–1404/5), still in the cloister of the Chartreuse. The Musée des Beaux-Arts in Dijon, in the palace of the dukes of Burgundy, contains the tomb of Philip the Bold (1389–1410), now extensively restored. The Musée Archéologique in Dijon contains fragments of the Calvary group (1395–1400), which was originally the upper part of the "Puits de Moïse," including the head and upper torso of the Christ. (C.D.Cu.)

BIBLIOGRAPHY. Receipts and accounts by and concerning Sluter and the ducal workshop are located in the Archives de la Côte-d'Or and the Bibliothèque Municipale (Dijon), and are also catalogued by the Musée des Beaux-Arts (Dijon). An important catalogue of that museum, from the exhibition "La Chartreuse de Champmol, foyer d'art au temps des Ducs Valois" 1960, contains plates of Sluter's works and an extensive bibliography.

Comprehensive biographical studies are AENNE LIEBREICH, *Claus Sluter* (1936); HENRI DAVID, *Claus Sluter* (1951); and the article by HENRI PAUWELS in the *Encyclopedia of World Art*, vol. 13, col. 113–119 (1967). An important critical study is D. ROCCEN, *Les pleurants de Klaas Sluter a Dijon* (1936). Important critical studies considering the work of Sluter in the context of his period and his influence on European sculpture include: A. KLEINCLAUSZ, *Claus Sluter et la sculpture bourguignonne au XVe siècle* (1905); GEORG TROESCHER, *Claus Sluter und die burgundische Plastik um die Wende des XIV. Jahrhunderts* (1932); and THEODOR MÜLLER, *Sculpture in the Netherlands, Germany, France, and Spain: 1400 to 1500* (1966).

Small Arms, Military

Military small arms are the weapons of infantry soldiers and other troops, including sea and air forces. They include firearms, usually issued in companies and platoons and operated by individuals or by small crews. For primitive, ancient, and shock weapons and larger ordnance, see WEAPONS AND DELIVERY SYSTEMS; GUNNERY. For

civilian firearms, see GUNS, SPORTING AND TARGET. For details on propellants and explosive charges, see AMMUNITION.

Development of small arms

HISTORY TO 1890

Shock and missile arms of various types had reached a considerable state of efficiency long before explosives were practical for military use. Small military firearms were used in Europe during the 14th century.

Hand cannon. As soon as artillery became effective, inventors began a crude process of miniaturization. Early hand cannons were small enough to be handled by one man but required him to direct his attention towards two different objectives. The weapon had to be aimed with one hand and fired with the other; both operations required part of the soldier's vision. These weapons were fired by inserting a hand-held, red-hot wire into the powder charge through a touchhole on top of the rear of the barrel. Hitting a moving target was difficult at best.

An early improvement was to make the weapon larger and to employ a crew of two to handle it: one man aimed while the other fired on command. Firearms of this sort, however, were heavy and usually required a support. Neither type of hand cannon was militarily effective. Two other early improvements helped. A slow-burning match, consisting of a soft cord that had been soaked in nitre and dilute alcohol and then dried, was substituted for the red-hot wire about 1400. The touchhole was moved from the centre of the barrel to the side, and a small pan for priming powder was added.

Matchlock weapons. The first great small-arms invention appears to have been made about 1425. A length of glowing match was secured in the end of an S-shaped lever, or "serpentine," which pivoted on a pin. When the firer pressed on one end of this serpentine, the other carried the glowing end of the match precisely to the priming powder in the pan. A soldier could concentrate on his target and know that positive firing depended only on his pressing the lever.

With a matchlock weapon, individual enemies could be hit even while moving. The new firearms were accepted almost immediately. They were improved by making the lock itself (*i.e.*, the mechanism for igniting the charge) more compact, by enclosing it within the weapon, and by having the serpentine operate by trigger pressure against a spring. A cover for the pan holding the priming powder was introduced, and a fence was installed behind the touchhole and pan to shield the face and eyes of the firer from the flash of the priming powder. The match was improved; loading was made more convenient. A few matchlock handguns or pistols were also used, but this form of ignition was not suitable for horsemen.

For more than a century from around 1425 to 1550 matchlock shoulder weapons in widely varying sizes and shapes were used more or less haphazardly in battle. A curved stock to reduce recoil and facilitate aiming was probably introduced about 1500. A Spanish general produced a semi-standardized weapon and introduced tactics that for the first time made infantry firearms truly effective in battle. Spanish infantry in formation began to use matchlock *mosquetes* ("muskets") that were capable of sending bullets through the best armour that could be worn by a mobile soldier. These weapons weighed as much as 25 pounds (11 kilograms) and usually required a forked staff as a rest to enable a man of normal strength to fire them accurately from the shoulder. They were slow and clumsy to load, so that pikemen had to be included in infantry battalions to protect musketeers from enemy cavalry. Almost overnight, however, firepower from muskets became the dominant force in war.

The matchlock musket and pike were virtually the only armaments of infantry from about 1550 to 1675. The muskets became smaller as more powerful gunpowder was created; fully armoured soldiers almost disappeared from European battlefields toward the end of the 16th century. Armour-piercing capability was no longer required so that lighter weapons used without rests were normal.

Firing
by red-
hot wire

Pikemen gradually became less effective and decreased in numbers until another major small-arms invention eliminated them. The long muskets of the 17th century could be converted into tolerable short pikes by mounting knives in or around their muzzles. This improvement began modestly in the French infantry around the middle of the 17th century. The name bayonet probably originated in the town or district of Bayonne in southwest France. Plug bayonets, which fitted into the muzzles of muskets, were used first. Ring and socket bayonets, which attached to the barrel without obstructing the bore, became common early in the 18th century; sword or knife bayonets, which could be used for a variety of purposes, appeared soon thereafter and are still in use.

Firelock muskets. All matchlock muskets required a long piece of match secured in the small vise at the end of the serpentine before the weapons could be fired. In a rainstorm, the match could not be ignited or kept alight. Surprise was nearly impossible for soldiers armed with matchlock muskets because of the smell, glow, and noise of the matches themselves. There was always the danger that a matchlock-armed infantryman would accidentally set off his own or a companion's ammunition.

Two other forms of firearms ignition were known for at least a century before the end of the military matchlock era. Both were called firelocks in most records that survive, though they are now known as wheel locks and flintlocks. They have several advantages over matchlocks. Both can be loaded and primed at leisure and then fired with only a moment of notice. They were not, however, as satisfactory as matchlock muskets in sureness of fire or in the number of rounds that could be fired in a given time on a fine day without cleaning. Both were considerably more expensive and more likely to need repairs.

The wheel lock may have been invented by Johann Kieffuss at Nürnbreg, Germany, about 1515. It was never widely employed by infantry. A military wheel lock musket of the earliest successful type is similar to a matchlock, save in its method of ignition. The lock itself is more complicated, bulkier, and composed essentially of a serrated wheel wound under spring tension and a piece of iron pyrites held against it in a doghead vise (not shown). When the trigger (see Figure 1) is pressed a

er one shot even in a rainstorm. On the other hand, it was slow to load and more complicated. Military wheel-lock weapons were found to be appropriate for cavalry because they could be carried, loaded and ready to fire, in holsters for hours or even days. Long, heavy pistols of this type had a considerable influence on tactics in north Europe.

Flintlock muskets are believed to be not so old as the wheel-lock types but were known by the middle of the 16th century, about a hundred years before they made their appearance in quantity in infantry units. A flintlock musket is similar to a wheel lock except that ignition comes from a blow of flint against serrated steel, with the sparks directed into the priming powder in the pan. This lock was an adaptation of the tinderbox concept used for starting fires.

In the several different types of flintlocks that were produced, the flint was always held in a small vise, called a cock, which described an arc around its pivot to strike the steel (generally called the frizzen) a glancing blow (see

From H. Peterson, *Arms and Armor in Colonial America*

Figure 2: Typical flintlock mechanism (c. middle 17th century) with sear in safety position. Phantom view: (A) right side (outer), (B) left side (inner).

Figure 2). A spring inside the lock, similar to that used in most wheel locks, was connected through a tumbler to the cock. The sear, a small piece of metal attached to the trigger, either engaged the tumbler inside the lock, as shown, or protruded through the lock plate to make direct contact with the cock. Locks of the latter sort persisted in Spain and Spanish America until the end of the flintlock era.

Flintlocks were not as surefire as either the matchlock or the wheel lock, but they were cheaper than the latter, contained fewer delicate parts, and were not as difficult to repair in primitive surroundings, a virtue which probably accounts for their popularity in 17th-century America. In common with the wheel locks they have the priceless advantage, for use in the wilderness, of being ready to fire one shot immediately. A flintlock is slightly faster to load than a matchlock, if the flint itself does not require adjustment.

Percussion ignition systems. Early in the 19th century, several persons appear to have discovered a firearms ignition system based on the explosive property of potassium chlorate and fulminate of mercury, both of which detonate when struck a small, sharp blow. A Scottish clergy-

stream of sparks is directed, cigarette-lighter fashion, into the priming powder in the pan. A well-made device of this type, properly adjusted, wound, and dry, would almost surely fire if the weapon itself was properly loaded. Since this lock could be waterproof-covered and the trigger pulled without disturbing the covering, it could deliv-

man, Alexander John Forsyth, is credited with this invention in 1805. In the early Forsyth weapons, a small pill of detonating explosive was usually placed below a plunger at the entrance to the touchhole. A hammer, similar to the flintlock cock, struck the plunger when the trigger was pulled. Small tubes containing detonating substances were also used.

The percussion cap was invented about 1815, possibly by Joshua Shaw of Philadelphia. A truncated cone of metal—copper was best—contained a small amount of fulminate of mercury inside its crown, protected by foil and shellac. This cap was shaped to fit tightly over a steel nipple rigidly set in the gun barrel or an extension thereto. When the cap was detonated, a jet of flame passed down an open channel in the nipple into the powder charge. The rest of the lock was similar to that used in flintlock weapons, with a hammer substituted for the cock.

Percussion military muskets were possible before 1820; the advantages of the new system over the flintlocks were obvious both in regard to speed and sureness of fire. The percussion systems were simpler, cheaper, and did not require the special personal attention to small pieces of flint that was necessary for all flintlocks. The new form of ignition was not used regularly in any army, however, until the middle of the 19th century, probably because in Europe and to some extent in America most armies were oversupplied with flintlock muskets following the Napoleonic Wars; there was also the fear that units that relied entirely on the new caps might not always get a supply when needed.

Flintlock weapons predominated in the U.S. and Mexican armies that fought in 1846 and 1848, but many percussion arms were used in the British, French, Russian, and some other national forces which fought in the Crimea in 1854–56. By the American Civil War of 1861–65, flintlock weapons were obsolete. Percussion forms of ignition have been used in most firearms since that time.

Breech-loading weapons. Another major 19th-century advance in military small arms was breech-loading. Breech-loading weapons (*i.e.*, weapons loaded at the rear of the bore) were not new, and in fact the fieldpieces employed at the Battle of Crécy in 1346 were probably breechloaders. A few breech-loading flintlock rifles were used briefly by a small corps in the British Army during the American Revolution. Breechloaders, both rifles and smoothbores, were made and issued in small numbers to special American units between 1819 and the middle of the century. Percussion ignition, however, greatly simplified breechloading and made it practical for general military use. Literally dozens of new military breechloaders were invented and used in small numbers between 1820 and 1865. One group required that the projectile and the propellant, perhaps wrapped in paper, be introduced at the breech but fired by means of a separate percussion cap on a nipple outside the barrel as if it were a normal percussion muzzle-loader. Among the best known of these were the American Sharps and the British Westley Richards. Both are sometimes referred to as cap-and-ball breechloaders.

Another group of breechloaders used paper- or cloth-wrapped cartridges but included inside them a percussion primer. The German Dreyse military rifle, by far the best known of this type, was widely used in the Prussian and allied armies for many years. In the Dreyse paper cartridge, the percussion cap is located in the base of the bullet. A long, slender firing pin pierces the cartridge from the rear, goes entirely through the propellant powder, and strikes the primer. This system worked fairly well as far as sureness of fire went but allowed gas to escape at the breech in the user's face. Dreyse weapons required considerable maintenance and fouled badly with continued firing. The needlelike firing pins had to be replaced frequently. The early French Chassepot rifle also used an internally primed cartridge similar to the Dreyse, but with the primer in a disk to the rear.

There were many percussion systems that combined unburnable cartridge cases with separate percussion caps, but none was militarily important. The American Burnside

carbine may have been the best. It used copper or brass cartridges that contained the propellant and the bullet, but it required a musket cap to be placed on a nipple in the breechlock.

Rim- and centre-fire cartridges. The first cartridge containing propellant, bullet, and primer to be successfully employed in war was the U.S. Spencer *rimfire*, in the American Civil War. A ring of fulminate of mercury was deposited all around the entire base of a thin copper cartridge. Force from an external hammer crushed the case rim in one spot and fired the round. Tens of thousands of Spencer carbines and millions of rimfire cartridges for them were used by the U.S. cavalry during the Civil War.

Rimfire cartridges were not satisfactory for infantry use, however, because they had to be made of a metal that would be light and soft enough to crush easily and positively. A powerful cartridge such as was thought necessary for infantrymen would create too much pressure and rupture the rimfire cases. Spencer infantry rifles were unsatisfactory. There were also entirely self-contained pinfire cartridges, fired by means of a small rod that crushed a fulminate cap inside the base, but these were used mostly in pistols.

The concept of centre-fire ammunition, with the percussion cap positioned in the centre of the base of a strong cartridge case, was known before the middle of the 19th century, but practical copper and brass cases of this type were not issued until after 1865. Within a decade they had replaced all other types for military use. A soldier could load his weapon from the breech, fire it, and quickly remove the cartridge case. The closure at the breech was complete; most of the fouling went out in the discarded case. The weapon could be fired many times without cleaning, although accuracy fell off with bore fouling.

Centre-fire metallic cartridges of drawn brass, containing propellant, bullet, and primer, are still essentially the same after more than a century. Bullets are longer, but smaller in diameter; new priming compositions have been introduced from time to time, but fulminate of mercury is still the most positive. Propellant powders are more powerful and burn cleaner and practically without smoke. In aggregate, however, ammunition changes over the past century have been limited.

The early rifles and their disadvantages. A projectile that spins about its long axis in flight is more accurate than one that moves unpredictably; the feathers in arrows and fins on crossbow bolts were sometimes placed at an angle to the shaft to cause the missile to revolve in flight. Spiral or rifling grooves on the inside of a barrel can cause bullets to spin in the same manner. These were first used as early as the 16th century. Some early rifles, however, have straight grooves, perhaps to inhibit spin or reduce fouling.

Rifled small arms, which make their bullets spin, have been used for accurate shooting at game and targets for some 400 years. Even today, a single bullet carefully loaded into a rifled wheel-lock weapon more than 300 years old will shoot with precision to about 150 yards (140 metres). Every shot can be placed on a man-sized target at this range, an achievement that is virtually impossible with a smoothbore musket at 75 yards (70 metres).

Efforts were made to take advantage of this increase in accuracy of rifled arms in military weapons, but they were not practical because of loading difficulties. In order to spin accurately in flight, a bullet has to fit tightly into the rifling of the barrel, either with direct lead-to-iron contact, or by means of a patch of cloth or leather between the two. Loading a spherical lead ball of the proper size tightly into a clean bore is not difficult. As the bore becomes dirty from repeated firing, however, the loading operation becomes progressively more difficult. For this reason, early rifle-armed military units were not a success. Daniel Morgan's famous battalion of Pennsylvania and Maryland riflemen of the American Revolution were re-equipped with smoothbore muskets before the end of the war, because these weapons were more satisfactory for use in battle.

A special loading procedure was used in British rifle

Few changes in ammunition

Early problems with rifled barrels

Breech-loaders at Crécy

units during the Napoleonic Wars, so that the Baker military flintlock rifle could be loaded with patched balls for accurate shooting when the weapon was clean and then with bare balls smoothbore-fashion thereafter. The early rounds were accurate, but those fired later were inferior to bullets from regular Brown Bess muskets—smoothbore shoulder weapons used in the British and other services for about 150 years. Several other flintlock and percussion rifles employing essentially the same system with spherical lead bullets were used around the world, but with limited success. A small increase in accuracy was offset by loading problems. The obvious solution—breech-loading, so that the balls did not have to be forced down clogged bores—encountered another problem: sealing the breech was almost impossible before metallic cartridges. Modern test-firing of such weapons as Ferguson and Hall flintlock breech-loading rifles casts serious doubt on their military efficacy.

The Minié and contemporary systems. Beginning about 1830, a number of men in different countries began to experiment with ways to load a rifle easily from the muzzle and have the bullets take and hold the rifling on the way out. A number of workable systems were invented. Perhaps the simplest arrangement was to abandon spherical bullets in favour of a formed projectile of some sort to fit special riflings. Elongated cylindrical projectiles with two or four ribs cast into them to fit the wide, deep rifling grooves in their barrels showed promise. Another system was to make the inside of the bore in the shape of a regular polygon with rounded corners, and a twist. Whitworth rifles, used briefly in the British army and in the Confederacy during the American Civil War had hexagonal bores and bullets with a relatively quick twist.

Years before the Whitworth system was developed several French officers conducted experiments in which they deformed spherical and elongated projectiles in the breech of their rifles so that the bullets actually filled the grooves in the rifling before they were fired. Accuracy was poor, however, because the deformed bullets had poor ballistic shapes.

In 1849 a French captain, Claude-Etienne Minié, developed a better rifling concept. Minié used a cylindrical projectile with a rounded point and a hollow base into which a conical plug was fitted. The bullet's diameter was such that it slid freely down the bore. On being fired, however, the conical plug in the hollow base was driven forward to expand the lead bullet into the rifling grooves. This muzzle-loading Minié system was an immediate success. It did not even require the plug; powder gases alone sufficed to expand the lead bullet. Minié bullets were superior to almost all others not only in accuracy, but also in range. Spherical bullets lost velocity because they were light in proportion to their cross-sectional area. The elongated bullets of the Minié and other similar systems were stable in flight even out to 1,000 yards (900 metres).

Muzzle-loading percussion rifles designed to fire Minié bullets were introduced into several armies in the 1850s and were of extreme importance tactically. Infantry armed with them could be effective with fire up to five times the maximum range of the old muskets, with little or no sacrifice in speed of loading. The old balance between infantry and cavalry was at once upset in favour of the infantry: horsemen received five times as many bullets before they were close enough to use their sabres or lances, essentially their only effective weapons when mounted. The old infantry–artillery balance was also upset. Gunners and their pieces could at one time approach infantry to within 200 yards (180 metres) and fire multiple-projectile charges known as grapeshot and canister, the only really lethal ammunition of that era. The Minié rifles kept enemy artillery so far back, however, that the pieces were nearly useless. They could only reach enemy infantry with solid projectiles or the ineffective shell of that era, which burst into only a few fragments.

Breech-loading small arms. The Minié system, in spite of its great advantages over its predecessors, was short-lived. The breech-loading, metallic-cartridge firearms made all muzzle-loaders obsolete soon after 1865. A bullet loaded at the breech did not need to be expanded at

the moment of firing in order for the grooves in the bore to grip it tightly. The early rimfire cartridges were not powerful enough for infantry rifles, but centre-fire cartridge rifles, introduced as early as 1866, were fully equal to the muzzle-loading Minié types.

Most armies changed from muzzle-loaders to breech-loaders without adopting entirely new weapons. In several cases, Minié-type muzzle-loaders were converted to breechloaders by cutting off the rear of the barrel, threading it, and screwing it into a new single-shot action. The British calibre .577 Snider was of this type. (Calibre is a measure of bore diameter; in British and United States firearms, it is expressed as a decimal fraction of an inch.) In the American Allin-Springfield, the conversion was made in this manner: but the old barrel was reduced to calibre .50 by the insertion of a liner. Similar new single-shot, metallic-cartridge, military breechloaders were developed in France by Antoine-Alphonse Chassepot, in Germany by Paul von Mauser, and in the United States by the Remington Arms Company, among others.

Repeating rifles. During the 1880s, new breech-loading rifles gained another dimension by becoming repeaters. Mauser, Chassepot, and others added tubular magazines under the barrels of their rifles. Spencer rifles and carbines had a magazine in the buttstock which contained seven cartridges that were fed by means of a trigger-guard operating lever into the chamber in succession. None of these early repeating systems, however, was entirely satisfactory for military service. Mauser, the Austrian Ferdinand Ritter von Mannlicher, Remington Arms Company, and others gradually developed more practical box magazines which by the late 19th century were almost universal. The basic bolt action Mauser rifle of this sort, first made for Belgium in 1889, was adopted by armies throughout the world with small changes and modifications until it became the most popular type. The U.S. Model 1903 Springfield and the Japanese Arisakas, used in both world wars, are remarkably similar.

The early infantry breechloaders fired bullets similar in diameter and shape to those used by the Minié muzzle-loaders, about 0.5 inch (1.25 centimetre) in diameter. These weapons used essentially the same propellant, black powder, that had been employed for centuries, but in a more efficient manner. Cartridge and bullet diameters were soon reduced slightly, usually to about calibre .45 (11 millimetres).

Nitrocellulose, or guncotton, was invented in 1846 but was not utilized successfully for propellants until smokeless powder (nitrocellulose or nitroglycerin–nitrocellulose) was first used for military purposes by the French about 1885. This powder is much more powerful because it burns more completely; rifle projectiles could be made longer and thinner and be given more energy by a smaller charge because their lighter weight and better shape gave them higher velocities. Bore diameters dropped again to about calibre .30 (eight millimetres), with increases in both range and accuracy.

These smokeless-powder rifles generally fired jacketed lead bullets that weighed half an ounce or less, travelled at a velocity of between 2,000 and 2,800 feet (600–850 metres) per second leaving the muzzle, and were reasonably accurate up to 1,000 yards (900 metres) under ideal conditions. Their high muzzle energies gave them lethal power at as much as 3,000 yards (2,700 metres). Cartridges were usually made of drawn brass; the lead bullets were normally encased in a harder jacket that contained copper or nickel or both. In emergencies, both cartridge cases and the bullet jackets could be made of soft iron.

The new bolt action had a number of variations. The Mauser, Dreyse, and Chassepot rifles, along with the American Green, were all bolt-action breechloaders, in which the bolt itself turned. In all early bolt actions one or more projections, frequently called lugs, revolved from open space into recesses in the receiver, the rear portion of the weapon. The bolt handle itself often acted as a locking lug, the only one in some early types. In the Mauser actions of 1889 and later, however, locking lugs were at the front end of the bolt, which is still the most common position.

The principle of Minié rifling

First use of smokeless powder

In another type of bolt-action military rifle, the bolt itself does not turn at all, but simply slides backward and forward for extraction, ejection, and reloading. Locking is accomplished when the lugs are thrust out into recesses at the end of each forward stroke. When all goes well and ammunition is clean, straight-pull rifles can probably fire faster than turning bolt types. The Austrian, Swiss, and some other armies found them satisfactory; the Canadian Ross straight-pull rifle was not reliable for combat in World War I.

Military pistols. The early hand cannon and wheel-lock pistols for cavalry were succeeded by flintlock and percussion muzzle-loading handguns and single-shot, metallic-cartridge pistols. All functioned similarly to contemporary shoulder weapons but were far less useful. Mechanical repeating pistols existed toward the end of the 19th century but were too complicated and expensive for general issue. In fact, pistols have rarely been effective in military combat, because of inherent range and accuracy disadvantages in comparison with shoulder weapons. They are essentially personal-defense weapons that may be more important psychologically than for their ability to harm an enemy in battle.

From an early date, however, officers and others in military service wanted repeating handguns. Flintlock revolvers and even mechanical flintlock repeaters were made. So-called pepperbox percussion revolvers, essentially several separate small pistols revolving around a central pivot, saw some service. Heavy and bulky for their power, they were not really practical.

Toward the middle of the 19th century, several inventors separately perfected repeating pistols in which a cylinder could be loaded from the front with five, six, or more rounds with a percussion cap on each chamber. The pistol could then be operated to fire all chambers in succession when the hammer was cocked by hand and the trigger pulled. These cap-and-ball revolvers were popular because several moderately powerful shots could be fired before reloading, and the weapon was of reasonable bulk and weight. They were widely issued in some armies for cavalry service and when satisfactory metallic cartridges were available, revolvers became even more attractive. All handguns continued, however, to have inherent disadvantages in accuracy and range.

DEVELOPMENTS TO 1918

Machine guns. The desire to fire a number of projectiles from a single weapon in a brief time was first satisfied by the simple expedient of charging a weapon with more than one bullet. The results were not very effective, because all projectiles from a single discharge followed roughly the same path, and the propelling charges gave reduced velocity under the heavier weight of projectiles. A similar idea was to load more than one charge into a single barrel and fire them successively through different touchholes. Military weapons of this type survive from an early date, but test firing has not shown them to be satisfactory. Volley shoulder weapons were also tried from time to time; they generally involved a number of barrels loaded separately, but fired together. Dispersion, obtained by making the barrels not quite parallel, was rarely uniform.

The middle years of the 19th century brought dozens of inventions involving larger military weapons that would fire several projectiles either together or serially. The percussion system of ignition helped in regard to these. A number of volley field pieces were designed and made, especially in the United States and France. Less effective than howitzers loaded with grapeshot and canister, they took longer to load because of their many barrels and were more expensive to produce.

Even the concept of the modern machine gun, a number of serial discharges from a single barrel, is of ancient origin. A small revolving cannon that required a manually applied match to fire was patented in England as early as 1718; examples of it survive in museums. Even after percussion ignition was well established, mechanical repeaters not using mass-produced metallic cartridges were not really satisfactory for military use. But as soon as

centre-fire rifle cartridges of satisfactory quality were produced in large numbers, there were dozens of inventions, many of which were produced and tested. The best known were the U.S. Gatling gun and the French mitrailleuse, both developed in part before metallic cartridges were common, but both requiring mass-produced centre-fire ammunition to be militarily effective.

The Gatling gun and the mitrailleuse. Gatling guns had several barrels mounted around a central stem and revolved by means of a hand crank. After a barrel fired a round, it went through successive unlocking, extracting, ejecting, reloading, and relocking. In the most successful Gatling guns, magazines held 400 cartridges, but, by means of a feed device, stacks of rounds could be fed to give continuous fire for long periods. Gatling weapons were made to take a variety of ammunition, up to a full inch (2.5 centimetres) in bullet diameter. Though practical, they never saw extended service in a major war. A few were used by United States forces in Cuba in 1898 and in minor military operations around the world. Gatling guns operated best with ammunition loaded with fulminate of mercury primers and black powder propellants, a combination in which ignition was sure and quick. They were often unsatisfactory with the early smokeless powder propellants because a cartridge that did not go off precisely when its primer was struck—a hangfire—would damage the mechanism.

The French mitrailleuse was also a multibarrelled, serially fired weapon. It used a loading plate that contained a cartridge for each of its 25 barrels. The barrels and the loading plate remained fixed, but a mechanism (operated by a crank) struck individual firing pins in succession. The mitrailleuse issued in the French Army fired standard Chassepot rifle ammunition. The weapon weighed more than 2,000 pounds (900 kilograms). The French forces in the Franco-Prussian War of 1870–71 endeavoured to use them in a manner similar to artillery, but they were no match for Prussian, steel, breech-loading cannon made by Krupp, firing explosive shell. For a time the failure of the mitrailleuse discouraged machine-gun development. Several more manually operated types were made and tried out. Some were put into service in small numbers in various armies and navies, generally chambered for artillery ammunition of small size.

Maxim guns. The first successful automatic machine gun was invented by Sir Hiram Stevens Maxim, an American working in Europe. Beginning about 1883, he produced a number of weapons in which operation was based on recoil energy. In all Maxim guns, the force that opened and closed the action, feeding successive rounds to the chamber and ejecting spent cartridges, came from the cartridge itself as it was fired. The bullet's recoil energy was employed to unlock the bolt (or breechblock) from the barrel, to eject the fired case from the gun, and to store sufficient energy in a main spring to push the bolt forward, pick up a fresh round, load the chamber, and lock the piece. If the trigger was held back, the weapon fired again and continued to fire until it had expended all the rounds in the magazine. Both barrel and action recoiled a short distance to the rear locked together; then the action continued back alone after unlocking. An early feature of Maxim automatic machine guns was a positive control of the rate of fire, from one round in ten seconds, or even slower, to about 13 rounds per second, depending on ammunition. This variable fire control feature, however, was not retained.

Maxim weapons were ideal for firing the new smokeless-powder rifle cartridges. Until the cartridge went off there was no power to operate the weapon; though delayed firing was almost certain to damage a Gatling gun, it did no harm in a Maxim weapon, because the cycle did not begin until the cartridge actually fired. Since it operated by the power of the cartridges, it could be made lighter than the mechanical types. Its light weight made it satisfactory for use by special infantry elements. Since the effectiveness of combat infantry depended on firepower from rifles, weapons delivering several hundred bullets per minute with accuracy considerably increased the combat potential of foot soldiers.

guns

Maxim guns were first used by the British in a colonial war in 1895 and were employed on a much larger scale in the Russo-Japanese War (1904–05). The Russians used Maxim water-cooled machine guns manufactured in Great Britain. The Japanese used the French Hotchkiss (see below). The Maxim guns sold to most European nations were chambered for the national rifle cartridge. The Russian Model 1910 weighed about 160 pounds (70 kilograms), including mount, water-cooling apparatus, and a steel shield for the gunner. The German Model 1908 with sled mount weighed 100 pounds (45 kilograms). On the eve of World War I, armies differed radically in how to place machine guns in their organizations. In the German infantry, some companies were equipped with machine guns but British rifle battalions—each of which consisted of several companies—had no weapons of this type; they were used throughout the war by Great Britain in a separate machine-gun corps.

Machine guns of the heavy Maxim type were deadly throughout World War I, from 1914 to 1918. Their defensive fire so limited the offensive power of enemy infantry that the entire Western Front, from the Swiss border to the English Channel, became one vast siege operation. A few of these weapons sometimes caused thousands of casualties. On the other hand, because of their bulk and weight, they were only marginally useful for offensive operation by the infantry.

Other machine guns of World War I. Not all the heavy machine guns of World War I were of the water-cooled Maxim type in which recoil pushed both the barrel and the action to the rear for a short distance before unlocking. Gas operation was also employed. A piston located in a cylinder below the barrel was driven to the rear by gas from the barrel through a port to unlock the action and sent the bolt back to extract, eject, and compress the main spring; a new round was picked up, moved into the chamber, and fired on the forward stroke. The best known gas-operated heavy machine gun was the French Hotchkiss. It was air-cooled, but the barrel itself was heavy and provided with metal fins to increase heat radiation. The breech remained open at the end of each burst, a feature possible with any machine gun and used by many of them. Two machine guns of this type are said to have fired 75,000 rounds each in the defense of Verdun, and remained serviceable.

The Austrian Schwarzlose Model 1907/1912 operated on a third principle often called "blowback." In this, the action and barrel are never locked rigidly together; the barrel does not move, nor is there a gas cylinder and piston. To prevent too early opening of the action and case rupture, the block is heavy and the main spring strong. There is usually also a linkage of parts not quite on centre to delay the actual opening. Finally, the barrel is shorter than standard. The Schwarzlose, which was water-cooled and in the Maxim class in weight, was a delayed blowback. The weapon was entirely satisfactory in combat.

Light machine guns and automatic rifles. Heavy machine guns of the Maxim and Hotchkiss types were satisfactory for defensive roles but were not really portable. A number of lighter machine guns that could be carried by one man without great inconvenience began to be used in 1915 and later. These include the British Lewis gun (invented in America but manufactured and improved in Great Britain), the French Chauchat, several German weapons, and the U.S. Browning automatic rifle known as the BAR. All these were light enough to be carried and fired by one man. They could be fired rifle-fashion but were also capable of delivering from a prone position, with bipod, full automatic fire almost as effective as that from the heavy machine guns, restoring some of the offensive power of foot soldiers.

Most, but not all, of these light weapons were gas-operated. Almost all were air-cooled. Generally, a light machine-gunner had an assistant to help him carry ammunition. Toward the end of World War I, one light machine gun was issued per squad or section of six to ten men in most armies. These light machine guns usually fired from magazines rather than belts of ammunition because they

were more convenient and more easily transported. The guns weighed as little as 15 pounds (7 kilograms), giving rise to the idea that a similar infantry rifle could be constructed that would operate semi-automatically. Several such automatic rifles were issued in small numbers by 1918, but none was a military success. Recoil-operated weapons were prohibitively expensive at that time, and the gas-operated types needed too much cleaning to remain reliable. The principle causes of malfunctions in all weapons of this type are the accumulation of powder residue in the gas system and the breakage of small parts.

Automatic pistols and submachine guns. The anticipated success of the automatic machine guns late in the 19th century led to dozens of different so-called automatic pistols, actually semi-automatic; when the trigger is pulled, the cartridge in the chamber is fired producing power to extract and eject the empty case, load another round, and cock the weapon. There is no mechanical problem in making a pistol fully automatic (*i.e.*, causing it to fire continuously until the trigger is released or the weapon is empty), but only the first bullet will be target effective, the rest going high.

The early automatic or self-loading pistols operated by means of recoiling or blowback action. There have been no successful gas-operated military pistols. If the cartridge power is high, recoil operation is preferable. The best known military pistols of this class used in World War I were the German Lugers and Mausers and the U.S. Model 1911. Similar pistols used in other armies included the British Webley, the Austrian Steyr, and the Italian Glisenti. In all of these, the barrel and action move a short distance to the rear before unlocking.

Simple blowback-operated pistols were also widely used, firing relatively weaker cartridges. These have less than half the muzzle energy of the more powerful pistol ammunition. Accuracy and range are both limited compared with that of a shoulder weapon. Early in the history of self-loading pistols, however, the more powerful types were often equipped with a detachable stock that functioned as a holster when the weapon was not in use. Probably the most widely issued weapon of this sort was a special long-barrelled German Luger with a 32-shot drum magazine. It was normally carried as a secondary arm by machine-gunners; it fired only one shot per trigger pull.

This Luger and other similar arms confirmed the belief that a shoulder small arm that fired pistol ammunition could be militarily effective. The result was the submachine gun. The first successful weapon of this type was developed by a German, Louis Schmeisser, who at first used the 32-shot Luger magazines and the nine millimetre Parabellum or Luger cartridge. The Model 1918 Schmeisser was of rifle weight and conformation, but with a barrel only 7.9 inches (20 centimetres) long. It was blowback operated, easily possible with this cartridge and barrel length, because of the relatively heavy bolt and main spring, and was moderately effective in the few months it was used before the end of World War I.

Other fully automatic shoulder weapons firing pistol ammunition in World War I included the Italian Villar Perosa and the Pedersen device, but neither was of much combat importance. The Villar Perosa was used mostly in dual mounts for missions better accomplished by light machine guns. The Pedersen device allowed the standard U.S. Springfield to deliver fully automatic fire with a special, powerful, calibre .30 pistol-type cartridge, but the rifle could be converted back to fire rifle ammunition quickly if the soldier had not lost his bolt. Pedersen devices were in France before the Armistice in 1918; training results with them were encouraging, but they saw no combat service. All were scrapped soon after the war ended, although the cartridge was used later in French semi-automatic pistols and submachine guns.

Infantry support weapons. The widespread use of water-cooled machine guns in field fortifications and other innovations in World War I encouraged the introduction of new weapons into rifle companies. A small, light cannon firing a low-velocity explosive shell about 37 millimetres (1.5 inches) in diameter gave units of this size a

gun
at Verdun

means of destroying enemy machine-gun nests, although weapons of this type were not totally successful. The advent of tanks led to the development of infantry anti-tank weapons. The Germans produced a single-shot **Maus**er rifle of about calibre .51 (13 millimetres) capable of penetrating the armour of most 1918 tanks. It gave trouble because of its excessive weight and recoil but was reasonably effective.

The conditions of trench warfare also led to the reintroduction, after about 150 years, of hand grenades. Heavier bombs were projected in a number of ways, but simple muzzle-loading mortars were by far the most common. These trench mortars of about three-inch bore continued in the infantry inventories of the major armies after the war was over but were soon known simply as mortars.

CHANGES AFTER 1918

Research and development in small arms as in the other weapons was virtually suspended in most countries at the end of World War I, partly because of peace, partly because of the vast stocks on hand. With the rise of Hitler in Germany in the 1930s, militarism and military production began to revive.

Rifles and assault rifles. To improve on the bolt-action, box-magazine rifles of 1914–18, every nation having an arms industry sought to produce a semi-automatic or self-loading weapon that would load the next round in the chamber without the necessity of pulling back the bolt. The Soviet army was equipped in part with Tokarev semi-automatic rifles, but in 1941 these were abandoned after a few months of combat. The Germans produced only a small quantity of semi-automatic rifles (FG-42s) chambered for their full power 7.92-millimetre round. The United States armies of 1942 and later were supplied, however, with an ever-increasing flow of the U.S. M1 Garand semi-automatic rifles. The Japanese produced a copy of the **Garand**, but poor material and execution made it unsatisfactory.

In addition, many fully automatic weapons of infantry weight (eight to ten pounds) were designed. The search for a satisfactory light machine gun before and during World War I led to experimental production of self-loading arms in the rifle-weight class. Several different principles worked well in sporting arms, including both short and long recoil, gas operation, and various forms of delayed blowback operation. The submachine gun, though not used in quantity during World War I, became extremely popular in the next 20 years. These weapons will be discussed below, but their use in the German Army led to what may be called a new infantry weapon, the assault rifle.

The Germans used a number of good submachine guns early in World War II, but all were chambered for the nine-millimetre Luger, which lacked both range and power. The German FG-42, firing a full-power rifle round, recoiled too much for burst-fire accuracy even in a prone position. A round was developed in 1943, the 7.92 Kurz (short), which fired a bullet intermediate in power between the 7.92-millimetre **Maus**er rifle and the Luger pistol. The German assault rifle finally developed to fire this round is usually called the MP-44. Bursts from it were as accurate as from most submachine guns, but effective out to at least 300 metres (about 1,000 feet).

After World War II the Soviets adopted the German assault rifle in their **AK-47** (Kalashnikov Model 1947). This assault rifle (see Figure 3) was more powerful than a submachine gun and more stable in burst fire than weapons chambered for full-power rifle rounds. Later they were equipped with detachable box magazines to facilitate reloading. A Soviet carbine, the SKS or Simonov, had to be recalled because of loading troubles when ammunition was transferred from long clips into an integral box magazine. Both the MP-44 and the AK-47 were gas-operated with cylinders and pistons above the barrel, fired both fully and semi-automatically, and weighed about 12 pounds (five kilograms) loaded with detachable 30-round box magazines. Both fired from closed bolts but differed from each other in minor respects.

Figure 3: Soviet AK-47 assault rifle.

From W. Smith, *Small Arms of the World*

Communist armies, including the Chinese, adopted the AK-47 and an associated family of small arms firing the same cartridge. Other armies, however, had little success at first with the assault-rifle concept. In the early 1950s, the United States was unwilling to give up full-power rifle ammunition. The North Atlantic Treaty Organization (NATO) armies adopted a new common round, the 7.62-millimetre NATO, in 1952, which is shorter and lighter than most old rifle cartridges but is still of full rifle power. Several new rifles, chambered for this round, have been introduced into various Western armies. The best known are the Belgian FN, the German G3, the U.S. M14, the Japanese Model 1962, and the Italian Beretta.

In the early 1970s, however, the U.S. Armed Forces were changing from the World War II M1 and the more recent M14 to a new weapon, once called the AR-15, but now known as the M16, which fires a 5.56-millimetre round. The M16 is a true assault rifle, capable of delivering bursts with reasonable accuracy. Its great advantage is lightness of both weapon and ammunition; roughly twice as many rounds can be carried for the same total load, weapon and ammunition combined. But the M16 has a much shorter effective range than the full-power rifles, perhaps 350 yards (320 metres) compared with about 1,000 yards (900 metres). The Soviet 7.62 intermediate-power cartridge is heavier than the 5.56 but probably has more effective range. U.S. allies in Southeast Asia have many M16 rifles and some other weapons firing the same cartridge, and the British Army has about 6,000.

Pistols and submachine guns. Pistols have never been satisfactory for military use because of their lack of accuracy and power. In the 20th century, many major nations have endeavoured to abandon military pistols entirely, but none has succeeded. Some soldiers cannot perform their major duties encumbered by any form of shoulder weapon, yet need something for personal defense. In guerrilla war situations, all war personnel need some kind of weapon, but often the need is for something convenient to carry, especially into and out of vehicles (for example, see Figure 4).

Figure 4: Colt semi-automatic pistol, calibre .45.

Submachine guns, which developed astonishingly after 1918, have distinct advantages. They are shorter than rifles but are much more accurate and have greater magazine capacity than pistols. Submachine guns lack rifle or even assault-rifle power and range, but they can fire reasonably accurate bursts, an enormous psychological advantage.

Hugo Schmeisser of Germany (son of Louis Schmeisser

The
NATO
common
round

mentioned above), who produced the best submachine gun of World War I, developed a new model in 1928, which took long, straight magazines, extending out to the left side. This widely copied weapon was blowback-operated. An infantry soldier equipped with a weapon of this sort was thought to be more effective in some combat situations, especially in towns, than if he had a rifle. During the Spanish Civil War of 1936–39, rifles and submachine guns were issued in about equal numbers in some infantry units. The riflemen took care of long-range targets, and the submachine gunners gave close-in firepower.

Both the German and Soviet armies issued submachine guns widely in infantry units during World War II. The Germans used mainly Schmeisser types. The Soviets had two submachine guns: the first, known as the PPSH often used a 71-round drum magazine that gave trouble and fired too fast for accuracy (900 rounds per minute); the second, the PPS, was an outstanding success because it was simple, slow firing, and light. The 7.62 Soviet pistol and submachine gun cartridge had greater range than the German nine-millimetre Parabellum because of its smaller diameter bullets, which had higher velocity. A spare magazine loaded with 35 rounds weighed only 1.5 pounds (less than a kilogram). Many Soviet infantrymen used the PPS in their final successful offensives against the Germans late in 1944 and in 1945.

The first submachine gun issued in the United States armed forces was the well-designed Thompson Model 1928, the "tommy gun" of the American underworld and motion pictures. The early Thompsons were satisfactory, but complicated and expensive, and needed careful cleaning and maintenance. They were not at first straight blowbacks but used a locking system that was not necessary. They were employed in small quantities by American troops in Caribbean actions and by the Western Allies early in World War II. A wartime redesign changed them into the U.S. M1 submachine gun, in which they did become blowbacks. The M1 was replaced by the M3, which fired more slowly and reliably and could be produced for a fifth of the man-machine hours.

The U.S. during World War II had another weapon midway between the rifles and pistols in power, the semi-automatic M1 carbine, which fired a special calibre .30 cartridge. Toward the end of the war, this weapon was issued with a switch to allow fully automatic fire, but results were not satisfactory—the weapon was too light for the rate of fire.

Other individual weapons. Bayonets and knives continue to be carried in most modern infantry units. A few Japanese officers used swords during World War II. Grenades are still widely issued, although their effectiveness when hand thrown is subject to question. Special skill, strength, and coordination are required for range and accuracy in combat. Shotguns have high efficiency when range is short, but they are ineffective beyond about 75 yards (70 metres) and their ammunition is heavy.

The outstanding new individual small arm since World War II is the U.S. M79 grenade launcher, a light, single-shot, shoulder-fired rifle with a large (40-millimetre) bore designed to project small bombs at the remarkably low velocity of 250 fps (foot-pound-second). These little shells weigh slightly less than six ounces, but their segmented wire and powerful explosive give them about the same killing power as World War I hand grenades. Maximum range is said to be 400 metres (about 435 yards).

The concept of discharging bombs from a small arm has also been incorporated into a 2.5-pound attachment for an infantryman's rifle. These were used in combat in small numbers in Vietnam with mixed results. The combination of a rifle and grenade launcher is versatile, but clumsy and heavy. Supplies of ammunition for both are difficult to carry in rough terrain during poor weather.

Machine guns. The heavy, water-cooled machine guns of World War I were widely used during World War II and later, but lighter, air-cooled weapons began to take their place during the 1930s. The most important were the several different models known collectively as the German MG-34, all recoil-operated. Their greatest vir-

tue lay in their effectiveness both as light machine guns fired from bipods and as substitutes for the old heavy machine guns when mounted on tripods for sustained fire. A shift in terms occurred between the wars. In 1918 a heavy machine gun was typically a water-cooled Maxim, firing rifle cartridges. In 1939 the same weapon was considered to be medium; the term heavy now referred to machine guns firing cartridges of several times rifle power.

The MG-34s and the similar MG-42s were reliable and satisfactory in both light and medium roles, especially models with barrels that could be changed quickly. Even with their tripods, they were lighter and more portable than the weapons they replaced. These dual-purpose machine guns used belts for holding their ammunition, but short lengths could be carried in containers like magazines.

Light machine guns. The light machine guns of World War II, usually issued with bipod mounts only, were normally magazine-fed. There is a difference in tactical value between belt-fed and magazine-fed types in regard to firepower. If a weapon fires from a magazine, it is out of action between the time one magazine is exhausted and another is installed. Belt-fed weapons can be in action continuously for short periods at least, because one belt can be attached to another while the first is being fired. Belt-fed weapons on the other hand, are usually longer, heavier, and more troublesome when carried in thick jungle than those that use magazines.

The best-known light machine guns of World War II were the Soviet Degtyarev (DP and DPM), the British Bren, and the already mentioned U.S. BAR. There are different models of each of these, but all are gas-operated and magazine-fed, and weigh from slightly over 20 pounds (nine kilograms) to more than 30 (14 kilograms) loaded. They fire slowly enough to deliver accurate bursts from their bipods, 350–600 rounds per minute. In general, lighter weapons must be fired more slowly to achieve accuracy.

Heavy machine guns. The new heavy machine guns were designed partly to overcome the insufficient power of rifle ammunition for some tactical missions, especially for attacking armoured vehicles. Even before World War I, fully automatic weapons were used with ammunition more powerful than rifle cartridges, but smaller than that for conventional artillery. Such ammunition was not necessary for infantry missions, however, until foot soldiers encountered armoured vehicles. During the 1930s, many higher powered weapons were manufactured and tested. Several were actually adopted, although only two had outstanding success. The U.S. calibre .50 Browning is still widely used throughout the non-Communist world. The cartridge delivers bullets of various weights and types at high muzzle velocities, roughly five to seven times the energy of full, rifle power ammunition. The weapon is essentially the Model 1917 calibre .30 weapon, increased in size. It is recoil-operated and was at first water-cooled, but this refinement was found to be unnecessary for most ground missions. Firing rate is about 450 rounds per minute; the air-cooled M2 weapon with tripod and 500 rounds joined with disintegrating links weighs about 300 pounds (135 kilograms). The Soviet 12.7-millimetre weapon, the DShK, is similar and is almost as widely used in the Communist armies, but is gas-operated. The two bullets are almost identical in diameter, and the cartridge cases and ballistics are similar.

Since 1945, several super-heavy machine guns (above calibre .50) have been developed in several countries, mostly for aircraft and antiaircraft use. The Soviets introduced a 14.5-millimetre weapon into their ground forces especially for use in armoured vehicles. It is recoil-operated and belt-fed and has a barrel that can be changed quickly. Armoured personnel carriers also often carry small automatic cannon, up to even 30 millimetres, but these cannot be considered small arms.

At the other end of the modern machine-gun spectrum, there are weapons firing assault-rifle ammunition of intermediate power. In the early 1970s the Communist nations, their allies, and their weapons customers were using

"Tommy gun"

a machine gun chambered for the 7.62 intermediate round. A successful light machine gun firing the same cartridge used in rifles offers advantages at the platoon level, but lack of effective range may more than counterbalance them.

Additional platoon and company support weapons. During World War I, small mortars came to be associated with infantry instead of artillery. Weapons with bores of two to three inches (50 to 75 millimetres) in diameter were issued throughout World War II in most infantry platoons or companies and continue to be used by them to deliver high-angle fire like artillery. Accuracy and range depend, of course, on size, stabilization, mounting, and sighting equipment as well as the skill of the crew. A good crew with the latest in equipment can deliver effective fire out to 4,000 metres (13,000 feet). Larger mortars are usually classified as artillery.

Infantry antitank weapons became extremely important early in World War II. The Germans had a single-shot rifle that delivered an extremely high-velocity 7.92-millimetre rifle bullet with a hardened core that could penetrate the armour of tanks of the 1939–41 era. The British had a calibre .55 "shoulder" rifle similar to the German Mauser of World War I, save that the British weapon had a recoil-absorbing device incorporated in the stock. Tank armour soon became too strong and thick, however, for either of these. Kinetic-energy projectiles (*i.e.*, those that penetrate because of their own weight and velocity) that could defeat tank armour after 1943 required a delivery system too heavy for infantry companies.

On the other hand, a discovery made before World War II led to a highly effective means of attacking armour with light weapons firing low-velocity projectiles. A hollow cone of high explosive, with its open end toward the target, was detonated several inches from the armour to be penetrated. A jet of white-hot gas and molten steel was projected forward and penetrated several inches of the best armour plate. These "shaped-charge" projectiles could be delivered even by means of fin-stabilized rifle grenades discharged from the muzzle of an individual soldier's weapon, though they were more effective in larger sizes. Two new types of infantry-support weapons were introduced to launch larger projectiles: the bazooka, from which a rocket was launched out of an open tube; and a recoilless device such as the German Panzerfaust. The Panzerfaust was held in the hands of a soldier; the thrust is generated as in artillery, but with an exact balance between the energy of the projectile moving forward and gases from the propellant moving to the rear. These weapons resembled rocket launchers but were better in both accuracy and range. The backblast, however, gave away the position of the firer.

Following World War II, both the rocket and recoilless principles of delivery were used in infantry antitank weapons. The weapons themselves were reduced in weight and bulk but increased in effectiveness. Rifle units now have recoilless weapons with bores of 82–90 millimetres that can be carried by one man but will defeat the armour of any known tank at any range at which a hit can be scored, probably a maximum of about 400 metres (1,300 feet). Communist countries throughout the world also possess a lighter weapon for use at squad level, an adaptation of the German Panzerfaust, in which the projectile is launched recoillessly but then given additional velocity and increased range by means of rocket assistance. It is known officially as the RPG-7 antitank weapon but is often called a grenade launcher. In the early 1970s, the United States and her allies used a light 66-millimetre non-reloadable rocket launcher known as the LAW (light antitank weapon) weighing less than four pounds but with a shaped charge capable of destroying any enemy tank it can hit in a vital spot.

Contemporary small arms

Modern mechanical concepts being thoroughly international, military small arms generally vary less from army to army than do uniforms. A no less striking generalization is that nothing radically new has been introduced in small arms in this century.

OBSOLESCENT WEAPONS

Manually operated rifles are still used in many parts of the world. Well-aimed single shots are still effective. Bolt-action arms stand up better to extremes of climate and abuse than more complicated types. Most of those still used are of the turning bolt type.

Pistols are of two main types, revolvers and semi-automatics. The revolving principle of operation was used in firearms before metallic cartridges were available. A cylinder containing several chambers is aligned with the barrel successively so that each metallic cartridge can be fired in turn. The power required for this operation is normally supplied by the pull on the trigger. An automatic revolver in which recoil energy revolved the cylinder one step and cocked the weapon was once issued in small numbers in the British army. Most military revolvers are now of the double-action type; by merely pulling the trigger, the weapon is cocked and fired and the cylinder is rotated. These weapons can also usually be cocked with the thumb and fired single-action, a more accurate procedure because less trigger pressure and travel are required.

Semi-automatic military pistols were being made before the end of the 19th century. Those that fire low-power cartridges, up to and including the nine-millimetre short Browning or .380 ACP, operate on the blowback principle. Recoil pressure causes the cartridge to fly free and stores enough energy in the main spring to close the slide on a new round, which is stripped from a magazine in the butt of the pistol. In a semi-automatic pistol, the trigger must be released and pulled again for each shot.

Military pistols firing more powerful cartridges are generally recoil-operated, the barrel and breechblock, or slide, moving to the rear a short distance locked together. The breechblock then separates and goes all the way back and forward again to complete the cycle. More powerful cartridges require a more complicated action, because if they were fired in a light blowback weapon, they would open before the pressure inside had dropped sufficiently and might rupture the case. In general, pistol actions are designed not to open until the bullet has left the barrel.

Semi-automatic pistols firing powerful cartridges were more popular than either revolvers or blowback automatics through World War II. The Soviets have since adopted a pistol cartridge less powerful than the nine-millimetre Parabellum and two blowback weapons to fire it, and some other armies, including those of Italy and Turkey, use similar pistols.

Full-automatic fire from a weapon held in one hand is ineffective. Holster-stock pistols, which have wooden or metal-and-leather holsters that can be attached to the pistol, allow both hands and the shoulder to be used for greater stability; they have long been equipped with burst-fire switches. A variation of the Mauser pistol Model 1896, one type of Browning Model 1935, and one of the Soviet handguns mentioned above, the APS or Stechkin, are of this type. A pistol with a stock attached is actually a light, or submachine, gun. With the possible exception of the Stechkin, such weapons usually have cyclic rates that are too high for burst-fire accuracy.

Almost all submachine guns are blowback-operated, because the moving parts and the mainspring are substantial enough to keep the breech closed until the bullet has left their short barrels. Perhaps the most modern and effective submachine gun is the Israeli Uzi, which is certainly the most compact when used with a folding metal stock, or without a stock. The Uzi breechblock extends forward around the chamber, telescope-wise, to allow this compactness without sacrificing stability or barrel length. This weapon can also be equipped with a wooden stock, a conformation especially favoured in Israel where the Uzi is often issued instead of a rifle.

Nearly all submachine guns have several features in common. They fire from an open breech, which means that the bolt remains to the rear until the trigger is pulled. The bolt then closes, picking up a loaded round from the top of the magazine and firing it, usually by means of a fixed firing pin. Most weapons of this sort have switches for either single-shot or fully automatic fire.

Pistol
types

Shaped
charges

Mortars
and
rocket
launchers

Mortars are among infantry support weapons that are obsolescent. They are generally muzzle-loading; a round of ammunition that consists of a projectile with a propellant charge in or around its base is dropped down the barrel so that the primer hits on a fixed firing pin at the bottom and fires instantly. Some weapons of this type can be loaded from the muzzle and trigger-fired. A few infantry mortar weapons are loaded from the breech and trigger-fired like a small artillery piece. Accuracy is attained in mortars by rifling inside the barrel, or by means of stabilizing fins during flight.

Rocket launchers of various types are still in use in some armies and in reserve units, but they appear less effective against enemy armour than recoilless weapons. Both rocket launchers and recoilless weapons are lighter than standard artillery pieces of similar projectile size, but their ammunition is heavier. Loading and firing are simple, but rockets are relatively inaccurate and recoilless weapons shorter ranged than conventional cannon. Recoilless devices also have backblast.

NEWER WEAPONS AND OPERATION

Rifles and assault rifles. Modern military rifles are all at least semi-automatic, that is, automatically reload after firing. Many armies now allow a soldier to determine whether he will fire one round per trigger pull or several by changing a lever or switch. Detachable box magazines holding 20–30 rounds have become standard.

Most military rifles of the 1960s and early 1970s were gas-operated; that is, the power for the unloading–reloading cycle came from the propellant gases in the barrel before the bullet left the muzzle. In such a rifle a port in the barrel, usually closer to the muzzle than the breech, is uncovered when the bullet passes; gas enters, forcing a piston to the rear, and compressing a main spring, an operation similar to the early gas-operated machine gun. Both full and intermediate power cartridges can be handled equally well in light gas-operated actions. In assault rifles, the operating cylinder is frequently above, rather than below, the barrel in order to provide for an "in line" stock. Assault rifles generally fire from a closed breech.

The Soviet SKS gas-operated carbine, for a time more popular in the Soviet Army than the AK-47, is still in wide use in China. It is an effective semi-automatic weapon.

The new German G3 family of rifles does not rely on either gas or recoil operation but employs instead a roller principle involving friction; the breech is held closed while the pressure inside the cartridge case is high but opens when pressure has fallen to a safe level. The bolt is securely locked under high pressure but opens easily later. Malfunctions are even less frequent than in gas-operated rifles.

Machine guns. There are no radically new principles of operation for weapons of this sort. Recoil systems still hold their own in the heavier types, though gas operation is also employed. The roller-operated G3 principle is also applicable to machine guns.

The dual-purpose weapon called in the British Army the GPMG (general purpose machine gun) and the U.S. M60 (see Figure 5) are both gas-operated, belt-fed, and cap-

Figure 5: Components of a typical machine gun (U.S. M60).

able of effective fire, either bipod-mounted in a light role, or from a tripod for heavier duty. The West German MG 42-59 is recoil-operated. The GPMG and the MG 42-59 can deliver fire at variable cyclic rates. In the MG 42-59, three different sets of components can be assembled into

the same weapon to allow nine different cyclic rates from below 600 rounds per minute to as high as 1,400. A low cyclic rate is best for ground combat, but the highest possible number of bullets are more useful for firing at aircraft and for use in helicopters against ground targets.

Machine guns and other automatic weapons have successfully used operating principles other than those mentioned above. Blowbacks with heavy blocks and springs work well; delays introduced by various expedients can be both simple and effective. A continuing problem is an acceptable ammunition holder. Belts are not good for use in jungle. A simple practical means of converting a belt-fed weapon to handle magazines is still being sought. The Communist armies have a 7.62-millimetre, full-power, dual-purpose machine gun that can be made either belt- or magazine-fed by changing only three components, requiring only 15 seconds. Ten years after the introduction of this system, however, it was still not widely employed for full-power machine guns, presumably because of its disadvantages. On the other hand, the Soviet gas-operated RPD light machine gun, which handles the intermediate-power (AK-47) rounds, normally fires from belts that are satisfactorily housed in round metal containers attached to the weapon, 100 cartridges in each magazine. This feed arrangement can, of course, be changed easily to accommodate longer belts in boxes. Later weapons of this type sometimes are fitted with an integral adapter to use AK-47 magazines. If intermediate-power cartridges are satisfactory tactically, this weapon is one of the best.

The new heavy machine guns, those of about calibre .50–.60, do not differ in operating principles from those already discussed. Both gas and recoil operation are regularly employed. Barrels can be changed easily in some, but not in others. The Gatling principle of operation has also been reintroduced, with the weapon driven mechanically, usually by means of an electric motor. The modern Gatling weapon, known as the Mini-gun, has a number of barrels and actions employed to deliver extremely high rates of fire; these weapons are chambered for various cartridges, from intermediate rifle power to 20-millimetre cannon rounds. The latter, known as the Vulcan, are useful for firing at both aerial and ground targets; they are not in the small-arms category because they are not used at infantry-company level, though they might be so assigned in special circumstances. In rifle calibres, a single Mini-gun can fire at a rate of 6,000 rounds per minute and even more.

Guided missiles. An entirely new sort of weapon that has appeared, even at platoon level, is the guided missile. A single infantryman can carry and launch one of these unassisted. There are two general types, classified according to the targets they attack. One type is essentially a high-speed rocket with an internal guidance system that can lock onto a heat source, such as the manifold of an enemy aircraft, and then fly along a path to hit it. The other type, which is employed by infantrymen in attacking tanks and similar vehicles, uses one of two systems of guidance, both requiring the attention of skillful operators throughout the projectile flight. In one system, the missile unwinds two thin wires, and the gunner, who watches the projectile through binoculars, controls its motor by means of them. The other guidance system, which is more advanced and effective, does not require wires; it allows the gunner to hold the crosshairs of his sight on his target continuously (see ROCKETS AND MISSILE SYSTEMS).

Small arms of the predictable future. Basic small arms, rifles, submachine guns, and machine guns, at least, operate according to principles worked out in the 19th century. Even rockets are of ancient origin; recoilless weapons are the only newcomers, and they are no longer really new. Most of the small arms used today were developed slowly over the last three-quarters of a century.

This static small-arms situation is not likely to continue indefinitely. The science and engineering that devised nuclear warheads and put men on the moon should also be capable of producing much better individual weapons. Many nations are spending millions of man-hours trying to evolve new and dramatically effective weapons. For a

New
recoil
principle

brief discussion of the more likely possibilities, see WEAPONS AND DELIVERY SYSTEMS.

BIBLIOGRAPHY. An entire literature composed of hundreds of authors and thousands of volumes and articles has grown up in this field since weapons of all types began to be studied exhaustively in the 19th century. The following books are especially recommended: JOHN G.W. DILLIN, *The Kentucky Rifle* (1946); WILLIAM B. EDWARDS, *The Story of Colt's Revolver: The Biography of Col. Samuel Colt* (1953); T.F. FREMANTLE, *The Book of the Rifle* (1901); CLAUD E. FULLER (comp.), *Springfield Muzzle-Loading Shoulder Arms* (1930); IAN GLENDINNING, *British Pistols and Guns, 1640-1840* (1951); ALDEN HATCH, *Remington Arms in American History* (1956); THOMAS J. HAYES, *Elements of Ordnance: A Textbook for Use of Cadets of the United States Military Academy* (1938); G.S. HUTCHISON, *Machine Guns: Their History and Tactical Employment, Being Also a History of the Machine Gun Corps, 1916-1922* (1938); MELVIN M. JOHNSON, JR., and CHARLES T. HAVEN, *Automatic Weapons of the World* (1945); BERKELEY R. LEWIS, *Small Arms and Ammunition in the United States Service* (1956); W. KEITH NEAL, *Spanish Guns and Pistols* (1955); THOMAS B. NELSON, *The World's Sub-machine Guns (Machine Pistols)*, vol. 1 (1963); H. OMMUNDSEN and ERNEST H. ROBINSON, *Rifles and Ammunition and Rifle Shooting* (1915); HAROLD L. PETERSON, *Arms and Armor in Colonial America, 1526-1783* (1956); W.H.B. and JOSEPH E. SMITH, *The Book of Rifles*, 3rd ed. (1963); Great Britain, WAR OFFICE, *Textbook of Small Arms* (1929).

(J.We.)

Smith, Adam

After nearly two centuries, Adam Smith remains a towering figure in the history of economic thought. Known primarily for a single work, *An Inquiry into the nature and causes of the Wealth of Nations* (1776), the first comprehensive system of political economy, Smith is more properly regarded as a social philosopher whose economic writings constitute only the capstone to an overarching view of political and social evolution. If his masterwork is viewed in relation to his earlier lectures on moral philosophy and government, as well as to allusions in *The Theory of Moral Sentiments* (1759) to a work he hoped to write on "the general principles of law and government, and of the different revolutions they have undergone in the different ages and periods of society," then *The Wealth of Nations* may be seen not merely as a treatise on economics but as a partial exposition of a much larger scheme of historical evolution.

Early life. Unfortunately, much more is known about Smith's thought than about his life. Though the exact date of his birth is unknown, he was baptized on June 5, 1723, in Kirkcaldy, a small (population 1,500) but thriving fishing village near Edinburgh, the son by second marriage of Adam Smith, comptroller of customs

at Kirkcaldy, and Margaret Douglas, daughter of a substantial landowner. Of Smith's childhood nothing is known other than that he received his elementary schooling in Kirkcaldy, and that at the age of four years he was said to have been carried off by gypsies. Pursuit was mounted, and young Adam was abandoned by his captors. "He would have made, I fear, a poor gypsy," commented his principal biographer.

At the age of 14, in 1737, Smith entered the University of Glasgow, already remarkable as a centre of what was to become known as the Scottish Enlightenment. There, he was deeply influenced by Francis Hutcheson, a famous professor of moral philosophy from whose economic and philosophic views he was later to diverge, but whose magnetic character seems to have been a main shaping force in Smith's development. Graduating in 1740, Smith won a scholarship (the Snell Exhibition) and travelled on horseback to Oxford, where he stayed at Balliol College. Compared to the stimulating atmosphere of Glasgow, Oxford was an educational desert; one of the few known instances of interference by the University with Smith's intellectual development was its confiscation of his copy of the philosopher David Hume's *Treatise of Human Nature*, a book popularly thought at that time to be heretical and atheistic. Those years were spent largely in self-education, from which Smith obtained a firm grasp of both classical and contemporary philosophy.

Returning to his home after an absence of six years, Smith cast about for suitable employment. The connections of his mother's family, together with the support of the jurist and philosopher Lord Henry Kames, resulted in an opportunity to give a series of public lectures in Edinburgh—a form of education then much in vogue in the prevailing spirit of "improvement." The lectures, which ranged over a wide variety of subjects from rhetoric to history and economics, made a deep impression on some of Smith's great contemporaries. They also had a marked influence on Smith's own career, for in 1751, at the age of 27, he was appointed professor of logic at Glasgow, from which post he transferred in April 1752 to the more remunerative professorship of moral philosophy, a subject that embraced the related fields of natural theology, ethics, jurisprudence, and political economy.

Glasgow. Smith then entered upon a period of extraordinary creativity, combined with a social and intellectual life that he afterward described as "by far the happiest, and most honourable period of my life." During the week he lectured daily from 7:30 to 8:30 AM and again thrice weekly from 11 AM to noon, to classes of up to 90 students, aged 14 to 16. (Although his lectures were presented in English, following the precedent of Hutcheson, who had abandoned the earlier practice of discoursing in Latin, the level of sophistication for so young an audience today strikes one as extraordinarily demanding.) Afternoons were occupied with university affairs in which Smith played an active role, being elected dean of faculty in 1758; his evenings were spent in the stimulating company of Glasgow society.

Among his wide circle of acquaintances were not only members of the aristocracy, many connected with the government, but a range of intellectual and scientific figures including Joseph Black, a pioneer in the field of chemistry, James Watt, later of steam-engine fame, Robert Foulis, a distinguished printer and publisher and subsequent founder of the first British Academy of Design, and, not least, David Hume, a lifelong friend whom Smith had met in Edinburgh. Smith was also introduced during these years to the company of the great merchants who were carrying on the colonial trade that had opened to Scotland following its union with England in 1707. One of them, Andrew Cochran, had been a provost of Glasgow and had founded the famous Political Economy Club. From Cochran and his fellow merchants Smith undoubtedly acquired the detailed information concerning trade and business that was to give such a sense of the real world to *The Wealth of Nations*.

"The Theory of Moral Sentiments." In 1759 Smith published his first work, *The Theory of Moral Sentiments*. Didactic, exhortative, and analytic by turn, the

Theory lays the psychological foundation on which *The Wealth of Nations* was later to be built. In it Smith described the principles of "human nature," which, together with Hume and the other leading philosophers of his time, he took as a universal and unchanging datum from which men's social institutions, as well as their social behaviour, could be deduced.

One question in particular interested Smith in *The Theory of Moral Sentiments*. This was a problem that had attracted Smith's teacher Hutcheson and a number of Scottish philosophers before him. The question was the source of man's ability to form moral judgments, including judgments on his own behaviour, in the face of his seemingly over-riding passions for self-preservation and self-interest. Smith's answer, at considerable length, is the presence within each of us of an "inner man" who plays the role of the "impartial spectator," approving or condemning our own and others' actions with a voice impossible to disregard. (The theory may sound less naïve if the term *superego* is substituted for "the impartial spectator" and if the question is reformulated to ask how instinctual drives are socialized.)

The thesis of the impartial spectator, however, conceals a more important aspect of the book. Smith saw man as a creature *driven* by passions and at the same time *self-regulated* by his ability to reason and—no less important—by his capacity for sympathy. This duality serves both to pit men against one another, and to provide them with the rational and moral faculties to create institutions by which the internecine struggle can be mitigated and even turned to the common good. He wrote in his *Moral Sentiments* the famous observation that he was to repeat later in *The Wealth of Nations*: that self-seeking men are often "led by an invisible hand . . . without knowing it, without intending it, [to] advance the interest of the society."

Travels on the Continent. The *Theory* quickly brought Smith wide esteem and in particular attracted the attention of Charles Townshend, himself something of an amateur economist, a considerable wit, and somewhat less of a statesman, whose fate it was to be the chancellor of the exchequer responsible for the measures of taxation that ultimately provoked the American Revolution. Townshend had recently married and was searching for a tutor for his stepson and ward, the young duke of Buccleuch. Influenced by the strong recommendations of Hume and his own admiration for *The Theory of Moral Sentiments*, he approached Smith to take the charge.

The terms of employment were lucrative (an annual salary of £300 plus travelling expenses and a pension of £300 a year thereafter), considerably more than Smith had earned as a professor. Accordingly, Smith resigned his Glasgow post in 1763 and set off for France the next year as the tutor of the young duke. They stayed mainly in Toulouse, where Smith began working on a book (eventually to be *The Wealth of Nations*) as an antidote to the excruciating boredom of the provinces. After 18 months of ennui he was rewarded with a two-month sojourn in Geneva, where he met Voltaire, for whom he had the profoundest respect, thence to Paris, where Hume, then secretary to the British embassy, introduced Smith to the great literary salons of the French Enlightenment. There he met a group of social reformers and theorists headed by François Quesnay, who called themselves *les économistes*, but are known in history as the physiocrats. There is some controversy as to the precise degree of influence that the physiocrats exerted on Smith, but it is known that he thought sufficiently of Quesnay to have considered dedicating *The Wealth of Nations* to him, had not the French economist died before publication.

The stay in Paris was cut short by a shocking event. The younger brother of the duke of Buccleuch, who had joined them in Toulouse, was assassinated in the street. Smith and his charge immediately returned to London. Smith worked in London until the spring of 1767 with Lord Townshend, a period during which he was elected a fellow of the Royal Society and broadened still further his intellectual circle to include Edmund Burke, Samuel

Johnson, Edward Gibbon, and perhaps Benjamin Franklin. Late that year he returned to Kirkcaldy, where the next six years were spent dictating and reworking *The Wealth of Nations*, followed by another stay of three years in London, where the work was finally completed and published in 1776.

"The Wealth of Nations." Despite its renown as the first great work in political economy, *The Wealth of Nations* is in fact a continuation of the philosophical theme begun in *The Theory of Moral Sentiments*. For the ultimate problem to which Smith addresses himself is how the inner struggle between the passions and the "impartial spectator"—explicated in *Moral Sentiments* in terms of the single individual—works its effects in the larger arena of history itself, both in the long-run evolution of society and in terms of the immediate characteristics of the stage of history characteristic of Smith's own day.

The answer to this problem enters in Book III, in which Smith outlines the four main stages of organization through which society is impelled, unless blocked by deficiencies of resources, wars, or bad policies of government: the original "rude" state of hunters, a second stage of nomadic agriculture, a third stage of feudal or manorial "farming," and a fourth and final stage of commercial interdependence.

It should be noted that each of these stages is accompanied by institutions suited to its needs. For example, in the age of the huntsman, "there is scarce any property . . . ; so there is seldom any established magistrate or any regular administration of justice." With the advent of flocks there emerges a more complex form of social organization, comprising not only "formidable" armies, but the central institution of private property with its indispensable buttress of law and order. It is of the very essence of Smith's thought that he recognized this institution, whose social usefulness he never doubted, as an instrument for the protection of privilege, rather than one to be justified in terms of natural law: "Civil government," he writes, "so far as it is instituted for the security of property, is in reality instituted for the defence of the rich against the poor, or of those who have some property against those who have none at all." Finally, Smith describes the evolution through feudalism into a stage of society requiring new institutions such as market-determined rather than guild-determined wages, and free rather than government-constrained enterprise. This later became known as *laissez-faire* capitalism; Smith called it the system of perfect liberty.

There is an obvious resemblance between this succession of changes in the material basis of production, each bringing its requisite alterations in the superstructure of laws and civil institutions, and the Marxian conception of history. Though the resemblance is indeed remarkable, there is also a crucial difference: in the Marxian scheme the engine of evolution is ultimately the struggle between contending classes, whereas in Smith's philosophical history the primal moving agency is "human nature" driven by the desire for self-betterment and guided (or misguided) by the faculties of reason.

Society and the "invisible hand." The theory of historical evolution, although it is perhaps the binding conception of *The Wealth of Nations*, is subordinated within the work itself to a detailed description of how the "invisible hand" actually operates within the commercial or final stage of society. This becomes the focus of Books I and II, in which Smith undertakes to elucidate two questions. The first is how a system of perfect liberty, operating under the drives and constraints of human nature and intelligently designed institutions, will give rise to an *orderly* society. The question, which had already been considerably elucidated by earlier writers, required both an explanation of the underlying orderliness in the pricing of individual commodities and an explanation of the "laws" that regulated the division of the entire "wealth" of the nation (which Smith saw as its annual production of goods and services) among the three great claimant classes—labourers, landlords, and manufacturers.

This orderliness, as would be expected, was produced

Smith's
view of
human
nature

The role of
competition

by the interaction of the two aspects of human nature, its response to its passions and its susceptibility to reason and sympathy. But whereas *The Theory of Moral Sentiments* had relied mainly on the presence of the "inner man" to provide the necessary restraints to private action, in *The Wealth of Nations* one finds an institutional mechanism that acts to reconcile the disruptive possibilities inherent in a blind obedience to the passions alone. This protective mechanism is *competition*, an arrangement by which men's passionate desire for bettering their condition—"a desire that comes with us from the womb, and never leaves us until we go into the grave"—is turned into a socially beneficial agency by pitting one man's drive for self-betterment against another's.

It is in the unintended outcome of this competitive struggle for self-betterment that the "invisible hand" regulating the economy shows itself, for Smith explains how the mutual vying of men forces the prices of commodities down to their "natural" levels, which correspond to their costs of production. Moreover, by inducing labour and capital to move from less to more profitable occupations or areas, the competitive mechanism constantly restores prices to these "natural" levels despite short-run aberrations. Finally, by explaining that wages and rents and profits (the constituent parts of the costs of production) are themselves subject to this same discipline of self-interest and competition, Smith not only provided an ultimate rationale for these "natural" prices but also revealed an underlying orderliness in the distribution of income itself among workers, whose recompense was their wages; landlords, whose income was their rents; and manufacturers, whose reward was their profits.

Economic growth. Smith's analysis of the market as a self-correcting mechanism was impressive. But his purpose was more ambitious than to demonstrate the self-adjusting properties of the system. Rather, it was to show that, under the impetus of the acquisitive drive, the annual flow of national wealth could be seen steadily to *grow*.

Smith's explanation of economic growth, although not neatly assembled in one part of *The Wealth of Nations*, is quite clear. The core of it lies in his emphasis on the division of labour (itself an outgrowth of man's "natural" propensity to trade) as the source of society's capacity to increase its productivity. *The Wealth of Nations* opens with a famous passage describing a pin factory in which ten persons, by specializing in various tasks, turn out 48,000 pins a day, compared with the few, perhaps only one, that each could have produced alone. But this all-important division of labour does not take place unaided. It can occur only after the prior accumulation of capital (or stock as Smith calls it), which is used to pay the additional workers and to buy tools and machines.

The drive for accumulation, however, brings problems. The manufacturer who accumulates stock needs more labourers (since labour-saving technology has no place in Smith's scheme), and in attempting to hire them he bids up their wages above their "natural" price. Consequently his profits begin to fall, and the process of accumulation is in danger of ceasing. But now enters an ingenious mechanism for continuing the advance. In bidding up the price of labour, the manufacturer inadvertently sets into motion a process that increases the supply of labour, for "the demand for men, like that for any other commodity, necessarily regulates the production of men." Specifically, Smith had in mind the effect of higher wages in lessening child mortality. Under the restraining influence of a larger labour supply, the wage rise is moderated and profits are maintained; the new supply of labourers offers a continuing opportunity for the profit-seeking manufacturer to introduce a further division of labour and thereby add to the system's growth.

Here then was a "machine" for growth—a machine that operated with all the reliability of the Newtonian system with which Smith was quite familiar. Unlike the Newtonian system, however, Smith's growth machine did not depend for its operation on the laws of nature alone. Human nature drove it, and human nature was a complex rather than a simple force. Thus, the wealth of nations would grow only if men, through their governments, did

not inhibit this growth by catering to the pleas for special privilege that would prevent the competitive system from exerting its benign effect. Consequently, much of *The Wealth of Nations*, especially Book IV, is a polemic against the restrictive measures of the "mercantile system" that favoured monopolies at home and abroad. Smith's system of "natural liberty," he is careful to point out, accords with the best interests of all men but will not be put into practice if government is entrusted to, or heeds, "the mean rapacity, the monopolizing spirit of merchants and manufacturers, who neither are, nor ought to be, the rulers of mankind."

The Wealth of Nations is therefore far from the ideological tract it is often supposed to be. Although Smith preached laissez-faire (with important exceptions), his argument was directed as much against monopoly as government; and although he extolled the social results of the acquisitive process, he almost invariably treated the manners and manoeuvres of businessmen with contempt. Nor did he see the commercial system itself as wholly admirable. He wrote with discernment about the intellectual degradation of the worker in a society in which the division of labour has proceeded very far; for by comparison with the alert intelligence of the husbandman, the specialized workman "generally becomes as stupid and ignorant as it is possible for a human being to become."

In all of this, it is notable that Smith was writing in an age of preindustrial capitalism. He seems to have had no presentiment of the gathering Industrial Revolution, harbingers of which were visible in the great iron works only a few miles from Edinburgh. He had nothing to say about large-scale industrial enterprise, and the few remarks in *The Wealth of Nations* concerning the future of joint-stock companies (corporations) are disparaging. Finally, one should bear in mind that if growth is the great theme of *The Wealth of Nations*, it is not unending growth. Here and there in the treatise there are glimpses of a system that has reached its "full complement" of riches, at which point an impoverished stagnation reigns.

The Wealth of Nations was received with admiration by Smith's wide circle of friends and admirers, although it was by no means an immediate popular success. The work finished, Smith went into semi-retirement. The year following its publication he was appointed commissioner both of customs and of salt duties for Scotland, posts that brought him £600 a year. He thereupon informed his former charge that he no longer required his pension, to which Buccleuch replied that his sense of honour would never allow him to stop paying it. Smith was therefore quite well off in the final years of his life, which were spent mainly in Edinburgh with occasional trips to London or Glasgow (which appointed him a rector of the university). The years passed quietly, with several revisions of both major books but with no further publications. On July 17, 1790, at the age of 67, full of honours and recognition, Smith died; he was buried in the churchyard at Canongate with a simple monument stating that Adam Smith, author of *The Wealth of Nations*, was buried there.

Beyond the few facts of his life, which can be embroidered only in detail, exasperatingly little is known about the man. Smith never married, and almost nothing is known of his personal side. Moreover, it was the custom of his time to destroy rather than to preserve the private files of illustrious men, with the unhappy result that much of Smith's unfinished work, as well as personal papers, was destroyed (some as late as 1942). Only one portrait of Smith survives, a profile medallion by Tassie; it gives a glimpse of the older man with his somewhat heavy-lidded eyes, aquiline nose and a hint of a protrusive lower lip. "I am a beau in nothing but my books," Smith once told a friend, to whom he was showing his library of about 3,000 volumes.

From various accounts, he was also a man of many peculiarities that included a stumbling manner of speech (until he had warmed to his subject), a gait described as "vermicular," and above all an extraordinary and even comic absence of mind. On the other hand, contempo-

raries wrote of a smile of "inexpressible benignity," and of his political tact and dispatch in managing the sometimes acerbic business of the Glasgow faculty.

Certainly he enjoyed a high measure of contemporary fame; even in his early days at Glasgow his reputation attracted students from nations as distant as Russia, and his later years were crowned not only with expressions of admiration from many European thinkers but by a growing recognition among British governing circles that his work provided a rationale of inestimable importance for practical economic policy.

Over the years, Smith's lustre as a social philosopher has escaped much of the weathering that has affected the reputations of other first-rate political economists. Although he was writing for his generation, the breadth of his knowledge, the cutting edge of his generalizations, the boldness of his vision, have never ceased to attract the admiration of all social scientists, and in particular economists. Couched in the spacious, cadenced prose of his period, rich in imagery and crowded with life, *The Wealth of Nations* projects a sanguine but never sentimental image of society. Never so finely analytical as David Ricardo, nor so stern and profound as Karl Marx, Smith is the very epitome of the Enlightenment: hopeful but realistic, speculative but practical, always respectful of the classical past but ultimately dedicated to the great discovery of his age—progress.

Smith, William

William Smith lived during what has been called the "heroic age of geology" when the foundations of the subject were being laid in Great Britain and Europe. He was the first person to recognize that sedimentary rock layers occur in regular sequences, which are traceable over long distances, and that different strata can be identified by the fossils they contain. These observations revolutionized the practice of geology, especially in Britain. Smith's great geologic map of England and Wales (1815) set the style for modern geologic maps, and many of the colourful names he applied to the strata are still in use today.

Smith was born March 23, 1769, his father an Oxfordshire blacksmith of farming stock. Only seven when his father died, Smith was cared for by a farming uncle. He attended a village school, learned the basic methods of surveying from books he bought himself, and collected the abundant fossils of his native Cotswold hills. In 1787 he became an assistant to Edward Webb, a surveyor in nearby Stow-on-the-Wold, who in 1791 helped Smith become established in the Somersetshire coal district southwest of Bath. The steam locomotive had not yet been invented, and canal-building was at its height, particularly for the transportation of coal. There was also abundant work in the enclosure and drainage of fields.

During preliminary surveys for a proposed Somerset-

shire Coal Canal in 1793, Smith discovered that the strata outcropping in the northern part of the region dip regularly eastward, like so many "slices of bread and butter." On a long trip in 1794 to examine canals and collieries, he had an opportunity to extend his observations. His suspicion that the strata of Somerset could be traced far northward across England was brilliantly confirmed as the familiar beds were encountered again and again during this journey. Excavation of the new canal began in 1795; and Smith, studying the fresh cuts, found that each stratum contained "fossils peculiar to itself."

His work on the canal continued until 1799, when he was abruptly dismissed, probably over an engineering dispute. But Smith had a good reputation in Bath, at that time a major intellectual and social centre, and quickly built a far-flung business as a geological engineer. In 1804 he moved his business headquarters to a house in London, where his fossil collection and geologic maps were always on display.

In 1799 Smith dictated to an amateur geologist in Bath his now-famous table of strata in the vicinity of Bath, which became a principal means for circulating his revolutionary discoveries. He also exhibited his maps and stratigraphic sections at agricultural fairs, such as the Holkham "Sheepshearings," which he regularly attended. Much of his professional work was for the gentleman farmers who supported these shows, but he also supervised major reclamation projects in Norfolk and Wales, restoration of the hot springs at Bath, and a multitude of canal and colliery projects, sometimes travelling 10,000 miles a year (an incredible total made possible by the inauguration of fast mail coaches in 1784).

Smith's intelligence and practical knowledge of geology and groundwater took him to the front rank of his profession, but he never became wealthy because of his personal objective: mapping the geology of England. He always made copious notes of what he saw on the job and spent all his extra time and money on side trips to fill in blank spaces on his map, often sleeping in the coach on the way to his next appointment. Where exposures were few, he used soil, topography, and vegetation to identify underlying rock. His epochal geologic map of England and Wales appeared in 1815 under the title *A Delineation of the Strata of England and Wales, with part of Scotland*. This was followed by an excellent series of county maps between 1819 and 1824.

During these years, Smith was in financial straits, undoubtedly exacerbated by the agricultural depression that followed the Napoleonic Wars. Failure of a quarry in Somerset lost him the property and forced the sale of his fossil collection to the British Museum in London. When creditors seized his London property after he had spent ten weeks in debtor's prison in 1819, he sold out

Early
practical
experience

The 1815
geologic
map of
England
and Wales

and left for Yorkshire. For some years he had no permanent home but finally settled in Scarborough among a small band of geological enthusiasts, one of whom retained him as a consultant on his nearby estate. Recognition of his achievements came from other sources. In 1822 his work was praised by William D. Conybeare and William Phillips in their textbook on English stratigraphy, *Outlines of the Geology of England and Wales*. In 1831 he received from the Geological Society of London the first Wollaston Medal and in 1832 a yearly pension from the crown. He died August 28, 1839, on his way to a scientific meeting in Birmingham.

Assessment

Smith was not only exceptionally observant but possessed the power to integrate his observations. He saw that different rock layers contained different fossils and used this fact to trace strata over hundreds of miles. So great was his ability that geologists still use all of the techniques he introduced, and current geologic maps of England differ from his primarily in detail. Between 1815 and 1817 he published a few thin volumes on his work, but in a sense they were too late. Smith had always talked freely to anyone interested, and his knowledge was already public property being applied by geologists in every part of Britain. The fame Smith achieved in his lifetime remains undimmed to this day, and he is universally admired as the "Founder of Stratigraphy."

BIBLIOGRAPHY. JOHN PHILLIPS, *Memoirs of William Smith* (1844), still definitive, though as rare as Smith's own works. L.R. COX, *William Smith and the Birth of Stratigraphy* (18th International Geological Congress, 1948), an excellent short biography; J.M. EYLES, "William Smith, Some Aspects of His Life and Work," in C.J. SCHNEER (ed.), *Toward a History of Geology* (1969), with an indispensable bibliography.

(R.W.Ma.)

Smollett, Tobias

An outstanding exponent of the early English novel in the mid-18th century, Tobias George Smollett is not the equal of his older contemporaries, the novelists Samuel Richardson and Henry Fielding, but he is unrivalled for the pace and vigour that sustain his comedy. He is especially brilliant in the rendering of comic characters in their externals, thus harking back to the manner of the Jacobean playwright Ben Jonson and looking forward to that of Charles Dickens. By modern criteria, his art as a satirical novelist is defective, his model being the "picaresque" novel, relating loosely linked episodes in the life of a rogue hero. But his panoramic picture of the life of his times is surpassed only by that given by Henry Fielding, while his account of conditions in the Royal Navy is especially valuable.

Smollett was baptized in the parish church of Cardross, Dumbartonshire, on March 19, 1721. He came of a fami-

Smollett, oil painting by an unknown Italian artist, c. 1770. In the National Portrait Gallery, London.

ly of lawyers and soldiers, Whig in politics and Presbyterian in religion. In 1727 or 1728 he entered Dumbarton grammar school, proceeding from there to the University of Glasgow and apprenticeship to William Stirling and John Gordon, surgeons of that city. His first biographer states that he "attended the anatomical and medical lectures," and, if his first novel, *Roderick Random*, may be taken as evidence, he also studied Greek, mathematics, moral and natural philosophy, logic, and belles lettres. He left the university in 1739 without a degree and went to London, taking with him his play *The Regicide*. A year later he was commissioned surgeon's second mate in the Royal Navy and appointed to HMS "Chichester," which reached Port Royal, Jamaica, on January 10, 1741. It is probable that Smollett saw action in the naval bombardment of Carthage. In Jamaica he met and was betrothed to—and perhaps there married—an heiress, Anne Lassells. He returned to London alone to set up as a surgeon on Downing Street, Westminster, his wife joining him in 1747. He failed to secure a production of *The Regicide*, but in 1746, after the defeat of the Jacobite rebels at Culloden, he wrote his most famous poem, "The Tears of Scotland." He had by now moved to cheaper accommodations in Chapel Street, Mayfair, no doubt because, despite litigation, he had managed to recover only a fraction of his wife's considerable dowry, which was invested in land and slaves. It was in Chapel Street that he wrote *Advice and Reproof*, verse satires in the manner of the Roman poet Juvenal.

In 1748 Smollett published his novel *The Adventures of Roderick Random*, a graphic account of British naval life at the time, and also translated the great picaresque romance *Gil Blas* from the French of Alain-René Lesage. In 1750 he obtained the degree of M.D. from Marischal College, Aberdeen. Later in the year he was in Paris, searching out material for *The Adventures of Peregrine Pickle* (1751). This work contains a great comic figure in Hawser Trunnion, a retired naval officer who, though living on dry land, insists on behaving as though he were still on the quarterdeck of one of His Majesty's ships at sea.

In 1752 he published "An Essay on the External Use of Water," an attack on the medicinal properties of the waters of a popular English health resort, Bath. The essay made him many enemies and little money. His financial difficulties were intensified by his generosity in lending money to a hack writer called Peter Gordon, who employed legal stratagems to avoid repayment. Smollett came to blows with Gordon and his landlord and was sued by them for £1,000 and £500, respectively, on charges of trespass and assault. In the event, Smollett was required to pay only small damages. He was now living at Monmouth House, Chelsea, where he was host to such leading literary figures as Samuel Johnson and Oliver Goldsmith, the actor David Garrick, and John Hunter, a famous surgeon and anatomist. On Sundays, if one may take a passage in *Peregrine Pickle* as autobiographical, Smollett threw his house open to "unfortunate brothers of the quill," whom he regaled with "beer, pudding, and potatoes, port, punch, and Calvert's entire butt-beer." He himself seems to have been a man irascible, pugnacious, infinitely energetic, courageous, and generous.

The Adventures of Ferdinand Count Fathom (now, with *The History and Adventures of an Atom*, the least regarded of his novels) appeared in 1753. It sold poorly, and Smollett was forced into borrowing from friends and into further hack writing. In June 1753 he visited Scotland for the first time in 15 years; his mother, it is said, recognized him only because of his "roguish smile." Back in London, Smollett set about a commitment to translate *Don Quixote* from the Spanish of Miguel de Cervantes, and this translation was published in 1755. Smollett was already suffering from tuberculosis. Early in 1756 he became editor of *The Critical Review*, a Tory and church paper, at the same time writing his *Complete History of England*, which was financially successful. A year later, his farce *The Reprisal: or, The Tars of Old England* was produced at Drury Lane and brought him a profit of almost £200. In 1758 he became what today might perhaps be called general editor of *Universal History*, a

Education and early literary works

Career as translator and editor

compilation of 58 volumes; Smollett himself wrote on France, Italy, and Germany. His friendship with the politician John Wilkes enabled him to secure the release of Francis Barber, Dr. Johnson's Negro servant, from the press-gang. But a libel on Adm. Sir Charles Knowles in *The Critical Review* led to Smollett's being sentenced to a fine of £100 and three months' imprisonment in the King's Bench Prison. He seems to have lived there in some comfort and drew on his experiences for his novel *The Adventures of Sir Launcelot Greaves* (1762), which was serialized in *The British Magazine*, of which Smollett became editor in 1760.

Two years later he became editor of *The Briton*, a weekly founded to support the prime minister John Stuart, the 3rd earl of Bute. He was also writing an eight-volume work entitled *The Present State of all Nations*, and he had begun a translation, in 36 volumes, of the varied works of the French writer Voltaire. Smollett was now seriously ill; attempts to secure a post as physician to the army in Portugal and as British consul in Marseilles or Madrid were fruitless. In 1763 the death of his only child, Elizabeth, who was 15 years old, overwhelmed him "with unutterable sorrow." He severed his connection with *The Critical Review* and, as he said, "every other literary system," retiring with his wife to France, where he settled at Nice.

In 1766 Smollett published *Travels Through France and Italy*, his one nonfiction work that is still read. He returned to England in that year, visited Scotland, and at Christmas was again in England (at Bath), where he probably began what is his finest work, *The Expedition of Humphry Clinker*, an epistolary novel that recounts the adventures of a family travelling through Britain. In 1768, steadily weakening in health, he retired to Pisa, Italy. During the autumn of 1770 he seems to have written the bulk of *Humphry Clinker*, which was published on June 15, 1771. He died, probably near Leghorn, on September 17, 1771.

MAJOR WORKS

NOVELS: *The Adventures of Roderick Random*, 2 vol. (1748); *The Adventures of Peregrine Pickle*, 4 vol. (1751); *The Adventures of Ferdinand, Count Fathom*, 2 vol. (1753); *The Adventures of Sir Launcelot Greaves* (serially, 1760–61; 2 vol., 1762); *The Expedition of Humphry Clinker*, 3 vol. (1771).

PERIODICAL JOURNALISM: Contributions to *The Critical Review* (1756–59); *The Briton* (1762–63).

TRANSLATIONS: *The Adventures of Gil Blas of Santillane*, 4 vol. (1748; no known copy); *The History and Adventures of the Renowned Don Quixote*, 2 vol. (1755); *Select Essays on . . . Useful Subjects* (1754); *The Works of Mr. de Voltaire*, 35 vol. (1761–65).

POETRY: "The Tears of Scotland" (c. 1746); "Ode to Independence" (1773).

DRAMA: *The Regicide* (1749); *The Reprisal* (1757).

OTHER WORKS: "An Essay on the External Use of Water" (1752); *The History and Adventures of an Atom*, 2 vol. (1769); *A Complete History of England*, 4 vol. (1757–58); *Travels Through France and Italy*, 2 vol. (1766).

BIBLIOGRAPHY. There is no collected edition of all Smollett's works. There is an edition of the novels by GEORGE SAINTSBURY, 12 vol. (1895), and an Oxford edition, 11 vol. (1925–26). Individual novels are readily obtainable, especially in Everyman's Library and World Classics. Smollett's *Letters* were edited by EDWARD S. NOYES (1926, reprinted 1969); this edition was superseded by that of LEWIS M. KNAPP (1970), which also contains details of Smollett manuscripts. The most authoritative biography is LEWIS M. KNAPP, *Tobias Smollett: Doctor of Men and Manners* (1949). The relevant chapters in WALTER SCOTT, *The Lives of the Novelists*, 4 vol. (1821–24), are also recommended, as is the article by THOMAS SECCOMBE in the *Dictionary of National Biography*, vol. 18 (1909). ROBERT ALTER, *Rogue's Progress: Studies in the Picaresque Novel* (1964), is a useful critical work. ROBERT D. SPECTOR, *Tobias George Smollett* (1968), is a study of fundamental techniques in Smollett's minor works, and an analysis of the structure, themes, and fictional devices of the major works. Of more interest to the student than to the nonspecialist reader is GEORGE M. KAHL, *Tobias Smollett, Traveler-Novelist* (1945), which is valuable for its information on Smollett's sources.

(W.E.A.)

Smuts, Jan

"But my dear lady, I am only a general in my spare time." This was Jan Smuts's reply to an American botanist who wondered why he, a general, should be an authority on grasses. He was, in his spare time, a philosopher, botanist, and lawyer. His full-time occupation was that of a South African and world statesman and, during three wars, a soldier.

EB Inc.

Smuts.

Early life. Jan Christiaan Smuts was born on May 24, 1870, on a farm near Riebeeck West in the Cape Colony. His ancestors were mainly Dutch, with a small admixture of French and German but no English, though he was born a British subject. Until he went to school at the age of 12 Smuts lived the life of a South African farm boy, taking his share in the work of the farm, learning from nature, and developing a life-long love of the land.

At 16 he went to Victoria College (subsequently the University of Stellenbosch) where he studied science and arts and obtained first-class honours in both. At Stellenbosch he fell in love with a fellow student, Isie Krige, whom he later married and who remained a source of strength through the stresses and strains of an eventful life. In 1891 he obtained a scholarship and entered Christ's College, Cambridge, where he read law and was generally recognized as one of the most brilliant law students Cambridge had had. He was the first ever to take both parts of the law tripos examinations in the same year, and in both he came first. From Cambridge he went to London, where he came first in the Inns of Court honours examination and was awarded two prizes. It seemed clear that a distinguished academic career lay ahead of him; nevertheless, Smuts wanted to return to South Africa.

Apart from law he read widely in philosophy, poetry, and science, and it was at this time that he first read the poems of Walt Whitman. Many years later he compared the effect that Whitman had on him to St. Paul's experience on the road to Damascus. Whitman's conception of natural man liberated him, he believed, from the sense of sin induced by a strict Calvinist upbringing. Before he left England he wrote a book about Whitman but failed to find a publisher.

Political career. Returning to Cape Town in 1895, Smuts was at once drawn into politics. At first he supported Cecil Rhodes, prime minister of Cape Colony. But the raid of L.S. Jameson on the Transvaal destroyed his confidence in Rhodes, and, finding himself without political attachment and with insufficient legal work, Smuts decided to move to Johannesburg. At the end of 1897 he married Isie Krige, moving to Pretoria a year later when he was appointed state attorney by President Paul Kruger. At the age of 28 he was thus at the centre of Transvaal politics and, in effect, at the centre of South African politics. From then until his death he was continuously involved in South African and world affairs.

Achievements at Cambridge

Role in
the Boer
War

For the first nine months of the South African (Boer) War, which began in October 1899, Smuts was part official and part soldier, moving between Pretoria and the front. When Pretoria was occupied by the British he became a full-time soldier, eventually receiving an independent command. He was an apt pupil in the guerrilla tactics that were so successfully exploited against the overstretched British lines of communication. In April 1902 he invaded the Cape Colony—to within 120 miles (190 kilometres) of Cape Town, but by then his force was too little and too late. When the war ended he had to be recalled, under British escort, to take part in drafting peace terms.

The Boers lost their independent republics, but Smuts remained firm in his belief in the future of a united South Africa. He returned to Pretoria and family life but was inevitably drawn into public affairs. He and Gen. Louis Botha combined to oppose the high commissioner Alfred Milner's narrow interpretation of the peace terms and to insist on Boer rights. It was a remarkable partnership, in which Smuts supplied the intellectual vigour and Botha a deep knowledge of his fellow men and great wisdom in dealing with them. Their first objective was responsible government for the two former republics; after that would come union of the four colonies. Smuts played a major role in the achievement of responsible government for the Transvaal (1906) and the Union of South Africa (1910).

When Smuts went to England at the end of 1905 to urge the cabinet to give the Transvaal self-government he came to know a new English world. At Cambridge he had known few Englishmen, and after his return to South Africa he had to devote his energies to fighting the British. But from 1905 his personal friends in England were the intelligent, liberal-minded people whom he now began to meet. To them he escaped from the exacting and exhaustingly boring official social life of London; with them he found the intellectual and spiritual refreshment that, because of long absences, he too seldom enjoyed at home. He had the reputation of being cold and aloof, but among his friends and in his own family circle he was a different man—relaxed and genial, fond of and easy with children.

Just as Smuts was drawn into the public life of his own country, so, after the outbreak of World War I, he was drawn into international affairs. When he and Botha had suppressed rebellion in South Africa, conquered South West Africa, and launched a campaign in East Africa, he went to England for an imperial conference (March 1917). Prime Minister Lloyd George at once recognized his abilities and made him minister of air. From then on he was used in a variety of tasks. He organized the R.A.F. and was concerned in all major decisions about the war. At the peace conference at Versailles, the English economist J.M. Keynes regarded him as the greatest protagonist of a moderate peace that would not crush Germany, and he may justly be called one of the principal progenitors of the League of Nations.

A few months after their return from Versailles, Botha died, and Smuts became prime minister. Nearly five years later he was defeated by a coalition of the Nationalist and Labour parties and remained in opposition until 1933, when he and J.B.M. Hertzog joined forces against the more extreme nationalists. Smuts was content to serve under Hertzog, but they were in deep disagreement about whether South Africa should go to war if Britain did. When the crisis came in September 1939 Smuts's view prevailed by a narrow majority of 13 in Parliament. Smuts became prime minister, and South Africa declared war on Germany.

During World War II South Africa played a much greater part than in World War I, but Smuts himself was not as important a figure as he had been during 1914–18. He was consulted by Sir Winston Churchill and other Allied leaders, but his main role was to mobilize all his country's resources to prevent Germany and Italy from conquering North Africa. Once that objective was achieved, he and his country became of relatively minor importance. Smuts represented South Africa at the 1945

San Francisco Conference at which the Charter of the United Nations was drafted.

At the general election of 1948 Smuts' party was defeated by the Nationalists. Dr. D.F. Malan became prime minister, and one of his first acts was to offer Smuts an official airplane to go to Cambridge, where he was to be installed as chancellor, an offer that Smuts accepted. Two years later, at his home near Pretoria, he died.

Assessment. Despite his great abilities and achievements, Smuts was not a popular leader—he had a subtle and sophisticated mind, was impatient, could not tolerate mediocrity, was immensely hardworking, and had no time for the sociabilities that make for popularity. For almost half his lifetime—from 1912 to 1950—he was derided, mistrusted, reviled, and even hated by an increasing majority of his fellow Afrikaners. He was called a lackey of the empire and a betrayer of his own people. Before and during the South African War he was staunchly anti-British and in favour of a united Afrikaner people. In 1917 and 1919 he persuaded British statesmen to grant dominion status and (in 1920) to drop the word empire. It was believed by some that Smuts was trying to break up the empire. In fact, he knew that the only way to preserve it was to allow as much independence as possible to its components. Nationalist Afrikaners knew this, too—hence, their detestation of Smuts. He was a great South African; they wanted him to be a great Afrikaner. He wanted an independent South Africa closely linked with the Commonwealth; they wanted an independent republic outside the Commonwealth. Ten years after his death the Nationalists achieved their aim.

BIBLIOGRAPHY. WILLIAM KEITH HANCOCK, *Smuts*, vol. 1, *The Sanguine Years, 1870–1919* (1962), and vol. 2, *The Fields of Force, 1919–1950* (1968), is the definitive biography. See also J.C. SMUTS, *Jan Christiaan Smuts: A Biography* (1952), written by his son; and F.S. CRAFTON, *Jan Smuts: A Biography* (1943).

(L.Ma.)

Snow and Snowflakes

In the broad sense, snow is the solid crystalline phase of water that forms in the free air of the atmosphere and covers, permanently or temporarily, about 23 percent of the earth's surface. Snow is a common Indo-Germanic word (German *Schnee*, Latin *nix*, French *neige*, Russian *sneg*) that is indiscriminately used for falling and lying snow. The Eskimo, for whom snow is of great importance, distinguishes the two kinds of snow by different words (*qanit*: falling; *aput*: lying snow).

Snow cover has a strong influence on climate and on plant, animal, and human life. The small intake of radiative heat by snow and its poor heat conductivity induce a cold climate. The great amounts of heat needed for the removal of a snow cover delay the coming of spring. The low heat conduction protects small plants, wild and cultivated, from the effects of the lowest winter temperatures, but the late disappearance of snow and the cooling of the ground by meltwater delay the growth of summer crops. A snow cover represents a store of moisture that can supply water for irrigation and for shipping in rivers at a time when it is most needed and would not be available from precipitation. Many rivers that are fed to an important degree by the melting of winter snow have their highest runoff in spring and early summer.

Heavy snowfalls hinder or even block traffic on streets, roads, railways, and airports; the cost of snow clearing can be very high. In regions with cold winters the period of *snowmelt* can make the countryside quite impassable, particularly where permanently frozen ground prevents the infiltration of meltwater. In regions of heavy snowfall roofs have to be strengthened and to be steeply inclined to withstand the additional load and to let the snow glide down. Avalanche tracks determine in mountain regions the location of settlements and necessitate extensive structures for protection. On the other hand, a snow cover allows transport in many otherwise inaccessible areas. In many mountain regions timber is transported on sledges or slides downhill on snow races. The life of many Eskimo tribes would not have been possible without a snow

Role in
World
War I

Importance
of snow

cover for the use of sledges and the building of snowhouses. In recent decades the economy of many mountain regions has been completely changed by the growth of winter sports, particularly of skiing, which depend upon the presence of a snow cover.

This article treats the formation and properties of ice crystals and snowflakes in the atmosphere, the precipitation of snow and its properties, occurrence, and distribution on the ground. For coverage of relevant atmospheric aspects, see PRECIPITATION and CLOUDS; for the ultimate consequences of snowfall, see ICE SHEETS AND GLACIERS; and for an overview of the place of snow in the physical world, see CLIMATE and HYDROLOGIC CYCLE.

Snow in the atmosphere. Snow in the atmosphere can be subdivided into ice crystals and snowflakes. Ice crystals generally form on ice nuclei at temperatures appreciably below the freezing point. Below -40°C (-40°F) water vapour can solidify without the presence of a nucleus. Snowflakes are aggregates of ice crystals that appear in an infinite variety of shapes, mainly at temperatures near the freezing point of water.

From earliest times snow crystals and flakes have attracted attention and admiration. The book of Job

(38:22) hints at the beauty of snow. Numerous early Chinese writers have dealt with the hexagonal form. Olaus Magnus depicted the crystals in a book published in 1555 in Rome. Johannes Kepler, in a pamphlet "On the Six-Cornered Snowflake" (1611), was intrigued by the fact that all elements of snow were hexagonal. The invention of the microscope increased the knowledge of the snow structure. The English physicist Robert Hooke published in 1665 illustrations of snow crystals seen through a microscope. Early in the 19th century, William Scoresby Jr., English whaler and explorer, who had made observations in the Arctic regions, provided a classification of snow that was basic for almost 100 years. Photomicrography made documentation of the endlessly varying shapes possible. A wonderfully rich collection of photographs was published by the American farmer W.A. Bentley in 1931. More recently, the conditions of formation of different shapes of snow crystals have been experimentally studied. The forms of these crystals and of snowflakes can be retained in a replica film produced from a dilute (0.5 to 3 percent) solution of polyvinyl formal (Formvar) dissolved in ethylene dichloride and cooled a few degrees below 0°C (32°F).

Physical properties and conditions of formation

Snow crystals generally have a hexagonal pattern, often with beautifully intricate shapes. Three- and 12-branched forms occur occasionally. The hexagonal form of the atmospheric ice crystals, their varying size and shape notwithstanding, is an outward manifestation of an internal arrangement in which the oxygen atoms form an open lattice (network) with hexagonally symmetrical structure. According to a recent internationally accepted classification there are seven types of snow crystals: plates; stellars; columns; needles; spatial dendrites; capped columns; and irregular crystals; and three types of other solid precipitation—graupel, sleet, and hail. They are shown in Figure 1. "Graupel" and "sleet" in American terms are "soft hail" and "ice pellets" in British terms. The size and shape of the snow crystals depend mainly upon the temperature of their formation and upon the amount of water vapour that is available for deposition. The two principal influences are not independent; the possible water vapour admixture of the air decreases strongly with decreasing temperature. The vapour pressure in equilibrium with a level surface of pure ice is 50 times greater at -2°C than at -42°C , the likely limits of snow formation in the air. Crystal shape and temperature at formation are related in the Table.

At temperatures above about -40°C the crystals form on nuclei of very small size that float in the air (heterogeneous nucleation). The nuclei consist predominantly of silicate minerals of terrestrial origin, mainly clay minerals and micas. The contribution of meteoritic dust is not definitely established. At still lower temperatures ice may form directly from water vapour (homogeneous nucleation). The influence of the atmospheric water vapour depends mainly upon its degree of supersaturation with respect to ice.

Snow and ice crystals in clouds

If the air contains a large excess of water vapour, the snow particles will grow fast and there may be a tendency for dendritic (branching) growth. With low temperature the excess water vapour will be small, and the crystals will remain small. In relatively dry layers the snow particles will have simple forms. Complicated forms of crystals will cling together with others to form snowflakes that consist occasionally of up to 100 crystals; the diameter of such flakes may be as large as one inch. This process will be furthered if the crystals are near freezing point and wet, possibly by collision with undercooled water droplets. If a crystal falls into a cloud with great numbers of

Relation of Crystal Shape and Temperature at Formation			
temperature ($^{\circ}\text{C}$)	form	temperature ($^{\circ}\text{C}$)	form
0 to -3	thin hexagonal plates	-12 to -16	dendritic crystals
-3 to -5	needles	-16 to -25	hexagonal plates
-5 to -8	hollow, prismatic columns	-25 to -50	hollow prisms
-8 to -12	hexagonal plates		

such drops, it will sweep some of them up. Coming into contact with ice they freeze and form an ice cover around the crystal. Such particles are called soft hail or graupel. Sleet or ice pellets may consist of either frozen raindrops or melted and refrozen snowflakes. Hail consists of layered spheres of ice.

Snow particles constitute the clouds (*q.v.*) of cirrus type, namely cirrus, cirrostratus, and cirrocumulus, and many clouds of alto type. Ice and snow clouds originate normally only at temperatures some degrees below the freezing point; they predominate at -20°C . In temperate and low latitudes these clouds occur in the higher layers of the troposphere. In tropical regions they hardly ever occur below 15,000 feet. On high mountains and particularly in polar regions they can occur near the surface and may appear as ice fogs. If cold air near the ground is overlain by warmer air, a very common occurrence in polar regions, especially in winter, mixture at the border leads to supersaturation in the cold air. Small ice columns and needles, "diamond dust," will be formed and float down, glittering, even from a cloudless sky. In the coldest parts of Antarctica, with temperatures near the surface below -50°C on the average and rarely above -30° , the formation of "diamond dust" is a common occurrence. The floating and falling ice crystals produce in the light of the sun and moon the manifold phenomena of atmospheric optics, halos, arcs, circles, mock suns, some coronas, and iridescent clouds. Most of the different optical appearances can be explained by the shapes of the crystals and their position with respect to the light source.

Most of the moderate to heavy rain in temperate latitudes depends upon the presence of ice and snow particles in clouds. In the free atmosphere droplets of fluid water can be quite considerably undercooled; typical ice clouds originate mainly at a temperature near -20°C . At an identical temperature below freezing point the water molecules are kept more firmly in the solid than in the fluid state; the equilibrium pressure of the gaseous phase is smaller in contact with ice than with water. At -20°C , which is the temperature of the formation of typical ice clouds (cirrus), the equilibrium pressure with respect to undercooled water (relative humidity 100 percent) is 22 percent greater than the equilibrium pressure of the water vapour in contact with ice. Hence, with an excess of water vapour beyond the equilibrium state the ice particles tend to incorporate more water vapour and to grow more rapidly than the water droplets.

Precipitation from ice clouds

Being larger and, hence, less retarded by friction, the ice particles will fall more rapidly. In their fall they will sweep up some water droplets, which on contact become frozen. Thus a cloud layer originally consisting mainly of undercooled water with few ice crystals will be transformed into an ice cloud. The development of the anvil shape at the top of a towering cumulonimbus cloud shows this transformation very clearly. The larger ice particles overcome more readily the rising tendency of the air in the cloud. Falling into lower levels they grow, aggregating with other crystals and possibly with water drops, melt, and form raindrops when near-surface temperatures permit.

The ice crystals in clouds, their collisions, their breaking up, and their interaction with undercooled water droplets produce electrical charges that result in radio static and frequently in lightning discharges. St. Elmo's fire, a quiet, brushlike discharge of atmospheric electricity, also is often connected with the action of ice crystals, snowflakes,

and soft hail. Blowing snow, driven nearly horizontally along the surface by heavy wind, also carries strong electrical charges.

It has been known since 1947 that substances exist that can more readily serve as nuclei for the formation of ice crystals than the naturally occurring and sometimes sparse nuclei. This holds particularly for silver iodide (AgI), which has a crystal structure similar to that of ice and which can be very finely dispersed (10^{15} particles per gram). It is also possible to induce the formation of ice crystals in a supercooled water cloud by the introduction of solid carbon dioxide ("Dry Ice"). This cools a thin sheet of air to about -70°C , far below the limit of homogeneous nucleation. The presence of ice particles fosters the growth of the cloud elements, which then become able to fall out of the cloud. These facts are at the base of the endeavours to induce the precipitation of snow and rain and thus forestall the development of towering clouds, in which thunderstorms and hail might form (see also WEATHER MODIFICATION).

Snow cover. If the temperatures of the air and of the snow are sufficiently low, fallen snow does not melt but forms a cover on the solid ground. The thickness of the snow cover can be measured by stakes. In order to know the deposited mass, the density of the snow must be known. Thickness and density can be established by weighing the content of a coring sampler that has penetrated the whole snow layer. To measure the accumulation in remote places a radioactive source is placed on the surface, and a detector is placed at a fixed distance above. As the accumulating snow covers the source, the intensity of the radiation at the detector diminishes. The information can be telemetered to an inhabited place. Where the snow cover persists for several years, the accumulation can be measured by the seasonal differences in the appearance of the deposited snow or by differences in the

proportion of the stable isotopes deuterium and oxygen-18, which varies with the temperature at which the ice crystals are formed.

A lying snow cover takes up little of the radiative energy from sun and daylight sky. Fresh snow absorbs not more than about one-sixth to one-eighth of it, and even old snow does not absorb more than one-half. Soil and water, however, will absorb about nine-tenths of the energy. The absorption is mainly in the infrared range; in the visible range clean snow reflects nearly all incident radiation because it is almost perfectly white. In the range appropriate to its own temperature, at or below 0°C , snow emits almost the maximum possible energy. Hence the radiative economy of a snow cover tends toward a deficit. Because a loose snow cover is a poor conductor of heat, the loss of radiative energy from the surface is poorly replaced from below. The heat conductivity of loose snow is only one-tenth of that of soil. The surface layers of a snow cover get cold. They transmit their low temperature to the adjacent air layer. A low temperature of air near the ground with warmer air above, an inversion of temperature, is typical for snow-covered regions. On the other hand, the poor heat conduction of the snow prevents the cold of the surface from penetrating into the deeper layers. In a snow cover not much more than one foot thick, surface temperatures of less than -18°C can be accompanied by temperatures close to the freezing point at the interface with the underlying rock. Snow and ice have a rather high heat capacity and a very high heat of fusion and sublimation; much heat is needed to melt lying snow and even more to evaporate it.

The texture and density of freshly fallen snow depend largely upon the meteorological conditions. The size of the individual grains of snow varies with temperature and wind. They range from fractions of a millimetre to one or two millimetres. With temperature near freezing point,

Radiation
budget of
lying snow

Properties
and forms
of snow

the grains are generally larger than with lower temperature. Strong winds lead to collisions and to fragmentation of the blown snow particles; small rounded grains with a diameter of about 0.10 millimetre result. The density of a freshly deposited snow cover varies from 0.05 grams per cubic centimetre for fluffy snow under calm conditions to 0.45 for the small closely packed particles of blown snow deposited during a gale.

Once deposited, the snow cover undergoes continuous modification. It is diminished by melting and runoff, by percolation into the ground, and by evaporation. It becomes more dense by compaction under its own weight, by pressure of the wind, and by refreezing of meltwater. Strong winds form a hard crust at the surface. Helped by the impact of hard snow particles, the wind transforms the surface into a pattern of ridges and grooves, *sastrugi*, which stretch in the direction of the wind, and deposits the loose snow in rounded piles termed whaleback dunes. At a smaller scale and with lighter winds the surface becomes pitted and small transverse ripples are formed. Under special conditions of insolation and humidity of the air and of snow structure, the snow cover of tropical mountains can be transformed into bizarre shapes, *nieves penitentes*, several yards high.

Internally, too, a snow cover is subject to incessant changes. Neighbouring snow particles grow bonds and cause the snow cover to become more coherent with time, though this is frequently nullified by other forces. All snow grains are surrounded by a layer of water vapour in equilibrium with the ice surface. The equilibrium pressure of the vapour is higher at strongly convex surfaces than at straight or concave parts. This means that the pressure near the most pointed parts of the ice grain represents supersaturation at other points. The water vapour migrates to and solidifies at the less curved parts. The solid phase at the points tends to re-establish the equilibrium pressure by evaporation. This produces a rounding off of the snow grains. In the same way, a migration of substance occurs from the smaller, more curved grains to the larger grains. For a similar reason, namely a higher equilibrium pressure at the warmer than at the colder parts of the snow cover, there is also a transfer of mass from the warmer to the colder layers. In this respect the heat flux from the unfrozen ground below and the diurnal temperature change at the surface can be of importance. These changes tend to lower the coherence within a snow cover. Layers of loose, rounded particles, called depth hoar, can be formed. The snow may be enabled to overcome the internal friction within the layer and the friction between the snow layer and the ground. On an inclined base the snow will then move down, the speed varying from a slow creep to a rapid slide to snow avalanches that can reach a rapid speed of 200 miles per hour.

Snow cover is a very widespread feature on earth; 50 percent of the land and 10% percent of the sea—23 percent of the globe, or 48,000,000 square miles—are permanently or temporarily snow covered. Where a snow cover survives for some years it is transformed into ice, frequently with the aid of melting and refreezing, at permanently low temperatures by mere compression under the growing load. In this way the permanent ice cover of the glaciers is formed. The areas of prevailing accumulation of glaciers on earth, almost 6,000,000 square miles, are always covered by snow.

The thickness and duration of a temporary snow cover depends upon the amounts of solid precipitation, the snow transport by wind, the air temperature, and the strength of the solar radiation. Mountain regions, with lower temperature and generally higher precipitation, tend to have a relatively thick and long-lasting snow cover. Normally the snow cover will last longer in high than in lower latitudes. Three types of temporary snow cover can be distinguished. (1) In some areas snow cover lies without interruption during the colder part of the year. This requires a temperature of the coldest month not higher than -3°C . Most of northern Europe, the Soviet Union, Canada and Alaska, and the northern fringe of the United States belong to this type. There are,

however, regions where even with low winter temperatures no permanent snow cover persists because the precipitation is very small. The region east of the Canadian Rockies and parts of Turkestan and of the Tibetan plateau are examples. (2) Other regions have snow covers that form almost every winter but do not last throughout the winter. They are enclosed roughly between the isotherms of the coldest month of -3°C and 4°C . Europe west of 20° east and most of the United States north of 30° north belong to this type. (3) In still lower latitudes a snow cover of short duration will occasionally form. Jerusalem is such a place. The equatorial border of snowfall, as opposed to snow cover, is at sea level on the average not far from 30° north and 35° south. In southern China, eastern Mexico, and possibly southern Brazil, snowfall near sea level occasionally reaches the tropics.

Generally, the proportion of precipitation falling as snow and the duration of the snow cover increase with height. The level at which more snow is deposited than is removed is called the firm line and is the level above which glaciers form. It is lower in regions of heavy snowfall and higher in drier regions. The firm line descends in high Arctic latitudes to 1,000 feet and in the Antarctic to sea level. At the Equator the firm line is at about 16,000 feet. It rises in the dry tropical regions of Central Asia and South America to well above 20,000 feet.

Soaps and Detergents

Soaps and detergents are substances that, when dissolved in water, give it the ability to remove dirt from surfaces such as the human skin, textiles, and other solids. The seemingly simple process of cleaning a soiled surface is, in fact, complex, and consists of the following physical-chemical steps:

1. Wetting of the surface and, in the case of textiles, penetration of the fibre structure by wash liquor containing the detergent. Detergents (and other surface-active agents) increase the spreading and wetting ability of water by reducing its surface tension, that is, the affinity its molecules have for each other in preference to the molecules of the material to be washed.

2. Absorption of a layer of the soap or detergent at the interfaces between the water and the surface to be washed and between the water and the soil. In the case of ionic surface-active agents (explained below), the layer formed is ionic (electrically polar) in nature.

3. Dispersion of soil from the fibre or other material into the wash water, facilitated by mechanical agitation and high temperature; in the case of toilet soap, soil is dispersed in the foam formed by mechanical action of the hands.

The chemical steps in cleaning

World distribution of snow cover

4. Preventing the soil from being deposited again onto the surface cleaned. The soap or detergent accomplishes this by suspending the dirt in a protective colloid, sometimes with the aid of special additives. In a great many soiled surfaces the dirt is bound to the surface by a thin film of oil or grease. The cleaning of such surfaces involves the displacement of this film by the detergent solution, which is in turn washed away by rinse waters. The oil film breaks up and separates into individual droplets under the influence of the detergent solution. Proteinic stains, such as egg, milk, and blood, are difficult to remove by detergent action alone. The proteinic stain is non-soluble in water, adheres strongly to the fibre, and prevents the penetration of the detergent. By using proteolytic enzymes (enzymes able to break down proteins) together with detergents, the proteinic substance can be made water-soluble or at least water-permeable, permitting the detergent to act and the proteinic stain to be dispersed together with the oily dirt. The enzymes may present a toxic hazard to some persons habitually exposed.

If detached oil droplets and dirt particles did not become suspended in the detergent solution in a stable and highly dispersed condition, they would be inclined to flocculate or coalesce into aggregates large enough to be redeposited on the cleansed surface. In the washing of fabrics and similar materials, small oil droplets or fine, deflocculated dirt particles are more easily carried through interstices in the material than are relatively large ones. The action of the detergent in maintaining the dirt in a highly dispersed condition is therefore important in preventing retention of detached dirt by the fabric.

In order to perform as detergents (surface-active agents), soaps and detergents must have certain chemical structures: their molecules must contain a hydrophobic (water-insoluble) part, such as a fatty acid or a rather long chain carbon group, such as fatty alcohols or alkylbenzene. The molecule must also contain a hydrophilic (water-soluble) group, such as $-\text{COONa}$, or a sulfo group, such as $-\text{OSO}_3\text{Na}$ or $-\text{SO}_3\text{Na}$ (such as in fatty alcohol sulfate or alkylbenzene sulfonate), or a long ethylene oxide chain in non-ionic synthetic detergents. This hydrophilic part makes the molecule soluble in water. In general, the hydrophobic part of the molecule attaches itself to the solid or fibre and onto the soil, and the hydrophilic part attaches itself to the water.

Four groups of surface-active agents are distinguished:

1. Anionic detergents (including soap and the largest portion of modern synthetic detergents), which produce electrically negative colloidal ions in solution.
2. Cationic detergents, which produce electrically positive ions in solution.
3. Non-ionic detergents, which produce electrically neutral colloidal particles in solution.
4. Ampholytic, or amphoteric, detergents which are capable of acting either as anionic or cationic detergents in solution depending on the pH (acidity or alkalinity) of the solution.

The first detergent (or surface-active agent) was soap. In a strictly chemical sense, any compound formed by the reaction of a water-insoluble fatty acid with an organic base or an alkali metal may be called a soap. Practically, however, the soap industry is concerned mainly with those water-soluble soaps that result from the interaction between fatty acids and alkali metals. In certain cases, however, the salts of fatty acids with ammonia or with triethanolamine are also used, as in shaving preparations, for instance.

HISTORY

Use. Soap has been known for at least 2,300 years. According to Pliny the Elder, the Phoenicians prepared it from goat's tallow and wood ashes in 600 BC and sometimes used it as an article of barter with the Gauls. Soap was widely known in the Roman Empire; whether the Romans learned its use and manufacture from ancient Mediterranean peoples or from the Celts, inhabitants of Britannia, is not known. The Celts, who produced their soap from animal fats and plant ashes, named the product *saipo*, from which the word soap is derived. The importance of soap for washing and cleaning was apparently

not recognized until the 2nd century after Christ; the Greek physician Galen mentions it as a medicament and as a means of cleansing the body. Previously soap had been used as medicine. The writings attributed to the 8th-century Arab savant Jābir ibn Ḥayyān (Geber) repeatedly mention soap as a cleansing agent.

In Europe, soap production in the Middle Ages centred first at Marseilles, later at Genoa, then at Venice. Though some soap manufacture developed in Germany, the substance was so little used in central Europe that a box of soap presented to the Duchess of Juelich in 1549 caused a sensation. As late as 1672, when the German, A. Leo, sent Lady von Schleinitz a parcel containing soap from Italy, he accompanied it with a detailed description of how to use the mysterious product.

The first English soapmakers appeared at the end of the 12th century in Bristol. In the 13th and 14th centuries, a small community of them grew up in the neighbourhood of Cheapside in London. In those days, soapmakers had to pay a duty on the soap they produced. After the Napoleonic Wars, this tax rose as high as three pence per pound; soap-boiling pans were fitted with lids that could be locked every night by the tax collector in order to prevent production under cover of darkness. Not until 1853 was this high tax finally abolished, at a sacrifice to the state of over £1,000,000. Soap came into such common use in the 19th century that Justus von Liebig, a German chemist, declared the quantity of soap consumed by a nation was an accurate measure of its wealth and civilization.

Early soap production. Early soapmakers probably used ashes and animal fats. Simple wood or plant ashes containing potassium carbonate were dispersed in water, and fat was added to the solution (see Figure 1). This mix-

Figure 1: A French soap-boiling plant with the vessels for lye (far left) and the circular boiling pans; engraving published in Paris, 1771.

ture was then boiled; ashes were added again and again as the water evaporated. During this process a slow chemical splitting of the neutral fat took place; the fatty acids could then react with the alkali carbonates of the plant ash to form soap (this reaction is called saponification).

Animal fats containing a percentage of free fatty acids were used by the Celts. The presence of free fatty acids certainly helped to get the process started. This method probably prevailed until the end of the Middle Ages, when slaked lime came to be used to causticize the alkali carbonate. Through this process, chemically neutral fats could be saponified easily with the caustic lye. The production of soap from a handicraft to an industry was helped by the introduction of the Leblanc process for the production of soda ash from brine (around 1790) and by the work of a French chemist, Eugène-Michel Chevreul, who in 1823 showed that the process of saponification is the chemical process of splitting fat into the alkali salt of fatty acids (that is, soap) and glycerin.

The method of producing soap by boiling with open

Enzymes

Types of surface-active agents

steam, introduced at the end of the 19th century, was another step toward industrialization.

Early synthetic detergents. If turkey-red oil, *i.e.*, sulfated castor oil, still used in textile and leather industries today, is considered as the first synthetic detergent, the industry began in the midst of the last century. The first synthetic detergents for general use, however, were produced by the Germans in the World War I period so that available fats could be utilized for other purposes. These detergents were chemicals of the short-chain alkyl naphthalene-sulfonate type, made by coupling propyl or butyl alcohols with naphthalene and subsequent sulfonation, and appeared under the name of Nekal. These products were only fair detergents, but good wetting agents, and are still being produced in large quantities for use in the textile industry.

In the late 1920s and early '30s, molecules consisting of long chain alcohols were sulfonated and sold as the neutralized sodium salts without any further additions except for sodium sulfate as an extender. In the early '30s molecules consisting of long chain alkylaryl sulfonates (with benzene as the aromatic nucleus and the alkyl portion made from a kerosene fraction) appeared on the market in the United States. Again, these were available as the sodium salts extended with sodium sulfates. Both the alcohol sulfates and the alkylaryl sulfonates were sold as cleaning materials but did not make any appreciable impression on the total market. By the end of World War II the alkylaryl sulfonates had almost completely swamped the sales of alcohol sulfates for the limited uses to which they were applied as general cleaning materials, but the alcohol sulfates were making big inroads into the shampoo and fine detergent fields.

Historically, synthetic detergents began as mainly a substitute for fat-based soap but developed into a sophisticated product, superior in many respects to soap.

Soap forms a scum or precipitate in hard water, leaving a ring around the bathtub, a whitish residue on glassware, and a sticky curd in the rinse water of the laundry tub. Not so easily perceived is the relation of this hard-water scum to a dull, lustreless condition of hair after shampooing, yellow spots on laundry after ironing, and a heavy usage of soap in the household. All these effects point to a serious defect of soaps, namely, their reaction with the calcium and other metal salts present in hard water to give a precipitate that constitutes the hardness of the water. Soaps also react with traces of acidic compounds to form a precipitate. On the other hand, the synthetic detergents generally are unaffected or very little affected by metal salts or acids; although they may react chemically with them, the resulting compounds are either soluble or remain dispersed in colloidal form in the solution. Other useful properties of the synthetics, such as solubility in cold water and flexibility in formulation, also contributed to their rapid replacement of soap products.

SOAP MANUFACTURING PROCESSES AND PRODUCTS

Hot caustic alkali solution, such as caustic soda (sodium hydroxide), acts on natural fats or oils, such as tallow or vegetable oil, to produce sodium fatty acid salt (soap) and glycerin (or glycerol). This reaction, called saponification, is the basis for all soapmaking. If industrially produced fatty acids are used in place of natural fats or oils, the reaction with caustic soda yields soap and water instead of soap and glycerin.

Raw materials and additives. The major raw materials for soap manufacture are fat and alkali. Other substances, such as optical brighteners, water softeners, and abrasives are often added to obtain specific characteristics.

Alkali. Sodium hydroxide is employed as the saponification alkali for most soap now produced. Soap may also be manufactured with potassium hydroxide (caustic potash) as the alkali. Potassium soaps are more soluble in water than sodium soaps; in concentrated form, they are called soft soap. Though soft soaps are declining in importance, potassium soap is still produced in various liquid concentrations for use in combination with sodium soaps in shaving products and in the textile industry.

Certain alkaline materials (builders) are almost univer-

sally present in laundry soaps, functioning to increase detergency. The most important are sodium silicate (water glass), sodium carbonate (soda ash), sodium perborate, and various phosphates.

Fats and oils. Fatty raw materials for soap manufacture include animal and vegetable oils and fats or fatty acids, as well as by-products of the cellulose and paper industry, such as rosin and tall oil. Four groups of these raw materials can be distinguished according to the properties of the soap products they yield:

1. Hard fats yielding slow lathering soaps include tallow, garbage greases, hydrogenated high-melting-point marine and vegetable oils, and palm oil. These fats yield soaps that produce little lather in cold water, more in warm water; are mild on the skin; and cleanse well. This is the leading group of fats used in the international soap industry, with tallow the most important member.

2. Hard fats yielding quick-lathering soaps include coconut oil, palm-kernel oil, and babassu oil. (Palm-kernel oil is extracted from the kernel of the fruit of the oil palm, whereas palm oil, listed above in 1, is expressed from the pericarp or outer fleshy portion of the fruit.) These fats are not very sensitive to electrolytes, such as salt; thus, they are suitable for manufacture of marine soap, which must lather in seawater. This is the second most important group of soap fats, with coconut oil the most used.

3. Oils yielding soaps of soft consistency, such as olive oil, soybean oil, and groundnut (peanut) oil are most important here, and linseed and whale oils also belong to the group, as do some semi-drying or drying oils. Because these oils readily undergo changes in air or light or during storage, soaps made from them may become rancid and discoloured.

4. Rosin and tall oil form a group in themselves. Rosin is used in laundry soap, less expensive toilet soaps, and specialty soaps in various industries. Tall oil (a resinous by-product of the manufacture of chemical wood pulp) is mainly used in liquid soap.

Optical brighteners. Now an integral part of all washing powders, optical brighteners are dyestuffs absorbed by textile fibres from solution but not subsequently removed in rinsing. They convert invisible ultraviolet light into visible light on the blue side of the spectrum, causing the fibre to reflect a greater proportion of visible light and making it appear brighter. Furthermore, since the tone of the extra light reflected is on the blue side of the spectrum, this blue-violet tinge will complement any yellowishness present on the fibre to make it look whiter as well as brighter. The chemical structures of optical brightening agents are complicated; many formulas are trade secrets.

Though the action of optical brighteners resembles old-style laundry blueing in some ways, the two methods must not be confused. In the old method, a blue dye or pigment is adsorbed onto the fibre; this blue tends to absorb yellow light falling on it, reflecting light richer in blue. With blueing, however, the fabric absorbs some of the light falling on it and hence reflects less light than it receives. Thus, the fabric looks whiter, not brighter.

Sequestering or chelating agents. EDTA (ethylenediamine tetraacetic acid) or its sodium salt has the property of combining with certain metal ions to form a molecular complex that locks up or chelates the calcium ion so that it no longer exhibits ionic properties. In hard water, calcium and magnesium ions are thus inactivated, and the water is effectively softened. EDTA can form similar complexes with other metallic ions.

Abrasives. Water-insoluble minerals such as talc, diatomaceous earth, silica, marble, volcanic ash (pumice), chalk, feldspar, quartz, and sand are often powdered and added to soap or synthetic detergent formulations. Abrasives of an organic nature, such as sawdust, are also used.

Soap production processes. Several techniques are employed in making soap, most of which involve heat. Processes can be either continuous or on a batch basis.

Boiling process. Still widely used by small and medium-sized producers is the classical boiling process. Its object is to produce neat soap in purified condition, free from glycerin. Neat soap is the starting material for making bars, flakes, beads, and powders. The boiling process

Advantages of synthetic detergents over soap

Laundry blueing

Drawing by D. Meighan based on N. Shreve, *Chemical Process Industries*, 3rd ed. (1967); McGraw-Hill Book Co.

is conducted in a series of steps called changes; these occur in the kettle (called the pan in Great Britain).

In the first step, melted fats are placed in the kettle, and caustic soda solution is added gradually. The whole mass is then boiled with open steam from perforated coils within the kettle. The saponification reaction now takes place; the mass gradually thickens or emulsifies as the caustic soda reacts with the fat to produce both soap and glycerin.

To separate the glycerin from the soap, the pasty boiling mass is treated with brine. Contents of the kettle salt out, or separate, into an upper layer that is a curdy mass of impure soap, and a lower layer, that consists of an aqueous salt solution with the glycerin dissolved in it. Thus the basis of glycerin removal is the solubility of glycerin and the insolubility of soap in salt solution. The slightly alkaline salt solution, termed spent lye, is extracted from the bottom of the pan or kettle and subsequently treated for glycerin recovery.

The grainy, curdy mass of soap remaining in the kettle after the spent lye has been removed contains any unsaponified fat (usually traces that escaped reaction during saponification) plus dirt and colouring matter present in the original oils. During the next step, called strong change, strong caustic solution is added to the mass, which is then boiled to remove the last of the free fat.

The final stage, called pitching and settling, transforms the mass into neat soap and removes dirt and colouring matter. After the strong change, the soap may be given one or more salt-water washes to remove free alkali, or it may be pitched directly. Pitching involves boiling the mass with added water until a concentration is attained that causes the kettle contents to separate into two layers. The upper layer is neat soap, sometimes called kettle soap, of almost constant composition for a given fat (about 70% soap, 30% water); the lower, called nigre,

varies in soap content from 15% to 40%. Since colouring matter, dirt, salt, alkali, and metal soaps are soluble in nigre but relatively insoluble in neat soap, and since most of the impurities are dense and tend to settle, the nigre layer takes these from the neat soap.

Continuous soapmaking—the hydrolyzer process. The boiling process is very time consuming; settling takes days. To produce soap in quantity, huge kettles must be used. For this reason, continuous soapmaking has largely replaced the old boiling process. Most continuous processes today employ fatty acids in the saponification reaction in preference to natural fats and oils. These acids do not contain impurities and, as explained at the beginning of this section, produce water instead of glycerin when they react with alkali. Hence, it is not necessary to remove impurities or glycerin from soap produced with fatty acids. Furthermore, control of the entire process is easier and more precise. The fatty acids are proportionally fed into the saponification system either by flowmeter or by metering pump; final adjustment of the mixture is usually made by use of a pH meter (to test acidity and alkalinity) and conductivity-measuring instruments.

The continuous hydrolyzer process begins with natural fat that is split into fatty acids and glycerin by means of water at high temperature and pressure in the presence of a catalyst, zinc soap. The splitting reaction is carried on continuously, usually in a vertical column 50 feet (15 metres) or more in height. Molten fat and water are introduced continuously into opposite ends of the column; fatty acids and glycerin are simultaneously withdrawn. Next, the fatty acids are distilled under vacuum to effect purification. They are then neutralized with an alkali solution such as sodium hydroxide (caustic soda) to yield neat soap. In toilet-soap manufacture, a surplus of free fatty acid, often in combination with such superfatting agents

Salting
out

as olive oil or coconut oil, is left or added at the final stage so that there is no danger of too much alkali in the final product. The entire hydrolyzer process, from natural fat to final marketable product, requires a few hours, as compared with the four to 11 days necessary for the old boiling process. The by-product glycerol is purified and concentrated as the fatty acid is being produced.

Cold and semiboiled methods. In the cold method, a fat and oil mixture, often containing a high percentage of coconut or palm-kernel oil, is mixed with the alkali solution. Slightly less alkali is used than theoretically required in order to leave a small amount of unsaponified fat or oil as a superfatting agent in the finished soap. The mass is mixed and agitated in an open pan until it begins to thicken. Then it is poured into frames and left there to saponify and solidify.

In the semiboiled method, the fat is placed in the kettle and alkali solution is added while the mixture is stirred and heated but not boiled. The mass saponifies in the kettle and is poured from there into frames, where it solidifies. Because these methods are technically simple and because they require very little investment for machinery, they are ideal for small factories.

Finishing operations. Finishing operations transform the hot mass coming from the boiling pan or from continuous production equipment into the end product desired. For laundry soap, the soap mass is cooled in frames or cooling presses, cut to size, and stamped. If soap flakes, usually transparent and very thin, are to be the final product, the soap mass is extruded into ribbons, dried, and cut to size. For toilet soap, the mass is treated with perfumes, colours, or superfatting agents, is vacuum dried, then cooled and solidified. The dried solidified soap is homogenized (often by milling or crushing) in stages to produce various degrees of fineness (see Figure 2). Air can be introduced under pressure into the warm soap mass as it leaves the vacuum drier to produce a floating soap. Medicated soaps are usually toilet soaps with special additives, chlorinated phenol, xylol derivatives, and similar compounds, added to give a deodorant and disinfectant effect. As mentioned above, shaving creams are based on potassium and sodium soap combinations.

Anionic detergents. Among synthetic detergents, commonly referred to as syndets, anionic-active types are the most important. The molecule of an anionic-active synthetic detergent is a long carbon chain to which a **sulfo** group ($-\text{SO}_2$) is attached, forming the negatively charged (anionic) part. This carbon chain must be so structured that a **sulfo** group can be attached easily by industrial processes (sulfonation), which may employ sulfuric acid, oleum (fuming sulfuric acid), gaseous sulfur trioxide, or chlorosulfonic acid.

Raw materials. An important group of raw materials for anionic synthetic detergents is that of the fatty alcohols. Development of commercially feasible methods in the 1930s for obtaining these provided a great impetus to synthetic-detergent production. The first fatty alcohols used in production of synthetic detergents were derived from body oil of the sperm or bottle-nosed whale (sperm oil). Efforts soon followed to derive these materials from the less expensive triglycerides (coconut and palm-kernel oils, and tallow). The first such process, the **Bouveault-Blanc** method of 1903, long used in laboratories, employed metallic sodium; it became commercially feasible in the 1950s when sodium prices fell to acceptable levels. When the chemical processing industry developed high-pressure hydrogenation and oil-hardening processes for natural oils, detergent manufacturers began to adopt these methods for reduction of coconut oil, palm-kernel oil, and other oils into fatty alcohols. Synthetic fatty alcohols have been produced from ethylene; the process, known as the **Alfol** process, employs diethylaluminum hydride.

Soon after World War II, another raw material, alkylbenzene, became available in huge quantities. Today it is the most important raw material for synthetic detergent production; about 50% of all synthetic detergents produced in the United States and western Europe are based on it. The alkyl molecular group has in the past usually

been $\text{C}_{12}\text{H}_{24}$ (tetrapropylene) obtained from the petrochemical gas propylene. This molecular group is attached to benzene by a reaction called alkylation, with various catalysts, to form the alkylbenzene. By sulfonation, alkylbenzene sulfonate is produced; marketed in powder and liquid form, it has excellent detergent and cleaning properties and produces high foam.

An undesirable effect of the alkylbenzene sulfonates, in contrast to the soap and fatty-alcohol-based synthetic detergents has been that their high foam is difficult to get rid of. This foam remains on the surface of waste water as it passes from towns through drains to sewers and sewage systems, then to rivers, and finally to the sea. It has caused difficulties with river navigation; and because the foam retards biological degradation of organic material in sewage, it caused problems in sewage-water regeneration systems. In countries where sewage water is used for irrigation, the foam was also a problem. Intensive research in the 1960s led to changes in the alkylbenzene sulfonate molecules. The tetrapropylene, which has a branched structure, was replaced by an alkyl group consisting of a straight carbon chain which is more easily broken down by bacteria.

Processes. The organic compounds (fatty alcohols or alkylbenzene) are transformed into anionic surface-active detergents by the process called sulfonation. Sulfation is the chemically exact term when a fatty alcohol is used and sulfonation when alkylbenzene is used. The difference between them is that the detergent produced from a fatty alcohol has a sulfate molecular group ($-\text{OSO}_3\text{Na}$) attached and the detergent produced from an alkylbenzene has a sulfonate group ($-\text{SO}_3\text{Na}$) attached directly to the benzene ring. Both products are similarly hydrophilic (attracted to water).

Recent sulfonation methods have revolutionized the industry; gaseous sulfur trioxide is now widely used to attach the sulfonate or sulfate group. The sulfur trioxide may be obtained either by vapourizing sulfuric acid anhydride (liquid stabilized SO_3) or by burning sulfur and thus converting it to sulfur trioxide.

The basic chemical reaction for a fatty alcohol is

fatty + sulfur = fatty alkyl
alcohol trioxide hydrogen sulfate

and for an alkylbenzene is

R in both reactions represents a hydrocarbon radical.

Following this, caustic soda solution is used to neutralize the acidic products of the reaction. Figure 3 shows the principles of this process.

Research on the part of the petrochemical industry has evolved new anionic synthetic detergents, such as directly sulfonated paraffinic compounds—alpha olefins, for example. Paraffins have been transformed directly into sulfonates by treatment with sulfur dioxide and air using a catalyst of radioactive cobalt.

Non-ionic detergents. The most important non-ionic detergents are obtained by condensing compounds having a hydrophobic molecular group, usually a hydroxyl (OH) group, with ethylene oxide or propylene oxide. The most usual compounds are either alkylphenol or a long chain alcohol having a hydroxyl group at the end of the molecule. During the condensation reaction, the ethylene oxide molecules form a chain which links to the hydroxyl group. The length of this chain and the structure of the alkylphenol or alcohol determine the properties of the detergent.

The reaction may take place continuously or in batches. It is strongly exothermic (heat producing), and both ethylene and propylene oxide are toxic and dangerously explosive. They are liquid only when under pressure. Hence, synthesis of these detergents requires specialized,

Drawing by D. Meighan

explosion-proof equipment and careful, skilled supervision and control.

Other non-ionic detergents are condensed from fatty acids and organic amines (alkylol amines). They are important as foam stabilizers in liquid detergent preparations and shampoos.

Some non-ionic synthetic detergents may cause problems with unwanted foam in waste-water systems; the problem is not as serious as with anionic synthetic detergents, however.

Cationic detergents. Cationic detergents contain a long-chain cation that is responsible for their surface-active properties. Marketed in powder form, as paste, or in aqueous solution, they possess important wetting, foaming, and emulsifying properties but are not good detergents. Most applications are in areas in which anionic detergents cannot be used. Cationic-active agents are used as emulsifying agents for asphalt in the surfacing of roads; these emulsions are expected to "break" soon after being applied and to deposit an adhering coat of asphalt on the surface of the stone aggregate. These agents absorb strongly on minerals, particularly on silicates, and therefore make a strong bond between the asphalt and the aggregate. Cationic detergents also possess excellent germicidal properties and are utilized in surgery in dilute form.

Ampholytic detergents. Ampholytic detergents are used for special purposes in shampoos, cosmetics, and in the electroplating industry. They are not consumed in large quantities at present.

Finishing synthetic detergents. The largest quantities of synthetic detergents are consumed in the household in the form of spray-dried powders. They are produced from an aqueous slurry, which is prepared continuously or in batches and which contains all the builder components. Builders, consisting of certain alkaline materials, are al-

most universally present in laundry soaps. These materials give increased detergent action. The most important are sodium silicate (water glass), sodium carbonate (soda ash), and various phosphates; the latter have contributed to the problem of waste-water pollution by contributing nutrients which sustain undesirable algae and bacteria growth, and much work is being done to find acceptable builders which may replace, at least partially, phosphates. The slurry is atomized in heat to remove practically all the water. The powder thus obtained consists of hollow particles, called beads, that dissolve quickly in water and are practically dust free. Another portion of the syndets is transformed into liquid detergent products and used primarily for hand dishwashing. Though syndet pastes are seldom produced, solid products, manufactured in the same way as toilet or laundry soap, were being sold in greater and greater quantity in the 1970s. Sodium perborate is sometimes added to the spray-dried beads to increase cleaning power by oxidation. Enzymes may be added as well. Many modern washing powders combine synthetic detergents, anionic and non-ionic, with soap, to give maximum efficiency and controlled foam for use in household washing machines.

Applications and economic aspects. Soap and detergents are used mainly for cleaning and washing in the household but also in textile, metal, and paper industries and commercial laundries. Wherever strongly alkaline or acid or inorganic salts are used, synthetic detergents have replaced soap in industry.

Table 1: Annual Per Capita Consumption of Soap and Synthetic Detergents in U.S. and Western Europe, 1966 (kilograms)

U.S.	18.8	France	12.4	Portugal	9.2
Switzerland	14.1	Canada	11.9	Spain	9.0
West Germany	13.1	Italy	11.6	Finland	8.6
Belgium—	13.0	The Netherlands	10.7	Greece	6.2
Luxembourg		Norway	10.7	Ireland	6.2
Sweden	12.9	Austria	10.6		
Denmark	12.5	Iceland	9.8		

Table 1 shows annual per capita consumption of soap and synthetic detergents (1966) in the U.S. and western Europe. The lower figures in some countries are partly explained by their use of laundry soap, which is more concentrated than compounded soap or syndet products and used in smaller quantities by weight. Table 2 shows world soap and synthetic-detergent production (1967).

Table 2: World Soap and Syndet Production, 1967 (000 tons)

Soaps	
Laundry soap	4,464
Toilet soap	1,293
Soap flakes	121
Soap powder	528
Syndets	
Syndet powder	5,174
Liquid syndets	1,280
Scouring powder	686
Other syndet products	971
Total soap and syndet production	14,760

Social and Cultural Change

Social and cultural change consists of the modification of society and culture through time—modification in social institutions, ideas, values, technology, and other products of human interaction. The current body of knowledge regarding social and cultural change is neither large nor certain. It began barely two centuries ago to differentiate from the vast accumulation of philosophic and religious commentary on permanence and change. It consists of a heritage of grand theory, often utilizing analogies between organic growth and human progress, deriving from the thought of such philosophers as Comte and Oswald Spengler, continuing into the late 20th century through the contributions of the English historian Arnold Toynbee and the American anthropologist Alfred Louis Kroeber. It is composed also of ideas drawn from the great 19th-century efforts to compare all human societies, past and present and simple and complex, in terms of rationally conceived evolutionary stages from "savage y" to "civilization," as defined by such anthropologists as Sir Edward Burnett Tylor, Lewis Henry Morgan, and Henry Maine (see CIVILIZATION AND CULTURAL EVOLUTION). A third component derives primarily from the ideas and voluminous analyses of processes of industrialization and technological innovation inaugurated by Marx and furthered in different ways by subsequent investigators. A fourth major influence has stemmed from detailed studies of the effects of Western contacts on primitive or peasant societies in the 20th century.

THE CONCEPT OF SOCIAL AND CULTURAL CHANGE

Historical background. The great speculative literature on change, to which men have turned for comfort and inspiration for thousands of years, derives from both East and West and includes the conceptions of cycles in human affairs as offered in the *Upaniṣads* of India and in the great sermon of the preacher in the Jewish book of Ecclesiastes. It includes the concept of the unchanging and eternal as enunciated by Gautama Buddha in his view of Nirvāṇa and the realm of unchanging ideas as defined by Plato. It includes the ancient Greco-Roman conception of the universe as an ever-changing flow and the Confucian conception of an ongoing familial network of mutual obligations among sons and fathers.

The first known questions about the nature of permanence and change were asked in Greece by Heraclitus around 500 BC. What he and philosophers to follow him were concerned with, however, were not social and cultural phenomena but rather the physical elements, fire, water, earth, and air. It required another 2,000 years before the question began to be asked specifically regarding men's social life. In 1748 Montesquieu in *De l'esprit des lois* (*The Spirit of Laws*) encouraged the process of objectifying human institutions by asking about the nature of law and how laws vary. It has been no simple matter for men to develop concepts by means of which they are able to stand outside their customs and analyze them quite apart from making judgments on them. Although beginnings were made by Montesquieu and later by the English jurist Henry Maine with regard to the law and by the English philologist Sir William Jones and later the Brothers Grimm with regard to language, it was not until the 1870s that a general concept came into use that moved men decisively in the direction of the necessary objectification. This was the concept of culture, as presented by the English anthropologist Edward Burnett Tylor, which has ever since been accepted largely in his terms, namely, as having the meaning of "all those habits and capabilities acquired by man as a member of society." The concept has aided immensely in enabling men to stand aside from their own learned behaviour and ways of thought and subject them to the kind of analysis that the sciences require.

"Culture," "social," and "change." Cultural change is now taken generally to mean change in any learned behaviour and beliefs and their products (such as tools, paintings, books, or dwellings). Cultural change deals, then, with changes in technology, in languages, in kinship systems, in political and economic institutions, in the

arts, in human value orientations, in ideologies, and in religions, these being some of the generally accepted subdivisions of any culture.

Nevertheless, the concept is regarded by many social scientists as not the most useful for focussing attention on the locus of change in human institutions. For such students culture seems to refer to the inferred products of human interaction. As such it is an abstraction from many interactions, and it is the specific interactions that maintain social relationships and in which changes take place. For such investigators, it seems important that the term social be used for the phenomena under examination in order to keep a focus on the real world in which one observes people in action. The phenomena to be observed are for them social relations. On the surface, the distinction may not seem to be important. There are, however, important contributions to the understanding of cultural change in which a distinction between the social and the cultural has to be made. Clifford Geertz, an American anthropologist, for example, advocates a distinction between observable social interactions and the web of meanings that those actions have for the participants. He has pointed out how the ritual activities of migrants from rural to urban communities in Indonesia change before the meanings of those rituals do. Making a distinction between social interactions and their significance provides a basis for fruitfully analyzing the effects of changing action patterns on the traditional culture. American sociologist Talcott Parsons has made a somewhat different, though related, distinction. Like many others, he sees "social" as referring to role relationships and the maintenance of these as constituting the social system, which exists in turn in an environment that includes a cultural system. Each type of social system depends for its existence on certain controlling cultural orientations or patterns. Changes in the cultural system immediately affect the social system and vice versa.

Although there is considerable agreement on the nature of the social and the cultural, there is less agreement on what constitutes change. This uncertainty is age-old and runs as a constant theme through the questions and answers of the philosophers. The old French saying "The more it changes the more it remains the same thing" expresses the bemusement with the passing scene and the paradox of its apparently ceaseless flow. If all is change, and there is no permanence, then the category cultural change has no utility or significance. Yet, in the face of the unmistakably constant flow of events, one must take the position that there are relatively unchanging features of societies and cultures; otherwise, one must abandon the concept of cultural change. There is a paradox here that must be resolved.

All societies exist by virtue of ceaseless interaction. Every member of a society is different, and consequently every combination of individuals in interaction is unrepeatable. There is indeed constant flow. It is only when one adopts the concept of role that one has a tool for distinguishing permanence and change. A role is that part of the behaviour of individuals in interaction that is traditional, which each expects of the other as a result of his having been socialized in that society. A social structure is maintained through the repetition in the role situations. The persistence of legal codes for decades, centuries, and even millennia with basic principles and even wording merely added to but not replaced, for example, is a phenomenon not so obvious but just as certain as the relatively frequent changes of the personnel who administer the legal codes. The persistence of such "products of interaction" as legal codes exemplifies the kind of permanence that characterizes human society. The ceaseless activities of judges, legislators, policemen, and citizens of the state constitute not change but structural stability.

As the processes of interaction go on, certain necessary functions are performed for the continuing existence of these social institutions. What looks to ordinary people like change, such as putting persons out of political office and putting others in, is actually a process of renewal of personnel enabling the state structure to continue to be the same structure that it has been. Every society has its

Important
of
social
roles

Concept
of
culture

renewal processes; these are not change but maintenance. Processes of renewal of personnel, processes of intensification of solidarity of groups, processes of distribution of economic goods and their production, these and many others are maintenance processes. They are not the focus of concern in the effort to understand sociocultural change.

The maintenance of social and cultural systems may be seen to take place in rhythmic cycles; that is to say, in many recurrent series of events. Not only the more obvious sequences, such as recurrent elections characterizing certain kinds of political organizations, but also shorter cycles, such as daily gathering of a family for a meal in the evening with perhaps some group ritual or the seasonal recurrences of planting and harvesting—such cyclic activities are the stuff of which the persistence of groups and their cultures are made. There are, however, other kinds of recurrent sequences that are not clearly part of the maintenance processes of societies. These have been regarded by some students of cultural change as important for understanding the dynamics of societies. They range from cycles in women's dress through recurrent rises and falls in prices and wages to the rise and decline of "civilizations."

Older, related concepts. In trying to understand the scope of current concepts of sociocultural change, it is necessary to dispense with older views of the subject. For many decades, interest was largely confined to certain kinds of long-term change called cultural or social evolution. Many 19th-century anthropologists, social scientists, and philosophers focussed attention on evolutionary change. Each varying specific conception became a hook on which information about different social systems was hung. The most important of these was probably Herbert Spencer's view, which, influenced by the biology of the time, held that human societies in the long run become more heterogeneous and differentiated as they adapt to different environments. His vast collection of data for demonstration of this long-term trend was not much used by other cultural evolutionists; but his view is essentially that which remains most influential in the interpretation of succession of technologies today. Evolutionary development, however, whether in Spencer's terms or others, does not subsume the subject of cultural change. Evolutionary processes are only one kind of change process among many that exist.

Still less is social and cultural change to be identified with that pervasive and deeply influential conception of long-term change that has been called the idea of progress, a concept that has been a dominating influence for 200 years or more. The idea that societies and cultures move more or less steadily toward better and better conditions for men has affected numerous students of sociocultural change. This assumption was inherent in much of the work of the students of cultural evolution in the 19th century, when it was held that all non-Western societies were moving toward economic, political, and religious conditions comparable to those prevailing in the countries of western Europe. The ethnocentrism of these early investigators has been repudiated long since, even though their works are still read and used. Nevertheless, something very like the 19th-century concept of progress toward west European conditions pushes unsuspected into current comparative studies of "modernization" and industrialization. Not only the idea that change moves inevitably in the direction of west European and North American technology and economy but also the value judgment that this is somehow good creeps in. Progress as defined by members of various societies is an interesting phenomenon and must be studied, but the tendency, long existent and still present, of Westerners to assume that all change or at least change most worthy of study is a progress toward conditions that they value highly runs counter to sound method.

THE PROCESS OF SOCIOCULTURAL CHANGE

The general process of sociocultural change is characterized by three phases: innovation, selection, and integration.

The innovative phase. Innovation includes any new combination of cultural elements. The key word here is combination, for innovations are made up not out of thin air but of well-known elements of the cultural system. They are new in the sense that, under conditions favourable to innovation, some member of a society or some group puts familiar items into new relationships. Most people are aware of the process of innovation whereby the automobile emerged as a new combination of wheels, steam engine, horse-carriage body, and so on or whereby the clock emerged in the monasteries of medieval Europe as the combination of gears, coiled springs, and escapement, all of which had long been known as separate items but not in combination. People in fact are inclined to associate innovation exclusively with mechanical invention, so well have the records on technological innovations been compiled. But the same sort of recombination of familiar elements into new structures has been documented for social organization, such as the city-manager form of municipal government, and for belief systems, such as the Black Muslim doctrines of the 20th century.

The process of combination itself is understood better than the general sociocultural conditions that encourage or inhibit innovation. The analysis of specific innovations often seems to be based on an assumption that the process is an individual psychological matter. Some writers, for example, have emphasized the importance of what they call dissident, disaffected, and resentful types of individuals in the creation of innovations. Others have not only pointed to the innovation-mindedness of individuals but have also emphasized the kinds of social relations and cultural orientations that tend to encourage the development of such individuals in certain types of societies. It is clear enough that certain societies do put high value on innovative activities. One is familiar with this tendency in industrialized societies, which establish groups of individuals organized specifically, as in modern chemical and automobile industries, to produce new products. Such organized innovation, it should be noted, is nevertheless guided by what have become traditional interests in the industrialized societies. Innovations in technology are sometimes sought as means of maintaining the social or economic status quo. The question indeed may be asked as to whether such planned activity should be classified as true innovation.

If the study of sociocultural change is to avoid bogging down in the analysis of fads and fashions—that is to say, unimportant variations—distinctions among types of innovations might be recognized. No terminology has yet been developed for this purpose, but perhaps one kind of innovation might be designated as novelty. Innumerable new combinations are produced daily in every modern society. Most never go through the third phase of the change process—integration. They remain unimportant with reference to any aspect of the cultural system, are accepted only briefly, and ultimately disappear without leaving any mark.

The selective phase. The second phase of the general process is selection—also called acceptance, diffusion, and so on. Change in the sociocultural system can come about only if individuals accept the innovations into their stock of behaviour and beliefs. The acceptance is a process of social interactions. It involves a series of choices or decisions by individuals or groups of individuals.

In complex societies it is normal to have a large number of alternatives. Innovations may be created and added to the ranks of the alternatives. This area of alternatives must be understood to be the arena in which competition among elements decisive for the future takes place. A shift in the number of individuals choosing one alternative as opposed to another may begin a trend in a direction leading to extensive reorganization of the whole society and its culture. Choice, or selection among alternatives, may thus be seen as a necessary phase in all sociocultural change.

It should be clear that a given trend toward change may become apparent only in this so-called second phase; the implications of an invention begin to be developed not in terms of its being an alternative but in terms of its becoming

Combination in innovation

Cultural evolution

The question of choice

ing the dominant mode of behaviour or belief. Under such circumstances what happens in the selective phase, rather than in the innovative phase, becomes the significant focus of analysis for understanding change.

The integrative phase. The third phase, integration, is the process whereby the innovation (or selected alternative) is adapted to all parts of the system into which it enters. Admittedly, the integration begins with the selection phase, and the two phases are not really separable; but for analytical purposes they are better separated. The selection subprocess is best thought of as initial social interactions through which the innovation becomes established as part of the social system; it may then be regarded as extending farther as more and more persons accept the innovation throughout the society. In short, the selection phase focusses directly on the innovation. Then the integration phase might be regarded as the process of modification of the innovation as it is adapted to the beliefs, sentiments, and common understandings of the cultural system. This is a matter of mutual adaptation of both the innovation and the parts of the system.

There are a host of rather well-known examples of integration. Following its initial acceptance by politically powerful families, the factory system in Japan, for instance, was adapted to Japanese family and ritual kinship institutions and to the village economies in such a manner as to make it quite different from the factory system developed in England. The whole story of this process of mutual adaptation or integration of the factory into Japanese social life and Japanese culture is very complex. Similarly, the integration of single elements, such as the automobile or the radio, into the sociocultural system of the United States, as traced in several studies, demonstrates very complex mutual adaptations. The continuing process of integration, moreover, seems often to have no end; it is not possible to pinpoint the time when Japanese feudal society became an industrialized society. Human interaction is a continuum, and it must be always arbitrary to say that the effects of the introduction of a certain innovation have come to a conclusion. The criteria for industrial society may be arbitrary, but there can be no question about a decisive difference between the Japan of the 1870s and the Japan of the 1970s.

DIFFERENT CONCEPTIONS OF CHANGE

Various specific processes of change have been identified within the general concept of sociocultural change.

Culture contact. A variety of change that has attracted anthropologists for some 100 years has been called acculturation, or, more simply, culture contact—defined as all those processes that come into operation when societies with different cultures come into contact. Until recently this study was developed in the colonial areas of the European empires in Africa and Asia and among the "internal colonials" of the American countries. The term acculturation came to be used when contacts involved colonial people being subordinated and required to adjust to the cultures of the Western colonial powers.

Under colonial conditions, there was deemed to be a superordinate and subordinate society. In all such situations, the superordinate society made an effort to change the subordinate society in some way and even to direct that course of change in some degree. This change may occur only in certain specialized areas of contact, such as in employment in factories or plantations, or it may be on a very broad scale, as in the case of the Indians of the United States who experienced directed culture change through schools, jobs, agricultural development, household management, and many other aspects of life under the direction of the Bureau of Indian Affairs. Some writers have made a distinction between directed culture change and processes of change in which choice was free. The implication of the term is not that the management of change is successfully directed by the dominant society (frequently the results are the reverse from what it desires) but simply that the dominant society's cultural values and social sanctions become deeply involved in the subordinate society's life. The selection phase here is affected powerfully by the dominant society's interests.

A second distinctive feature of contact change has been called syncretism, or cultural fusion. The fusion of elements from diverse cultural sources—in religious belief and ritual, in the lexicons of languages, in technologies, and more recently in economic and political organization—testifies to the importance of this kind of ultimate integration of borrowed or imposed cultural elements in the growth of civilizations. Important in situations in which empires were built by conquest, it was also important in connection with the diffusion of the great world religions, and now, with the spread of industry and representative democracy, one finds again the great tendency to fuse and combine cultural elements. Cultural fusion may also take place whenever a receiving society tries to reject the dominant society's impositions, as in the well-studied phenomena of nativistic and nationalistic movements.

It is notable that the concept of acculturation, though developed in the study of "primitive" societies under colonial conditions, has larger and more current applications. Complex modern societies are composed of sub-societies often as different in cultural tradition, structure, and orientation as were isolated, simpler societies of the 19th century and the colonial powers that dominated them. Thus, within modern political units of nation-states there are contact situations characterized by phenomena similar to those of the earlier colonial environments.

Conflict and cooperation. In the work of Marx, there is an explanation for sociocultural change, called dialectic, that has been of great influence. This concept, intended to account for change throughout human history, has been less and less accepted in the Western world and more and more in the Eastern; nevertheless, its influence in conflict theories of the causes of change is important. Change is initiated, according to the theory, by conflict between classes; that is, collectivities of individuals whose interests are determined and limited by their roles in the production process. In various forms, this view of the basic impetus for change is used in modern analysis. Some writers have used ideas regarding tension management and release; certain roles are said to have built into them the means of creating tensions among individuals. Societies may be forced to change their structure in an effort to alleviate tensions, or they may devise techniques that keep the tensions under control.

At present, perhaps equally vigorous as any conflict theory of change are theories of change through cooperation. There is a view, for instance, that, whenever individuals are brought into working relationships, their adaptations result in changes in the system of which they are a part. The change, in other words, is a result of bringing people together on a cooperative working basis. There is a question, however, as to how much, if any, of this represents sociocultural change and how much merely constitutes adjustments toward maintaining given systems.

Environment. Theories have been offered from time to time regarding environmental influences on societies and cultures, theories sometimes labelled geographical, or environmental, determinism. Although the old ideas that man is somehow at the mercy of his environment have been abandoned, it is nevertheless recognized that the physical environment does set some measure of limitation on the possibilities for change and development in a society. The more isolated a society, as in the case of the Eskimos two centuries ago, the more important the influence of environment. Beginning in the 19th century, however, societies heretofore isolated have been subjected to contacts with the outside world, and relationships between any society and its immediate physical environment have assumed less and less importance. Nevertheless, in the study of change there has appeared a school of cultural ecology that is much concerned with the environmental influences and has focussed, for instance, on what has been called core culture; that is, those elements of a culture most positively and directly related to the environment. The core responds to changes in the environment, and the process of adaptation itself in turn affects the environment. As the ecologists have expanded their interest into modern societies, they have broadened

Cultural fusion

Marx and the concept of conflict

Cultural ecology

Mutual adaptation of the innovation and the system

their conception to include the social as well as the physical environment, so that they take into consideration such factors as competition and cultural fusion.

A similar but theoretically much more elaborate approach characterizes the work of the sociologist Parsons, in whose view the social system exists in a complex environment composed of four other systems—namely, the cultural system, the personality system, the organic-life system, and the system of the physical environment. The cultural system is sometimes defined as the set of legitimizing values for the social order or as a network of roles in the social system. The personality system is regarded as the system of human motivations causing participation in the social systems. The organic-life system consists of the human biology out of which personality arises. And the physical environmental system is composed of the interrelated elements of climate, topography, fauna and flora, and so on. Each of these systems has its own requirements, and all are articulated. Changes in one may initiate a sequence of events ultimately reflected in the others. The environment is thus conceived as a number of specialized relationships, and change is conceived as originating in any of them.

Demographic factors. Another set of factors increasingly taken into consideration by students of sociocultural change is the demographic conditions. Population size and density, age, and sex distribution, and birth rates and death rates are dealt with as sources of extensive change. Social relations, whether in family, community, or state, must constantly adapt to the numbers and distributions of the human individuals involved. For instance, the worldwide lowering of the death rate has been accompanied by a whole series of other demographic shifts, and these seem to be correlated with industrialization. It is not that the demographic shifts entail industrialization or vice versa but merely that the demographic shifts and the processes of industrialization are correlated. Each is an indicator of the other, and thus, wherever there is evidence of a declining death rate, changes in the labour supply and other socioeconomic phenomena associated with the processes of industrialization can also be predicted.

Another approach involving efforts to understand the train of social and cultural changes accompanying population shifts is that of two British anthropologists, Godfrey and Monica Wilson. They phrase the analysis in terms of social scale, which has to do with the size or scope of a society but is not to be conceived in the simple terms of population rises and falls. Social scale is affected by changes in the number of people in a given area, but what is decisive with regard to the scale of the society is the number of people involved with one another in active social relations and the intensity—that is, the frequency—of those social interactions. Furthermore, social scale is affected by other things, such as the introduction or increase of literacy. Through reading, the scale of the society is increased, because people are in a sense interacting with persons not physically present. It should be clear that scale is no simple concept of population curve but is nevertheless much involved with changes in the population. The Wilsons have related increase in scale, as exemplified in European expansion into Africa, with a large number of correlated changes in the character of African societies, such as a decrease in the use of magic for control of the environment, an increase in contractual as contrasted with personal relations, and a development of social mobility.

The expectation of discovering a unitary theory of sociocultural change in the sense of a master single source of innovation, such as technology or the natural environment, has steadily faded. Instead, the analysis of sequences of events is carried on in terms of many factors that in combination, it is assumed, encourage innovation or the selection of those alternatives that lead decisively to one or another kind of change.

BIBLIOGRAPHY. WILBERT E. MOORE, *Social Change* (1963), is the broadest and most compact summary of our knowledge of sociocultural change. All others, except for a textbook or two like BRYCE F. RYAN, *Social and Cultural Change* (1969); and DON MARTINDALE, *Social Life and Cultural Change* (1962),

are specialized in some direction or reflect only the interests of a single discipline. AMITAI and EVA ETZIONI (eds.), *Social Change: Sources, Patterns, and Consequences* (1964), achieves a broad survey by means of quotations from major thinkers and investigators. Among classics from which ideas are constantly drawn, but which offer special viewpoints rather than broad coverage are: HERBERT SPENCER, *The Principles of Sociology*, 3 vol. (1876–96); FERDINAND TOENIES, *Gemeinschaft und Gesellschaft* (1887; Eng. trans., *Community and Society*, 1957); MAX WEBER, *Wirtschaft und Gesellschaft*, pt. 1 (1922; Eng. trans., *The Theory of Social and Economic Organization*, 1947); WILLIAM F. OGBURN, *Social Change, with Respect to Culture and Original Nature* (1922; rev. ed., 1950); PITIRIM A. SOROKIN, *Social and Cultural Dynamics*, 4 vol. (1937–41); and A.L. KROEBER, *Configurations of Cultural Growth* (1944). H.G. BARNETT, *Innovation; The Basis of Cultural Change* (1953), is the most comprehensive summary of what has been called the first phase of sociocultural change. Limited largely to contact situations between industrialized and nonindustrialized societies, GEORGE M. FOSTER, *Traditional Cultures: And the Impact of Technological Change* (1962); and CHARLES J. ERASMUS, *Man Takes Control* (1961), nevertheless attempt interesting generalizations about the selection process. CHARLES P. LOOMIS, *Social Systems: Essays on Their Persistence and Change* (1960), discusses all phases of change in a special framework. MELVILLE J. HERSKOVITS, *Cultural Dynamics* (1964); and GODFREY and MONICA WILSON, *The Analysis of Social Change* (1965), are inclusive in their handling of processes, but nevertheless reflect the peculiar (and fruitful) biases of anthropologists. JULIAN H. STEWARD, *Theory of Culture Change* (1955), focusses on multilinear evolution but also summarizes an ecological approach to cultural change. Although outdated in some ways, still one of the most basic discussions of acculturation is RALPH LINTON (ed.), *Acculturation in Seven American Indian Tribes* (1940).

(E.H.S.)

Social and Welfare Services

The terms "social service," "social work," and "welfare service," and such related phrases as "social administration" and "social welfare administration" and most of the policies and programs involving these terms are essentially formulations and practices of the 20th century. Admittedly in some form or other, most of the things done today by individuals, charitable societies, or governments as social and welfare services have been done in the past in many societies. The Mosaic Law, the sociopolitical systems of classical Greece and the Roman Empire, the edicts of Aśoka, the simple rules of early Christian communities, and the institutions of family, village, and caste in India, to mention only a few instances, contained the elements of what are today called social and welfare services. The Elizabethan English are known for their pioneering work in some fields of social and welfare services, which they called "relief of the paupers." Closer to current times, the Victorian reformers who were distressed by poverty, child neglect, and other social ills were pioneers in many of today's social and welfare services, although they too had called such services by various other names such as "organized charity," "philanthropic work," or "relief of destitution."

There are no universally valid definitions of such terms as "social services" and "welfare services." Some countries, notably the newly independent and developing countries of the East, have attempted to apply the term social services to those services, such as education and health, that are addressed to the general population and to apply the term welfare services to services rendered to vulnerable groups—groups that are socially, economically, physically, or mentally handicapped or special groups like children, youth, or the aged. Thus welfare services would apply to those persons who because of the misfortunes of circumstances have tended to lag behind or fall by the wayside.

Another classification of social and welfare services focusses on their remedial, preventive, and supportive roles. Remedial services express the basic humanitarian and social responsibility of society toward people in dire need or distress. They seek to meet the special needs of various sections of the population, such as the young, the old, the destitute, and the handicapped. Such aims may be achieved through a variety of needed services on the wel-

Terminology

Concept of social scale

fare front and through a redistribution of income in favour of the needy on the economic front. Preventive services seek to lessen the stresses and strains of life resulting from social and technological changes. They try to provide built-in safeguards to meet the problems facing individuals and families, particularly in times of economic growth. If effective, they should reduce the need for more expensive remedial programs. Supportive services deal with educational programs, health services, population policies, manpower planning, employment and training, and community development projects.

Broadly speaking, there have been two rationales for social and welfare services. The "residual" view considered them as a collection of emergency measures to be provided when normal mechanisms—including the market economy, the individual, and the family—failed to meet the needs of the people. This view has been replaced in modern times by the "institutional" view, which accepts social and welfare services as a necessary function of any society, not only to provide for unmet needs but to serve individuals and groups positively so that they may develop and achieve to the fullest extent possible.

The background of social and welfare services

MODERN INFLUENCES

Factors that seem to have affected the status and course of social and welfare services in developed countries have been growth of population, changes in the composition of labour force, the change from agricultural to industrial employment, migration from rural to urban areas, changes in the pattern of family life, and the progress of medical and social sciences leading to a better understanding of human needs, physical, psychological, and social, and the provisions for meeting them.

On the continents of Asia and Africa, where traditional economic and social institutions have been functioning undisturbed for centuries, the dramatic changes trailing technological advances in the industrial and agricultural fields often have led to the breakdown of the built-in systems of caring for the individual and family. The close ties of kinship in India, for example, have provided a measure of economic, emotional, and social security in the past, but they could not function effectively in the changed circumstances of today. The attainment of independence by about 600,000,000 people in Asia following World War II and the wave of rising expectations among them have greatly influenced the course of social and welfare services. In particular, the population explosion in the developing countries, where widespread poverty and scarcity of resources are already limiting the scope of economic and social progress, creates special problems in the provision of social and welfare services. The level of fertility clearly marks off the developing countries from the rest, with the developed countries consistently having a birthrate that is just half of that in the developing countries. This has many implications for social and welfare services, particularly in attempts to lower the birthrate in the developing countries, which can least afford to have the kind of population growth that they are experiencing.

Age distribution also shows much variation. Censuses in the late 1960s show that younger persons (0–19 age group) in more than 16 developing countries comprise from 49 to 55 percent of the population, whereas they represent only between 31 and 42 percent in the developed countries. Thus the problem in the developing countries is that the needs of the young persons will consume a proportionately higher share of the national income for social and welfare programs, and it is significant to note that youth represent largely an economically unproductive group. This would affect savings and investment in other fields.

The proportion of those above 65 years of age was estimated in the late 1960s as only 3 percent of the population in the developing countries, whereas it was about 10 percent for the developed countries of Europe and North America and about 7 percent for Oceania and the Soviet Union. The dependency ratio—the ratio of consumers to producers—reflects the proportion of those under 15 years of age and those above 65 to the rest of the popula-

tion. This is highest in the developing areas of Africa, Asia, and Latin America, where it ranges between 79 and 86, whereas it is only 63 to 66 in North America, Oceania, and the Soviet Union, and 59 for Europe. The world average is 72.

The average life expectancy has shown much advancement, particularly in the developed countries. Norwegians, for instance, have an average life expectancy of 71 years for males and 76 for females. The proportion of old and young persons in the populations greatly determines the social and welfare services needed.

One of the major changes in the composition of the labour force that has had a far-reaching impact on social and welfare services is the increase in the proportion of women in the labour force. The increased participation of women, a large proportion of whom are working mothers, both in the developed and developing countries, has created the need for new social and welfare services to deal with the management of home and children. In the United States the total labour force increased from 41,600,000 in 1920 to 82,000,000 in 1970, and the number of women in the labour force increased in the same period from 8,500,000 to 31,000,000. The proportion of women employed in the different branches of the economy in the Soviet Union varies from 46 to 86, women dominating in fields like public health and education. In the Soviet Union, it is a criminal offense to refuse to employ a pregnant woman or a nursing mother.

Finally, the rapidly increasing urbanization has thrown up many new challenges. Whereas the total world population increased by 61 percent from 1920 to 1960, the urban population increased by 200 percent. The projections for urban population growth show that by 1980 about one-third of the world population will be living in urban localities, although the increase in the developed countries is expected to be 52 percent, as contrasted with a 24 percent increase in developing countries. These trends call for changes in approach to and emphasis on problems of social and welfare services in the urban areas.

HISTORICAL BACKGROUND

The history of social and welfare services can be traced to the personal charity that has characterized human society from very early times. Either as a natural expression of feelings of compassion or in a pursuit of virtue, individuals have always exercised personal charity, but this seldom has been an adequate answer to problems of need and distress. So from time to time groups of people and governments have sought to meet current need in a variety of ways. Most of these have been attempts at organizing charity and administering it with legal or ecclesiastical sanction. The English Poor Law of 1601 in the reign of the first Elizabeth (popularly known as the Elizabethan Poor Law) is an instance in point. Here the responsibility for poor relief was entrusted to the parish. Poor relief in the United States in the 17th and 18th centuries followed the broad framework of the Elizabethan Poor Law. Paupers received a little relief, but the treatment and punishments that they had to endure for the violation even of the simplest of regulations included severe penalties. It was only in the 18th century that the use of almshouses and workhouses became common. Earlier the poor were "auctioned" and given away to the lowest bidder who "took care" of them on payment of the sum agreed upon. The churches also used to be active in charitable work, but it was generally confined to their own members.

The course of social and welfare services in the 18th and 19th centuries was influenced by certain rigid attitudes that prevailed in the Western world. The most important among these was the belief that the government that governed least was the best and that it should confine itself to protecting its subjects from internal disturbance and external aggression. Basic to this was the assumption that the existing socioeconomic structure was sacrosanct and that the individual's freedom to pursue his best interests as he conceived them was immutable. The individual **should** find fulfillment in the expression of his free will and conversely should accept personal responsibility for failure. This kind of rugged individualism would admit of

female
roles

New popu-
lation
growths

Influence
of
laissez-
faire

little interference with the individual's course of action, even if it were to prevent general poverty or destitution.

The dawn of the 20th century coincided with the first development of the systematic organization of charity and its objects. An attempt was made to delve deeper into the causes of social evils instead of confining one's concern only to external manifestations. A beginning in this direction was made by Charles Booth, who conducted investigations into the lives of the people of London; the publication of his report entitled *Life and Labour of the People in London* (17 volumes, 1892–1903) had far-reaching effect, for it revealed that about one-third of London's population lived in poverty. Seebohm Rowntree's investigations in York in 1900 led to nearly the same conclusions. These studies had a profound influence on the thinking on the subject of poverty and the ways of dealing with it.

Organized
charity
in the
late 19th
century

The best instance of institutionalized charity in the late 19th and early 20th centuries was the so-called charity organization movement that began in England in the 1860s and was later adopted in the United States. This represented a basic shift from personal philanthropy to more organized and institutionalized forms of charity. One of the criticisms of personal charity that were widely prevalent until then was that provision of indiscriminate relief, unrelated to needs, perpetuated the problem it sought to remedy. Edward Denison and Octavia Hill had founded the Charity Organization Society (cos) in London in 1869; Charles Loch, who remained its general secretary for four decades, was greatly instrumental in developing the principles and policies on which it worked. The COS was opposed to public relief and believed that charity should be dispensed in such a manner as to enable the recipients to become self-supporting. Basic to this approach was the conviction that the individual, and not the socioeconomic framework, was to be blamed for his failure. State intervention was to be kept to a minimum, implying that the problems of destitution and distress can be and should be dealt with by private charity. The greatest contribution of cos was to pioneer the system of investigation into the conditions of the recipients through its volunteers and, later, paid workers. Material relief on the basis of the assessed needs of the persons was to be given, but more important was to be the moral influence of the visitors in changing the life pattern of the poor.

Reformist developments toward government responsibility. The direction of social welfare in the 20th century was affected by a marked change in the conception of the role of the state in the provision of welfare services. Adherents of the philosophy of rugged individualism gave way increasingly to those advancing the philosophies of socialism and the welfare state and the betterment of the working classes. The existence of pockets of widespread poverty side by side with the prosperity of the few set some people thinking. The leaders of organized labour were the first to see that they had nothing to lose by state intervention. In Germany and England the political influence of the middle and working classes had already begun to assert itself in the area of social and welfare legislation. What was needed to wipe out the destitution of the poor and the insecurity of the working classes was a bold new initiative to deal with their problems—namely, comprehensive programs of social insurance and public assistance. Between 1897 and 1930 most of the western European countries had adopted social security measures, Germany starting them as early as 1883.

Early
develop-
ment of
social
insurance
and
public
assis-
tance

One of the distinct developments in the present century is the growing consensus that the leadership and intervention of the state is called for in order to provide a comprehensive system of social and welfare services at the national level. In the democratic countries—particularly in the developed countries, where private charity had been most active—a partnership has developed between governmental and voluntary agencies so that each supplements and supports the other. In socialistic countries the state has assumed complete charge of social and welfare services, and these are integrated into the state's overall system of planning for social, economic, and cultural growth and development. Increased expenditure from

public funds for social and welfare services is a common trend in most countries of the world. In the developing countries, it is increasingly accepted that there is no alternative to government initiative and leadership for national programs. Confronted by mass socioeconomic problems and the inability of the existing institutions to deal with them, the governments have shown eagerness to participate in social and welfare programs. Often a paucity of resources, however, has prevented such governments from playing a more active role.

Professional social work. Charity workers, as the predecessors of modern social service workers, were a mixed lot but distinguishable by the end of the 19th century. Clergymen of many faiths, volunteer "friendly visitors" from the upper and middle classes, wealthy and influential citizens on agency boards and state boards of charities and correctional institutions, overseers of the poor, and paid charity agents were associated in a common effort. But as yet there was no bond of common education or united purpose to bind them together.

Mary Richmond in the United States was one of the first to proclaim that good intentions and common sense were not enough for charity work. She saw, too, that apprenticeship programs in each of the agencies were expensive, too narrowly focussed, and time consuming. With her successful proposal in 1897 that a training school of applied philanthropy be established, charity work took a giant step in the direction of social service as a profession. The time was ripe for action, for sociological studies of poverty and crime and the experience of charity workers in Europe and the United States had begun to give shape to a body of knowledge. The "scientific approach" to charity had given rise to defined methods of work. In London, as early as 1873, training activities initiated by Octavia Hill had evolved into a joint lecture and training program for both settlement and charity workers.

The New York Charity Organization Society launched a summer school of philanthropic work in 1898. A more significant step was taken in 1899 when an Institute for Social Work Training, the first full-scale school of social work in the world, was established in Amsterdam. That school offered a two-year course combining study of general sociological knowledge, socioeconomic problems, and legislation with supervised practical training in various fields of social work. By 1903 the training activities of the cos in England had led to the development of a two-year program of theory and practice in a formal School of Sociology. In 1904 the short course sponsored by the New York Charity Organization Society was transformed into a full-time one-year program in the New York School of Philanthropy, the first school of social work in the United States, which later became the Columbia University School of Social Work.

Early
schools of
social
work

The success of these early efforts, coupled with the recognized need for trained minds as well as good hearts in charity work, led to widespread development of schools of social work. Boston followed New York in 1904; Chicago and Berlin were next in 1908. The movement spread rapidly within Europe and throughout the United States, and by 1920 it had reached Latin America, where the first school was established in Santiago, Chile. Charitable and philanthropic work had by then become generally known as social work or social service; its personnel were identified and designated as social workers.

In the developed countries, where a generally higher standard of living and programs of social security have tended to meet the material needs of most people, professional social work has been called upon to deal with psychosocial problems largely through casework. The casework method derived from the idea, developed early in the charity organization movement, that each person (or family) represented a unique situation, or constituted an individual case, and that helping individuals or small groups to help themselves was the central goal and purpose of social service. In later years, however, the new challenges arising in complex urban industrial societies have tended to shift the emphasis from individual or group problems to broad social evils. There have arisen several unified efforts to induce social as well as individ-

Casework

ual change, to prevent social problems as well as to alleviate their end results, to affect the destiny of large population groups as well as to help individuals and families and small groups. This transitional situation is also reflected in new attempts to synthesize sociological and psychological knowledge and to undergird professional practice with social work's own developing theory.

The emerging new notion of social service as a force and instrument in the promotion of planned social change enlarges the scope of professional social-work activity, which, traditionally, has been associated with such fields of practice as child and family welfare, medical and psychiatric social work, school social work, corrections, and group services. To these significant tasks, the social-work profession, in the view of practitioners, is now adding newer responsibilities of joining with other disciplines to attack mass poverty at its source, to seek out and prevent the problems that blight the lives of people in affluent as well as struggling new societies, and even, it has been said, to reshape social structures in directions thought to provide new and better opportunities for productive and satisfying living. In developing countries, in particular, the methods of community organization seem to have far more relevance than casework or group work because mass problems are not amenable to individual treatment.

In addition to the basic methods of casework, group work, and community organization (which deal respectively with individuals, groups and communities), there have developed the methods of social research, social administration, and social action. In an earlier day, as already suggested, there tended to be a preoccupation with casework, and aspiring social workers tended to get almost all their training in casework. But more recently the trend in Europe, and to some extent even in the United States and Canada, is toward the "multipurpose" social-work functionary trained and disciplined in the use of all the different social-work methods, so that he can judiciously use appropriate methods as demanded by the circumstances. In some of the developing countries—particularly India—specialization in training and practice has developed not by methods but by fields, such as medical social work, school social work, and family and child welfare. In India, labour welfare and personnel management are taught as one of the fields of social work by most of the training institutions.

Another new trend is the increase in private practice by professional social workers, though this has been confined mostly to the United States. Although controversies centre on the propriety of private practice in social work (largely because it involves fees), the National Association of Social Workers in the United States has declared that private practice comes within the purview of social work practice.

Fields of service: problems and policies

PERSONAL SERVICES

Family welfare. Family welfare services are designed to enable individuals and families to meet their needs, cope with stresses, develop harmonious interpersonal relationships, and improve family functioning. The auspices under which these services are rendered differ from country to country: in some, each program is organized independently, whereas in many others, each program is integrated into larger programs of community centres. In most developed countries nationwide programs of cash assistance are an integral part of family welfare services, but in developing countries mass poverty and lack of resources make such cash assistance generally unavailable, or extremely limited if available. Apart from material help, family welfare agencies provide casework help and other assistance to deal with psychosocial problems.

Marriage counselling. One of the services offered mainly through family-welfare agencies is to assist marital partners in meeting marital responsibilities and to resolve marital conflicts. The urgent need for marriage counselling is indicated by the increasing rate of separations and divorce. Among developed countries, Canada has extensive family counselling services under public auspices. In Japan citizens' counselling services are super-

vised by the Ministry of Social Welfare. In the United States, Great Britain, and other western European countries marriage counselling and social casework services are available on a wide scale as part of family welfare services both public and private. In sharp contrast, there is almost complete absence of any formal system of marriage counselling in the Soviet Union, where the judges of the divorce courts are entrusted with responsibility of bringing about reconciliation between parties, failing which they grant divorce. Among some of the developing countries and some of the more conservative Western countries, family counselling and guidance is a relatively new service confined to urban areas only. In these countries, heads of joint or extended families and religious or community leaders give advisory or counselling help of an informal type. The formal type of family counselling services has been rudimentarily introduced in Malaysia, India, Indonesia, Italy, and South Africa.

Maternal care and family planning. Measures for promoting the mental and physical health of children from the prenatal stage onward and that of mothers, particularly during the gestation period, have been included in maternal care programs. These services are now an integral part of the public-health programs of most countries and are linked with social-insurance and maternity-benefit schemes. High rates of maternal and child mortality in developing countries are an index of the qualitative and quantitative inadequacy of maternal- and child-health programs. The extent of child- and maternal-care services needed in developing countries may be judged by the situation in India, where there are about 75,000,000 infants in the 0-5 age group and about 20,000,000 expectant and nursing mothers. Comprehensive programs for such a large number require enormous resources, which presently are unavailable. This gap between needs and resources is typical of most developing countries.

Among developing nations, India and Pakistan were the first to have launched family planning or birth control as part of the national development program under their Five Year Plans. Other Asian countries—South Korea, Ceylon (now Sri Lanka), Malaysia, and Singapore, for example—adopted family planning as part of governmental programs. Egypt, and Tunisia started family planning programs in 1955, followed by Kenya, Mauritius, Morocco, and Jamaica. In such countries as Chile, Colombia, Hong Kong, Thailand, and Venezuela family planning has been introduced by private agencies. Several Latin-American countries are introducing the family-planning movement primarily to solve the problems of widespread illegal abortions. Japan is the only country where population growth has been drastically cut by the legalization of abortions; with about 13,000,000 registered abortions and 6,000,000 unregistered, abortions in Japan since 1948 have exceeded the total number of births. Most eastern European countries, including the U.S.S.R., have legalized abortions; some western European nations—notably the United Kingdom—have a liberal policy on abortions, as do certain states of the United States (see also BIRTH CONTROL).

Family-life education. One of the services provided by family-welfare agencies, particularly in western Europe and North America, is family-life education. It seeks to develop through discussion, lectures, and radio and television programs healthy family relationships and efficient home economics. Initiated by a group of volunteers in the United States, family-life education has grown into a major movement. In some countries it started as a movement for parent education. In developing countries programs of this nature have been developed through women's clubs and other groups as part of community development programs. In Ghana, women's clubs are taking the lead in community development for "better homes" by demonstrations in home economics and home-making. In Belgium the government subsidizes courses promoting the improvement of family life.

Home-kelp programs. "Homemaker" service or "home-kelp" service is provided through public or voluntary welfare agencies to aid families to carry on household responsibilities and enable the family to stay together

Expansion
of
methods
and
fields

Birth
control

despite chronic illness, handicaps, or other types of family distress. Homemakers, selected for their skills and personalities and supervised by family service or children's agencies, are placed in homes where the mother is temporarily unable to care for the family. Such services have become increasingly important as the number of families without relatives or obliging neighbours attempt to survive in the impersonal atmosphere of large cities. Moreover, the concept is broadening to include services to adults in their own homes who are dependent, physically and emotionally ill, or handicapped. In Scandinavian countries, home-helper service is organized on a large scale, and per capita availability is much higher than in any other country. In 1963 there were 55,000 home-helpers in Great Britain (which offers such services under the National Health Service Act), whereas the United States, with four times the population of Great Britain, had only 4,000, providing only about one homemaker for 50,000 inhabitants.

Old-age care. The care of the aged is assuming greater importance with the general increase in longevity, particularly in the developed countries, where the old are at least measurably protected through social insurance or public assistance schemes and receive institutional care on a very large scale. The developed countries have organized systems that include pension schemes, old-age assistance, institutional care, clubs for senior citizens, homes for the aged, "meals on wheels" (mobile canteens for visiting from house to house), friendly visiting, home helps, adoption of grandparents (securing, in effect, foster homes for the elderly), mail order drugs at reduced cost, patient sitters, and cooperative buying. In developing countries, which are largely agricultural, the pattern of the joint or extended family had traditionally provided a built-in system of care of the aged within the family itself. Where there is no separation of the work place from residence, the aged are still able to retain social functioning in the family and the neighbourhood even after their economic productivity has ceased. This familial situation, however, is changing in developing countries; the old system does not provide sufficient protection to the aged in the changing socioeconomic circumstances but the developing countries lack the funds and resources to meet these new needs.

Child welfare. The field of child welfare is universally accepted as one of the most important. Its services seek to promote the healthy growth and development of children and meet their needs either through direct assistance or through assistance to parents or families. Supplying or supplementing family income so that parents can maintain a home for their children is usually the first such service to be provided. Assistance, usually by means of a public assistance program, may range from the distribution of food, medicine, and clothing to complex systems of social insurance. In addition to programs of general family relief, special assistance to broken families often is provided. In cases where parental care is temporarily or permanently unavailable, the child is given substitute care in the form of foster care, adoption, or institutional care. Although child welfare programs are common in the developed countries, they are inadequate or lacking in the developing countries, where 500,000,000 children represent three-quarters of the world's juvenile population.

Maternal and child health care. Although child welfare increasingly stresses social services, public health and medical services usually are the first to be organized in the newly developed nations. This recognizes the fact that the infant and maternal death rates are the primary indexes of a nation's progress in child welfare. In India, for example, the main programs for child welfare are health services, such as infant health centres, and provision of vaccination and immunization.

In many countries, particularly in Africa and Asia, the first steps were public health attacks on such diseases as yaws, tuberculosis, malaria, and leprosy and efforts to improve child nutrition. This was often followed by instruction of native midwives in the simple principles of hygiene. The assistance of the United Nations Children's Fund (UNICEF) and the World Health Organization

(WHO) was particularly significant in inaugurating three basic programs of infant and maternal welfare. The industrialized countries have gone far beyond this with the provision of professional prenatal, delivery, and postnatal care for mothers without reference to their ability to pay. Infant welfare clinics that provide expert advice on child care are widely available in Great Britain, where, in the 1960s, 80 percent of all babies received care in these clinics, and in the United States. Additional services in the United States under this program include, among others, health services to school-age children, dental care, hearing and vision services, immunizations and diagnostic treatment, and counselling services for mentally retarded children.

Protective services. Not all parents love their children and some are grossly incompetent and neglectful. Children of such parents require special protective services. Societies for the prevention of cruelty to children, organized under voluntary auspices, date from the middle of the 19th century and still exist under various names in some cities, although the trend has been to place responsibility for such services in public child-welfare agencies. In some jurisdictions probation officers of the family court or children's court carry on the work. Protective services are usually invoked on the complaint of neighbours or others aware of cases of parental abuse or neglect. The fact that the services are not sought by and may be resisted by the parents requires that the workers have special skills and that there be some modification of the usual casework practices. Because removal of a child from his own home, even if it is not a very good one, is such a serious matter, all reasonable efforts are made to avoid this drastic step.

Children who have been battered and abused and those whose emaciated bodies give evidence of neglect are not the only ones needing special assistance, although they are the ones most likely to be found in the case loads of protective agencies. Equally serious but less conspicuous are the emotional scars that many children bear. The subtler forms of emotional damage that parents can inflict on their children are only beginning to be recognized. In general, only in extreme cases, where the children are severely exploited by parents or others, are they removed from their homes by legal intervention. This caution of the courts is based on the conviction that the home, in spite of poverty or other disturbing conditions, is still the best place for the child to grow and develop.

Care of unwed mothers and their children. The care and protection of children born out of wedlock poses special problems arising from society's attitude toward premarital conception. From being tolerantly viewed or even expected, as in some tribal communities, some other communities impose extreme strictures, ostracize, or even exhibit violence toward the unwed mother and her child. Nevertheless, most modern societies recognize that the unwed mother should receive some assistance. Typical services for the unwed mother include maintenance, medical care, hospitalization, and above all casework to help her to meet the social crisis and to make a constructive decision for her own and for the child's future. Where family-welfare agencies operate, caseworkers counsel the mothers particularly about the arrangements either for keeping the baby or giving the child up for adoption. The services to the unwed mothers are provided in the developed countries of the West mainly through private agencies, supplemented by cash allowances from public funds, whereas in the Socialist countries of eastern Europe full maintenance is paid by the state; the child, for instance, can be kept in a children's home at state expense as long as the mother likes. In Scandinavian countries the state directly helps unmarried mothers in establishing paternity. Institutions known as *hôtels maternels* in France and working mothers' hotels in Great Britain admit unmarried mothers and look after their children. In developing countries services to unmarried mothers or their children are still in an elementary state and are dealt with by individual charity or private welfare agencies.

Day care. Day-care centres are intended for young children, generally between the ages of two and five, who

Prevention of cruelty to children

are looked after while their mothers are away at work. With more and more women employed either full-time or part-time both in developed and developing countries, the need for day-care services for the children has been universally felt. What was originally meant to provide custodial care for the children, however, has in many countries developed into broader health and educational services in collaboration with other child- and family-welfare agencies. The emphasis in the Soviet Union—unlike that in the United States and Japan—is more on care of children outside the family and in large groups under government supervision, some of the children returning to their homes only for weekends. In the developing countries there is great need for day-care centres, particularly in the urban and industrialized areas. In some countries of Asia, day-care centres must by law be provided by industries; in India, for example, every industrial establishment employing more than 50 women must maintain a crèche.

The various kinds of centres provide supervised indoor and outdoor play, a mid-day meal, and naps, as a minimum. In addition, there may be instructions in crafts, reading, music, and simple hygiene. Some centres are staffed with or have access to psychiatrists, pediatricians, and social workers and are used for the diagnosis and treatment of emotional problems of children and their parents.

Substitutes for parental care. Although most theories of modern child welfare place major emphasis on keeping children in their own homes, the unfortunate group of children who have to be removed from them absorbs more than half the time of all child-welfare personnel, at least in the United States.

There have been marked changes over the years in the reasons children have lost their homes, and corresponding changes in the kinds of care provided for them. Whereas death of parents and destitution used to lead the list, in the second half of the 20th century this was no longer the case. Most so-called orphan asylums have almost no orphans and many of them have acknowledged this fact by dropping the word orphan from their institutional names. Medical science and public health measures have succeeded in various ways in reducing the number of children who lost their parents by death. The most frequent causes for removal of a child from his home more recently have become marital discord, parental irresponsibility and neglect, separation, and illegitimacy. Temporary placement may sometimes be necessary because of behaviour problems of the child or because of family emergencies.

Foster-care services are designed for neglected or dependent children who lack the protective atmosphere of home for short or long periods and are hence placed with families or institutions. It is now accepted that a children's agency should be able to make available both types of care since experience has shown that not all children can benefit from foster-family care. For example, children whose experiences with their own parents have been emotionally devastating may not be able to fit into the intimacy of a foster family and may do better in the more impersonal life of an institution. The same is frequently true of emotionally disturbed adolescents.

Modern standards for foster care emphasize careful selection of homes, close supervision of the children placed in them, and payment of board. Clothing, medical and dental care, and allowances for the children are often provided by the placing agency. Particularly important are the counselling services provided by the agency's caseworkers to foster parents. In the absence of such services children may be needlessly uprooted and shifted from one home to another with damaging results. It is open to doubt whether remuneration can be an important factor in the foster parents' decision to take a foster child. The most successful foster parents do it because they like to have children around them, and in Great Britain it was found that women who had had more than one foster child also had children of their own.

Instead of the former austere buildings with rows of beds in dormitories and children sitting silently at long tables in the dining rooms, the modern foster institution is more likely to be of the so-called cottage type. Under the cot-

tage system there are small homelike units with living rooms, and single and double bedrooms, each housing from five to ten children along with a housemother or couple. Meals may be served in a common dining room although many cottages have their own dining rooms and have food delivered from a central kitchen. The purpose is to create a family rather than an institutional atmosphere. It should be noted that the shift from the congregate- to the cottage-type institution has been slower in Europe and in other parts of the world where the institutions are under religious auspices or where funds and resources are very limited.

Many new types of foster care are being devised for dependent, neglected, delinquent, or otherwise handicapped children. New kinds of foster homes have been started—professional foster homes, group foster homes, agency-owned foster homes. New patterns of institutional care are emerging—smaller groups, professional staff, experimental cottages, off-campus cottages. And, somewhere between these two groups of resources, another type of facility referred to as agency-operated group homes is being established. The children live together with a group of mature and responsible young people, usually volunteers, capable of exercising a stabilizing influence. In contrast to foster care, adoption is a social and legal process by which a child is received as a permanent member of the adopting family, with legal rights including that of inheritance. As a child care measure it seeks to take children of deceased or incapacitated natural parents and provide them with substitute parents and a healthy home environment. The procedure connected with adoption differs from country to country, but the general pattern is that legislative provisions seek to ensure that separation from natural parents is resorted to only where absolutely essential and only on the basis of consent if the parents live. Social agencies or departments arranging for adoption conduct social investigations for matching the child against the background of the adopting parents after study of their age, character, and motivation.

Youth welfare. While the basic needs of youth normally are met within their own families, a wide range of cultural, social, recreational, vocational, and counselling programs, whether public or private, may be needed to help youth assume leadership and responsibility. The programs can involve playgrounds, recreation centres, or hostels and can be organized around friendship clubs, classes, athletic teams, or interest or hobby groups. For such groups social services provide a place to meet and a group leader, teacher, or coach, as appropriate.

Almost all European countries have large youth organizations. Sweden, for instance, has "leisure-time groups" that serve small groups of five to 24 members in the age group of 12 to 24 years old. The popularity of these groups can be judged from the fact that in the period from 1955 to 1965 the number of such groups increased from a little over 9,000 to nearly 100,000. The Soviet Union contains the largest youth organizations in the world, all of them governmentally sponsored and not private or voluntary in the Western sense. Membership is encouraged in the Pioneers (for youth aged eight to 15) and in the Komsomols (for young people aged 14 to 26). Together with various physical culture organizations, such Soviet societies are said to reach membership of some 45,000,000. In most countries, there are Boy Scouts, Girl Guides or Girl Scouts, 4-H Clubs, the Young Men's Christian Association, the Young Women's Christian Association, and a number of national organizations with programs varying with local needs and conditions—for example, the Young Buddhists Association or the Young Men's Indian Association. Some such groups have "permanent" memberships, whereas others offer various programs for temporary get-togethers. Although most have at least some kind of meeting place or places, there are also such programs as Great Britain's Outward Bound, which draws together youth who sign up for various kinds of short-term camping, mountaineering, sea outings, and the like. The international Youth Hostels provide accommodations for youth gaining the experience of travelling either abroad or within their own countries.

tions

Many programs try to involve youth in nation building and other constructive endeavours, whereby both society and the individual youth profit. One of the new developments in India is that all university students are compelled to engage in cocurricular activities in military training, sports activities, or social service. It is hoped that the use of millions of Indian college students as volunteers in community improvement projects and social-welfare activities will fill a gap that today exists in the availability of educated youth leaders in nation-building activities. Israel is one of the countries that has successfully used its youth volunteers in larger nation-building activities, particularly in the development of new communities in unsettled areas. A well-known overseas program is the U.S. Peace Corps, which, during the 1960s, distributed thousands of young Americans into technical assistance projects around the world. A similar domestic U.S. program, VISTA (Volunteers in Service to America), sent youth to impoverished city slums and depressed rural areas.

Finally, in many countries, particularly such developed Western countries as the United States, there have developed the new "guidance" professions among social workers, who offer youth vocational, educational, and personal-social advice and counselling. Such guidance originally was provided mainly for special categories of youth—for example, school dropouts or leavers looking for jobs, emotionally disturbed children, college-bound youth, slow-learning students, or juvenile delinquents. Many private and public guidance agencies still serve special groups such as these, but more recently guidance has come to be viewed as valuable for all students.

Youth agencies recognize the need to extend services to the "hard to reach" youth and others who do not voluntarily come forward to take advantage of the recreation and other youth welfare programs. It is clear that in some countries youth welfare services must deal with not only the conventional physical handicaps but also social handicapping situations such as very low standard of living and unfavourable social conditions.

Group welfare. Social settlements and community centres. Neighbourhood social-welfare agencies—variously called social settlements, settlement houses, community centres, or neighbourhood houses, centres, associations, or guilds—began with the founding of Toynbee Hall in London in 1884. S.A. Barnett, then vicar of St. Jude's parish, invited a number of university students to join him and his wife in "settling" in a deprived area. The movement spread to the United States when Stanton Coit, who was one of the early visitors to Toynbee Hall, established Neighborhood Guild, now University Settlement, on the Lower East Side of New York City in 1886. In 1889 Jane Addams, another Toynbee Hall visitor, and Ellen Gates Starr bought a residence on the Near West Side of Chicago and started Hull House. In the same year Jane E. Robbins and Jean Fine (Mrs. Charles B. Spahr) opened the College Settlement in New York City. Two years later Robert A. Woods established Andover House, later called South End House, in Boston. The movement spread to other countries—particularly in western Europe, Southeast Asia, and Japan—mainly through the influence of visitors from those countries to settlements in England or the United States.

Settlements seek to develop harmonious relationships among community groups of different cultural, economic, religious, and social characteristics and to help people to act together as an informed citizenry to improve their living conditions and environment. Under the leadership of pioneer workers, social settlements have helped win the enactment of legislation providing for juvenile courts, mothers' pensions, workmen's compensation, and the regulation of child labour; they have promoted playgrounds and recreation centres, maternal, infant, and child health clinics and services, and adult-education programs and have taken part in housing and other reforms.

The difficulty of finding financial support in smaller communities that are less well organized (for purposes of social welfare) has tended to confine settlements to metropolitan areas where such support can be found. Some small agricultural and newer industrial communities,

however, have been helped—often by religious organizations—to establish and maintain a community centre, similar to a settlement. Dispersion of industry outside of metropolitan areas has brought into being new towns that need this general purpose type of community service. Communities of migratory agricultural labour, particularly where children are involved, have claimed the attention of religious organizations in the United States, with the result that some settlement houses have been established.

Services to migrants, aliens, and transients. One of the largest of social services has been directed toward migrants moving within nations and across international boundaries. The early settlement houses in the U.S. were particularly concerned with helping the foreign born survive the trials of living in a new environment; before this, migrants were generally left almost completely helpless.

A major problem in the 20th century has been that of involuntary migrants or refugees who have been forced by political circumstances to flee their original houses (see REFUGEES). The partition of India and Pakistan in 1947 and the Arab-Israeli conflict since 1948 have been occasions when millions of people were uprooted from their homes. The intercountry movement of refugees in Europe during and after World War II was on a scale unprecedented in history, requiring services and relief operations for millions of refugees.

In Europe and North America various church denominations and religious orders have been active in providing services to immigrants and transients. In the United States also, services for migratory farm workers and their families have been provided since 1920. Those migrating from European countries to other parts of the world are assisted by the Intergovernmental Committee for European Migration. With the increase of immigrants to Britain from Commonwealth countries in Asia and Africa, local authorities have taken increased interest in the welfare of immigrants; liaison officers who speak the language of the immigrants are employed to help the migrants with problems they face in the initial stage. Similar services are available in many countries.

As an example of the growth of such services, in the early part of the 20th century, a U.S. domestic movement called Americanization developed several agencies and centres directed toward the "correction" of what were considered "deficiencies" in the foreign born. The core of the curriculum was the English language, American history, and the governmental structure of the United States, all necessary for naturalization. Soon the offering included courses in such things as millinery, cooking, social amenities, and the care of children, all presented as "essential" and elements of American culture. Occasionally such centres as Hull House did try to preserve a respect for the alien cultures. Eventually, especially after World War II, the term Americanization began to be shunned; instead of the old idea of supplanting all foreign traits by a standard pattern, there grew up the idea of cultural pluralism, the preservation of separate cultures within the national boundaries. Still other critics contended that this pluralism itself would gradually disappear over the years, that the American character was still in the process of formation and that as it gradually emerged, it would be enriched by the blending of the admirable features of the various foreign nationalities. Thus, although special programs of education still exist to help children and adults make their primary adjustment to life in a new land, the quality and emphases of such programs have changed.

Aid to transients has been characteristic of countries that have had to cope with large numbers of mobile individuals. In the United States and Canada, for instance, there are the Travelers Aid societies, which shepherd the aged, the very young, the handicapped, and the foreign visitor through transportation difficulties at airport and railway terminals, offer counsel or aid to runaway youths, the emotionally disturbed, or the physically injured, give technical or legal advice to aliens and other newcomers, and even provide emergency financial help or job assistance.

between races and castes—have become increasingly versatile instead of relying on any one method or technique. The debate as to whether one must first reduce prejudice before embarking on legislation to combat discrimination, or whether the approach should be the other way round, has yielded to the conviction that both procedures should be followed simultaneously. As a result, in many nations there have developed programs of education and information, including the revision of school textbooks, and there have arisen various informational and self-help societies and associations, all designed to improve attitudes toward certain ethnic groups. At the same time there have been efforts to strengthen laws that make racial and caste discrimination a punishable offense.

Services for the handicapped. In an earlier day services for the physically and mentally handicapped hardly went beyond the provision of shelter and food; now the emphasis is on rehabilitation—helping the patient to overcome immediate domestic difficulties and to reconcile himself and his family to his condition. In general, the emphasis throughout is on self-help and productive work, not entirely from financial considerations but because self-help maintains self-respect and affords an outlet for the creative drive, while productive work is more pleasurable for most people than enforced idleness. In Denmark, for example, therapists, job specialists (*e.g.*, engineers), vocational guidance experts, and employment exchanges cooperate to achieve for the disabled employment conditions as near normal as possible. In the U.S.S.R. the Ministry of Social Welfare retrain the handicapped and obliges employers to give them suitable work and conditions, while special medical commissions supervise them and research institutes study their labour problems. Austria, France, West Germany, Great Britain, Greece, and Israel have "quota" arrangements for employment of the handicapped; that is, certain classes of employers are required by law to have in their work force a specific percentage of handicapped.

Services for military veterans. Services for persons who have completed a term of service in the armed forces have been provided from very early times. Down to the 20th century one of the most common solutions for the "veterans' problem" was to grant tracts of land to disbanded soldiers. Land grants were offered to encourage enlistments, reward military service, avoid unrest among veterans, or promote the settlement of frontier territory. By 1945, however, with war veterans more numerous, society more urban and industrial, and farm operation more complex, land settlement for veterans lost its traditional appeal; instead, the governments of the warring powers adopted a variety of plans, including public works programs, job reinstatement, educational aid, counselling services, employment preference, housing programs, and loans for veterans.

Unlike most other countries, the United States at an early date adopted a policy of granting liberal military pensions. Pensions for war widows and orphans were not common in Europe until World War I, but they existed in the United States from the time of the American Revolution. Pensions also were granted to U.S. veterans with a "service-connected disability," a term that was flexibly interpreted. Demobilization aid to disabled servicemen, however, reached high levels after World War II among all the warring nations. Great progress was made in medical and surgical treatment, in re-education, and in vocational guidance and placement services (even though there have been occasional exposures of inadequate or corruptly governed services). Veterans' preference and the reservation of certain civil service positions for the disabled were practically universal, while training allowances and disability benefits were more liberal than ever before.

There are also many voluntary associations and ex-servicemen's organizations that provide financial and personal services to disabled former servicemen and former servicewomen and their families. One special feature is the close coordination between the work of welfare offices of government departments and the voluntary bodies.

Disaster relief. Disaster relief refers to assistance to persons who are deprived of the essential needs of life

because of natural disasters resulting from flood, fire, earthquake, volcanic eruption, cyclones, or similar catastrophes. The term is also extended to assistance to communities and people suffering from the effects of war. During World War II, for instance, a nationwide civil defense program in Great Britain prevented the loss of many lives and helped to reduce some of the suffering following bomb attacks. Plans have since been developed by many countries to provide relief in the event of catastrophe, whether it results from war or natural causes.

Several research studies have been made in order to determine the human and organizational reactions to disaster. During and immediately after World War II several social surveys in the cities of Great Britain, Germany, and Japan that had been subjected to incessant bombing indicated the morale and interpreted the behaviour of those affected by disaster. Such studies revealed that in many cases, far from becoming panicky or hysterical, the people organized themselves with remarkable presence of mind and dedication, maintaining the morale and the tempo of relief operations. Breakdown of law and order and antisocial behaviour such as looting were relatively rare.

Relief operations. Before 1900, disaster relief consisted largely of emergency grants of food, clothing, and medical care, and the provision of mass shelter through hastily organized local committees, often with the aid of voluntary contributions of money or supplies from other communities or countries. In the 20th century disaster relief became one of the chief activities of such organizations as the International Red Cross, which originally had been organized in the 1860s to aid the victims of war. National systems have included nationwide expansion of disaster preparedness in Red Cross chapters, including the training of volunteers to serve in emergencies and the development of plans and programs to be used in case of either natural disaster or enemy attack. Other voluntary organizations that have been especially active in providing supplies and services for relief in cases of natural disasters have been the Cooperative for American Relief to Everywhere (CARE), the Salvation Army, and church groups.

In many countries, cities and regional administrative areas have established some disaster programs and prepared inventories of resources available in case of an emergency and of individuals with knowledge of the location of such resources. Locally, the mayor or some designated official is usually the top authority for directing the services when needed. In most instances the major city department involved is the fire department. (This more or less follows the pattern established in Great Britain during World War II.) Other officials generally represented on a disaster relief authority include the commissioners of police and health departments, officials of public and private welfare agencies, hospital authorities, representatives of the local medical society, and transportation authorities. In many communities the Red Cross and public services are organized to determine the need for food, clothing, and shelter in the event, for example, of a large fire. In case of a disaster affecting a large area, transportation facilities—public or commercial—are drawn into service. Emergency medical services and hospital care are important elements in relief after serious fires, floods, and windstorms. In countries like India, famine relief follows a pattern laid down by the Famine Code, whereby the state assumes control of the supply, distribution, prices, and movement of food grains and also grants exemptions from levies on land holdings. Where health standards are low, efforts to check the spread of epidemic diseases such as typhoid, cholera, dysentery, and smallpox are given special priority.

Warning services. Although it is possible to give warnings about certain kinds of disasters, people tend not to heed the warning. One common reason is the inherent optimism, indifference, or disbelief of the people, who tend to underestimate the seriousness of any impending calamity. But warning and preparedness must go hand in hand. Establishing flood control schemes in areas susceptible to flood, controlling epidemics like plague by preventive health programs, counteracting famine conditions by crash agricultural development programs, building up of buffer stock of food grains, maintaining fleets of trans-

Civil
defense
and
emer-
gency
programs

Services
for
disabled
veterans

port for men and materials to be rushed to the needed areas, and promoting effective systems of meteorological prediction and warning are steps that, in varying degree, can considerably lessen the adverse impact of many of these disasters. Meteorological departments in different countries, in collaboration with the International Meteorological Organization established in 1878, have been active in giving warnings particularly about cyclonic storms and floods.

COMMUNITY DEVELOPMENT

One of the definitions of community development formulated by the United Nations indicates its areas and objectives by saying that it consists of the "processes by which the efforts of the people are united with those of governmental authorities to improve the economic, social and cultural conditions of communities in the life of the nation and enable them to contribute fully to national progress." Its main rationale is that developmental programs must be initiated with the active support and participation of the local community. The importance of motivation and self-help has been brought out by community development projects in India that seek "to bring about a change in the mental attitude of the people, and to instill in them an ambition for higher standards of life, and the will and determination to work for such standards . . . to arouse enthusiasm in them for new knowledge, and new ways of life, and fill them with the ambition and will to lead a better life." Thus it seeks to effect changes in the attitude of people by engendering a feeling of dissatisfaction with the existing low levels of living and by arousing the enthusiasm for leadership, self-help, and mutual aid.

In such developed countries as the United States, community-development programs have aimed at eliminating the imbalances between highly developed industrial centres on the one hand and backward rural communities on the other—or even backward communities within otherwise affluent metropolitan areas. These programs have been organized by government agencies (such as the U.S. Department of Agriculture) aiming at either agricultural and farm improvement or urban-slum amelioration of various kinds.

In developing countries, community development is usually more intimately geared to the nation's overall development plan. Although the actual content of each program or its emphasis has shown a great deal of variation in different countries, the general trend has been to begin with village improvement projects, focussing on such things as roads, schools, hospitals, community centres, and recreation facilities. These have been attempted first because people are likely to generate general enthusiasm for obtaining these physical amenities. In developing countries that are predominantly agrarian, programs of community development have also focussed on agricultural development and extension work in rural areas; this is so because community development can make headway only if it can make an economic contribution and help improve living standards. In certain countries governmental grants are made available on a matching basis, usually 50–50, the contribution of the community being regarded as an index of the community's recognition of its needs and its willingness to participate to meet its needs. In poorer regions, some local communities have found it difficult, however, to raise matching resources for development programs; some others perceive needs and possess resources but lack leadership. In many such cases the national governments do not have the wherewithal to intervene. But in some Asian and African countries, an effort is being made to use idle manpower by directing the unemployed and underemployed into productive avenues for development purposes, and usually there is some kind of administrative machinery trying to link together the various self-governing units at different levels and to coordinate their programs.

Various techniques have evolved to cope with local conditions. One special feature in Lebanon is the dependence on existing village institutions such as village councils to get things going. In Egypt there have been established Rural Social Units, which handle not only local commu-

nity development projects but also social and welfare services generally under the Ministry of Social Affairs. A special feature of community development in Ghana, which started as early as 1945, is the leading role played by women workers and volunteers; one of their projects, Better Homes, aims at the all-round improvement of the home and its environs and the introduction of supplementary income through poultry-keeping and vegetable gardening.

Urban areas have their special problems of community involvement. The special features of urban life such as over-crowding, growing urban anonymity, poor amenities, absence of communication, impersonal relationships, frequent changes of jobs or residences, lack of involvement in the life of the community outside, and the depressing conditions of slums and other blighted spots put severe limitation on the extent of community feeling and involvement in urban community developmental programs.

SERVICES IN THE CONTEXT OF OTHER AGENCIES

Medical social service. The social and psychological conditions of patients can obviously help or hinder their recovery. Some do not recognize that they are ill, whereas others do not want a cure. Some do not want to do anything, whereas others are too upset by the diagnosis to do anything. The course and success of treatment thus may depend on the help of such personnel as medical social workers, who try to (1) give the physician a picture of the social and psychological factors causing or aggravating an illness, (2) help patients to make full use of all available facilities, (3) work with family and community to tap resources in support of the treatment and aftercare of the patient. Areas in which the skills of social workers have greatly benefitted patients have been those in which long-term medication and observance of various precautions are needed—involving such conditions as diabetes, cardiac disorders, handicapping conditions like poliomyelitis, stigmatized diseases like tuberculosis, leprosy, epilepsy, and venereal disease, and various psychosomatic conditions. Particularly in developing countries with low educational levels among the mass of the population, a great deal of the social worker's time is taken up with educating patients and families about the nature of diseases, the course of treatment, and the precautions to be taken.

The medical social worker also helps to arrange finances or offers counselling on economic situations centering on the job, housing, and family. Whereas in developed countries medical-care programs are often comprehensive enough to make the social worker's duties largely psychological, in developing countries a great deal of attention is additionally paid to financial help and to programs of family planning and health education.

Psychiatric social service. Assisting a clinical team of psychiatrists, psychologists, and other professionals is often a psychiatric social worker, who provides casework and group-work services for patients suffering from mental illness and who helps plan for their rehabilitation and aftercare. He also works with parents and relatives, and he engages in various preventive services in the area of mental health. Psychiatric social services made a beginning in the United States in 1905, when some of the neurological clinics attached to hospitals in Boston and New York started employing psychiatric social workers; specialized training began at the same time. During and after World War II, there was great demand for psychiatric social services, which were provided under military auspices and with the help of the American Red Cross.

In many countries mental patients not requiring active treatment are placed in suitable boarding or foster homes, "halfway houses," and community residences, usually under the guidance of psychiatric social workers. In Great Britain the National Health Service provides a broad range of social services for patients with mental disorders, including job placement and the help of social centres. Psychiatric treatment facilities in most of the developing countries, however, are inadequate. Even the few mental hospitals that exist in these countries are not properly equipped in terms of staff, equipment, or services. For example, with a total of only about 1,500 beds in mental

social
workers

Grants
in aid

hospitals, India in the early 1970s had 33 beds per 1,000,000 persons, compared with 3,500 and 2,780 beds per 1,000,000 persons in the United States and Great Britain, respectively.

School social services. School social workers deal with children who, potentially or actually, face problems of adjustment in the family, the school, or the neighbourhood to such an extent as to interfere with their studies. The actual problems faced by school children are different in the developed countries—where schools provide advanced educational facilities and where education is generally compulsory—from those of children in many developing countries, where educational facilities are inadequate. Even these limited facilities often go unutilized because children stay away from school or withdraw from school in order to support the family or to look after younger children. The school social worker tries to see that better use is made of the existing educational facilities. Among the social services available in schools are health services, psychiatric services, vocational guidance and counselling, supplementary diet programs, hobby centres, and other extracurricular programs. One of the trends in school social work is the development of an interprofessional approach involving social workers, educators, and other professionals like doctors and psychiatrists. Teamwork with parents and teachers for the solution of children's problems has been found to be very effective. There is much wider involvement of the parents and community in dealing with the problems of school children. Parents who have children with handicaps need special help; group meetings with parents of children with some handicaps have been found useful in sharing their insights and lightening their burden. School social workers play a crucial role in all of these programs.

Correctional services. Although there obviously are many views on the treatment of criminals and delinquents, the dominant conflict of views is between those who put their faith in severe punishment in the belief that this will prevent the criminal from repeating his crimes and also serve as a deterrent to others and, at the other extreme, those who emphasize the futility of punishment and the evil effects of prison life. The advocates of this latter position often conceive of the criminal as a victim of social and psychological forces outside his control. A compromise position located between the two extremes seems to be the one toward which most nations and most social workers are moving. The evils of prison life are admitted, but it is proposed to mitigate them by imposing shorter sentences, by using probation, fines, and other substitutes for imprisonment, by improving conditions within prisons, and by experimenting with new kinds of prisons and rehabilitative techniques. It is also commonly recognized that some criminals must be incarcerated for long periods of time, not so much for the sake of severity as for the protection of society. The major correctional areas in which social workers are involved are probation, parole, and delinquency control.

Probation. The probation process begins with a presentence investigation of the offender after his guilt has been established. This investigation—usually by a social worker—serves first to help the court determine whether the offender is suitable for probation and second to outline a plan of corrective treatment. It is primarily concerned with the offender as an individual, his personality and background, education and employment, and his family and social environment. When probation is approved by the court, the offender is placed under the supervision of a probation officer or a person appointed by the court—usually a person with a background of social work. The probation officer's fundamental task is to help the probationer become a more responsible and better adjusted person. The essence of probation is good casework, not mere supervision, and its aim is individual rehabilitation, not the relief of crowded institutions. Individual counselling and available social, occupational, educational, and mental-health resources are employed to help the probationer resolve specific problems, conflicts, and attitudes that led to his delinquent behaviour.

Unlike the United Kingdom and the United States,

which have generally established official, salaried probation officers, most continental European countries have delegated the personal supervision of probationers to social welfare organizations dependent on volunteer services. A general trend toward professional probation services has been exemplified in the Belgian, French, Dutch, and Swedish systems. There, trained probation consultants are responsible for indoctrinating volunteer agents, supervising their work, and in many cases giving direct services to probationers. The move toward professionalization has been accompanied by increased central government responsibility for coordination, regulation, or administration of probation services.

Those metropolitan areas in Latin America, Asia, and Africa where the juvenile court philosophy has been embraced offer probation services largely limited to juveniles. Voluntary welfare organizations usually have provided the necessary supervision and treatment services.

Parole. Various forms of parole or conditional release from prison have been adopted in the majority of countries around the world. The responsibilities of a parole board and a parole officer are comparable to those of a court offering probation and a probation officer: parole selection involves the evaluation of emotional, psychological, and social traits of offenders; and parolees are subject to field supervision by parole officers (sometimes identical to probation officers) or, in several European countries, by private social or rehabilitation agencies.

Parole supervision is based on the concept that the individual parolee has the capacity to accept help and to change his behaviour. But the parolee may need counselling on such matters as continued vocational training, employment placement, and adjustment to unexpected marital, economic, or other personal or family problems. The skills of the parole officer when applied through counselling and casework or group-work services can contribute much to the continuing rehabilitation of offenders. Parole supervision varies in quality from little more than perfunctory monthly reporting to skilled individual casework treatment. Given adequate administration and sufficient budgets to command competent staff with reasonable case loads, experience has shown that four out of five parolees will respond to constructive guidance and supervision by satisfactorily completing their paroles.

Delinquency control. Faced with mounting public concern over juvenile delinquency and the apparent failures of various programs of treatment and prevention, many countries and smaller jurisdictions have experimented with methods of control. Notable among these have been attempts to coordinate the work of agencies in local communities, to identify gaps in youth services and fill these gaps with new programs. Several methods of both treatment and prevention have recognized the importance of peer groups for the behaviour of youngsters. Group therapy has been widely practiced in institutions and in the community as an adjunct of probation. Work with "street corner" gangs has taken a variety of forms, usually involving extension of the services of a social agency by assigning personnel as "street workers" rather than primarily within traditional agency programs and facilities. Neighbourhood youngsters and adults have been organized and in many instances hired to aid in coping with delinquency and other community problems related to youth. "Opportunity theory" (*i.e.*, the theory that many young people lack the opportunity to succeed in conventional, accepted ways) has had a notable impact on youth services, especially in the U.S., where federal support has been extended to local communities on a broad scale to improve educational and economic opportunities. Other programs have been based on a variety of intensive clinical services.

Despite rising public concern and widespread experimentation with techniques of rehabilitation and prevention, youth services in most countries still are extremely limited, and the discretion of the juvenile court in most jurisdictions is severely handicapped by the paucity of available alternatives for treatment or protection of children. Supervision within the community (probation from the court, or "aftercare"—parole—following release from

Parole officers

Probation officers

an institution) is handicapped by staffs that are inadequate in numbers and in training; institutions tend to be primarily custodial in nature, with professional personnel limited to diagnostic rather than treatment functions.

Social Behaviour, Animal

Humans have long been interested in the societies of other animals. The Paleolithic cave paintings of southern Europe bear witness to the keen attention paid by early man to the social lives of the animals he hunted. Aristotle, in the 4th century BC, noted the dances by which honeybees tell each other the distance and direction of food. Chicken ranchers have now learned that two chickens penned together will eat more food and produce more meat or eggs than if they are kept in separate pens.

Knowledge of the social behaviour of screwworm flies (*Cochliornia hominivorax*), tsetse flies (*Glossina* species), and desert locusts (*Schistocerca gregaria*) has helped mitigate ancient plagues. Man studies the aggressive kinds of sociality in animals to see how war can be avoided. Finally, humans study animal social behaviour as an avocation as human societies become more crowded. The study of animal social behaviour thus helps to stave off all four horsemen of the Apocalypse—starvation, plague, war, and "death" by malaise.

This article is divided into the following sections:

- I. The characteristics of social behaviour
 - General features
 - Factors involved in social interaction
- II. Types of animal societies
 - Parental societies
 - Parental behaviour among simple organisms
 - From flatworms to insects

- Complex associations
- III. Dynamics of social behaviour
 - Costs and gains
 - The costs
 - The gains
 - Development factors
 - The evolution of sociality

I. The characteristics of social behaviour

GENERAL FEATURES

Social behaviour among animals takes many forms. The American naturalist and artist John James Audubon observed one of the largest social groups that man has ever known, in the fall of 1813 near Henderson, Kentucky. The species was the passenger pigeon (*Ectopistes migratorius*), once incredibly numerous but hunted to extinction by the end of the 19th century. Audubon wrote:

The air was literally filled with pigeons; the light of noonday was obscured as by an eclipse; the dung fell in spots not unlike melting flakes of snow The people were all in arms For a week or more, the population fed on no other flesh than that of pigeons. . . . The atmosphere, during this time, was strongly impregnated with the peculiar odour which emanates from the species Let us take a column of one mile in breadth, which is far below the average size, and suppose it passing over us without interruption for three hours, at the rate mentioned above of one mile in the minute. This will give us a parallelogram of 180 miles by 1, covering 180 square miles. Allowing 2 pigeons to the square yard, we have 1,115,136,000 pigeons in one flock.

The largest social organizations ever known are those of desert locusts; the pigeons were second; and present-day China is probably third, although some pelagic fish schools may be next. Persecution by man is reducing all the large social organizations except his own: the bison and the anchovies off California and Peru have fared poorly compared to smaller groups.

Large numbers or crowding do not in themselves constitute social behaviour. It is usually true, for instance, that a fish that produces a million eggs tosses them out less socially than does a fish that produces a single young and cares for it much more, and that a polygamous bird is less social than a faithfully monogamous one. Overcrowding leads to many social abnormalities. Crowded cats, for instance, develop a "despot" and "pariahs," and there is an almost continuous frenzy of spiteful hissing, growling, or fighting. Crowded rats display, in addition, hypersexuality, homosexuality, and cannibalism.

Animals sometimes are brought together by some localized attraction or scarcity, as are moths around an electric light, animals at a water hole in the dry African savanna, birds and bees at a fruit-bearing tree, or iguanas crowding to nest on islands free of predators. To determine if a grouping is social or not, it is necessary to examine the distribution of the animal within the limits of its needed habitat. Most animals require a certain sort of habitat—woodland for a squirrel, or nearly bare ground for a horned lark. Within the correct habitat, the animal also requires certain resources, such as food and water and nesting or roosting sites. The needed habitats and resources collectively form the "niche" of the animal. If an animal's niche is locally distributed, the animal may be found clumped, even if it is not particularly social. If the niche or habitat is patchily or irregularly distributed and the animal cannot move easily from one patch to another, it is said to live in a "coarse-grain" environment or to have a "coarse-grained" niche. Such animals often seem social when they are not. If the niche or habitat of an animal is rather uniform, so that the animal can move about and find what it needs in many places, it is said to live in a "fine-grain" environment or to have a "fine-grained" niche. Such animals often seem solitary when they actually are reacting to each other and hence are social. They tend to be solitary because they do not need to follow others to get to the right environment.

Within a fine-grain environment, or within one "grain" of a coarse-grain environment, animals may occur in groups even when they are not social. A "random" pattern of distribution, in which animals wander without re-

Social and nonsocial behaviour

gard to each other, brings asocial animals together at times. An even distribution is much more common, as in territories of many songbirds in which each pair occupies its own plot of ground; these are actually social animals, in the sense that each interacts with its neighbours so as to keep them at a certain long distance. "Clumped" distribution of animals is also common; this usually is truly social in the sense that each animal interacts with its neighbours so as to keep them at a certain short distance. Regularity of the short or long distance an animal keeps from its neighbour is thus as much an indication of sociality as is grouping; only the theoretical (and probably nonexistent) animal that completely ignores its neighbours is truly nonsocial. Time is also a factor in spacing; truly social animals have a tendency to move to the correct distances from each other and to maintain those positions over specifiable time periods, such as for the morning hours each day.

Leadership and dominance

FACTORS INVOLVED IN SOCIAL INTERACTION

Social interaction in time and space is sometimes shown to the ethologist by patterns of following and leadership, although neither of these is necessarily social; following occurs in a dog tracking a rabbit, and leading is seen in an anglerfish luring a smaller fish for dinner by dangling a fleshy protuberance on the snout. In the Eurasian red deer (*Cervus elaphus*), an old female leads the does and fawns about. Spanish merino sheep have been bred to follow each other, while the Scottish highland sheep have been bred to be more independent; following may thus vary within a species according to its needs or to the environmental pressures on it.

Following need not mean there is a leader. The first bird in a migratory "V" of geese or pelicans is not continually the same, and the leaders of a school of fish change every time the school changes direction.

Leadership is sometimes, but not always, associated with a dominance hierarchy or peck order, which may or may

not be a sign of social behaviour. Peck order, first noted in bumblebees, means that A pecks B, B pecks C, etc., but it does not necessarily mean that A leads C or B or that the three are interacting constructively. The dominant central males of a baboon troop tend to influence the direction taken by the rest of the troop around them; but the bullying dominant stag circling around a held of red deer has to follow wherever the females decide to go, and his initiative is limited to running straying females back to the herd.

Dominance hierarchies may occur whether or not there is social behaviour in the usual sense. Among several species of birds that follow swarms of army ants in Panama to catch insects flushed by the ants, the big ocellated antbird (*Phaenostictus mcleannani*) is dominant, the medium-sized bicoloured antbird (*Gymnophithys bicolor*) is next, and the small, spotted antbird (*Hylophylax naevioides*) is chased by all the other members of the flock (Figure 1).

Crowding almost any two solitary animals together will produce a dominance hierarchy, in which one animal becomes boss or kills the other. This is a major cause of deaths in zoos and aquariums, but it is not necessarily social behaviour. Some biologists even say that dominance hierarchies are evidence of antisocial rather than social behaviour and are expressions of inadequacy in overcrowded social systems. It is certainly true that most peck orders appear in unnatural situations, such as among chickens in a henyard or animals in a cage. In most animals, the absence of a dominance hierarchy, rather than the presence of such, in a crowded context is a sign of a high development of social behaviour.

A further interaction that the ethologist watches for in social animals is division of labour. Any two animals will, of course, divide up food or any other resource between them. Indeed, no two animals in nature ever have precisely the same niche; if two species have similar niches, they will tend to develop different ways of doing things, or one will exterminate the other. Ecologists call this the "competitive exclusion principle." Man attempts to reduce insect competition by various methods of "control." He kills off other animals by cutting down the trees in which they live. Most animals are less destructive and tend to divide up the world rather than to exterminate other species. Evolution, before the advent of man, seems to have produced continuously more kinds of animals and a greater division of niches, except in periods of environmental disaster. The three antbirds mentioned above tend to specialize in large, medium, and small prey; to the degree that these birds take different foods, they are cooperating better with each other.

Division of labour also occurs within a species. Males and females of some woodpecker species forage in different places in the trees, taking different types of food. Some animals use the same resource but do different things to get it. The male huia (*Heterolocha acutirostris*), an extinct bird of New Zealand, apparently used his short straight beak to open logs while the female, with her long curved beak, removed the insect larvae from the long tunnels he exposed. Male and female birds often build nests together, dividing the labour equally in some cases.

Social insects have more elaborate divisions of labour. Animals that cooperate by division of labour tend to use varied resources and to find more uses for them.

Division of labour seems to be a passing phase in the evolution of most animals other than man. It is evidently of little advantage to most animal societies. The honeybee, the leaf-cutter ants, and other animals with division of labour nearly always occur only where there is little competition from more specialized animals. Few of the most advanced insects or other animals show division of labour. In habitats such as the coral reef and the tropical forest, division of labour tends to be among different species rather than within a species.

Social interactions of various types are more important in determining degree of sociality than are most of the above characteristics. The only interactions between animals that are seldom considered social are behaviours

Division of labour

Drawing by Christian D. Olsen

in which animals take something needed by others. The question arises, however, as to how to classify the parasitic relationships of a fetus in the mother and the male anglerfish (*Photocorynus spiniceps*) on his mate, or the fact that killing by predators may help animals to avoid overgrazing their habitats. One could speak of communication of feint and chase in the interaction between moose and wolves. When a bird chases another off its territory, it uses communication and interacts with the other bird very strongly.

Humans often consider chimpanzees or bees as more social than desert locusts, because the locusts have rather simple interactions. Male hummingbirds and birds of paradise, however, have their elaborate plumages and social displays because the females get together with them so seldom that they might not recognize a suitable mate without the displays. It seems generally true that elaborate rituals evolve where social bonds are most fleeting or likely to be disrupted. To determine sociality, one must look at the total spectrum of social interactions as well as at their diversity and productivity, rather than just at a single feature such as complex communicatory rituals.

Communi- cation

Social behaviour commonly includes communication, which may be defined as the sending of a message through a medium to a receiver so as to change the status and perhaps the behaviour of the receiver. Communication need not be overt or frequent or complex; one flick of an eyebrow by a dominant baboon is sometimes enough to send others away. Communication takes many forms. The voluble babble of a group of birds mobbing or attacking an owl is communication. The purveying of falsehoods also occurs in nature: the katydid that mimics or looks like a leaf, or the phasmid insect that looks like a stick, is telling predatory birds that it is inedible. Animals commonly exaggerate their characteristics to impress a mate, a rival, or a predator, puffing themselves out or blustering even if they do not lie outright. It has been well stated that a patch of colour on an animal is almost certain to have communicating functions, to mean something when displayed in exaggerated fashion to its social companions. Some animals also communicate by taste or odour, by voice, by electric impulses, by heat, or by touch; and many animals have more than one of these systems.

Communication between animals of different species becomes of increasing importance as environmental associations grow more complex. In such ecologically advanced habitats as coral reefs and tropical forests there is much interspecific communication.

Altruistic behaviour

Altruistic social behaviour is often found among animals. An altruistic animal is one that expends some of its energy helping another without direct benefit to itself, be it a mother bear protecting her cubs against their hungry father or a bird giving an alarm call that warns its neighbours of a hawk. An alarm call may help the bird itself, of course, by startling the predator or warning it that this alert bird will be hard to catch.

Psychologists have found that a rat or monkey will slow its rate of pressing a lever for food if that lever also gives an electric shock to a nearby rat or monkey. Rats will take turns sitting on a platform so that others can feed without being interrupted by electric shock. Rats or pigeons can be trained to cooperate in getting food.

Since the altruistic animal always loses something by its behaviour, the question arises why altruism exists. One answer is that, as the evolutionist Charles Darwin suggested, when an animal protects its offspring, it helps its kind to survive the process of natural selection. When porpoises help an injured relative to the surface where it can breathe, they seem to be following a pattern of behaviour that can be accounted for by evolution. Their altruism clearly helps the group and therefore becomes part of the genetic endowment. Altruism, significantly enough, is usually limited to an animal's relatives. Most social animals, such as penguins, feed only their own young. When the individual animal loses more than it or its relatives gain, as when female seals nurse young not their own, the question arises whether this serves the

survival of the larger group or the species. Under some conditions, the survival of the group may be more important even than survival of the individual, as when the honeybee dies defending the hive. The worker honeybee, which is not able to reproduce, is in the biological sense not an individual so much as an extra limb of a collective animal.

Reciprocal altruism, in which a benefit is later returned to the benefactor, need not be between related animals and may not even seem altruistic. Alarm calls of birds often alert entirely unrelated kinds of birds, which later may return the favour. An act that seems selfish in the short run is sometimes altruistic in the long run, or vice versa, in the case of maladaptation. Wasps, ants and termites that cannibalize or dominate nestmates at times of food shortage may better keep the colony from starving. Individual ants and bees are often lazy, spending most of their time resting or wandering aimlessly, but these unemployed individuals form an easily mobilized reserve in times of danger.

Individual and group recognition are often important aspects of social structure. Ovenbirds (*Seiurus aurocapillus*) in North America recognize neighbouring males by their songs and react aggressively mainly to songs of strange males. Animals that have long parental bonds often show individual recognition. Herring gulls (*Larus argentatus*), for example, recognize chicks or mates by slight differences in voice or appearance. The larger or more ephemeral the society, the less there can be individual recognition between distant individuals and the more important becomes recognition by group characters, such as the "nest odours" of social insects. Ants, bees, and termites often attack strangers, or even members of their own colony that have been experimentally removed for a few days or washed. Many kinds of parasitic insects (beetles, flies, butterfly caterpillars), however, provide food or scents that gain them entry to a nest, then prey on larvae there.

Other internal characteristics of societies are age structure, birth rates, and death rates. A young wasp or termite colony has few old animals, a mature colony has more, and a declining colony or one that is producing reproductive forms has few young. The old colony has a lower percentage of foraging workers than does the young colony, and has a lower birth rate and higher death rate as a consequence; but only the old colony produces reproductive forms.

Societies also perform movements, such as nomadism and migration. Army ants wander nomadically after prey. Wildebeest and locusts of Africa emigrate to green areas of local rains; flocking or solitary birds migrate back and forth to escape winter or drought; anadromous fishes, such as salmon, move to the sea for food and to rivers to spawn; catadromous ones, such as eels, do the reverse.

Migrants are often placed at a disadvantage compared to residents, for the latter can take the regular food supplies and leave only ephemeral sources for migrants. Migrants that follow army ants for food in Central America are subordinate to residents, and succeed only when residents are absent. The migrant can turn its world from a coarse-grained one to a fine-grained or dependable one by migrating from one patch to the next; and by force of numbers migrants sometimes displace residents.

Societies can make use of seasonal environmental changes by migrating locally, such as sowbugs clustering to estivate in hot weather or ladybugs hibernating in masses. Other societies show food storage; e.g., harvester ants (*Messor*) and wood or pack rats (*Neotoma*). Honey ants (*Myrmecocystus*) have a "replete" caste that bloats their abdomens with stored honey and hang from the roofs of underground chambers until tapped by other workers.

Societies show population fluctuations, from extinction to explosion. Mass emigrations in some, such as lemmings and squirrels, occur mainly after population explosions or periodic extirpations of food supplies. Some populations, such as many protozoans, worms, and in-

sects, normally undergo violent fluctuations, but are resistant to extinction. These are animals in which the adults emigrate or both adults and young emigrate. Animals in which the adults normally occupy a fine-grained habitat and only the young move, such as most higher animals, normally have relatively stable populations, but are easily killed off by a new predator or temporally unpredictable events.

A major external characteristic of the more complex societies is that they construct things, or modify their environments. The elaborate air-conditioned castles of some termites, the path systems of feral house cats, and the patterns of singing at dawn among birds of ephemeral or coarse-grain habitats, all are "structures" created by animals.

Cooperation and competition are major aspects of animal social behaviour. Social facilitation, as when yawning spreads through a pride of lions or chickens eat more rapidly together, shows that cooperative competition can be social. Social animals, which live close together, often interfere and fight more with each other, especially in early stages, than do solitary ones. A fair percentage of the communication between social animals involves "agonistic" or threat-submission behaviour. If this behaviour results in a more adaptive dispersion of the animals, it has been altruistic. Grouped goldfish and other animals survive heat, cold, metallic ions, and other "pollution" better than do isolated animals; but if too many animals aggregate, they pollute each other. Social groups therefore have an optimum size and density, based upon an equilibrium between advantages and disadvantages.

Linking the internal and external characteristics of social systems are flows of energy and materials. Social systems use energy in building structures, or information-rich systems. Physically, one can measure the success of a social system by how efficiently and extensively it uses energy and materials and converts them to physical, biological, or cultural structures. However, success in the short run can lead to disaster in the long run, as when elephants or humans destroy an African forest and then must starve or emigrate. Energy and material flows involve an interspecific web, the ecosystem, and must be measured over the long run and in general as well as locally or in the short run.

Social behaviour, therefore, must include interactions between different kinds of animals. A flock of sandpipers in flight is not less social if it includes two species rather than one. If species cooperate, a flock of two species can even be more social than a flock of one species. At African waterholes, baboons keep the lookout while associated antelope are good at scenting predators. Symbiosis is social, even though the late biologist Traian Savescu of Romania was half right when he joked "Symbiosis is like marriage—a mutual exploitation." Like all social organizations, it is both cooperative and competitive.

Social behaviour may thus be defined as "more or less diverse and constructive interactions among two or more animals." Social behaviour is usually constructive, productive, and adaptive; but it sometimes persists for a time after the evolutionary basis for it is gone. For instance, many kinds of hawks in the eastern United States have almost disappeared, but the flocks of small birds that were formerly their prey still form as vigilante groups.

II. Types of animal societies

To understand social behaviour more fully, it is necessary to examine it throughout the range of animal life. W.C. Allee, in his classic book *The Social Life of Animals*, distinguishes two major types of animal societies. One is the parental, or familial, society, in which parent and offspring stay together for varying lengths of time. The other is the pair bond, or club, society, composed of individuals that come together from different families. This type was much emphasized by the 19th-century English philosopher Herbert Spencer because it corresponded to his social Darwinist ideas. The social Dar-

Douglas P. Wilson

winist does not like to admit that a weak son can win out if he has powerful parents; but recent work with rhesus monkeys shows clearly that the son of a high-ranking mother tends to be protected by his mother and hence gets to the top of the hierarchy even if he himself is a weakling. Parental societies are very common.

PARENTAL SOCIETIES

Parental societies are found at all levels, from the cell to the monkey troupe. All animals provide for their young in some way. In every animal there is a period when the young is part of the parent and receives materials from the parent. Later, the young may partly or completely separate from the parent; in some animals, the more or

less separate young is then helped by the parent, or helps it.

Parental behaviour among simple organisms. Even some of the simplest organisms show colonial aggregations of the parental type. Some viruses form inclusion bodies in the cells they attack; these bodies are thought to be colonies of daughter viral strands. Other viruses form ordered arrays.

Bacterial colonies

Bacteria, only a few steps up the evolutionary scale beyond viruses, also show parent–young colonies. Diplococci, which can cause pneumonia, are dot-shaped bacteria that have two daughter cells in each group. Streptococci form chains, and staphylococci arrange themselves in grapelike clusters. In all of these, and in a large number of other colonial bacteria, the offspring that are produced by a dividing parent stay together for some length of time.

Protozoa, a few steps beyond bacteria, also show parental sociality. Many reproduce by simple division and hence give the daughters help only before the split. Under difficult conditions, protozoans commonly form a protec-

tive "cyst" and divide within it. In such divided cysts 2, 4, 8, 16, 32, or even more daughter cells may associate until the cyst "hatches."

Some protozoans form definite colonies in addition to or in place of cysts. Volvox and many other slow-moving or sedentary colonial protozoans show differentiation or division of labour between cells of a colony. In Volvox, the forward cells have large eyespots and a few rear cells take care of reproduction (Figure 3, top).

It is almost certain that sponges evolved from colonial flagellate protozoans. Sponges are integrated networks of cells, some of them amoeboid (amorphous) and some flagellate. It has been shown that if a sponge is strained through cloth so that the cells are separated, they will reunite and form new sponges so long as a flagellate collar cell can rejoin an amoeboid cell. The sponge is thus on the border between colonial organization and integrated multicellular organization (Figure 2, top). One advantage of integrated multicellular organization, with different types of cells performing different functions, was probably that the sponges could become much larger than the largest multinucleate or even colonial protozoans and thus could capture these protozoans. This type of organization also provides strength: some cells can hold on in swift currents, while some can secrete skeletons and others concentrate on food getting. Thus cooperation gave sponges and similar multicellular animals an advantage in competition with even the largest and most aggressive single-celled animals.

Sponges and coelenterates

The colonial organization of cells into protozoan colonies or into multicellular animals will be referred to below as the "colonial-1" stage (Figure 3, top), in contrast to the colonial organization of attached multicellular animals—the "colonial-2" stage. The colonial-2 stage is well developed in successful aquatic animals just above the sponges; the coelenterates (hydroids, jellyfishes or medusae, sea anemones). Coral reefs bear witness to the success of colonial-2 growth in other coelenterates (Figure 3, bottom). Many different types of free-swimming colonies, such as the dangerous fish-killing Portuguese man-of-war (*Physalia*), exhibit huge complexity on the colonial plan (Figure 2, bottom). In corals and other colonies, the original individual is linked to its offspring in a network. Food material and chemicals are often exchanged between individuals over the tubes of this network. Often the different individuals in this network show division of labour. Sometimes, as in *Obelia*, there are only reproductive and feeding individuals. In *Physalia*, there are swimming individuals, stinging ones, and many others, including one that serves as a gas-filled float. The interdependence and communication in such a colony is so extensive that the colony seems almost to be an individual and is sometimes called a superorganism.

Despite the great success of sponges and coelenterates, the main line of evolution goes onward through colonial-1 animals. The link was probably wormlike animals somewhat like present-day flatworms. Most flatworms and higher worms show little association between parents and young.

From flatworms to insects. The main line of evolution leading from flatworms to insects shows little parent–young cooperation or colonial development. The entoproct Bryozoa, or moss animals, form treelike colonies like those of corals and thus show type-2 coloniality; but it is not certain whether the Bryozoa actually belong to the line leading to insects. A few wheel worms or rotifers, such as the free-floating *Conochilus volvox*, form colonies. A few annelid worms, such as sybellid fan worms, bud off chains of individuals in a manner like the flatworm *Catenula*. This is a common method of breeding in some annelids; the special rear "worm," or "epitoke," breaks off and swims to the surface where it releases sperm or eggs and dies, often in huge swarms of epitokes as in the Samoan palolo worm (*Eunice viridis*).

Typically such worms as roundworms and earthworms strew their eggs about or attach them to something as soon as they are fertilized or brood the eggs only briefly. A few nemertine worms are viviparous—i.e., they produce live young. The annelid worm *Ctenodrilus* is said to

Figure 3: (Top) Glass model of protozoan colony Voivox (magnified about 75 X). (Bottom) Colony of coral animals *Astrangia danae* magnified about 3 X.

be truly viviparous, the nutrition of young coming via maternal blood vessels. Most mollusks take little care of their young. One *chiton*, *Callistochiton viviparus*, gives birth to young that have undergone development in the ovary. In a few bivalves such as the European oyster (*Ostrea edulis*), the eggs develop in the gill filaments. Most squids release single eggs or chains of eggs, but some members of the octopus group stay near their eggs and remove debris from them. The paper nautilus, *Argonauta*, forms a paper nautilus shell and the mother takes care of her eggs in it. At times the male hides in the shell.

Peripatus and its relatives, the onychophorans, are intermediate between annelid worms and arthropods and have well-developed parental systems. Some Australian forms lay eggs, but others keep the eggs inside until young hatch; many of these are viviparous, giving the young secretions from the uterus.

Not until one reaches such jointed-legged animals as crabs and insects (arthropods) does one find much extended association between young and their parents. A few scattered arthropods still have no parental care other than production of eggs. The female walkingstick casually drops eggs as she moves about. Many ostracods and copepods, and many of the edible shrimps, shed eggs into the ocean waters. Most arthropods, however, care for their young briefly.

**Parental
care
among
arthropods**

Scorpions are all viviparous or ovoviviparous (eggs developing in the mother), and many carry their young about. The female pseudoscorpion of the leaf litter often builds a little nest, and the young get nourishment from her in a belly pouch. The female solifugid, or sun scorpion, makes a burrow for her eggs and then brings prey to the young after they emerge from the burrow. The female whip scorpion attaches eggs to herself and carries them until the young go through several molts; she dies as soon as they leave. Spiders generally weave a silken case for eggs and young. The female wolf spider carries her young on her back. Some young spiders build a family or community web together. The harvestmen and mites mostly lay eggs in the environment, but some mites carry eggs until they hatch. Some ticks deposit egg masses, and hundreds of young seed ticks may stay together, to the dismay of a human when such a mass drops on him and starts to spread. Sea spiders (pycnogonids) are strange, for the male takes the egg mass from the female and cares for the eggs until they hatch, or slightly longer. Most crustaceans briefly brood their eggs, or eggs and young, often in special pouches on the body of the female.

Millipedes often form a nest; the young *Spirobolus* later eat the material of that nest. Some female millipedes coil about the eggs for several weeks. Many centipede females brood eggs, but others do not. In symphylans, often considered a link to insects, the female carries eggs in cheek pouches.

**Insect
families**

Social insects. Insects show the greatest development of family structure among animals. Most so-called insect societies are, strictly speaking, families. Sometimes they are called colonies, but the individuals are not directly attached to each other as in the "colonies-1" of protozoa and multicellular animals or the "colonies-2" of corals. They might be called "colonies-3" because they are "attached" by chemicals as well as by social behaviour. The young stay with both parents or with the mother and form social organizations of high complexity. Social behaviour of this type is known among the thrips (Thysanoptera), Zoraptera, book lice (Psocoptera), web spinners (Embiopoda), termites (Isoptera), and roaches (Blattoidea) of the more primitive insects, and in some groups of the higher insects—the aphids and lace bugs of the Heteroptera, and especially, in the ants, bees, and wasps of the Hymenoptera. Some of these groups bear little resemblance to the families of vertebrates. A critical observer might say of insect societies that the parents enslave their first children or their sisters, frequently with "drugs," and thereby ensure better care of their later ones.

Societies of lower insects are simple. The female (or male in the case of mole crickets, *Gryllotalpa*), works hard to build a nest and to protect its first offspring. The

Figure 4: Bivouac of army ants (*Eciton*) between trees, which are about 14 inches apart. Inset is detail of bivouac magnified slightly larger than life.

Carl W. Rettenmeyer

offspring may reciprocate by helping to build a colony web under a stone or leaf or under tree bark, as in the web spinners and book lice. In wood roaches, such as *Cryptocercus punctulatus* of the southeastern United States, the young must stay with the adults, because all have symbiotic protozoans inside them that digest wood cellulose: at every molt the roach loses all its protozoa (because the linings of the fore- and hindgut are also molted) and must eat the feces of another roach or die.

In termites, the male and female lose their wings after a dispersal flight and dig a cavity in which they raise the first young. These young have their sexual growth inhibited by chemical secretions from their parents; instead of reproducing themselves, they work hard to make more chambers and get food for the next young. They often get fecal material from each other full of symbiotic protozoa to digest wood and also use the fecal material to build houses. The more advanced forms chew up wood and grow fungus on it. The young have a division of labour, some being workers and some soldiers; there are also nasutes, which have snoutlike processes that eject a sticky substance used in warfare to protect the colony. Such colonies may become huge and build houses higher than a man's head. The first parents are not so much the leaders of the colony as egg-producing machines cared for by their first offspring. Eventually some of the slaves achieve their freedom when the chemical secretion from their parents runs short; they develop wings, fly off, and start new worlds of their own.

Some beetles show behaviour approaching the social. A British rove beetle defends its eggs and young against intruders. Dung beetles dig burrows and store dung for their larvae. The male and female burying beetle cooperate to dig away the soil underneath small dead animals; the female feeds her larvae on regurgitated food. Bark and ambrosia beetles dig tunnels in wood and grow fungal spores; the female feeds her young on pieces of fungus while the male keeps away other males.

Some moths and butterflies associate in the caterpillar stage. Social caterpillars, such as the tent caterpillars (*Lasiocampidae*) and the larvae of small ermine moths

(*Yponomruta padella*), make webs similar to those of colonial spiders but use them only to hide in rather than to catch prey.

Bees and wasps

The origins of social behaviour can be seen in bees and wasps. There are solitary bees and wasps, all of which prepare a protected place for the egg and later the larva. Some "gall wasps"—as in "gall aphids" and some mites—sting plants, which then provide fleshy galls for the young larvae. The parent often provides food for the larva. The tarantula-killer wasp will sting a huge spider and store it in a drugged state by the egg. The "parasitoid" hymenopterans lay an egg on or in a wandering caterpillar to parasitize it. Some bees or wasps return to put a new spider or other food source into the nest after the first food has been eaten, a process called progressive provisioning. From this it is only a short step to having a single female care for several young in a compound nest, as in *Polistes* wasps, and another short step to having sisters or young stay around the nest and help care for the later young. In some insects, such as wasps of the genus *Polistes*, this is done by having the first or strongest female harass or dominate the later or weaker ones. Their sexual growth is repressed and they cannot lay eggs as long as the dominant female is there. Chemical dominance, or drugging, is the next step; in the more social bees and ants, chemicals produced by the queen are actually needed by the workers, and exchange of food and drugs (trophallaxis) is regular.

Polymorphism and behaviour

Division of labour often occurs in ant and bee societies. Ants are often polymorphic, with small individuals working in the nest and medium or medium-large ones working outside; huge-headed individuals become protective soldiers or even use their heads as plugs to stop up the nest entrance to all besides members of the colony. Honeybees have division of labour by age—the youngest bees feeding larvae, older ones building the comb, and still older ones flying out for nectar and pollen and bee glue. Many of the polymorphic differences are apparently determined by food, as when the new queen bee gets royal jelly regularly, while the smaller workers get royal jelly for only a few days. Other differences are genetic, as in the case of the male ant or bee, which comes from an unfertilized egg.

These family societies of insects are diverse and successful. Termites and ants are among the most common tropical insects, bees and wasps among the common subtropical and temperate ones. The houses of termites—earth castles with shingled construction to shed rain and porous outer layers to control carbon dioxide and humidity—are equalled in their intricacy only by those of man. The honeybees communicate with chemicals and dances to tell each other the distance and direction of flowers.

The ferocious defense of the nest by wasps and hornets avails them little, however, against the onslaughts of marauding hordes of army ants (tribe *Ecitonini*) in the tropical forests of the Western Hemisphere, and of hordes of driver ants (tribe *Dorylini*) in Africa. The army ants (see Figure 4) do not eat trees or people, as early stories would have it, but they tear apart arthropods. The driver ants, which have scissor-like mandibles that cut flesh, can tear apart humans if given the chance. These are probably the largest of the familial or "colonial-3" societies. It has been estimated that a large colony of the army ant *Eciton burchelli* includes 1,500,000 individuals, and the colonies of the driver ant *Anomma wilverthi* probably contain up to 22,000,000.

The leaf-cutter ants of the Western Hemisphere live in huge underground colonies. They, along with termites and a few beetles and moths, are agriculturalists. The leaf-cutter ants cut strips of green leaves and make a paste of them in which they grow fungus. Their underground chambers may reach several yards. It is hard to realize that such huge colonies are extended families.

From bryozoans to humans. In the other great line of evolution, which leads to man, the social use of the family has taken a different tack. Where the first line began with actively moving, wormlike individuals and ended with drugged, tiny individuals in huge families, the line that leads to humans begins with colonial, attached animals of

the general appearance of corals but of the structure of worms and ends with social animals in which families play an important but relatively small role.

Some early wormlike animals evidently settled down on the floors of ancient oceans, and to protect themselves had to develop shells (as in the lamp shells or brachiopods) or colonies with specialized defensive members (as in the moss animals or bryozoans). Brachiopods are solitary and shed their gametes into the seawater. Moss animals form colonies in which there is direct or partially impeded exchange of body fluids. Their societies show more division of labour than do termite colonies. There are feeding individuals, reproductive individuals, special whiplike individuals (vibracula), and bird-head individuals (avicularia) that hit or bite other animals settling on the colony.

Wormlike animals

It seems incongruous to suggest that active vertebrates developed from tiny wormlike animals living sedentary and colonial lives, but the future does not always belong to the strongest, biggest, or fastest animals of a given age. The moss animals, with their tiny encrustations or filamentous colonies, are internally much advanced over the more abundant corals.

One major side branch of this line of descent does lead to the nonsocial echinoderms—starfish, brittle stars, sea cucumbers. Few of these animals take care of their offspring, and even their gametes tend to be shed broadcast into the seawater. Some sea stars, brittle stars, and sea urchins of the Arctic and Antarctic brood their eggs. In some, as the brittle star *Ampkipholis squamata*, the young are attached to the mother and get nourishment from her. Some sea cucumbers, equally divided among cold-water and warm-water forms, brood their eggs externally or, as in *Thyone rubra* of California, inside. A few sea lilies or crinoids brood eggs or young.

There is also little parental care in several of the wormlike side branches of this line of descent. Pogonophoran worms, which even lack a digestive tract, sometimes brood eggs in their tubes in the ocean mud. Arrowworms (*Chaetognatha*) occasionally carry eggs about, but most release them into the ocean waters where they swim. The arrowworms are successful predators, but the line to vertebrates leads for the most part through the colonial or sedentary filter feeders—the pterobranchs, the acorn worms, and the tunicates or sea squirts.

The pterobranchs are sedentary, colonial wormlike animals, with a central stalk in some colonies but no direct connection in others. The individuals of the latter wander in and out of the colony tubes. Pterobranchs are related to burrowing solitary acorn worms, the hemichordates. All these animals release their eggs and sperm rather casually into the ocean.

The sea squirts (*Tunicata*) are mostly soft spongelike masses that cling to rocks or pilings in the sea. Most shed eggs into the sea, but some brood eggs or young and release them partly grown. The young are either free-swimming tadpole-like animals or are budded from the adult to form a colony.

The line of descent up to this point is, curiously enough, closely associated with colonial animals, while the line that led to insects produced rather few colonial animals. It has been suggested that advances made during periods of coloniality may produce better free-living individuals and vice versa; the inference is that drastic new changes in a colonial animal can be perpetuated because of feeding by the rest of the colony and later be incorporated in a viable free-living combination.

Some biologists, including Darwin (with his vested interest in competition), have suggested that the sea squirts and all the other colonial animals are unimportant sidelines in evolution. They suggest that the mainline passed through nonsocial, competitive, free-living, wormlike and, later, tadpole-like animals. Wormlike animals led to animals like arrowworms, to the tunicate tadpole, and then to fishlike animals such as *Amphioxus*.

Certainly the next steps were through free-swimming animals with relatively little family life—cephalochordates (lancets) and the jawless fishes. Modern lampreys make a nest for external fertilization, but the hatching

larvae make their own way to live as filter feeders in the muddy debris of stream bottoms.

Fish and
amphibians

Many jawed fishes take little care of their eggs or young, but there are some major exceptions. Many sharks, skates, and rays give birth to live young, and some have placentas to nourish them. Some fishes make nests; the Siamese fighting fish (*Betta splendens*) and others make bubble nests at the surface, while sticklebacks (*Eucalia*) and a mormyrid fish (*Gymnarchus*) make weed nests, and such fishes as salmon dig spawning nests in the bottoms of streams. Stickleback males fan their eggs until the young hatch, making sure there is enough oxygen. Other fish, such as the black-chinned mouthbreeder, fan their eggs by keeping them in their mouths. Other mouth-breeder fish periodically spit out the young fry and take them back in until the young are feeding well. Mouth-breeders include a freshwater catfish (*Loricaria typus*) and some marine catfishes (*Galeichthys felis* and its relatives), plus cardinal fishes (Apogonidae). There are several fish of a dozen different taxonomic assemblages that bear their young alive, among them the surf perches (Embiotocidae) and the mollies (Poeciliidae). Some have a placenta-like arrangement to nourish the young until birth.

While care of young by the male is frequent in fishes, it is rare among invertebrates (where the sea spiders are the only major example). Care by the males frees the female to obtain more food and hence raise more young per unit of time, which may be necessary in the event that food is difficult to find.

Male care of the young is well developed in lungfishes, predecessors of land vertebrates. Most salamanders and frogs, on the other hand, are not very good parents. The male Surinam toad (*Pipa pipa*) presses the eggs into the back of the female, and the young of *Rhinoderma darwini* go through development in the vocal pouch of the male. The live-bearing frog (*Nectopkrynoides*) of Africa, in which the young hatch within the mother and remain with her for protection, is another exception to the general rule that amphibians release their eggs and care for them little.

Higher
vertebrates

Among reptiles the best parental care is in alligators and some crocodiles, where the female makes a mound of dead leaves or sand and stays around to protect the eggs, to release them when they hatch, and to guard the young for perhaps as long as a year.

Birds are well-known for parental care. Most build nests, incubate eggs, and care for young. The males com-

monly help the females in this. Often young birds stay with their parents a year or more, and numerous examples are known of the young of one brood helping to feed the young of later broods. Often the young help the parents defend a "group territory," as among Australian bell magpies (*Cracticus*) and Mexican jays (*Aphelocoma ultramarina*).

The most advanced parental society yet recorded among birds is that of the ocellated antbird, which follows swarms of army ants in order to capture insects they flush in the neotropical forests. This bird's young stay with their parents for several months, then go and find mates, but return to their parents periodically for several years. The young bird and its mate are accepted as part of the extended family; they are not chased away as often as are unrelated birds.

An even greater organization of parental care is found in mammals, except that the males seldom help care for the young. The young are usually nourished before birth by the placenta of the mother, except in the egg-laying duck-billed platypus, the spiny echidna, and in marsupials. The young of marsupials are born prematurely and grow in the pouch of the mother for long periods. All mammal young, even the platypus and spiny echidna, must lap or suck milk produced by the mammary glands of the mother. This ensures that there is a strong family association between mother and young (Figure 5).

Commonly, groups develop around a mother, and may be joined by other such groups and by males to form bands, troops, and herds. Troops of monkeys and apes are basically families or grouped families. These and wolf bands include males, which may help to raise young. The "extended families" of humans lead to tribes, states, and nations.

Nationalism as a force in human affairs is commonly related to mother and home and family, as well as to interlocking family relationships even more complex than those of ocellated antbirds or wolf societies.

SOCIETIES WITH SEXUAL BONDS

Nonparental social relationships fall into two categories, sexual bonds and nonsexual bonds. Normally, only the latter can involve members of two or more species. Sexual bonds lead in many animals to parental bonds, of course, but differ in that the bond is normally between offspring of different families. The reason for this is that the main advantage of sexual union is to combine the good genetic features of two different lines. Some young, of course, will have the bad features of both lines and will be eliminated—a wastage tolerated in nature as a necessary expense.

Most animals depend on elaborate behaviour patterns to bring the male and female and their gametes together at the right time, rather than using the seemingly more certain processes of asexual reproduction, virgin birth, hermaphroditic self-fertilization, or male parasitism. Many marine animals shed eggs and sperm into the water or into special nests but do so only when chemically stimulated by the presence of substances from the opposite sex. Others use their "internal clocks" to release gametes only at a certain time of day or year. Samoan palolo worms form special gonadal body sections by budding, then release them to swarm in huge numbers at the surface of the ocean on a schedule set by the moon. The grunion (*Leuresthes tenuis*), a small Pacific fish of the silversides family, is famous for its males and females meeting to fertilize eggs high on the beach at the highest tide each month and at the highest waves of that tide as well. The synchronization of male and female requires them to have an internal lunar clock, such as that known for the colour changes of fiddler crabs.

Courtship must basically ensure two things: that the correct male and female get together at the right time with as little loss as possible; and that the offspring have the best possible chance to survive. Ensuring these two things has led to elaborate courtship patterns in animals. Where different kinds of animals that look, smell, or feel alike coexist, each individual must be especially careful not to hybridize with the wrong species. Otherwise it will

The
functions
of
courtship

Irven DeVore

Figure 5. Mother olive baboon (*Papio anubis*) and young.

waste its eggs or sperm in a union that will produce no young, or young that are malformed or maladapted for the world into which they emerge. Animals often develop complicated odours, colours, or voices as means of identification. There are many species of fruit flies of the genus *Drosophila*, and to avoid mismatings, each species has its own pattern of waving the wings by the male. The sight and sound of the wrong pattern of waving is enough to cause a female fruit fly to flee. (For further information on this aspect, see REPRODUCTIVE BEHAVIOUR.)

Where there is only a limited breeding area or a patchy environment in which the good areas are restricted, strong male-female differences are advantageous. In these cases the males have to advertise, often with song, to help females locate good areas. Males of species whose courtship displays are performed in groups usually have to compete more directly with each other and thus tend to develop large size or striking colours, overpowering scents or voices, or other exaggerated features. Female domestic chickens, sage grouse, and baboons tend to copulate mainly with the lordliest and most dominant males. This is not so evident in other animals, in which the females tend to mate with the male holding the best territory. The dominant male is likely to be the oldest one, the one that has proved he can survive and hence is "fittest."

The success of the "supermasculine" or lordly males in a few species may be advantageous only to those males. A few lordly males often usurp the few suitable places to breed, as in male sea elephants (*Mirounga angustirostris*) on Pacific beaches and in male red-winged blackbirds in North American marshes. If the lordly male blackbirds are eliminated, however, other males come in and the females breed with them just as quickly.

The supermasculine males in these species, full of pomp and strutting, seldom care for their young. Baboon males, it is true, do at times stop fights between lesser animals and drive away leopards or other predators. But usually the female takes care of the young herself. It may even be an advantage if she is "ladylike" and unobtrusive, so that the lordly male may draw predators away from the young. Keeping the male away from the young may also allow the female and her young more food. If environments are limited in food, keeping excess males out of the breeding area clearly is an advantage.

Supermasculinity, as well as being correlated with female care of the young, is also associated with polygamy. The mating of several animals of one sex with a single individual of the other sex tends to be associated in birds and mammals with great differences between the sexes. Serial polygamy, or the mating of an animal of one sex with several of the other sex at different times, may also occur. Promiscuity, or the mating of each female with several males and each male with several females, tends in supermasculine animals to resemble serial polygamy. Monogamy, or the mating of each male with one female, tends to occur mainly in animals with little difference between the sexes.

Having many mates does not necessarily mean that an animal is more social than if it has only one mate. In most cases, the polygamous male spends much time driving away other males and little time courting his females. His females spend little time with him, because they are busy raising many young—with little care for each. Among African weaver birds (*Ploceus*), monogamous species of the forest have smaller clutches than do polygamous ones of the savanna.

The whole system of lordly males, ladylike females, polygamy or serial polygamy, and multiple young, tends to occur mainly in animals with restricted and undependable sources of food and other necessities. One investigator found that males of the long-billed marsh wren (*Cistothorus palustris*) in Washington, where their marshes varied greatly in quality, had several mates; females went to males with good territories and left neighbouring males, with poor territories, mateless. Another investigator found that in Georgia, where the marshes were everywhere about equal in food supply and nesting cover, the long-billed marsh wrens were usually monogamous. The

correlation suggested by many recent studies is this: sexual dimorphism and diethism (behavioral differences) arise in animals in which environmental opportunities are restricted due to undependability or local distribution.

NONFAMILIAL SOCIAL BONDS

Social behaviour also occurs among animals that are not necessarily related by parental or sexual bonds. A "flock" or "band" of animals may be formed of only one family in some cases, but often several families or individuals join together.

Spacing. As previously noted, social organization within a species may be shown not only by the presence of clumping or positive movement of individuals but also by even spacing resulting from negative movements away from each other. Sociality is shown more by the presence of a definite spacing than by nearness.

There is little evidence for social spacing in protozoans and simpler beings, such as viruses and bacteria. Most recorded groups of unicellular or lower animals are probably parental or sexual groups. There seem to be few social interactions among micro-organisms, but this apparent dearth of social behaviour may be an artifact introduced by the disturbance of observation.

Most colonies of sponges and coelenterates seem to be parental colonies or aggregations in favourable sites rather than nonfamilial societies. There is little information on nonfamilial social organization among colonial animals, even among those that can move, such as the colonies of Portuguese man-of-war or the planktonic rotifer or sea-squirt colonies. Most worms and their relatives are not known to react to each other or to form social structures of the "flock" type. Little is known about mollusk organization; but the fact that mollusks do not pile up on top of each other suggests that there are negative social reactions.

Barnacle larvae prefer to attach next to another member of their own species or on a place where one of their species has just been removed. They avoid settling on top of another member of their own species, even though they readily settle on a member of another species. They react in part to chemicals that are specific to their species. Barnacles, then, aggregate in colonies but within a colony space themselves out. If the multicellular animal is a colony-1, the coral colony a colony-2, and the bee society a colony-3, the barnacle society may be called a colony-4. Colonies-4, in which the interactions are between unrelated, unmated, and unattached individuals, are regular in arthropods. In many cases the colony-4 is not obvious or is problematical. Bees form colonies-3 and perhaps also colonies-4, for colonies of bees space themselves out in the environment and avoid getting too close to other active colonies; but there is no evidence that bee colonies avoid getting too far apart, although if they did then mating between bees from different colonies would become difficult.

Colonies-4 are known among other arthropods. Tube-dwelling amphipods form colonies but chase each other and avoid getting too close. They show the phenomenon of "personal space," or "individual distance," as surely as do swallows sitting on a wire, in which a new arrival settling will sometimes cause shifting outward by individuals on both sides. Individual distance or personal space is a space around each individual that can be penetrated by another individual without hostility only after certain overtures.

The amphipod colonies also show the phenomenon of territoriality. Territoriality differs from personal space in that a territory is centered on some object outside the body of the animal itself. The male bitterling (*Rhodeus sericeus*), a European fish that lays its eggs inside a freshwater clam, will chase male intruders away from his clam even if the clam gets up and moves several feet. The male house finch (*Carpodacus mexicanus*) of North America chases other males away from his female, wherever she moves. More often, however, the external reference for territory is a fixed plot of ground, a nest hole, or some immovable set of objects. The animal may chase out intruders or tolerate them in the territory, but in his

Absence of spacing among simpler forms

Territoriality

Super-masculinity

territory he is in charge. Work with bicoloured antbirds in Panamanian forests suggests that a territory may be defined as "an external referent in which one animal or group dominates others that become dominant elsewhere." A pair of bicoloured antbirds permits others on its territory, but as soon as the pair crosses a boundary line into another territory, it becomes subordinate to the pair of that territory.

Territoriality is known to exist among insects such as dragonflies and ants, some fish, a few frogs, some lizards, most birds, and many mammals. It probably exists, at least in chemical forms, in tube worms of a muddy beach or rocky shore, and perhaps even among sedentary protozoans.

Swarming. Personal space and territoriality are definite negative signs of coloniality-4, but there are also positive signs. Mutual repulsion is only part of sociality, for mutual attraction must also exist. Mutual attraction is found in many arthropods above the barnacles. Some of the best studied examples are the mating swarms of ants, flies, midges, and, especially, fireflies. Another example of mutual attraction is the migratory horde, of which the African migratory locust (*Schistocerca gregaria*) is the best studied example.

Communal displays

The synchronized communal displays of the fireflies of Thailand are among the most impressive exhibitions of the insect world. The gatherings of thousands of males on the mangroves of the coastal swamps have been described as a city of pulsating glitter, every male anticipating the flicker of his neighbours and flashing in unison with them. Communal mating displays of this type are common in birds such as manakins, sage grouse, ruffs, and birds of paradise, and are called lek displays. Presumably, the communal display enables females to find the males more easily. Seldom do bird leks approach the numbers or synchrony of a firefly lek in Thailand, but several male manakins sometimes cooperate in a synchronized cartwheel dance. It is difficult to explain why males competing with each other for mates should help one another, but the phenomenon has been well documented.

The legendary colonies-4 of the migratory locusts are far larger and more impressive than the migratory colonies-3 of the army and driver ants. When food is abundant, the locusts disperse widely and grow up in what is called the "solitaria" phase. As the locusts crowd and encounter each other, they begin to change colour and enter the "gregaria" phase, in which they look so different that they were once considered a separate species. The "gregaria" locusts behave differently too, for they are excitable and social. They begin to march over the ground as food supplies diminish. Finally they take wing in huge hordes and fly downwind to a low-pressure area where rains have recently fallen. Here they descend on crops and other vegetation, eating it to the ground before flying to the next low-pressure area. The extinct migratory hordes of passenger pigeons were apparently similar in their effects on vegetation.

Many other examples of flocks occur in higher animals, especially insects and vertebrates. Most show little internal structure. The migratory hordes of armyworms that devastated midwestern corn fields in the United States before the days of synthetic insecticides, the swarms of male and female palolo worms in the ocean, the feeding swarms of sharks, and the dense schools of herring, are all examples of flocks with little internal structure. The Austrian ethologist Konrad Lorenz calls them "anonymous flocks," because it matters little if individuals change places and bonds are seldom individualized. When the fish school turns, it is like an army platoon turning to the flank, for the former side fishes are now the leaders.

The mating choruses at frog ponds provide an example of an auditory lek. Some salamanders congregate to breed, generally by sight and by odour, in running streams. Snakes form winter dens in which there may be hundreds of individuals rolled up in balls.

Flocks, herds, and packs

Among birds, pigeons (Columbidae), starlings (*Sturnidae*), and various blackbirds (*Icteridae*) form dense flocks that wheel about in the sky or mill along the

ground during foraging, the rearmost flying ahead to become briefly the leaders. Shorebirds and gulls gather on mud flats or elsewhere to feed. Such birds as the brown creepers (*Certhia familiaris*) reduce the winter cold by clumping together at night. Flocks of geese are made of many families of geese. Many birds gather into huge roosts, containing thousands or even millions of individuals in the case of the red-winged blackbirds (*Agelaius phoeniceus*) of North America. Tricoloured blackbirds (*A. tricolor*) of California are even more colonial than redwing blackbirds when nesting, and by sheer force of numbers push into colonies of the more dominant redwings and displace them. The nesting colonies of queleas (*Quelea quelea*) in Africa contain millions of nests. There are many such colonies of birds, such as the phenomenal colonies of seabirds that are found on islands throughout the world.

Mammals often form herds or packs. Many herds are more structured than bird societies, simply because many mammal groups are combined families plus males. Huge migratory herds of wildebeest and zebra wander the African plains. Each herd of zebra includes many familial harems that are held together by individual males. The herd of Scottish red deer is a matriarchal group led by an old female and composed of her extended family plus other extended families like hers.

George Porter—National Audubon Society

Figure 6: A herd of American bison (*Bison bison*).

Hunting mammals often have even more structured groups. A male and female wolf (*Canis lupus*) and their offspring form a hunting pack that may fuse with another pack or split apart. African hunting dogs (*Lycaon pictus*) and hyenas (*Hyaena* and *Crocuta*) form similarly flexible hunting packs, which are said to be even more effective than lion groups at running down prey.

Primate troops are often as complex as societies of hunting mammals or more so. Superimposed on their parental and sexual bonds is a group organization based on the occupation of a given area. The troop may also accept animals from outside. The society of baboons (Figure 5), as studied on the plains of Kenya, is very highly organized. Around the edge of the troop as it moves are the subadult males, watching carefully for predators and snatching bites of food when they can. Inside, the playful groups of juveniles stay close to the central hierarchy, a cooperating group of two or three big males that keep the subadult males at the periphery. The males of the central hierarchy are replaced, as they get old and toothless, by brash young males moving in from the periphery. With the central hierarchy march the females and their infants, protected both by the big males and by the peripheral younger males. The society is integrated by mutual grooming sessions, in which the big males get most of the grooming, and by domination by the big males.

INTERSPECIFIC ASSOCIATIONS

Individual animal interactions. Associations of animals often include more than one species. These groups

may be called colonies-5 or colonies-0, since there is recent evidence that the nucleus and other parts of the cell were originally symbiotic viruses and bacteria. The most intimate form of interspecific association is that known as symbiosis, or mutualism, in which dissimilar organisms live together (see BIOTIC INTERACTIONS).

Multicellular animals often live on or beside other animals. Small fish live in the tentacles of some jellyfish, sea anemones, and even the Portuguese man-of-war, yet are able to evade or inactivate the stinging cells. Some hydroids and worms live on tubes of other worms or on the shells of other invertebrates. The tubes of worms and shrimp often harbour other worms or fish. At times, the animal will live only on one kind of shell and is found nowhere else. Paleontologists have found some evolutionary sequences in which such an animal first lived on rocks and shells of a wide variety of types, then developed larger forms that lived on one type of animal and probably got food from it.

Complex associations. Slave making is a kind of social relation that verges on parasitism. Certain kinds of ants raid colonies of other kinds of ants, carry off their young, and raise them as slaves. The slaves are perfectly socialized members of the colony and probably do not even realize that their social behaviour is misdirected. They exchange food and drugs with their captors as willingly as they would have with their own species, had they been reared by their own workers.

One of the most complex associations is that of animals around army and driver ants. In the huge colonies of army ants live dozens of other kinds of insects, millipedes, and mites. Some help clean debris below the nests; some have chemicals that allow them to fool the ant security guards and enter the colony. Mites, beetles, and others ride on the ants or march in their columns. Some may help the ants by cleaning them or by giving them chemicals they crave. Others are like wolves in the fold, eating the food of the ants or even their larvae. The swarms of ants are also waited upon by many kinds of flies and birds. The flies lay eggs on insects and spiders fleeing from the ants. The birds capture animals flushed by the ants. In the tropics of the Western Hemisphere, nearly 50 kinds of birds follow the army ants persistently and would probably die without them.

Some of these associations may not be social in any accepted sense of the word. Humans are not social with rats and fleas merely because they live with them. Some interspecific associations, however, are definitely social. These include the mixed flocks of antelope, zebra, and wildebeest on the African plains, for example, and mixed flocks of birds throughout the world.

One can travel for hours across the African plains or through a tropical forest scarcely seeing an animal and suddenly be surrounded by a herd or flock of many kinds of animals. Usually each animal eats a different kind or type of grass or fruit or insect, although sometimes there is overlap in the foods taken or ways of feeding. The flock moves along together, not spending much time at each concentrated food source. Often it includes parental groups (colonies-2 in the case of mothers carrying young, or colonies-3 after the young separate).

The fact that forest flocks are usually of several species rather than one probably reflects the fact that forests have more species of animals, and hence each species has less of a food supply and must not allow competitors of its own species about it, even its own offspring. In less-complex habitats, there are usually very few species, and the animals can tolerate their own young even though these are competitors. They may even use their young—to detect predators (in the case of baboons) or to build a "city" (in the case of bees and ants).

When a forest is destroyed and begins to grow back, the first animals that come in tend to be kinds that are solitary and very antagonistic or uncommunicative. Later, flocking animals become more common, although they still resist groups of outsiders. Finally, as the mature forest re-establishes itself, one finds mostly paired animals that do not keep their young with them. These paired animals tend to associate with pairs of other

species to form mixed flocks. Eventually, every animal links itself with every other in the system, forming what ecologists call a complex "food web," "ecosystem," or "web of life." It is gradually being recognized that such a web is socially cooperative as well as socially competitive. The ecosystem eventually approaches a stage of "colony-6," or what the French biologist and philosopher Teilhard de Chardin called the noosphere.

III. Dynamics of social behaviour

COSTS AND GAINS

Social behaviour among humans is often regarded as an end in itself, the expression of a basic drive that has no necessary purpose. Biologists doubt that any animal has social tendencies without some adaptive advantage.

The costs. Social behaviour and communication not only take an animal's substance and energy; they impede feeding, drinking, and other inputs necessary for life. The first cells that associated with other cells to form multicellular filaments lost the ability to absorb on the side by which they were attached. Perhaps the reason most multicellular filaments occur among animals that are attached to the ground or to some other surface is that such animals lose less proportionately than members of free-floating aggregations; attachment on one side to the ground already limits their input. Locomotion is impaired if animals must stay together. The single-celled ciliates could not readily have evolved into higher organisms, because dividing them into many joined cells would have slowed down these fast-moving predators. A speedy golden plover trying to stay with other shorebirds in a mixed flying group near shore constantly turns back to keep with them; it is impeded by its social tendency.

Social behaviour also attracts enemies. Groups of animals have epidemics, while solitary animals seldom do. Many disease-carrying parasites spread much more easily at times when animals are together. Some rabbit fleas are even adapted to the hormonal cycles of the rabbits, so that they reproduce at the times of year the rabbits are reproducing and hence are social.

Predators, like parasites, often have an easier time if animals are crowded together; the animals are often busy reacting to each other and the predator can sneak up without being observed. Their communicatory systems may even attract predators. Tuna prey specifically on fish in schools; a small hawk in tropical America (*Accipiter superciliosus*) mainly on mixed bird flocks.

Social behaviour increases the number of interactions between animals and thus the chances of conflict. The conflicts may be solved by fighting, by patterns of dominance and submission (peck orders), or by mutual avoidance. Mutual fighting and mutual avoidance have the same result—a partitioning of resources for which the animals are competing.

The gains. Against these disadvantages of being social, it is possible to set a number of clear advantages. They fall into six broad categories, corresponding to the six possible kinds of animal behaviour. By social behaviour animals gain: (1) food and other resources, (2) reproductive advantages, and (3) shelter and space. They are enabled to avoid (4) physical and other small hazards, (5) competitors, and (6) predators or other large dangers. The first and third of these gains are reactions to desirable things of small (1) and medium to large size (3) respectively; the fourth and sixth are reactions to undesirable things of these sizes.

Food. The value of being social in getting food is obvious in the case of hunting bands. Cooperative hunting has been found among wolves and African hunting dogs, hyenas, lions, killer whales, porpoises, cormorants, white pelicans, pairs of eagles and of ravens, tuna when chasing small fish, army ants, primitive and modern men, and many other animals. Animals that hunt cooperatively can trap, chase, and tear apart prey that would otherwise be too fast, strong, or large for them. In African hunting dogs the chase is run by the leader of the pack, but the rest keep the antelope or other prey from dodging left or right and also help fall on it when the leader catches it. Flocks of wattled starlings (*Creatophora ci-*

Associa-
tions in ant
colonies

Conflict
and its
avoidance

Eco-
systems

Coopera-
tive
hunting

nerea) fly after African migratory locusts and surround one group after another, eating every trapped locust from each group. In army ants, the individuals are bound to each other by chemical "trail substances" so that no individual gets far from the group; when one finds prey, it grabs it and emits an "alarm" chemical that causes nearby ants to grab, bite, and sting so that the prey is overwhelmed within seconds. They then tear the prey, usually insects or other arthropods, limb from limb and carry it back to the nest.

Interspecific groups of birds are sometimes food-getting societies. Drongos (*Dicrurus* species) of Africa flush much food, and other birds follow them to get it. Honeyguides (*Indicator* species) of Africa lead honey badgers or men to bee nests and eat wax after the mammals break open the nests for honey. Hawks have been known to follow railroad trains for the same reason, and hornbills and hawks follow monkeys. The birds, lizards, flies, and other animals that associate with army ants offer other examples of interspecific food-providing associations. One animal may steal food from another, as American widgeons (*Anas americana*) steal grass from redheads (*Aythya americana*).

In addition to hunting and flushing food cooperatively, animals sometimes lead others to food or teach them to use it. Parents, especially among mammals, often teach their young to hunt or lead them to food. Animals that must migrate or depend upon seasonally available resources often depend on others to show them what foods are good and where. Vultures and jackals flock to carcasses on the African plains. American robins (*Turdus migratorius*) in California have been observed learning to use certain berries after flocks of cedar waxwings (*Bombycilla cedrorum*) came through and started eating the berries. Tests with a tape recorder show that the recorded calls of some birds that follow army ants will attract unrelated kinds of birds that also follow ants. In the laboratory, some animals learn to push a lever for food by watching others get food that way and learn to avoid distasteful foods by watching others cough it up. In studies of Japanese monkeys (*Macaca fuscata*), the habit of washing potatoes before eating spread from the younger to older monkeys of a troupe. In Britain, a few titmice learned to open milk bottles and drink cream; the habit spread much too rapidly to be a genetic change. (Coverage of learned behaviour is found in LEARNING, ANIMAL.)

Mating behaviour

Reproduction. The reproductive advantages of social behaviour have mostly been discussed earlier. It was noted that sex is a way of combining desirable genes from different lines, genes that otherwise might slowly or never get together. In many lines of animals, parental behaviour is clearly useful in protecting or teaching the young. This normally requires the adult to have fewer young. The careful parent loses in time and energy and number of offspring but comes to prevail in evolution if it has more descendants than does a careless parent that lets its young die. The careless parent prevails if it can get more young out by caring for each one less; some parasites are careless parents because each of the young needs little care and a large number must be produced to get to an extremely distant host.

Shelter. Social behaviour is often used in habitat selection and shelter selection, even to the extent of making it possible for the animal to improve the environment it finds. Male birds that later will fight with each other over territorial boundaries gather first at areas where they hear another bird singing, rather than hunting for a more isolated (and probably unsuitable) place. Certain beetles that attack pines put out a scent that attracts other beetles; only as a result of concerted attack by all beetles can the protective pitch of the tree be reduced so that all may enter. Movement to a flock is a good way to find a patch of habitat or a shelter. It has been suggested that flocking increases the accuracy of migration, since the average direction taken by a flock is more correct than the individual directions taken by individual birds. Small flocks of European starlings returning to a California roost were less accurate in their direction than large flocks. Cooperative building of structures is well-known

in humans, prairie dogs, and rats (whose tunnel systems rival the catacombs in complexity), beavers, certain weaver finches, wasps, bees, termites, and many others; symbiotic use of structures occurs in many animals.

Hazards. Social behaviour can also help animals avoid small hazards. This includes avoiding heat or cold and wet or dry situations as well as preening or grooming to keep off dirt, parasites, and other small environmental hazards. A goose cleaving the air for its companions at the front of a V-shaped flock, a parent bird brooding its young or sheltering it from the sun, a group of creepers roosting together to help each other survive the cold winter night, a group of baboons grooming each other to pick off ticks, furnish other examples.

Competitors. Dangers from competition are avoided by agonistic behaviour. The five basic types of agonistic behaviour are aggressive display (threat), submissive display (appeasement), attack, avoidance, and fighting.

Agonistic behaviour

Social aggressive display is not common. Males of a troupe of howler monkeys all yell at a neighbouring troupe to make them keep their distance. Baboon males in the "central hierarchy" cooperate to keep aggressive young males from winning, backing each other up with threats. Social attack occurs in some birds and mammals that keep group territories and may lead to fighting if the other group attacks or threatens.

Highly social submissive display and escape also are not common. A baboon troupe may retreat as another moves in at a water hole. But even when a single animal retreats from a competitor it is a social act. Territoriality is certainly a system in which an animal defends its right to be dominant in part of its home range. The basic feature of territoriality, however, is not aggression in a certain area but submission outside that area. The common idea that strong animals survive and the weak do not is true only in the short run, for in a few generations all reproducing animals are equally strong. Strong animals will begin to lose if they keep on chasing others. An animal that keeps too large a territory will spend more time chasing away intruders than it will in eating or reproducing, unless it can get others to help it. Bees get help by drugging the nonreproductive members of their colony. Most animals limit themselves so that the territory of the most dominant animal or group of animals never exceeds about twice the size of the least dominant animal or group of animals of that species. Most often the young animal has a small territory but defends a larger one as he gains experience, then gradually loses it as he reaches old age.

Predators. The final reason for social behaviour, and one of the most important, is to avoid predators or other large dangers. Just as animals can sometimes overcome large prey by grouping to attack it, so they can sometimes overcome large predators by grouping to defend against them. Cooperative and spirited attacks upon predators occur in most animals that protect their young and are a regular phenomenon in gull and tern colonies, in baboon troupes, in bees and wasps, and many others. "Mobbing" is a similar phenomenon in which the attack is not carried all the way to the predator but so harasses it that it departs or at least is prevented from getting its prey. The massed effect of many mobbing birds is more intimidating to a predator than is mobbing by one or two birds.

Grouping and flocking

Grouping also helps against predators because a predator is distracted by the "confusion effect" of so many shapes, sounds, or smells. Human hunters know that one cannot shoot a duck out of a flock by aiming at the flock; the shot is more likely to pass between the birds than if the hunter aims at one of them. Similarly, hawks have been seen to dive through a flock and miss every bird. Successful predators either dive to break up a flock and then grab a separate animal or pick off an outlying one at the start. Butterflies on tropical trails also swirl up in a confusion effect from a mud puddle. The phenomenon is caused by the difficulty the eye or other sense organ has in analyzing or following very complex motions that cross each other.

Another advantage of the group or flock is that many eyes can see a predator more quickly than can one pair of eyes. Ornithologists have found that social birds are ner-

vous outside of a flock and must spend too much time watching to be able to forage effectively. Certain species that forage by peering in dense vegetation are especially in danger and must associate with other species that look about more actively in open foliage. The peering species often are good at yelling and perhaps help the other birds by scaring or disturbing predators. This suggests that a social organization may have many reasons for being.

DEVELOPMENT FACTORS

Instinct
and
learning

Behaviour changes somewhat in the course of evolution. Biologists commonly call the genetic determinants of behaviour in a line of organisms "instinct." Every behaviour pattern, however, can be changed somewhat by the individual animal in the course of its experience, a process called "learning." The old view that instinct and learning are two different types of behaviour is seldom accepted now, even though some kinds of behaviour certainly have little learning superimposed.

The real question is how social behaviour develops. It is possible to breed animals for aggressiveness or nonaggressiveness, and by further crosses to study the inheritance of behaviour. Mouse strains that show different degrees of aggressiveness are easy to develop. Biochemical imbalances also affect behaviour: in many animals an over-supply of male hormone causes aggressive and anti-social behaviour. Pituitary hormones, especially luteinizing hormone, have the same effect in other animals, such as starlings.

Stimulation of the brain or removal of part of it gives evidence of a structural basis for behaviour; stimulation of the hypothalamus produces many social behaviour patterns, such as sexual activity and aggression. There are even "pleasure centres" that the animal will stimulate on its own, if given a bar to press that sends a shock to its head. Sexual centres are one of the "pleasure centres" that rats are fond of stimulating.

Another approach is to isolate the animal and see if it still develops a particular behaviour. Young pigeons reared in cardboard tubes will fly soon after release, showing that practice is not necessary. Some young songbirds reared in isolation develop normal songs, and many develop normal calls. Many songbirds must listen to songs of their own species at a particular age, however, to learn them.

An animal may develop social behaviour while still in the egg or mother. Baby ducklings peep to the calling mother from the egg. An animal may develop social behaviour soon after it emerges or at some critical period later. A young duckling follows the first object it sees, be it a duck or a duckling or the hand of the experimenter. Young birds, ants, and some mammals "imprint" on the first object they see to such an extent that they may court it or show agonistic behaviour to it later. A mother goat given a lamb in exchange for her kid soon after birth will adopt the lamb and drive away her own kid when it is returned to her.

Later learning also influences social behaviour. Mice that experience defeat learn to run rather than fight; the opposite holds for mice that win. Most animals, however, start at the bottom of a peck order and take defeats in stride, later becoming the dominant animals if they manage to survive. It has been found that association with other young monkeys helps a monkey to behave properly in sexual activity later, although many learn to copulate properly without this opportunity.

THE EVOLUTION OF SOCIALITY

Social
behaviour
as an
adaptation

The fact that bees and ants form complex societies, more complex in some ways than those of apes, shows that social behaviour occurs in small animals as well as in large ones, in animals with small brains or large ones, and in both major lines of evolution. If bacteria can be rather social and humans rather solitary, there is no reason to suppose sociality is more advanced in evolution than is solitary life.

Social behaviour is instead an adaptation to certain environmental opportunities. The evolution of sociality can be glimpsed in the line that leads from the earwig

through wood-eating cockroaches to termites, or in the line from solitary bees to social ones. Communication systems also evolve, as may be seen in the line leading from dully coloured monogamous crows to brightly coloured birds of paradise and plain bowerbirds in New Guinea. In this system, the male bird of paradise is brightly coloured to attract the crowlike female. The bright male also attracts predators. The bowerbirds have lost the bright plumage; instead they make elaborate maypoles or bowers decorated with flowers to attract females. One bowerbird even paints the walls of his bower, using a mashed berry or a straw stained in berry juice. These bowerbirds have become safely coloured, for they have replaced bright plumage with bright objects.

The ecological maturity and regularity of a habitat seem to determine to some extent how social its inhabitants will be. Among African weaver finches, the forest-living ones are solitary and monogamous; birds of savannas and marshes flock and nest polygamously; and those of very dry habitats tend to be relatively solitary. The same phenomenon has been noted for cats; leopards of the forest and cheetahs of very open country tend to be less social than lions of open savanna areas. Antelope, deer, monkeys, and apes show similar differences. The general rule is that, as an environment grows up from the level of bare ground to that of savanna and finally forest, the solitary animals are replaced by social ones and then by solitary ones again. In the forest, however, one-species societies decline in importance and societies of several species form. The same things happen as a marine community goes from bare rock to the complexity of a coral reef.

Societies of the same species, therefore, seem adapted for intermediate habitats that are in transition between bare ground and forest. It may be that the reason for this is that most intermediate habitats are unstable, likely to be limited in space or time.

ALLEE, *The Social Life of Animals* (1938), a readable classic, emphasizing peck order and social facilitation at the expense of other aspects of social behaviour; ROBERT ADREY, *The Territorial Imperative* (1966), a somewhat tendentious discussion of animal territories by a playwright; R.D. BARNES, *Invertebrate Zoology*, 2nd ed. (1968); J.T. BONNER, *Cells and Societies* (1955), a readable account of social life from the howler monkeys down to the cell; T.D. BROCK, *Biology of Microorganisms* (1970); J.H. CROOK (ed.), *Social Behaviour in Birds and Mammals* (1970), several excellent technical summaries of modern research in social behaviour, including a discussion of habitat and society; FRANK FRASER DARLING, *A Herd of Red Deer* (1937), one of the earliest field studies of a wild society, establishing that deer are matriarchal; IRVEN DEVORE (ed.), *Primate Behavior* (1965), the best collection of relatively nontechnical articles on the behaviour of free-living monkeys and apes; S.J. DIMOND, *The Social Behaviour of Animals* (1970), a discussion of recent experiments on learning of social behaviour in domestic and caged animals; JOHN F. EISENBERG, "The Social Organizations of Mammals," *Handb. Zool.* 10:1-92 (1965), a review of mammalian social behaviour that shows it derives mostly from maternal societies; PEGGY E. ELLIS (ed.), *Social Organization of Animal Communities* (1965), a useful set of rather technical articles, concentrating on social behaviour in insects; WILLIAM ETKIN (ed.), *Social Behaviour and Organization Among Vertebrates* (1964), a set of moderately technical articles on social behaviour; E.S.E. HAFEZ (ed.), *The Behaviour of Domestic Animals* (1969), a set of technical articles on animals such as cats, dogs, sheep, and goats, with an excellent discussion of physiology; S. MARK HENRY (ed.), *Symbiosis*, 2 vol. (1966-67), informative summaries of a few of the many symbioses known to occur, from viruses to man; DAVID LACK, *Ecological Adaptations for Breeding in Birds* (1968), a demonstration that the social behaviour of nesting birds depends on their habitats and their foraging; MARTIN LINDAUER, *Communication Among Social Bees* (1961), a fascinating account of evolution in and experiments on social bees; KONRAD LORENZ, *Das sogenannte Böse* (1963; Eng. trans., *On Aggression*, 1966), a discussion by a founder of ethology who maintains that aggression is needed for social bonds, but omits sexual and parental ties; LYNN MARGULIS, *Origin of Eukaryotic Cells* (1970), a discussion of the origin of cells by symbiosis; DESMOND MORRIS, *The Naked Ape* (1967), a witty and somewhat sensationalized examination of social behaviour by an experienced ethologist; HARRIET L. RHEINGOLD (ed.), *Maternal Behaviour in Mammals* (1963), a set of moderately technical articles on

the mother-infant relationship in mammals; JOHN PAUL SCOTT and JOHN L. FULLER, *Genetics and the Social Behaviour of the Dog* (1965), a scientific analysis of heredity and learning that shows how they interact; EDWARD C. SIMMEL, RONALD A. HOPPE, and G. ALEXANDER MILTON (eds.), *Social Facilitation and Imitative Behaviour* (1968), scientific articles on imitative learning in animals and men; NIKO TINBERGEN, *Social Behaviour in Animals, with Special Reference to Vertebrates* (1953), a popular account by a founder of ethology, concentrating on birds, fish, and insects; E.O. WILSON, *The Insect Societies* (1971), one of the best surveys of the behaviour of social insects, but omits locusts; V.C. WYNNE-EDWARDS, *Animal Dispersion in Relation to Social Behaviour* (1962), a polemic reviewing much of social behaviour to support the view that animals practice birth control by means of social behaviour—but control is usually by agonistic reactions.

(E.O.W.)

Social Class and Mobility

The term class began to be widely used in the early 19th century, first replacing such other terms as rank and order as descriptions of the major hierarchical groupings in society. The usage reflected changes in the structure of western European societies after the industrial and political revolutions of the 18th century. The feudal distinctions of rank were declining in importance, and the new social groups that were developing—the commercial and industrial capitalists and the urban working class in the new factories—were defined mainly in economic terms, by the ownership of capital, on one side, or dependence upon wages, on the other. This phenomenon was recognized by many writers in the 18th century, even though the older terminology continued to be used. Early examples of the use of the concept are found in the Scottish historian and social philosopher John Millar's *The Origin of the Distinction of Ranks* (1771); and, in North America, where a new type of society without feudal antecedents was being established, in *The Federalist*, in which the significance of the unequal distribution of property in creating different classes and producing antagonistic political interests was emphasized by one of the founding fathers, James Madison. As Marx later observed:

no credit is due to me for discovering the existence of classes in modern society, nor yet the struggle between them. Long before me bourgeois historians had described the historical development of this struggle of the classes and bourgeois economists the economic anatomy of the classes. (From letter to J. Weydemeyer, March 5, 1852.)

THE CONCEPT OF CLASS

Problems of definition. Although the economic basis of classes has been generally recognized, many disagreements have arisen as a result of attempts to define social class. First, there has been confusion about how widely the concept should be employed. It was used initially to denote the social groups that emerged in postfeudal societies, but it was then applied to the divisions in a wide range of societies. Madison, for example, said:

Those who hold property and those who are without property have ever formed distinct interests in society. Those who are creditors, and those who are debtors, fall under a like discrimination. A landed interest, a manufacturing interest, grow up of necessity in civilized nations, and divide them into different classes, actuated by different sentiments and views.

Similarly, Marx and Engels in *The Communist Manifesto* spoke of "freeman and slave, patrician and plebeian, lord and serf, guild master and journeyman" as being engaged in class struggles and regarded the distinctive feature of modern societies as being merely that the class antagonisms have been simplified, so that society is more and more splitting up into "two great classes directly facing each other: bourgeoisie and proletariat." In an unfinished chapter on social classes in *Das Kapital*, it seems to have been Marx's intention to confine the use of the term class to the "three great classes of modern society": wage labourers, capitalists, and landowners.

A major problem is that of choosing between a definition of class that would make it possible to apply the concept to all forms of society—ancient city-states, early empires, caste society, and feudal society, as well as to

modern capitalist societies—while taking into account the specific characteristics of each of these forms; and a definition that would confine the concept to the social divisions in modern societies, treating other forms of society as having quite different kinds of stratification, arising from other factors besides the ownership of property. It is difficult, for example, to apply the concept of class to the traditional Indian caste system, which seems to depend, to a large extent, upon occupational differentiation and religious distinctions and which also seems to result in a fragmentation of society that is an obstacle to the formation of broad social classes (see CASTE SYSTEMS).

Class and related concepts. Even when the term class is applied to modern societies differences of view arise about its scope and meaning. Some of these differences result from disagreements concerning the relations between classes and the influence of classes in political life, and they will be more fully considered below. There are also problems, however, in distinguishing classes in a precise way from elites, status groups, or interest groups. The concept of elite, for example, was elaborated by the Italian sociologists Vilfredo Pareto and Gaetano Mosca as an alternative to the Marxist concept of the ruling class, and, although it has not been used consistently in this way, it does still overlap, to some extent, with the notion of class. Among recent writers, an American, C. Wright Mills, used the term power elite instead of ruling class (1956), in order to avoid the assumption that political power is always based upon property ownership; others have made a careful distinction between elites and classes and have been concerned to examine the nature of the connection between them.

The distinction between classes and status groups was made most clearly by the German sociologist Max Weber, who regarded the former as being based upon economic interests, while the latter were constituted by evaluations of the honour or prestige of an occupation, cultural position, or family descent. But this distinction also has not always been observed, with the result that individuals having roughly the same social prestige, such as those in a particular category of occupations, have sometimes been regarded as forming a class (see SOCIAL DIFFERENTIATION AND STRATIFICATION).

It is also necessary to differentiate between social classes and interest groups (see SPECIAL-INTEREST GROUPS), even though classes themselves may be regarded as being, in a very broad sense, interest groups. In modern societies, particularly, interest groups are numerous. They include many occupational associations, as well as cultural, recreational, regional, and other groups that pursue their special interests by a variety of means. The number of social classes is, in the view of all writers on the subject, much more limited, and classes may be seen as pursuing the more general economic and political interests of their members and as being involved, to some extent, in shaping and changing the character of society as a whole.

Another major disagreement in the definition of social class exists between those who regard classes as real social groups, possessing a class consciousness and exhibiting a distinctive culture and style of life, and those who treat "class" as an analytical construct, useful for some purposes in distinguishing categories of individuals on the basis of their income, education, or occupation. The first kind of definition is to be found in Marxist theory, which is concerned particularly with the historical development of classes as social groups having a determining influence upon the course of social events. Marx himself sketched a historical account of the rise of the bourgeoisie and, subsequently, of the proletariat (see especially, *The Poverty of Philosophy*, 1847) and made a distinction between the "class in itself" (that is, a collection of individuals who were placed in similar economic conditions) and the "class for itself" (that is, a more or less organized group, pursuing in a conscious fashion definite economic and political ends). Among later Marxist writers, the Hungarian philosopher and critic György Lukács, in several essays collected in *History and Class Consciousness* (1923), emphasized the importance of class consciousness, while introducing a new element in his account of

Classes
and
elites

Early
use
of the
concept
of class

Marx's
two
concepts
of class

the role of revolutionary intellectuals in the formation of such a consciousness. It is, however, not only in Marxist theory that the idea of class, in Marx's latter sense, has prevailed, since non-Marxist sociologists have made studies of working class, middle class, and upper class as distinct communities; and Weber regarded class as one of the most important bases for communal action.

The concept of class as a collection of individuals sharing similar economic circumstances has been used widely in censuses and in studies of social mobility. Thus, the Office of Population Censuses and Surveys in Britain makes use of five broad categories of social class, based on an occupational classification; and studies of social mobility, examined below, have generally employed categories formed in a similar way by grouping together occupations that are regarded as being at approximately the same level in the social hierarchy. Some other sociological studies have made distinctions between categories of individuals in terms of prestige, without paying much attention to questions concerning the formation and development of classes.

THEORIES OF SOCIAL CLASS

Many disagreements over the definition of class are bound up with differences in theoretical approach, involving divergent conceptions of the importance of classes in the social structure and of the nature of the relationship between classes. Theories of social class were only fully elaborated in the 19th century as the modern social sciences, especially sociology, developed. Earlier writers, although they could not fail to observe the existence of great economic inequalities in their societies, did not attempt to formulate a general theory of the causes and consequences of such inequalities. At the most, they reflected, as did Plato and Aristotle, upon some of the more prominent features of social stratification and proposed ideal systems that would be conducive to political stability and rational government. Plato thus advocated a society divided into three classes—guardians, auxiliaries, and workers—in which the guardians would form a disinterested ruling elite, while Aristotle recognized in society three elements—the very rich, the very poor, and those in the middle—and considered the best political system to be that in which the middle strata had a preponderant influence.

Pre-Marxist approaches. In the 17th and 18th centuries a new discussion of social inequality and stratification began, provoked largely by the challenge to aristocratic rule from the bourgeoisie. In the writings of the English political philosophers Thomas Hobbes and John Locke there was developed an individualistic theory of property, corresponding with the growth of a market economy, which either assumed, in Hobbes' case, an equality among men, a struggle between individuals needing to be regulated by a powerful state, and the absence of cohesive classes; or, in the case of Locke, accepted the existence of a division between property owners and a labouring class. The French political philosopher Jean-Jacques Rousseau, in an essay on the origin of inequality (1755), made a distinction between natural inequalities and those that resulted from social conventions, but he conceived society in terms of the relations between individuals rather than between classes. Madison, writing in a society which had declared the principle of human equality and in which few aristocratic privileges existed, was more aware of the social divisions that might arise from divergent economic interests, and his emphasis upon the distinction between the owners of property and those without property foreshadows one of the important elements in Marx's theory. Madison, however, went on to distinguish a considerable number of interest groups as the basis of political factions, and he was far from conceiving society as a class system in which one class must necessarily dominate others.

Other writers in the later 18th and early 19th century who contributed elements of a theory of social classes include the Scottish philosopher Adam Ferguson and Millar, in whose works a distinction was established between civil society (*i.e.*, the nonpolitical elements in so-

ciety, such as the economic system and the family) and the state. The conditions of civil society, especially the property system, were seen as determining, to a large extent, the form of political life. This idea was expounded by the French social theorist Saint-Simon (1817), who argued that government was only a form that corresponded with the character of the underlying system of production and who analyzed the changes in production that led to the decline of the feudal ruling class and the rise of the new class of industrialists. In the writings of Saint-Simon's Socialist followers, a theory of the proletariat was first adumbrated (1824). A later work, by the sociologist and legal theorist Lorenz von Stein (1842), developed a conception of the proletariat as a major political force in modern society. This directly influenced the development of Marx's theory.

Another contribution to the theory of class came from political economy. In Adam Smith's *Wealth of Nations* (1776) the principal emphasis was upon social differentiation and stratification resulting from the division of labour, but the English economist David Ricardo (1817) treated the main factors of production—land, labour, and capital—as constituting economic interest groups or classes, between which there was a profound clash of interests.

Marx's analysis. These diverse elements were brought together in Marx's theory of class, which has dominated all later discussion. In the passage quoted earlier, Marx disclaimed any credit for having discovered the existence of classes or the conflict between them; what he had accomplished, he claimed, was to show: "(1) that the *existence of classes* is only bound up with *particular historical phases in the development of production*, (2) that the class struggle necessarily leads to the *dictatorship of the proletariat*, (3) that this dictatorship itself constitutes only the transition to the *abolition of all classes* and to a *classless society*." The starting point of his theory was an elaboration of the distinction between civil society and the state. The anatomy of civil society, according to Marx, was to be found in political economy. What distinguishes one type of society from another is its mode of production (that is to say, the nature of its technology and division of labour), and each mode of production engenders a distinctive class system in which one class controls and directs the process of production while another class is, or other classes are, the direct producers and the providers of services to the dominant class. The relations between the classes are antagonistic since the classes are in conflict over the appropriation of what is produced; and, in certain periods, when the mode of production itself is changing as a result of developments in technology and in the utilization of labour, such conflict becomes extreme and a new class challenges the dominance of the existing rulers of society. The dominant class at any time controls not only material production but also the production of ideas; it thus establishes a particular cultural style and a dominant political doctrine, and its control over society is consolidated in a particular type of political system. The subject classes and especially a class that is growing in strength and influence as a consequence of changes in the mode of production generate political doctrines and movements in opposition to the ruling class.

The theory of class is at the centre of Marx's whole social theory, for it is the social classes formed within a particular mode of production that are regarded as establishing a specific form of state, animating political conflicts, and bringing about major changes in the structure of society.

Marx distinguished several historical types of society: "In broad outline we can designate the Asiatic, the ancient, the feudal, and the modern bourgeois modes of production as progressive epochs in the economic formation of society" (1859). But Marx and the Marxists who followed him did not undertake any detailed historical studies of earlier forms of society, and he was not able to set out a convincing empirical account of the development of social classes over the whole span of human history. He restricted his analysis of class structure mainly

Marx's view of the inevitability of class antagonism

to modern capitalist society, and he was concerned above all with the rise of the proletariat, the progress of its struggles against the bourgeoisie, and the conditions arising out of the capitalist system of production that would make possible a successful working class revolution and the inauguration of a new type of society that would be without classes.

Post-Marxist analyses. Later theories of class have been concerned in the main to revise, refute, or provide an alternative to the Marxist theory and, in a similar way, have been concentrated upon the development of classes in modern capitalist societies. In recent years, however, a growing amount of attention has been given to the formation of new classes in the Socialist societies of eastern Europe and in the developing countries. The German sociologist Max Weber was one of the first to undertake a critical revision of the Marxist theory, mainly in his essay on class, status, and party (1922), but, in more general terms, in many of his writings. Weber, in the first place, questioned the importance attributed to social classes in the political development of modern societies and in the causation of major social changes. In his view, capitalism had been brought into existence by the influence of certain ideas and especially by the influence of Protestantism on economic behaviour, as well as by the economic interests of the bourgeoisie. He also argued that the development of the European countries in the late 19th century had been affected by nationalism as much as it had by class ideologies and movements. There was another factor, too, that limited the significance of class as a basis of political action, namely, the existence of social stratification in terms of social honour or prestige, which cut across class divisions and tended to produce a condition of social harmony in which peaceful competition and emulation prevailed, rather than an increasingly intense class struggle. More generally, Weber contested Marx's view of the future development of capitalist society, for, whereas Marx envisaged the successful outcome of the working class struggle as the creation of a liberated classless society, Weber foresaw a continuation of the increasing organization of social life and a monstrous growth of bureaucratic regulation, which would attain its greatest extent in a Socialist society.

From a different aspect, Pareto and, in a more qualified way, Mosca also rejected Marx's division of society into contending classes and propounded instead a theory based upon a distinction between the "governing elite" and the masses. Pareto praised Marx's conception of the class struggle as a major contribution to social theory but then transformed it into the idea of a conflict for the possession of political power between an established elite and a rising elite. This conflict resulted, throughout history, in the substitution of one ruling elite for another, while domination and exploitation of the masses continued; in Pareto's view there is no progressive movement toward a classless society as Marx thought. This notion of the rise and fall of ruling elites is to be found in much modern writing on the class structure; it appears, for example, in the U.S. economist Thorstein Veblen's account (1921) of the rise of the engineers (though, in other respects, Veblen remained closer to the Marxist theory) and in recent discussions of technocracy.

One of the most important issues that has divided social theorists in their analysis of class structure has been, in fact, the assessment of the extent and significance of class conflict. Those who have opposed the Marxist theory most strongly have focussed attention on the functional interdependence of classes and their harmonious collaboration. The sociological theory known as functionalism, which attained its greatest influence in the United States, has developed this theme. Functionalism stands quite clearly in a general opposition to Marxism by virtue of its unhistorical approach, by its emphasis upon the regulation of social life by values that are more or less universally accepted in a given society, and by the importance that it assigns to social integration as against social conflict. Functionalism does not offer, in the strict sense, a theory of class. Its concern is with stratification as it arises from social differentiation and the evaluation and

ranking of mainly occupational roles. The functionalist writers, therefore, take up the problem of social status, in the sense in which Max Weber distinguished this from the problem of social class, and they deal with the placement of individuals in the social hierarchy rather than with the formation of distinctive social groups.

Although the attention given to social status grew considerably in the two decades after 1945, partly under the influence of functionalist ideas, problems of class were far from neglected. Indeed, renewed reflection upon the nature and significance of social classes was stimulated by changes in class structure that seemed to be taking place, especially in Western industrial societies.

The theme of the relation between class and politics has figured prominently in most recent discussions. It is argued that in the new "postindustrial" society, which many believe is now emerging, the ruling class is no longer the property-owning bourgeoisie but the technocrats and bureaucrats who direct the process of technological innovation and economic growth; and the opposition to their rule is led not by the working class but by those groups that feel most keenly their dependent position and their exclusion from genuine political participation. Social conflict has therefore assumed a directly political character, instead of arising from economic antagonism.

The Marxist theory of class has thus been questioned in several respects. First, it has been claimed that classes in capitalist societies have tended to lose their distinctive character, while the antagonism between them has declined to such an extent that it no longer produces serious political conflict. From this point of view it may be argued that the class system has lost much of its social significance and that gradations of social status are now more important in determining the actions of individuals and groups. On the other side, however, it is suggested that although the major social classes of 19th-century capitalism have declined, new social classes are being formed in the advanced industrial societies (both capitalist and Socialist) that are beginning to engage in social struggles of a new kind. Furthermore, there are Marxists who would contend that, despite the uncertainties produced by the economic and social changes of the past few decades, the division between bourgeoisie and proletariat remains the fundamental source of conflict in society and continues to be expressed in the ideologies of vigorous social movements. These theoretical disagreements are far from being resolved, but further light may be shed on the problems that they pose by considering some of the ways in which differences between social classes have been characterized.

CHARACTERISTICS OF DIFFERENT SOCIAL CLASSES

In spite of controversies over the theory of class, there is a large measure of agreement among social scientists on the characteristics of the principal social classes, especially in modern societies. A distinction is habitually made between the upper class, the middle class, and the working class, but this needs to be refined and supplemented in various ways. Some writers have used the term lower class to refer to the working class, but others have distinguished a lower class, or lumpenproletariat, from the main body of the working class. This lower class may comprise particular ethnic groups, such as black and Mexican workers in the United States, and immigrant workers, such as those recruited from former colonial territories and from southern Europe by the industrially advanced European countries, as well as casual and unskilled workers in backward regions and declining industries, all of whom are characterized by exceptionally low levels of living, economic insecurity, and lack of social rights.

It is also necessary to take account of the peasantry as a distinct social class, though it was neglected for a considerable time by Western social scientists. In many European societies there are still a substantial number of peasant cultivators; and in the Socialist countries of eastern Europe, in particular, a description of social classes cannot ignore the development of the peasantry and its relations with other groups in society. The importance of the peas-

cance
of class
conflict

Conven-
tional
class
divisions

antsy has also been more fully recognized in recent years because of the role of political movements based largely upon peasant support in the developing countries. Marx's view of the peasantry as a predominantly conservative element in society and as a group that was unlikely to evolve an independent political consciousness or organization has been modified or abandoned by later Marxists. Radical social thinkers are now more inclined to attribute a major revolutionary role to the peasantry, or to large sections of it, in the countries of the Third World.

The delineation of the principal social classes does not imply that these classes have exactly the same character in all modern societies nor that they are entirely homogeneous groups. Nevertheless, there are broad differences between classes and common characteristics within them that make the distinction valid and useful.

The upper class. The upper class in Western capitalist societies is distinguished above all by the possession of largely inherited wealth. In Great Britain, for example, some 40 percent of all personal wealth is concentrated in the hands of the top 1 percent of property owners; in the United States, where the distribution of property is rather less unequal than in most European countries, the top 1 percent still owns about 30 percent of all personal property. Since the beginning of the 20th century, this concentration of wealth has tended to diminish in most countries, but the wider diffusion of property ownership is still mainly confined to the upper percent of the population. The ownership of large amounts of property and the income derived from it confer many advantages upon the members of the upper class. They are able to develop a distinctive style of life based upon expensive cultural pursuits and leisure activities, from which the great majority of the population is excluded, to exert a considerable influence upon economic policy and political decisions, and to procure for their children a superior education and economic opportunities that help to perpetuate family wealth.

Whether these characteristics make the upper class a ruling class in the Marxist sense is still vigorously debated. The question involves considering how far major political and economic decisions are influenced by the general interests of the upper class and how far this class is pre-eminent as a source of recruitment of top decision makers. On one side, it is argued that the upper class of large property owners provides the elites—economic, political, military, and intellectual—that determine the main course of a society's development, while, on the other side, it is claimed by the pluralist political thinkers that decision making results from the activities, often conflicting, of many different groups in society, none of which is clearly or permanently predominant.

In the Socialist societies of eastern Europe, personal wealth obviously has little significance in the formation of a class, but it has been argued by the Yugoslav writer Milovan Djilas that a new upper class, indeed, a ruling class, has emerged in these societies on the basis of the possession of political and administrative power. The members of this class are not able to accumulate personal property on a large scale but can acquire in other ways all kinds of privileges—in housing, education, travel, and consumption—that enable them to develop an exclusive style of life. One difference from Western capitalist societies is that such advantages are less easy to transmit by inheritance than is private property, and for this reason an upper class in the Socialist societies is likely to be less stable in its membership over time. Nevertheless, some advantages may well be transmitted as a result of the privileged access to higher education and to important jobs that the children of upper class families enjoy.

Although the upper class in most societies shows a considerable degree of continuity in its membership from generation to generation, changes do occur through the rise and fall of individuals and groups as a result of changes in the social structure, the occurrence of exceptional ability or lack of ability in particular individuals, or by sheer chance. Such changes are particularly evident in many developing countries, and there may be considerable variations in the composition of the upper class. In

some countries (as, for example, in Latin America or in the Middle East) large landowners may still form an important element in the upper class, though their pre-eminence is being challenged by the rise of a business class. Elsewhere, in Asia and Africa, nationalist political leaders who rose to prominence in the course of struggles against colonial rule and high officials or military leaders may form the nucleus of a new upper class, while in those countries in which revolutions have occurred, as in China, the new elites may be largely recruited from the working class and peasantry. They may tend, as in the countries of eastern Europe, to draw together in the formation of a new upper class, although some aspects of the Chinese cultural revolution seem to have been directed against such a development.

The working class. The principal contrast with the upper class in the industrial societies is provided by the working class, constituted essentially by manual workers in extractive and manufacturing industry. What characterizes the working class as a whole is lack of property and dependence upon wages. With this condition are associated relatively low levels of living and of education, restricted access to secondary and higher education, limited opportunities for leisure and cultural activities, and exclusion, to a large extent, from the spheres of important decision making. There are, of course, considerable differences within the working class, and a distinction has commonly been made between skilled, semiskilled, and unskilled workers, corresponding broadly with differences in income level. More recently, social scientists have emphasized the difference between the relatively prosperous workers in modern expanding industries and the less prosperous workers in some of the older industries.

There have been significant changes in the condition of the working class over the past few decades. Levels of living have risen, although as a consequence of general economic growth rather than any major redistribution of wealth and income; and access to education has improved, though it is still the case, in most countries, that a very small proportion of working class children enter higher education and hence make their way into the occupational and social elites. At the same time, the economic security of most workers has been increased by policies of full employment and by more extensive welfare services. These changes were widely interpreted during the 1950s as the *embourgeoisement* of the working class—that is, as an erosion of its distinctive characteristics and its gradual assimilation into the middle class. Such accounts have, however, been examined more critically in recent years, and the extent to which the working class remains socially, culturally, and politically distinct from other groups in society has been emphasized. The idea that the advanced industrial societies were becoming "middle class societies" and that this condition had already been more or less attained in the United States, which developed from the *embourgeoisement* thesis, was also sustained by the general shift in the economy from manufacturing to service industries, which involved a relative contraction in the numbers of manual workers and an increase in the numbers of clerical, technical, and professional workers. Thus, although there are still disagreements among social scientists about the size of the working class and the general features of its development, it can scarcely be denied that some important changes have occurred that require, at the least, a reconsideration of the Marxist theory of its political role.

It is evident that the position of the working class varies quite widely from one country to another. In some European countries, notably in France and Italy, a large part of the working class is strongly influenced by Marxist ideas and supports political parties that aim to bring about revolutionary changes in society, whereas in other countries—in Great Britain, West Germany, and Sweden, for example—the main working class parties are reformist in their policies. In the United States, on the other hand, there has been no major independent political movement of the working class since World War I, and class consciousness has had much less influence in political life than has been the case in Europe. These differ-

The
embourgeoisement
thesis

The "new
class" of
Socialist
societies

ences cannot easily be explained in general terms, but it has been observed that working class consciousness was more intense and took a more revolutionary form in those European societies in which the development of capitalism was slower and more backward than elsewhere; and this observation would apply also to Russia before 1917. In the case of the United States, the failure of a political movement of the working class to develop on anything like the European scale has been accounted for in various ways: by the exceptional opportunities for mobility (or at least the strong and pervasive belief that such opportunities existed), by the fragmentation and disruption resulting from massive immigration, by the existence of a large black lumpenproletariat, and by the divisions in the working class movement that were produced by World War I and the Russian Revolution. At all events, it is clear that the working class in different countries has assumed different characteristics and has espoused very diverse ideologies.

The middle class. While the upper class and the working class can be viewed as relatively homogeneous groups quite sharply differentiated from each other, the middle class often has been treated as a more varied, residual category, comprising those groups, mainly defined in terms of occupation, that do not clearly belong to one of the other classes. Marx, for example, referred to the "intermediate and transitional strata" that obscured the boundaries of the principal classes. Generally speaking, the middle class has been taken to include the various levels of clerical workers, those engaged in technical and professional occupations, supervisors and managers, and self-employed workers, such as small shopkeepers, farmers, and (in some societies) the wealthier peasants. At the top—in the case of wealthy professional men or managers in large corporations, for example—the middle class merges into the upper class, while at the bottom—where routine and poorly paid jobs in sales, distribution, and transport are concerned—it merges into the working class. When a contrast is drawn between middle class and working class styles of life it is often based implicitly upon "ideal types": the middle class individual is conceived as a professional or senior clerical worker, the working class individual as a factory worker.

To some extent, these distinctions within the middle class are recognized by references to the upper middle class and lower middle class, but there are other differences that do not coincide exactly with this division. There is, for example, considerable diversity of social and political outlook in the middle class: in Western societies the predominant political attitudes may range between liberal and conservative, but in some conditions a part of the middle class, at least, may adopt extreme right-wing views (as in its support for National Socialism in Germany); and, on the other hand, there is a well-known phenomenon of middle class radicalism, which became more prominent during the 1960s with the development of the largely middle class student movement. Other distinctions arise from longer term historical changes in the composition and social situation of the middle class. The "old" middle class, with which Marx and other 19th-century writers were largely concerned, consisted chiefly of small independent producers and independent professional men; the "new" middle class of the late 20th century is made up primarily of employees in public services and in large business enterprises at various levels of clerical, technical, and professional work. This transformation seems to have produced a greater diversity, fluidity, and uncertainty in the cultural and political character of the middle class, so that to speak of the advent of middle class societies, as the numbers of the new middle class increase, may not provide any clear indication of the form that such societies will eventually take.

The industrial countries resemble each other in their occupational structure, and the development of occupations under the influence of technological innovation and economic growth is also similar, but this does not prevent considerable differences in the class structure. There is, as has been noted, an important distinction to be made between the Western capitalist countries and

the Socialist countries of eastern Europe in respect to the character of the upper class or elites, and other classes in these two types of society may also show important differences, especially in their social outlook and political involvement.

International comparisons. It is difficult to make rigorous comparisons of the character of different classes in different countries, since comprehensive studies of the class system are lacking, especially in the Socialist countries, though a major study in Czechoslovakia (1969) provides much valuable information. Even within Western societies there is much diversity, and the degree of class consciousness and class conflict, in particular, varies widely from one country to another, as well as fluctuating over time. One observer, for example, wrote in 1914 of the first decade of the 20th century that it was a turning point in American society, when deep class feeling found expression in both political parties and brought to public attention the existence of a profound conflict between great wealth and the lower middle and working classes; but the feeling, and the conflict, subsided again, and in spite of a limited revival of class consciousness in the 1930s the general character of American society has been one of ideological classlessness. In most of the European countries, though, class consciousness has found expression in distinctive parties, and class conflict has been overt.

In the developing countries, modern social classes exist, for the most part, only in embryonic form. It has been observed already that the upper class in these societies may be far from homogeneous or stable and may include such disparate elements as feudal landowners, capitalist entrepreneurs, nationalist or revolutionary leaders, higher castes, and military chiefs. In those countries in which industrialization is not far advanced, the urban working class will be small, and, if the workers have only recently migrated to the towns, as is the case in many African and Asian countries, there may be little development of class consciousness. Similarly, the middle class is likely to be small, although some sections of it may be particularly privileged and influential by virtue of the educational level of their members, who may form part of a Western educated elite. Numerically, the most important class in African and Asian societies is the peasantry, and, even in the more urban and industrial societies of Latin America, this class is still relatively large. Consequently, peasant organizations and movements are of great political significance, and major social conflicts are likely to occur over issues of landholdings, land reform, and agricultural prices, rather than over industrial conditions. As industrialization proceeds, the occupational structure of the developing countries will come to resemble more closely that of the industrial countries, but the class structure may take various forms, depending upon historical traditions and political changes. Many developing countries aim deliberately to bring about a condition of much greater economic and social equality, and it has still to be seen what kind of class system, or classlessness, will emerge from the profound changes that are occurring in such societies as India, China, Tanzania, and Chile.

SOCIAL MOBILITY

The term social mobility, in its widest sense, refers to any movement of individuals, families, or groups between different sectors of society. Thus movement from one occupation to another, or from one region of a country to another, is a kind of mobility. On an international scale, migration is a very important type of mobility.

Types of mobility. A distinction is usually made between "horizontal" and "vertical" social mobility, the former involving no change in the position of the individual or group in the social hierarchy, while the latter does involve a change of social level. When an industrial worker moves from one factory to another or a manager takes a position in another company, there is no significant change in his social status or class membership. But, if an industrial worker or the child of an industrial worker becomes a wealthy businessman or lawyer, he has

changed quite radically his position in the class system. Vertical mobility may, of course, involve either upward or downward movement. A ruined aristocrat, or a member of an upper class dispossessed of his wealth in a revolution and obliged to enter a manual occupation, has experienced a change of social level that may affect his whole life or particular aspects of it. Modern sociologists have concentrated their attention mainly on upward social mobility, because they have been preoccupied with the question of equality of opportunity in the relatively open and democratic industrial societies; but it has been suggested more recently that the degree of downward mobility might be a better indicator of the "openness" of a society, since it would show the extent to which it is relatively easy or difficult for privileged individuals and groups to maintain and transmit to their descendants the advantages that they enjoy.

There has also been a marked preoccupation with the mobility of individuals, although it is evident that whole families, groups, and even classes may at certain times change their position in the social structure. One of the few writers to bring out the diverse aspects of vertical mobility was the economist Joseph Schumpeter (1927), who analyzed and illustrated what he termed the "rise and fall" of individuals, families, and whole classes within the class system. But Pareto, too, in his examination of the "circulation of elites" (1915-19), paid attention both to the movement of individuals into and out of the elites, and to the rise and fall of whole elite groups.

In studying the movement of individuals, sociologists have distinguished between intragenerational and intergenerational mobility; that is to say, between the mobility of an individual within his own adult lifetime and the mobility represented by a change in social level from the parental to the filial generation (almost always from father to son). Comprehensive national studies of mobility that have been undertaken in recent years have dealt almost entirely with intergenerational mobility, examining changes in occupation between father and son in terms of a scale of occupational prestige. At the same time, such studies have concentrated heavily upon educational opportunity as a major factor influencing upward mobility.

The rise and fall of families, groups, and classes is less easy to study in a quantitative manner, but such changes can be documented in other ways. The emergence of new ruling dynasties is one example of the upward mobility of families, and other examples can be found in the rise and fall of family businesses, of politically influential families, or of intellectual families. The mobility of particular social groups may occur as a result of economic, political, or cultural influences.

There have been important changes in the position of various groups in the modern industrial societies: the prestige and influence of scientists has increased, while that of clergymen has diminished; bureaucrats have become a much more important group, as have the officials of a dominant political party in some societies. Finally, the rise and fall of whole classes is a phenomenon that occurs when there are substantial changes in the whole structure of society. In the Marxist theory, such changes take the form of a social revolution, in which the established ruling class is overthrown by a new class, as in the rise to power of the bourgeoisie with the development of modern capitalism. But a change in the relative position of classes may also occur in a more gradual way, and an example may perhaps be found in the growth of the new middle class in present-day industrial societies.

Vertical social mobility is a feature of all societies, except perhaps the most simple and primitive. In European feudal societies, there were opportunities for upward mobility, one avenue being through the church, and these opportunities increased with the revival of the towns and the growth of trade. One study of the circulation of elites in France between the 11th and 18th centuries gives examples of the rise and fall of particular individuals and families, as well as tracing the fortunes of such groups as lawyers, financiers, and traders.

The problem posed by such historical studies is that they

largely provide illustrations and, for lack of data, do not show the degree of mobility; that is to say, the numbers of individuals or families who actually changed their position in the social hierarchy over a given period. Historical comparisons of mobility are thus difficult and largely speculative, and there are many problems even in examining the trends of mobility in the industrial societies in recent times. It is nevertheless generally considered that vertical social mobility (especially of individuals) is greater in modern industrial societies than in earlier societies. Modern studies suggest, however, that, even in industrial societies, mobility is limited and that there are no substantial differences between industrial societies in the amount of mobility, even though, for example, it has been generally believed that social mobility is greater in the United States than in European countries. In particular, the movement of individuals from the working class into the upper class is rare in all societies. Sociologists have, therefore, introduced another distinction between short-range and long-range vertical mobility; and comparisons between industrial societies show that the greater part of mobility is short-range.

These modern studies suggest a cautious interpretation of historical accounts of social mobility, which may give undue prominence to exceptional cases of upward or downward movement. It is likely that in all societies, at most times, there is a considerable stability of class membership that, even when not maintained by any formal sanctions, is ensured by the inheritance of property, educational advantages, or political influences.

The process of mobility. The nature and degree of vertical mobility in a society is affected by a variety of influences. One universal factor is the occurrence, in any population, of individuals who are exceptionally endowed—with intelligence, physical strength, beauty, skill in warfare or business, or the quality of charisma that enables them to become religious or political leaders. Beautiful women have risen to social eminence as the mistresses of kings and nobles and as film stars, just as men (and to a much lesser extent women) have risen by the accumulation of wealth, the attainment of political or military power, and intellectual or artistic achievement. But the manifestation of such personal qualities and the advantages that they bring are limited and controlled by many social factors.

Social determinants. In the first place, the open or closed nature of the class system has a powerful influence. It is not only that the individual in a closed system will encounter great practical obstacles if he seeks to escape from his situation as a slave, serf, or member of a lower caste; the ideology that upholds such a system and emphasizes the importance of everyone "knowing his place" tends to inhibit the development of personal talent and ambition at the lower levels of society. In the more open class systems of modern societies, on the contrary, there are no formal restrictions upon vertical mobility, and the ideas of equality and reward for merit, which have gradually entered the general social consciousness since they were formulated in the 18th-century revolutions, encourage an individualistic striving for success throughout large sections of society. Even in these societies, however, talented individuals in a lower social class have to surmount many obstacles, arising mainly from poverty and the difficulties of access to education. On the other side, less talented individuals are able to maintain their position in the upper class because of their inherited social advantages.

The extent to which individual talent will result in upward mobility is also limited by the general orientation of a society's activities. A tribal society that lives by hunting or is engaged in continual warfare will place a high value on physical strength and agility; a nation engaged in imperial expansion is likely to rate military qualities highly; and one that is chiefly concerned with industrial development may attach the greatest importance to business ability. The role of science and technology in present-day industrial societies makes certain kinds of intellectual ability (and the selection and training of such ability) particularly important, so that some writers have referred

Inadequacy of historical studies of mobility

Intra-generational and inter-generational mobility

Mobility
and
changes
in social
structure

to the rise of a "meritocracy" or a "scientific and educational estate" or a "technocratic elite."

One of the most profound influences upon mobility comes from the general changes in social structure. A revolution that dispossesses an existing upper class or a national liberation movement that overthrows foreign rule creates opportunities for other individuals, groups, and whole classes to establish themselves in a dominant position. In the early years of the Socialist regimes in eastern Europe, for example, the universities were opened to young people from working class and peasant families, while restrictions were placed upon the entry of those from the middle class. More gradual changes, especially in the occupational structure, also affect mobility. The expansion of clerical, technical, and professional employment involves a continuing movement out of manual work and accounts for a large part of the upward mobility in Western industrial societies. In earlier periods economic changes had similar effects; the revival of trade and the growth of towns in European feudal societies made it possible for serfs to embark upon new occupations and to escape the constraints of the feudal system. A similar movement from country to town is occurring in the present-day developing countries and involves, in most cases, upward mobility in terms of rewards, opportunities, and social status. There are also movements from poorer to wealthier regions in a particular country. The postwar movement in Italy from the relatively poor agrarian south to the more prosperous industrial north and the movement of black Americans from the South to industrial areas provide examples.

After a revolution a new system of stratification may emerge, and the rate of social mobility may decline again. Similarly, if there is little economic development or the rate of growth slows down, opportunities for mobility will be diminished. In such conditions, the possibilities of upward mobility will depend largely upon the extent of downward mobility. One other factor, however, may influence this situation. If the upper and middle classes practice family limitation to such an extent that they do not reproduce themselves from generation to generation, the vacant places may be filled by individuals who rise from lower classes. Such differential fertility, however, has rarely, if ever, been a major influence, and most analysts believe that it has been declining in the developed industrial societies during the past few decades.

International movements of population have been important at various times in promoting upward mobility. The colonial expansion of the western European countries from the 16th century on provided opportunities for individuals to enrich themselves as traders or settlers, at the same time as they subjugated and enslaved other peoples in Asia, Africa, and America. Later, with the creation by European settlers of new societies, especially in North America, fresh opportunities for mobility were provided by large-scale immigration. The expansion of U.S. society across the continent during the 19th century brought millions of working class and peasant immigrants from Europe who were leaving conditions of poverty and subordination that seemed unalterable in their own societies.

Consequences of mobility. The determinants of mobility outlined above are difficult to isolate and measure, as are the social consequences of mobility. On one side, it may be said that the movement of large numbers of people up and down the social hierarchy tends to break down the exclusiveness of social classes and to create a more uniform national culture. Presumably, this would also lead to a diminution of class prejudices and class conflicts. It has often been claimed, in fact, that the allegedly lesser degree of class consciousness in U.S. society, as compared with European societies, is due to a higher rate of mobility in the former. Although this may be doubtful in the light of recent studies that show no great differences in overall mobility in the industrial societies, the widespread belief that opportunities for upward mobility are actually greater than in other societies may itself have had an important influence. From another aspect, however, it can be argued that the preoccupation with

vertical mobility reinforces the class system; the individual who is concerned to rise or avoid falling in the social hierarchy accepts and indeed emphasizes the importance of class and status distinctions. It has been suggested that these distinctions might be diminished much more by the attainment of greater economic and social equality than by any amount of individual mobility.

Another consequence of mobility that is seen as beneficial from the point of view of society as a whole is the more effective use of ability. If individuals are confined to the social sphere in which they are born, many useful talents will remain undiscovered and unused. The expansion of education in modern industrial societies has been stimulated by the desire to provide opportunities for the development of all the abilities available in the population, though this is still very imperfectly achieved.

On the other hand, vertical mobility may have some undesirable consequences. Such mobility, whether upward or downward, imposes strains upon the individual striving for success and adapting to new social milieus and may be disruptive of families and local communities. More generally, a high rate of mobility may be regarded as producing in society the condition that the French sociologist Emile Durkheim called "anomie" (normlessness and resultant disorientation and anxiety), in which there is insufficient regulation of behaviour and the individual suffers from the "malady of infinite aspiration." The existence of such strains may lead to a higher incidence of mental illness among highly mobile individuals, but it seems doubtful that mobility is a major factor in mental illness, given that such illness has been increasing rapidly in the industrial societies, while there has been no correspondingly marked increase in mobility. It seems likely that it is the pace of economic and cultural change in general and the conditions of urban-industrial life that impose the greatest strain upon individuals.

CURRENT TRENDS

The economic development of Western industrial countries after 1945 and changes in social policy that resulted in the provision of more elaborate welfare services seemed to many observers to be generating significant changes in the class system. Diverse interpretations of these changes have been proposed. According to one view, there has been a general diminution in class differences resulting from higher levels of living, greater social mobility, and a limited redistribution of wealth and income. These changes, it is held, are reflected in a decline of class ideologies and class conflict. This interpretation of events could lead to a conception of Western societies as progressing toward a relative classlessness or as becoming predominantly middle class societies.

Other social scientists, however, have argued that new social classes are being formed, notably a new upper class comprising the managers and organizers of production in both the public and the private sector, and that class struggles are developing that are related less to economic questions and more directly to the degree of participation in or exclusion from political decisions that affect the general course of development of a society. This interpretation seemed more plausible with the re-emergence of profound ideological and political conflicts in the industrial countries of Europe and North America during the 1960s, after the relative social peace of the previous decade. It also had the merit of being applicable to the Socialist countries of eastern Europe, in which it may be claimed that a new upper class of economic managers and party officials has developed.

Some Marxist writers continue to uphold the traditional view of the class system in capitalist societies and to assert the fundamental importance of the opposition between bourgeoisie and proletariat, while attaching little significance to the growth of middle class occupations or to changes in the character of ideological and political conflicts. Others, as noted above, have concluded that the opposition between these 19th-century classes no longer has a major political influence. They go on to suggest that the most important division in world society is that between the industrial nations and the developing countries.

The concept of international class conflict

Many social scientists, in fact, would regard the gap between rich and poor nations as the principal modern manifestation of inequality, but to treat this as a difference between classes and to refer to "bourgeois" and "proletarian" nations is to use the term class in quite another sense from that which it has had in the social sciences for the past century or more and would require a more elaborate justification than has yet been given.

BIBLIOGRAPHY. Two short introductions to the study of social class are KURT B. MAYER and WALTER BUCKLEY, *Class and Society*, 3rd ed. rev. (1969); and T.B. BOTTOMORE, *Classes in Modern Society*, 2nd ed. (1966). The historical development of ideas and theories of class has not been very fully discussed, but some treatment is given in STANISLAW OS-SOWSKI, *Struktura klasowa w społecznej świadomości* (1957; Eng. trans., *Class Structure in the Social Consciousness*, 1963), which also contains a good account of the Marxist theory. Another exposition and critical examination of Marx's theory is provided by RALF DAHRENDORF, *Soziale Klassen und Klassenkonflikt in der industriellen Gesellschaft* (1957; Eng. trans., *Class and Class Conflict in Industrial Society*, 1959). The ideas of the early American sociologists are discussed in CHARLES H. PAGE, *Class and American Sociology*, new ed. (1969), which contains a long introduction surveying much of the research on social class and mobility over the past 30 years. MAX WEBER's writings on social class and status are to be found mainly in his work *Wirtschaft und Gesellschaft*, 4th ed., 2 vol. (1922; Eng. trans., *Economy and Society*, ed. by GUENTHER ROTH and CLAU WITTICH, 3 vol., 1968). The theory of elites is expounded by VILFREDO PARETO in *Trattato di sociologia generale*, 2nd ed., 3 vol. (1923; Eng. trans., *The Mind and Society*, 4 vol., 1935); more recent studies include C. WRIGHT MILLS, *The Power Elite* (1956); and T.B. BOTTOMORE, *Elites and Society* (1964). Among the general studies of class are REINHARD BENDIX and S.M. LIPSET (eds.), *Class, Status and Power*, 2nd ed. (1966); and GERHARD E. LENSKE, *Power and Privilege* (1966). Particular social classes are discussed in C. WRIGHT MILLS, *White Collar* (1951); G.A. BRIEFS, *The Proletariat* (1937); J.H. GOLDTHORPE et al., *The Affluent Worker*, 3 vol. (1968-69); and ERIC R. WOLF, *Peasants* (1966).

A pioneer survey of social mobility is P.A. SOROKIN, *Social Mobility* (1927, reprinted with an additional chapter on cultural mobility, 1959). Two major national studies are D.V. GLASS (ed.), *Social Mobility in Britain* (1954); and PETER M. BLAU and OTIS D. DUNCAN, *The American Occupational Structure* (1967). Comparisons between societies are discussed in S.M. LIPSET and REINHARD BENDIX, *Social Mobility in Industrial Society* (1959); and S.M. MILLER, "Comparative Social Mobility," *Current Sociology*, 9:1-89 (1960). Some aspects of the social context in which mobility occurs are examined, with reference to the United States, in ANSELM L. STRAUSS, *The Contexts of Social Mobility* (1971).

There are few studies of the class system as a whole, but reference can be made to C. WRIGHT MILLS, *The Power Elite* (1956); and JOHN PORTER, *The Vertical Mosaic: An Analysis of Social Class and Power in Canada* (1965). The class system and stratification in the U.S.S.R. and other Socialist societies has begun to be studied more fully; an early work was MILOVAN DJILAS, *The New Class* (1957); and more recent studies include DAVID LANE, *Politics and Society in the USSR*, ch. 12 (1970); FRANK PARKIN, "Class Stratification in Socialist Societies," *British Journal of Sociology*, 20:355-374 (1969); and the study of Czechoslovakia by PAVEL MACHONIN, *Cesty k beztržidní společnosti* (1961).

Changes in the class system in Western industrial societies are discussed in ALAIN TOURAINE, *La Société post-industrielle* (1969; Eng. trans., 1971); and there are earlier observations on European societies by S.M. LIPSET and RALF DAHRENDORF in S.R. GRAUBARD (ed.), *A New Europe?* (1963). In the case of the developing countries attention has been concentrated mainly on the emergence of new elites; see S.M. LIPSET and ALDO SOLARI (eds.), *Elites in Latin America* (1967), and PETER C. LLOYD, *Classes, Crises and Coups* (1971).

(T.B.B.)

Social Differentiation and Stratification

"Social differentiation" refers to the recognition and establishment in society of differences between groups or categories of individuals. It is evident that not all differences between individuals give rise to social differentiation. On the one hand there are personal qualities or combinations of qualities that distinguish a particular individual from all others; and on the other hand there

are some characteristics that may be possessed in similar degree or kind by a number of individuals—for example, height or weight, colour of hair or eyes, temperament—but which never, or very rarely, lead to social differentiation. Many differences between individuals, however, are invested with social significance (or may be said to be created by society), with the result that the individual is seen as belonging to specific groups and categories that define his position in society. Thus he can be described as male or female, middle class or working class, young or old, married or unmarried, or belonging to a particular ethnic, linguistic, or religious group; and these classifications will refer to typical or expected kinds of behaviour, styles of life, and opportunities.

Another way of describing the same phenomena is to say that each individual occupies or performs "social roles." A society is thus regarded as a system of differentiated roles, and the position of an individual in the society is, in some sense, a product of his various roles.

Whether social differentiation is conceived in terms of roles or in terms of the groups and categories to which an individual belongs or is assigned, it has diverse aspects that must be clearly distinguished. In the first place, differentiation is closely associated with stratification; many social differences are invidiously ranked, so that some categories or groups of individuals have higher status or belong to higher classes than others. Second, the social importance of the various recognized differences may be unequal, and it is generally the case that those differences accompanying social stratification have the greatest prominence. In society as a whole, the distinction between married and unmarried, or between young and old, is usually less significant than the distinction between an aristocrat and a commoner or between an executive of a large corporation and a manual worker. Third, the various positions that an individual occupies may be non-aggregative, incongruous, or conflicting. It does not seem possible, for example, to aggregate the roles of father and corporation executive into an intelligible whole; and from this it follows that differentiation needs to be observed in several distinct spheres of social life and that a distinction has to be made between those roles that fit together in a significant whole and those that do not. Incongruous or conflicting roles appear particularly in connection with stratification; thus, an individual may be highly educated but poor and socially despised, or on the other hand he may be wealthy or powerful but uneducated and lacking the cultural attributes of established members of an upper class. Fourth, it should be noted that social differentiation varies in character from one type of society to another, and even from one society to another within the same type, and that it changes over time. Indeed, one of the principal features to which sociologists have drawn attention is the growth of social differentiation (especially in the form of a more extensive division of labour) in the course of social development.

THE CRITERIA OF DIFFERENTIATION

It will be evident from what has been said that a great many factors enter into the process of differentiation. Initially, a broad distinction may be made between two kinds of factors: those that depend upon biological differences among human beings and those that arise wholly or largely from social or cultural conditions.

Biological factors. Sex differentiation. One of the most obvious differences among human beings is that between the sexes. In all societies men and women are treated differently (often unequally) and have different functions, or roles. Many social scientists from the 19th century onward (among them Karl Marx and Herbert Spencer) have suggested that the economic division of labour began with the division of tasks between the sexes; and this, it is generally held, would arise from biological differences—in particular, men's greater physical strength, which equipped them for the activities of hunting and warfare, and women's reproductive function, which tended to confine them to the area of the home or settlement. Many other social and cultural differences between men and women in early societies, and notably

Social differences between men and women

Definitions of "social differentiation" and "social stratification"

the male dominance in political life, may have followed from this original division of labour; and these differences were perpetuated and developed in later societies. Thus, in spite of considerable variations in the social position of women from one society to another, there has been a general male predominance which has continued up to the present time. In the new industrial societies of the 19th century, women still lacked many of the civil rights (especially property rights) and political rights enjoyed by men, and although they have now gained these rights in most modern societies, considerable differences remain: women workers are concentrated in the less skilled and lower paid occupations; disproportionately few women are in the higher professions; and women usually play little part in politics at the national level. Nevertheless, there have been gradual changes in all these spheres during the present century, and at the same time movements for women's rights—from the woman suffragists to the Women's Liberation Movement—have been a significant element in the more general movements of radicalism and reform.

The social differentiation of the sexes poses an important problem that is relevant to all discussion of the biological factors in social life. Some writers have argued that the physical differences between men and women determine the major psychological differences—of intellect and temperament—that largely account for the differentiation of social roles. Against this view it has been argued that biological elements acquire importance only when they are socially recognized and established; that there are in fact great variations, between societies and between historical periods, in the relative positions of men and women; and that in modern times the differences between the social roles of men and women have tended to diminish. Moreover, the existence of substantial, innate psychological differences between men and women is not securely established, and such differences as do appear can be explained as a consequence of social and cultural influences rather than biological inheritance. In this case, as in many others, the question of the relative importance of nature and nurture is still unsettled. At least, however, it can be said that the differences between men and women need not necessarily lead to economic and social inequality; and it may be claimed further that there is no longer any reason in advanced industrial societies for these differences to produce any large degree of differentiation at all outside the sexual sphere (see also WOMEN, STATUS OF).

Age differentiation. Another biological factor that leads to differentiation is age. In all societies a distinction is made between the young, the mature, and the old; and different roles are assigned to them. A more elaborate classification exists in many societies—for example, according to Hindu doctrine, four stages are to be distinguished in the individual's life (a period of preparation, a period as a householder, a period as a recluse, and a final period of renunciation of the world). In many modern societies it is common to distinguish the periods of childhood, youth (including the transitional stage of adolescence), middle age, and old age. The extent to which these stages are clearly defined or formally recognized, however, varies considerably from one type of society to another, as do the social attitudes toward the members of each category. In some tribal societies there are organized age sets that mark the progress of the individual toward full adult membership of the tribe. On the other hand, in modern industrial societies the points of transition from one age category to another tend to be less well defined, to change over time, and to vary from one sphere of social life to another. Childhood may be regarded as lasting until puberty (or, in social terms, adolescence), and it has corresponded also, to some extent, with the period of formal school education; however, the continuing extension of the period of education has meant that childhood now merges into youth while a condition of dependency continues, without the sharp break that occurred in earlier societies when the individual moved at an earlier age from school or family to adult work. At the same time, there has developed in modern societies in

recent decades a more distinctive "teen-age" culture within a broader youth culture. In the legal and political spheres there has been a tendency to recognize earlier maturation by reducing the age of majority and of acquisition of political rights (in Great Britain in 1970, for example, from 21 to 18 years), but there is still not a complete correspondence between the ages at which, in different spheres, individuals assume adult roles.

The evaluation of different age groups varies widely from one kind of society to another. In many tribal societies and traditional societies, the elders have considerable prestige and power as the possessors of a store of valuable knowledge and experience. In modern industrial societies, on the other hand, they may be regarded as old-fashioned and out-of-date, because of the rapid growth and transformation of knowledge.

Differentiation by age is accompanied by inequalities. In most societies economic resources and political power are in the hands of the middle-aged or old, though there are considerable variations and in periods of social upheaval the young may increase their influence or power. The inequalities arising from age differences, like those arising from the differences between the sexes, are in any case less prominent in most societies than those that emerge from property ownership and other directly social elements in stratification (see also YOUTH, SOCIAL ASPECTS OF; OLD AGE, SOCIAL ASPECTS OF).

Racial differentiation. Race differences have been another important source of social differentiation. In the first place, it may be claimed that the various races of mankind have created widely different civilizations. But this assertion raises difficulties of the kind already encountered in discussing the differences between men and women, namely, that it is not possible to establish a strict relation between the physical characteristics and the psychological and cultural features. In this particular case it seems clear that the diverse forms of nations and civilizations are mainly the product of geographical, social, and historical influences, although the actual creation of nations may have owed something to a sense of racial distinctiveness, among many other factors.

Perhaps the most important observation to be made about differences of race is that they may be either emphasized or treated as unimportant in different times and places, according to the prevailing cultural and political circumstances. Race relations in modern times have undoubtedly been most strongly affected by the colonial situation that followed the overseas expansion of the western European countries. Ideas of racial superiority and inferiority accompanied colonization, and these ideas have persisted up to the present time, sustained by the great discrepancies in wealth and power between the nations of western Europe and North America and the countries of the Third World. Not only were race differences and inequalities emphasized on a world scale during the period of modern imperialism, but they also became prominent within particular societies in which, for one reason or another, different racial groups lived together. Thus, in the Republic of South Africa, a white minority which possesses economic and political power maintains, through the institutions of apartheid, a strict separation between white, black, and coloured members of society in order to perpetuate its own supremacy. In the United States, a black minority originating in the African slave trade of the early period of colonialism has enjoyed formal political rights for a century, but it still occupies in practice a situation of economic, cultural, and political inferiority that is increasingly a source of major political conflict. More recently, in Great Britain, the growth of an immigrant population drawn mainly from the West Indies, India, and Pakistan has resulted in more widespread manifestations of racism and, on the other side, attempts by legislation and by other means to prevent racial discrimination.

The principal aspect of race differences in modern times, therefore, is that such differences have taken the form not merely of differentiation but of gross inequality. It is possible to conceive of a state of affairs in which the differences between races, and the cultural differences

Inequalities among age groups

Effects of modern colonialism and imperialism upon race relations

that have become associated with them, would be generally regarded as creating a pleasurable diversity of human life; but this is far from being the case at the present time. The colonial conquests established inequality as a principal element in the relations between races, and the dissolution of the colonial empires is still too recent for their historical consequences to have been eliminated (see also RACISM; MINORITIES AND ETHNIC GROUPS).

Intellectual differentiation. Besides the major biological factors of sex, age, and race, there are other genetic differences between individuals which may lead to social differentiation. One of those most frequently discussed is differences in intelligence. In this case social differentiation is directly linked with stratification; those who are intellectually more able, it is suggested, will attain the leading positions in society. This thesis is clearly most readily applicable to the modern industrial societies, in which social mobility (that is, movement from one level to another in the social hierarchy) is possible and even encouraged and in which, moreover, such mobility occurs to a large extent through the acquisition of educational qualifications. To say this, however, is to recognize that social differentiation and stratification do not by any means correspond with the variations in intellectual ability in all societies. Where there exists a rigid system of stratification (as in a caste system), an individual's position in society is fairly strictly determined by descent, and intellectual or other personal qualities can have little effect upon it. Again, intellectual ability may be more or less highly valued in different types of society; if the principal social activity is hunting or warfare, then physical strength, energy, and courage may be much more important. Even in modern industrial societies, the relation between intelligence and social position is far from straightforward. The inheritance of class position limits the possibility of social differentiation in terms of intelligence; moreover, it is generally acknowledged that there are social, as well as genetic, factors in intelligence itself, so that it may be said that those individuals born into high social positions will display, on average, high intelligence and hence are likely to maintain themselves in these positions, while those born into lower social strata will experience much greater difficulty in developing their intellectual qualities.

This consideration of the biological factors in social differentiation brings to light a question of crucial importance. Although sex, age, race, and individual qualities such as intelligence obviously play some part in social differentiation, they do not have a directly determining influence. Their effect depends upon the way in which they are conceived and treated in each society, and this, in turn, depends upon a great variety of social, cultural, and historical influences.

Social and cultural factors. Among the most obvious forms of social differentiation arising from social and cultural factors are (1) the diversity of nations and civilizations, and (2) the distinctions within societies between classes or status groups. The second of these forms will be considered later in discussing stratification. The distinctions between nations, or more generally between the numerous autonomous communities into which mankind has always been divided, are closely associated with differences of language and of culture. Primitive societies, relatively isolated from one another even in the same geographical region, differed in language, in kinship structure, in religious belief and practice, and in economic system—the latter depending partly upon the nature of the physical environment and partly upon the level of technological development in a particular society. Many of these features persist in present-day tribal societies, although they have been greatly modified by the impact of the industrial countries.

It is impossible now to trace the ways in which this differentiation of early human societies came about; and, even in the case of ancient societies that have left historical records, it is not easy to follow in detail the processes by which distinct political communities were created. War and conquest, associated with migrations, played an important part in creating new and larger scale societies,

but there were also contrary processes of disintegration and further differentiation. At a later stage, the world religions played a large part in forming distinct areas of civilization. The modern nation-states in Europe were formed largely on the basis of language and historical traditions, while in other parts of the world, more recently, new independent nations have been created on the basis of a religious or cultural identity or have established themselves as the successors to somewhat arbitrarily defined colonial territories (and consequently face difficult problems of social integration).

In considering social differentiation on a world scale, social scientists have been concerned not only with the distinctive features of particular societies and civilizations but also with *types* of society as they have appeared in different historical periods. The French sociologist Émile Durkheim in 1893, for example, distinguished between societies characterized by "mechanical solidarity" and those characterized by "organic solidarity." In the former (primitive and early societies) individuals differ little from each other and are uniformly subjected to the authority of the social group; in the latter (especially modern societies) there is great internal differentiation, individualism flourishes, and individuals are bound to each other by mutual dependence, especially through the extensive division of labour. A distinction that is similar in certain respects is that made by the German sociologist Ferdinand Tönnies in 1887 between *Gemeinschaft* (community) and *Gesellschaft* (society); in the former type of social system, men live in small-scale groups and have direct, face-to-face relations with one another, whereas in the latter type they belong to large-scale groups and are related indirectly and impersonally. This distinction, like Durkheim's, is, at least in part, one between primitive and early societies on the one hand and modern societies on the other.

Other writers have established quite different distinctions between types of society, often making use of economic criteria. One of the best known classifications along these lines is that of Karl Marx, who distinguished several types in terms of their mode of production and the class system arising from it: primitive communism, ancient society, Asiatic society, feudal society, modern capitalist society. More recently, another kind of economic distinction has been made, between industrial societies and nonindustrial or preindustrial societies, the latter being referred to quite frequently as the "developing countries." At the same time, a distinction is now increasingly made between socialist and capitalist economic systems and between the societies that develop upon these different economic bases, even though there are important similarities between all the industrial countries as a social type, on one hand, and the developing countries as a contrasting type, on the other, in spite of differences of economic regime within each type.

The consideration of social and cultural differences between whole societies, or types of society, or civilizations, involves treating these units as if they were themselves relatively homogeneous and undifferentiated. The aspect of social differentiation that has attracted most attention, however, is that which occurs within each society. Some kinds of internal differentiation related to biological characteristics, notably those resulting from sex and age differences, have already been mentioned; but the most prevalent types of social differentiation are those arising directly from social and cultural influences. Many social scientists have regarded the division of labour as the most important factor; one of the most obvious differences between individuals and groups in society is to be found in the kind of work that they perform. In the late 18th century the Scottish economist Adam Smith discussed not only the economic consequences of the extending division of labour but also its effects in determining the characteristics and life-styles of individuals. In the late 19th century the English philosopher Herbert Spencer conceived of the division of labour as a primary element in social differentiation and traced its development in the various parts of society. Similarly, Durkheim considered that the division of labour was the source of the individualism to

societies

be found in modern societies and that, although it posed problems of fragmentation and social disintegration, it offered the possibility of a new form of social solidarity based upon the interdependence of individuals and groups.

The great importance of the economic division of labour in producing social differentiation cannot be denied. Moreover, it is closely connected, as will be seen later, with the establishment and modification of social stratification. Nevertheless, it is now generally acknowledged that social differentiation extends beyond the economic division of labour and its effects; as one scholar noted, it "should be thought of as a differentiation of activity of every sort that has significance for the group." Spencer, for example, wrote in terms of the "specialization of functions" which resulted in a clearer distinction between the major parts of society—the governmental, the military, the ecclesiastical, the professional, the industrial—as well as a more intensive division of labour in the productive sphere. But the writer who brought out most plainly the complexity of social differentiation in modern societies was the German sociologist Georg Simmel. In his volume of essays *Über soziale Differenzierung* (1890; "On Social Differentiation") and in other works, he considered the great variety of influences that had contributed to the growth of individualism and the diversification of social groups in the western European countries during the 19th century. The rapid development of a money economy, the growth of cities, the mobility of individuals, the emergence of new social and cultural interests all have tended to produce more varied styles of life. In particular, city life offered the stimulus of diverse and competing intellectual and cultural outlooks, from which new kinds of differentiation could again arise, while the increase in the number of associations of all kinds, concerned with specific interests, permitted the individual to develop particular aspects of his own character and purposes. According to Simmel, in early societies the individual was more or less completely absorbed in the family group, but later he was able to enter into relationships with persons outside his circle on the basis of a similarity in character, tendencies, and activities. Thus new "social circles" arose which intersected the existing "natural groups." In modern societies a vast superstructure of social circles has grown up, and this process has been accompanied by an increase in individual liberty; in Simmel's view, the number of social circles to which the individual belongs is, to some extent, a measure of the development of civilization.

Although Simmel attached great significance to social differentiation, he also observed that differentiation was accompanied by a process of integration; and he suggested that human nature shows a fundamental need for both kinds of association—that association which differentiates individuals on the basis of competition and that which brings them together on the basis of cooperation. Thus, he observed that although there is a continual proliferation of more specialized circles because of the appearance of new occupations, new scientific pursuits, and new cultural styles, there is also a continual formation of large circles out of smaller ones—for example, the formation of a working class out of diverse occupational groups. This relationship between differentiation and integration can best be studied by looking at the historical development of social differentiation.

THE DEVELOPMENT OF SOCIAL DIFFERENTIATION

The process of social differentiation has often been taken as one of the principal indexes of social development. Thus, in 1926 the American sociologist Cecil C. North observed that the most significant distinction between a primitive and a highly civilized society was probably the degree to which functional differentiation had taken place. This followed the view of many earlier sociologists. Herbert Spencer for instance, had argued that it is

a character of social bodies, as of living bodies, that while they increase in size they increase in structure. . . . At first the unlikenesses among [society's] groups of units are inconspicuous in number and degree but as population aug-

ments, divisions and subdivisions become numerous and more decided . . . progressive differentiation of structures is accompanied by progressive differentiation of functions.

Spencer's ideas have been revived recently by the American sociologist Talcott Parsons, who has treated social change and development wholly as a process of increasing social differentiation.

It should be recognized, however, that although increasing social differentiation is one important aspect of social development, there are other features that have been regarded by many writers as having equal or greater significance in defining or explaining historical transformations of society. Spencer, for example, saw as one major element in social differentiation the emergence of dominant classes; this, too, was the crucial element in Marx's theory, which—in contrast to the idea of social development through a gradual, progressive differentiation of function—conceived of historical change as proceeding by revolutionary leaps whenever a new ruling class arose as a result of new modes of production. Many recent studies by sociologists and economists have emphasized particularly the distinction between industrial and nonindustrial societies and have considered industrialization, in which social differentiation is only one element, as the major form of social change.

Another important qualification must be applied to the view that social change consists essentially in the process of social differentiation. It is true that in many respects—especially in their occupational structures—modern societies are more differentiated and more heterogeneous than were earlier societies; but forces are also at work making for greater homogeneity. The rise of the European nation-states in the 19th century, the development of national systems of education, the improvement of communications, the increasing size of economic enterprises, and more recently the growth of the mass media have all contributed, in the opinion of many writers, to a greater uniformity of national culture and to the disappearance or attenuation of local and regional diversity. Such developments have been commented upon, from various points of view, in writings on "mass society" and the "consumer society." It has also been argued that increasing social equality in the industrial countries (a diminution of the differences between social strata and greater social mobility) has begun to create a more homogeneous national culture. The factual basis of this argument, however, is disputed, and the most that can be said probably is that the general rise of levels of living, rather than equalization, has had some effect in producing more uniformity in styles of life. The tendencies toward homogeneity are to be seen not only at the national level but also on an international scale, and it has been suggested that all the advanced industrial countries show certain fundamental similarities in their structure and culture—primarily because of industrialism, urbanism, vastly improved communications systems, and the influence of international economic organizations. It would be very difficult, nevertheless, to establish in a precise way the degree to which present-day societies are becoming more or less heterogeneous. What is important is to recognize that the two processes of differentiation and homogenization proceed together, both within and between societies.

The processes of differentiation and stratification. It will be evident from the preceding account that many socially differentiated roles are evaluated as being "higher" or "lower" in some scale of prestige. Social differentiation, that is, overlaps with social stratification, the arrangement of groups and categories of individuals in a hierarchical order. Men and women, different age categories, ethnic groups, religious groups, or occupations may be treated not merely as different but as unequal. Stratification within societies is one of the most important forms of differentiation, but it has been conceived in diverse ways. Most students of the subject would agree that its basis is primarily economic, but economic differentiation itself can be viewed from a variety of aspects. According to Marxist theory, the most important distinction in all societies beyond the most primitive was that between the owners of the means of production

The twin processes of individualism and diversification

Contrasting processes of differentiation and homogenization

and those who supplied their labour power. These two groups constituted the principal classes in every society (though Marx also recognized the existence of intermediate and transitional strata), and the relations between the classes determined the general course of social events in all spheres of life. Depending upon the character of the means of production and, thus, to a large extent, upon the level of technology, different forms of class society have existed. Marx distinguished, in the Western world, ancient society, feudal society, and modern bourgeois (or capitalist) society; and he envisaged the advent of a new form of society, socialism, in the future. In all cases, the rise of new classes and the struggle between classes were the principal causes of major changes in social structure. In the modern capitalist societies, according to Marx, it was the industrial working class, in the various forms of labour movement that are its political expression, that would accomplish such changes and inaugurate a new society.

Marx was not alone in recognizing the importance of social classes; many 19th-century historians, political scientists, and sociologists made similar observations, but they did not all explain the origins and development of classes in the same way, nor did they attach the same political importance to class conflict or envisage the future, as Marx did, in terms of a working class revolution to establish socialism. Spencer drew attention to the role of dominant classes, and Durkheim recognized the pervasiveness of class conflict in the modern European societies, but both considered that classes could coexist harmoniously in the industrial societies, so long as these societies continued to develop their relatively open and democratic character. Other writers, such as the Italian economist Vilfredo Pareto, while adopting the conception of class from Marxist thought, argued that the existence of a governing class, or elite was unavoidable and were chiefly concerned, as many later writers have been, with the effectiveness of the dominant class in maintaining a stable social order.

The Marxist scheme has, at various times, been ignored (largely because of its ideological orientation), criticized, and revised. One point of criticism concerns its applicability to all the diverse forms of stratification. It seems most relevant to the 19th-century European societies and to the transition from feudalism to capitalism in western Europe, but much less useful in dealing with such a phenomenon as the Indian caste system. Caste has undoubtedly an economic basis: the major caste categories (the *vargās*) resemble feudal estates, while the effective caste groups (the *jātis*) are closely related to differences of occupation. Nevertheless, the complexities of the caste system and the sanctions maintaining it can hardly be understood without taking account of the influence of religious ideas; and the historical relations between castes seem far removed from those which characterize the conflict between classes.

The interrelations of class, status, and power. A more general criticism of the Marxist theory leads to an alternative conception of social stratification. In writings published posthumously in 1922 the German sociologist Max Weber made a distinction between class, status, and power, arguing that these represented different forms of stratification that coexisted but did not necessarily coincide in modern societies. According to Weber, class situation was mainly determined by the ownership or nonownership of property (more or less along the lines that Marx had described); status situation was determined by the attribution of "social honour" on the basis of consumption or style of life; and the power situation was determined by possession or nonpossession of the means of command. Thus the relative importance of class and status in the stratification system has to be investigated in particular societies and periods: the predominance of one or the other would depend upon economic and cultural conditions that affect the extent to which men become class conscious or status conscious. Moreover, political power is relatively independent of both class and status; it is not regarded, as in Marx's theory, as being merely a consequence or reflection of class position.

The introduction of the notion of social status (which was developed from the feudal idea of legal status) led in due course to the formulation of a distinctive theory of social stratification. In contrast to the Marxist conception—according to which society was divided into major classes engaged in economic, political, and cultural conflict over the basic structure of society itself—the new theory viewed society as a hierarchy of status levels, with each level determined by a social evaluation of the importance or worth of the activities carried on by individuals at that level. The emphasis was upon the placement of individuals in the social hierarchy, not upon the formation of groups and their interrelations. The fact that numbers of individuals occupied the same rank position was considered (if at all) as a secondary phenomenon, and those occupying the same position tended to be treated as forming statistical categories rather than social groups. Thus, in many recent studies of social mobility the various social levels have been defined in terms of occupational prestige, and the scheme of ranking that has been constructed in this way is acknowledged to be a partly arbitrary set of categories, not a system of significant social groups. One researcher in 1954, for instance, distinguished seven occupational prestige categories for the purpose of studying movement between lower and higher social levels in Great Britain, while a pair of researchers in 1967 used a prestige scale of 17 types of occupation for their study of mobility in the United States.

Conceived in this way, stratification is very closely connected with social differentiation in the form of the division of labour, since it is the differentiation of occupations and their evaluation and ranking that are taken to be the source of stratification. It is clear, however, that this does not provide a complete picture of the social hierarchy. Besides the ranking of occupations, and the construction of categories of occupations that are judged to have equal prestige, there is a process of formation of social groups that, through their pursuit of particular interests, play a distinctive part in the system of stratification. Most of what are called the liberal professions, and even the professions as a whole, have generally been regarded as constituting groups of this kind, and it has also been widely recognized that there are various types of elites, not all based upon specific occupations, that have a major influence in shaping the institutions and culture of a society. Furthermore, the various stratified groups and prestige categories are themselves closely connected with social classes, as may be seen from the fact that occupations are thought of, and referred to, as being upper class, middle class, or working class in character. As Simmel observed, the process of occupational specialization is accompanied by an opposite process of incorporation of the occupations into social classes.

There is still another aspect from which the association between status, class, and power should be observed. The prestige of occupations, which is often taken to be the crucial element in establishing a hierarchy of status, at least in modern societies, is determined by social evaluations, but one needs to ask how these evaluations themselves come to be made and accepted. The importance or worth of particular occupations is not something established by nature, and it may be argued that it is those persons who are already wealthy or powerful (that is to say, dominant) in society who decide the scale of prestige. In this sense, therefore, the existence of a status system presupposes the existence of dominant and subordinate classes or of governing elites and subject groups. Nevertheless, other influences upon the prestige of occupations also seem to arise directly from economic and cultural conditions—for example, the changes brought about by the rise of modern science and technology, by the growing secularization of culture, and by the development of mass leisure that has given higher incomes and greater prestige to entertainers of all kinds.

The relations between class, status, and power, as different forms of social stratification, are complex and variable. In some times and places the formation of classes and the struggles between them for political power may be of pre-eminent importance, as was the case in

western Europe during the period of the rise of the bourgeoisie in feudal society, and again in the 19th century when the organized working class movement began to develop. Under other conditions, however, though class divisions exist, they may be less significant than differences of status arising from the diversity of occupations, ethnic origins, and styles of life, **influenced** by a variety of cultural factors including religious doctrines. It has been argued, for instance, that class differences in the Western industrial societies have begun to lose some of their cultural and political importance in recent decades as a **consequence** of such changes as the more extensive division of labour leading to a greater variety of status positions, greater social mobility, the expansion of education and of middle class occupations based upon educational qualifications, and higher levels of living. It remains a matter of controversy, however, whether or not social classes have yet ceased to be the principal source of political ideologies and conflicts in these societies.

Social mobility. In the earliest human societies, differences of class and status as one of the principal types of social differentiation may have emerged in various ways—partly as a result of the accumulation of property or the monopolization of leadership positions by particular individuals and families and partly by means of conquest and the enslavement of other social groups. Once established, these differences are maintained by inheritance and strengthened by the elaboration of cultural distinctions in dress, education (initially a distinction between literacy and nonliteracy, and, later, differences in quality and duration of education), and style of life as a whole; they are also consolidated by legal and religious codes. Occupations may become hereditary (either in a formal way, as in the Indian caste system, or on a customary basis); property is transmitted through the family; and political power is inherited by the members of royal and noble families. Of course, the inheritance of social position is never complete in the sense that no new men can attain to wealth, prestige, or power. Pareto exaggerated somewhat when he wrote that "history is a graveyard of aristocracies," but it is certainly true that in all societies there has been some circulation of individuals and families between different social levels. Even in the Indian caste system, which was a particularly closed form of social stratification, it was possible for individuals, and especially for caste groups, to rise in the social hierarchy by various means; and in the European feudal societies there were considerable opportunities for mobility, particularly after commerce and the towns began to develop.

It would seem that modern industrial societies are the ones in which social mobility has generally attained its highest degree and in which inheritance of social position has diminished most. But, in truth, it is difficult, and in many cases impossible, to make rigorous comparisons of the degree of social mobility in one society at different times or in different societies; for the judgments that are made about the relative openness of different types of society tend to be based more upon a consideration of formal opportunities and restrictions than upon an examination of actual movement between social levels. Thus there is controversy about whether or not social mobility in industrial societies has increased during the present century; and, moreover, it is quite clear that there is still a very significant inheritance of class position. The distribution of wealth is obviously highly unequal, and it is primarily through the transmission of property that families in the upper strata maintain their social position and exclude those from lower strata.

There are some conditions under which social mobility undoubtedly increases. After a revolution, for example, there is likely to be a general reshuffling of the dominant groups in society; thus, in the U.S.S.R. after November 1917, and in the countries of eastern Europe after 1945, many individuals from subordinate groups in society rose to positions of considerable prestige and power, while others who had previously been dominant fell in the social hierarchy. But at a later stage there may be a new consolidation of status positions. This is particularly noticeable in the sphere of higher education; immediately

after the revolutions in eastern Europe, the universities were thrown open to children of working class and peasant families, but as the new upper and middle strata of the population became established they began to acquire privileges for their children, in education as in other spheres, and the recruitment of university students from the working class and peasantry declined again.

Another, more gradual, process affecting social mobility has been the changing structure of occupations in the advanced industrial countries. There has been a steady decline in the numbers employed in agriculture and extractive industries and, more recently, the beginnings of a decline in the numbers of manual workers in manufacturing industry; whereas there has been a continual expansion of clerical, technical, and professional occupations. This process has gone farthest in the United States, where one-half of the employed population is now engaged in middle class occupations, but it is taking place, also, in the European industrial countries and Japan. Its result is to move a proportion of each new generation from low-status manual occupations to higher status white-collar occupations and, at some point, to create, as has been claimed for the United States, a predominantly middle class society. But this process has further implications for social differentiation; insofar as it establishes, over a large area of society, a middle class style of life, depending upon similarity of income and occupation, it diminishes differentiation and produces a greater uniformity. This is one aspect of the phenomenon mentioned earlier that sociologists have **characterized** as mass society. The extent of such uniformity is limited, however, even in the most advanced countries. There is still a clear distinction between the small group of wealthy property owners and the rest of the population; and there are **many groups**—such as certain ethnic groups, workers in backward or declining industries, and retired workers—who live in conditions of relative poverty far below the standards of middle class society.

The individual and society. The phenomenon of social differentiation throws some new light upon the **relations** between the individual and society. It is not the case that each individual, with his array of personal qualities, confronts the whole society to which he belongs. He is born into particular, **differentiated** social groups, and his life experiences in these groups do something to form his character and determine his outlook, aims, and achievements. Nevertheless, social differentiation may be regarded as one of the main factors responsible for modern individualism. In broad outline, Durkheim's contrast between early, relatively simple societies, in which the individual is molded to a single pattern of behaviour, and modern complex societies, in which the individual is more differentiated, seems valid if one takes into account not only the increasing division of labour but also the increasing cultural diversity (which arose partly from the criticism of established religious and moral ideas), the development of towns and the consequent opportunities for competition between ideas, and the greater mobility of individuals. Durkheim thought, in fact, that individualism had gone too far in France and was endangering the cohesion of the society. Simmel, on the contrary, writing at about the same time, toward the end of the 19th century in Germany, suggested that modern societies had achieved a better proportion of freedom and restraint than had earlier societies; the individual was freer to choose the social circles to which he would belong, but these numerous and diverse circles were more fully integrated into larger groupings and into the whole society. The proportion between freedom and restraint, between differentiation and individualism, on one side, and the overall regulation of social life, on the other, is clearly not established once and for all in a particular type of society. The industrial societies of the late **20th** century seem to many observers to have moved toward greater restraint in many areas of life; the sheer size of organizations, the more powerful means of control in the hands of governments, and the emphasis upon national unity in a century characterized by large-scale international conflicts have all contributed to a loss of individ-

Trends toward increasing restraint or permissiveness

Ways in which stratification develops

Ways in which social mobility develops

ality and widespread sentiments of individual powerlessness. These tendencies seem to have been countered only in a small degree, in limited areas of life outside the economic and political sphere, by the cultural "permissiveness" that has developed during the past two decades. It remains to be seen how a new balance between individualism and the general regulation of social life (which is needed increasingly on a world scale) will be achieved in the rapidly changing conditions of the late 20th century; but there seems no reason to doubt that it will have to take account of the duality that Simmel observed—the human need, on one side, for differentiation, diversity of life, and individual expression and, on the other side, for cooperation with other men within an ordered social framework in which similarities rather than differences are emphasized.

BIBLIOGRAPHY. The principal general studies of social differentiation are GEORG SIMMEL, *Über soziale Differenzierung: Soziologische und psychologische Untersuchungen* (1890); and C.C. NORTH, *Social Differentiation* (1926). Differentiation in terms of social roles is discussed in R. LINTON, *The Study of Man* (1936); H.H. GERTH and C. WRIGHT MILLS, *Character and Social Structure* (1953); and M.P. BANTON, *Roles* (1965).

There is a large literature on sexual differentiation, particularly from the aspect of the position of women in society, ranging from J.S. MILL'S classic essay, *The Subjection of Women* (1869), to anthropological studies such as MARGARET MEAD, *Male and Female* (1949); and more polemical works by SIMONE DE BEAUVOIR, *Le Deuxième sexe*, 2 vol. (1949; Eng. trans., *The Second Sex*, 1953); and KATE MILLETT, *Sexual Politics* (1970). Age differentiation is discussed in KARL MANNHEIM, "The Problem of Generations," in *Essays on the Sociology of Knowledge*, 2nd ed. (1952); S.N. EISENSTADT, *From Generation to Generation* (1956); and MARGARET MEAD, *Culture and Commitment: A Study of the Generation Gap* (1970). Racial differentiation has attracted increasing attention and concern; it is discussed from various aspects in OLIVER C. COX, *Caste, Class and Race* (1948); in the series of studies published by UNESCO, *The Race Question in Modern Science* (1951–53); and in PIERRE L. VAN DEN BERGHE, *Race and Racism: A Comparative Perspective* (1967).

The division of labour is treated at length in EMILE DURKHEIM, *De la division du travail social* (1893; Eng. trans., *The Division of Labour in Society*, 1933), which also deals with the differentiation of societies into types. Other classifications of the types of society include FERDINAND TONNIES, *Gemeinschaft und Gesellschaft* (1887; Eng. trans., *Community and Association*, 1955), KARL MARX and FRIEDRICH ENGELS, *Die deutsche Ideologie* (1846; Eng. trans. of pt. 1 and 3, *The German Ideology*, 1938), *Manifest der kommunistischen Partei* (1848; Eng. trans., *The Communist Manifesto*, 1933); RAYMOND ARON, *The Industrial Society* (1967).

The literature on stratification is extensive, but the following works provide a view of the major aspects: S. OSSOWSKI, *Class Structure in the Social Consciousness* (Eng. trans., 1963); MAX WEBER, "Class, Status, Party," in *Wirtschaft und Gesellschaft* (1922), Eng. trans. in H.H. GERTH and C. WRIGHT MILLS (eds.), *From Max Weber* (1946); J.A. SCHUMPFER, "Social Classes in an Ethnically Homogeneous Environment," *Imperialism and Social Classes* (1951); KINGSLEY DAVIS and WILBERT MOORE, "Some Principles of Stratification," in R. BENDIX and S.M. LIPSET (eds.), *Class, Status and Power*, 2nd rev. ed. (1966). On elite groups, see C. WRIGHT MILLS, *The Power Elite* (1956); and T.B. BOTTOMORE, *Elites and Society* (1964). There have been many studies of social mobility; two national inquiries which also deal with wider issues are D.V. GLASS (ed.), *Social Mobility in Britain* (1954); and PETER BLAU and OTIS D. DUNCAN, *The American Occupational Structure* (1967).

(T.B.B.)

Social Groups

A social group can be defined at the most general level as any set of human beings who either are, recently have been, or anticipate being in some kind of interrelation. The term group, or social group, has been used to designate many kinds of aggregations of humans. Aggregations of two members and aggregations that include the total population of a large nation-state have been called groups.

Most applications of the concept of group have been based on definitions more rigorous and limiting than that given above; they tend to identify narrower types of

groups by specifying one or another part of the general definition. The term small group, for example, which is treated later in this article, limits the number of members and sometimes the nature and extent of their interdependence. As another example, distinctions such as family or work group represent specifications of the basis for membership as well as of the type or extent of member interdependence.

TYPES OF GROUPS

Contrasting criteria for classifying groups. One of the earliest and best known classifications of groups was the American sociologist C.H. Cooley's distinction between primary and secondary groups, set forth in his *Human Nature and the Social Order* (1902). "Primary group" refers to those personal relations that are direct, face-to-face, relatively permanent, and intimate, such as the relations in a family, a group of close friends, and the like. "Secondary group" (an expression that Cooley himself did not actually use but that emerged later) refers to all other person-to-person relations, but especially to those groups or associations, such as work groups, in which the individual is related to others through formal, often legalistic or contractual ties. Cooley felt that primary groups were the fundamental agencies through which the individual's character or personality was formed. In more recent times, sociologist Talcott Parsons in the United States distinguished five dichotomous characteristics, or pattern variables, that help to distinguish primary groups from secondary groups; relations among members of primary groups, as contrasted with secondary groups, tend to be (1) diffuse, rather than specific or delimited; (2) particularistic, rather than universalistic; (3) ascription based (*i.e.*, who or what you are), rather than achievement based (*i.e.*, what you do or have done); (4) other oriented or group oriented, rather than self-oriented; (5) affective or emotion laden, rather than emotionally neutral. Secondary groups are sometimes viewed as the logical complement—that is, all groups that are not primary are secondary. It is probably more instructive to consider secondary groups as those in which relations between members tend to fit the opposite poles of the five pattern variables.

Historically, many other pairs of terms have been used to classify groups, and there is a great deal of overlap among them and between each of them and the primary-secondary distinction. The German sociologist Ferdinand Tonnies coined the now-famous distinction between *Gemeinschaft* and *Gesellschaft*, which is usually translated as community versus society or association and which for all practical purposes reflects the same distinction as primary versus secondary. The American anthropologist Robert Redfield distinguished between folk society and urban society. The English jurist Sir Henry Maine talked of societies of status and societies of contract. But all of these, too, are virtually coterminous with the primary-group-secondary-group distinction. There is also a close correspondence between these pairs of terms and the distinction between mechanical solidarity and organic solidarity, which was emphasized by the French sociologist Émile Durkheim.

Still other sets of terms are used, not as bases for distinguishing types of groups but as bases for describing the individual's relationship to different groups. Thus, the terms we-group and they-group, as well as the terms ingroup and outgroup, are used to contrast a group of which the referent or focal person is a member (often, a primary-type group) and some other group—not necessarily different in kind—of which the focal person (and other members of his ingroup, or we-group) is not a member and toward which he feels some degree of animosity or negative affect.

Another set of distinctions based on the individual's relationship to the group are the terms membership group and reference group. The former has the obvious meaning of a group of which the individual is a member, here and now, by reason of one characteristic or another (such as being a member of a particular family or a member of the sixth-grade class in Jefferson School). The

Primary
and
secondary
groups

Statistical
groups
and
actual
groups

term reference group has been used in two ways, to mean either a group for which the individual aspires to membership or a group whose values, norms, and attitudes serve as points of reference for the individual. In either case, the crucial feature is that the individual adapts his attitudes and behaviour to model those of the members of the reference group. Obviously, membership groups and reference groups are not mutually exclusive.

The term group, or social group, has been used to refer to very divergent kinds of aggregations of people. Indeed, the term has been used so broadly as to threaten its fruitfulness as a focal concept. For one thing, the word group has sometimes been used to designate the members of a social category based on possession of a common attribute, even when the members have no meaningful degree of interrelation. Thus, it has been used to refer to such collections as persons of a particular age, all persons having similar incomes or occupations, or all persons with similar reading habits. These are what might be called statistical groups, as distinct from actual groups, the latter being characterized by some kind and degree of interrelatedness among the members.

As soon as one differentiates between statistical groups based on possession of a specified attribute and actual groups based on interrelation of members, however, it becomes apparent that there are many forms of human relations that do not fit neatly within this dichotomy. For example, although "all of the residents of the state of Iowa" might be viewed as a statistical group but not an actual group, it is not necessarily clear that the members of that set are not interrelated, at least in regard to certain political decisions and economic events. It might be argued that "residents of Iowa" are not an actual group, because each member does not directly affect every other member, but by that criterion one would have to draw the same conclusion regarding many other aggregations, such as all employees of a particular industrial plant or all members of a certain religious denomination or even all members of some very large families. The same would be the case if one were to argue that "residents of Iowa" are not an actual group because each member is not simultaneously aware of and taking into account the attitudes and behaviour of every other member. Such a criterion would eliminate any but relatively small groups, and this is indeed one of the criteria that has been applied to define the small group.

Classifications of social groups and other social aggregates. Because of some of the problems of definition and classification, sociologists have attempted to distinguish among various kinds of social aggregates, some to be considered groups and others to be identified by other terms — audiences, publics, and the like. There is no generally accepted classification at this time; but the following distinctions, drawn in terms of the bases for membership and the degree of person-to-person influence, seem helpful in clarifying this complex picture.

Artificial aggregations

A statistical group, or social category: Members have one or more properties in common (*e.g.*, age; sex; political-party preference) but otherwise are not necessarily in any kind of interrelation or aware of one another.

Unorganized aggregates

An audience: Members are attending to a common set of stimuli (*e.g.*, a mass-media presentation; an eclipse) but are not necessarily in interaction or aware of the communality of this experience.

A crowd: Members are attending to a common set of stimuli and are in physical proximity with one another, hence interrelated, at least in terms of sensory stimulation.

A public: Members are attending to a common set of issues and are in at least indirect interaction on these issues and thus are aware of the communality of interest, though not necessarily in physical proximity or direct communication. Units with patterned relationships

A culture: All of the members share a common and patterned set of value orientations and common language, dress, and customs, although with patterned variations. Members are interdependent with respect to these aspects of the culture, though not necessarily explicitly aware of all of these interdependencies.

A subculture: Members share a set of value orientations,

language, etc., common to members of that subculture and in notable contrast to (often a variant of) the surrounding culture. At the same time, members of the subculture share many other features of the surrounding culture.

A kinship group: All of the members are related by birth or marriage. Depending on the surrounding culture, the recognized kinship group may be extensive or limited, and it may or may not function as a crucial basis for other organized social forms.

Structured social units

A society: The structured relations, formal and informal, among the members of a large, more or less autonomous social aggregate; usually within a single culture, in a defined geographical region, and with an integrated political system (*e.g.*, a large nation-state). Relations between members and subsets of members are characterized by a high degree of interdependence.

A community: A geographic or residency-based subdivision of a society in which members reside in close proximity to one another; are highly interdependent; interact frequently, in many relationships and over extended time; and are aware of their mutual interaction and interdependence (*e.g.*, a small town, a neighbourhood).

A family (also the kinship group above): A kin-based or residence-based basic unit of a social system or culture in which members share a dwelling and other resources are highly and pervasively interdependent and are aware of their interdependence.

Deliberately designed social units

An organization: A large aggregate of people and material, explicitly organized to pursue certain goals (*e.g.*, profit for a business organization, education for a school system). Members are recruited, selected, or hired with reference to specific roles or positions in the organization. They are related to one another in ways that specify how each member or subunit is to contribute to pursuit of the organization's goals.

A suborganization: The portion of an organization within which a particular member is located (*e.g.*, a division of a company, an office of an agency, a department of a university). It is the part of the organization that most directly affects that person's behaviour.

A crew (or work team): The small set of persons within a work organization with whom a given person is in continual or frequent face-to-face interaction on the job and with whom he is highly interdependent in terms of task performance, resources, rewards, and the like.

Less deliberately designed social units

An association (or voluntary organization or interest group): Members share and are aware of their common interests in certain issues and deliberately seek interaction dealing with these issues. The relationship among members can remain relatively limited in extent (thus approaching a public); or the interaction among members can become highly frequent, intense, and extensive (thus approaching an organization). For example, membership in a political party may vary from nominal membership to a full-time commitment in the form of a vocation.

A friendship group: Members associate voluntarily, frequently, extensively, on a continuing basis, and with positive affect or emotional relations. Such groups are relatively small in number of members. Their basic goal may be group interaction per se, rather than specific task attainments. A friendship group may overlap in membership with a work crew, a suborganization, a family, a kin group, a community, or an association or interest group.

This list gives an indication of the main kinds of distinctions that have been made about various social aggregates. Various social scientists would probably consider some kind but not all of these to be properly labelled as social groups.

THE STUDY OF SMALL GROUPS

Researchers and theoreticians who have concerned themselves with small groups have used many definitions, differing in detail and emphasis. But the definitions contain certain common features that can be taken as the essential conditions for defining the term:

1. The set of members must be few enough so that each one can directly apprehend and (potentially) communicate with every other member. Many authors have suggested an upper limit of the order of 20 to 30, though ten or fewer members are usual.

2. The members must be engaged in some enterprise or have some objective or goal or be immersed in some situation, such that their outcomes (rewards and costs) are interdependent.

Definitions
of
small
groups

This notion has been expressed in terms of members having a common fate.

3. The members must be aware of their interdependence with the other members; that is, they must perceive the existence of the group at least in terms of the relationship of the outcomes to the membership.

4. The above conditions imply that the members must be at least to some degree in communication or interaction with one another and that this relationship must continue (or has been continuing) for some meaningfully long period of time.

It should be noted that the definitional constraints do not specify that all of the members share the same goals, only that their goals be interdependent. Thus, members of small groups may be related in either competitive or cooperative relations; they may also be involved in a mixture of competition and cooperation.

As with the broader categories of social groups, small groups can and have been classified into types on many bases. For example, groups have been compared on the basis of difference in number of members: dyads (two-person groups), triads (three-person groups), and so forth. Groups have been classified as task-oriented or personally oriented groups. Task-oriented groups are those supposedly engaged in activities instrumental to some specific goal(s). Personally (or emotionally) oriented groups are those supposedly focussed on the personal relations among group members. Many real-life groups, such as the family, do not fit this dichotomy neatly; their members are engaged in both task-oriented and interpersonal behaviour. Indeed, many theorists hold that all groups are continually engaged in both kinds of behaviour.

History of small-group study. Man's interest in group phenomena probably goes back as far as recorded history. Certainly, the roots of issues concerning groups can be traced back to the ancient Greek philosophers, to thinkers of the Renaissance, and to western European scholars of the 16th, 17th, and early 18th centuries. But modern social psychology and sociology and the study of group phenomena within those disciplines really began in the latter years of the 19th century among sociologists in France, Germany, and the United States. In those years, the major effort was spent grappling with basic theoretical issues: the importance of innate instincts and what those basic instincts were; the role of experience or learning or habit on man's social behaviour; the "reality" of social groups and the existence of a "group mind"; principles of human behaviour alleged to be fundamental social forces, such as imitation, suggestion, sympathy. These efforts were largely theoretical—the product of speculative thought, based on personal experience and reading—rather than empirical, or based on systematic observation.

Decline of
theory
building

This theory-oriented period ended in the 1920s, and the field of social psychology and small-group study came under the sway of Positivism, with its emphasis on the collection and interpretation of empirical, or observational, evidence. At first, the social psychologists and small-group researchers brought their problems into the laboratory and borrowed the guidelines and methodology of the physical sciences. By the 1930s, however, social psychology and small-group research shed their laboratory confinement, though not their emphasis on data over theory, and began to grapple with problems in real-life settings. Perhaps this movement was in response to the worldwide economic depression and the social turmoil that accompanied it. Researchers began to study mass movements, prejudice, gangs and delinquency, and the like. But this decade also saw the development of the so-called group-dynamics movement, under the leadership of a German-born social psychologist, Kurt Lewin, and this movement in large part shaped the field of group research for years to come. In its early years, under Lewin's genius, the group-dynamics movement was a balanced blend of concern with theory, with its application to socially significant problems (frustration, leadership styles, attitude change, and so on) but with experimental or laboratory methodology.

In the 1940s small-group research, like everyone else, went off to war, so to speak. The new problems opened up

by the early promise of the group-dynamics movement and the "boom" aspects of the wartime setting stimulated large quantities of research. These served to advance the field in two ways: by generating much new evidence on certain substantive problem areas (such as leadership or attitude change in groups) and by producing a marked development and refinement of methods (such as techniques for measuring interpersonal feelings, techniques for constructing experimental groups of desired composition, and the like). But the strong theoretical orientation of Lewin's early work was apparently a casualty, perhaps in part because of the wartime spirit of urgent pragmatism.

Since World War II, although there has been a vast amount of research that has resulted in the piling up of evidence, there have been few significant attempts to formulate comprehensive theories. In the 1970s even the research has seemed to decline. Meanwhile, many persons in related fields have tried to find practical uses for the evidence and methods that have been developed. So-called group methods were introduced into psychotherapy, into teaching, and into business management, in efforts to improve practices in those fields. The efforts went under such names as group therapy, training group or training laboratory, encounter group, and sensitivity training. Many of these movements were and continue to be quite successful, in the sense of widespread adoption and ardent belief in them by their exponents. But remarkably little research has been done to assess the effectiveness of these practices in accomplishing substantial and enduring "improvements" in the groups in question.

Major areas of concern. Because the history of small-group research has been marked by a great deal of evidence gathering and very little theorizing and integration of the findings, it is difficult to put the information together into a coherent pattern. The sections that follow can indicate only the major constellations of evidence in a few problem areas.

The individual in relation to others in a social group. People influence one another in many ways. Such influences occur in many kinds of person-to-person relationships, which are not usually thought of as groups but which are closely related to effects that do occur in groups. It is useful to consider, first, some ways in which the presence and behaviour of other persons affect a given individual in a "one-way" relation and, second, some kinds of two-way relations between people.

The way in which an individual can be influenced may depend on the state of his relationship with others—that is, on the degree of his involvement or interaction with them:

1. The individual can be under observation by an audience. The audience can either be seen by him or unseen but known to him. The audience can be merely passively observing or observing and in some way obviously evaluating (as by applause or laughter).

2. The individual can be observing the behaviour of one or more other persons—either by himself (as an audience of one) or along with other members of an audience. The other person can be said to be modelling certain behaviours for the observer.

3. The individual can be engaged in the performance of some task, in the presence of others also engaged in that task but without the interdependence of his work with theirs. Persons in this relationship are sometimes said to be in a coacting group (as distinguished from an interacting group, below).

4. The individual can be engaged in performance of some task in the presence of or in communication with others also engaged in that task or in complementary tasks, under conditions of mutual influence. Persons in this relationship are sometimes referred to as in an interacting group (as distinguished from a coacting group, above).

There is considerable evidence that individual performance is influenced by the mere presence of others, as, for example, in an unseen (but known to be present) passive audience. The **influence** is greater for an active (*i.e.*, evaluating) audience, for a model observed by the person, and for other persons in a coacting relation.

Many early studies of individual performance focussed

Group
training
movements

Social facilitation

on the concept of social facilitation, which denoted that the sights and sounds of others somehow stimulated the individual and increased his efforts. The general findings from those studies were that the **presence** of others led to increased efforts or intensity of performance, yielding increased quantity of productivity and sometimes increased speed but also yielding reduced quality or accuracy. Results of these early **coaction** studies, however, were not always consistent; some studies showed performance gains, some performance decrements. The differences in results appeared to be attributable to the type of task and were interpreted by some to mean that social facilitation aided motor performance but was detrimental to performance on intellectual tasks.

More recent work has tended to clarify these effects of social facilitation. The presence of others seems to lead to an increase in physiological arousal. It had been shown in earlier work on human and animal learning that increased arousal tends to make the most dominant response (that is, the strongest or best learned habit) even more dominant. It would seem to follow, then, that the presence of others, leading to increased arousal, which in turn leads to an increasing dominance of the best learned response, will facilitate the performance of a well-learned response. But at the same time such arousal will hinder the learning of new responses. Thus, the presence of others helps performance on **well-learned** tasks (which many of the motor tasks used in the early studies were) but hinders performance on tasks that call for the learning of new responses (which was the case with many of the intellectual tasks used in the earlier studies).

Not only can the presence of other people be a source of arousal, but also their behaviour or their inactivity can function as a source of information for an individual. A person, for instance, is much less likely to respond to an apparent emergency when in the presence of others who do not respond (inactive bystanders) than when faced with the same situation alone. Under some conditions, the presence of other people may offer emotional support; a person anticipating an aversive situation (such as a painful injection or shock) apparently prefers to await the event in the company of others who are in the same predicament. This seems to hold true even if direct communication with the others is impossible, so that their comforting behaviour cannot be a factor. Again, this effect may arise in part because others represent a potential source of information about how to act in the threatening situation.

When an individual is kept in social isolation for an extended time, he apparently suffers more or less from deprivation of social contact. There are wide individual differences in such social deprivation, however; and it is not clear whether the effects of the social deprivation ensue from the lack of arousal (which the presence of others brings) or from the lack of information (which other people provide) that could serve as cues to the meaning and proper behaviour for the situation.

Overall, it is apparent that the presence and behaviour of other persons in any of several kinds of relations can influence the individual in any of several ways. Other persons can increase arousal, hinder learning but facilitate performance of already-learned responses, provide cues to appropriate behaviour and to the consequences of behaviour, and produce both positive and negative emotional effects.

Group composition. One major class of factors potentially influencing group behaviour has to do with the composition of the group. These factors consists of all of the attributes or properties that the individual persons bring with them to the group and that may affect their behaviour while members of the group. These factors may be conveniently divided into five classes: (1) biographical characteristics of members (sex, age, socioeconomic class, etc.), (2) personality characteristics of members, (3) abilities of members (both general abilities such as intelligence and specific abilities pertinent to the group's tasks), (4) attitudes of members (their beliefs and feelings about the task, the situation, and various outside persons, groups, and objects), and (5) position of

each member in the group (including aspects of his social position or status and aspects of his task position or physical location).

Though evidence in this area is not very clear-cut, it seems to suggest that personality factors do not affect a group's task performance as much as one might suppose. It may be that group behaviour is more apt to be influenced by the pattern of member traits—personality, biographical, or otherwise—than by the presence of some seemingly beneficial or adverse trait, in any one individual or average of individuals. These patterns of traits may involve many things but are broadly based on similarity of some needs (such as affection) or complementarity for other needs (such as control). In any event, there would seem to be no simple and general prescription for putting together an effective group on the basis of the personal attributes of potential members.

Neither do abilities necessarily predict the performance of the group as a whole (though they may predict the task performance of individual members somewhat). This is not surprising, in that the effective performance of group tasks often requires intricate teamwork or coordination, and such coordination is not directly reflected in the individual abilities of individual members. Indeed there are several ways in which the performances of individuals can be combined to yield a group performance, depending on the nature of the task and the organization of the group. One suggested list of patterns is the following:

1. Additive: the group product is the sum of individual outputs, as when several members each work independently, and their results are combined. Here, group performance should reflect the summation of member abilities.

2. Compensatory: the group product is achieved by a combination of member efforts such that one member's low or inaccurate production can be compensated for by other members' high production. Here, group performance should reflect the average member ability.

3. Disjunctive: the group successfully achieves the task if any one member achieves it successfully. Here, group performance should reflect the ability of the most able member.

4. Conjunctive: the group successfully does the task if and only if each member successfully does his part. This might be exemplified by team performance in a sport such as rowing. Here, group performance is limited by the ability of the least able member.

5. Complementary: the group task requires the blending or coordination of different kinds of performances by team members, simultaneously or in a close sequence. This might be exemplified by various complex routines within team sports, such as a complex play in hockey or football. Here, successful group performance requires not only that all of the requisite skills exist in sufficient degree among the group's members but also that the distribution of those skills among the members fits the distribution of task requirements among them.

In these terms it would seem that the abilities of members, combined according to the model that fits the particular group's task, will represent the upper limit of potential group performance. Actual performance may depart from that upper limit insofar as the group activities require coordination and also insofar as members are less than optimally motivated toward effective task performance.

It is through these processes of coordination and motivation, that many factors other than member abilities come to play a part in affecting group performance: interpersonal relations, authority and influence relations, member attitudes toward the task and one another, and so forth. Again, as with personality and biographical characteristics of members, the abilities of members contribute to but do not solely determine behaviour in groups; their contribution depends not so much on amount as on pattern; and the most effective pattern interacts with factors relating to the group's task and situation.

Power and influence. It is useful to distinguish between power, or the potential for influencing others, and influence, or the actual modification of the behaviour of others. At least five possible bases or sources of power may be listed:

Effects of individual personalities

Effects of individual abilities

Other persons as sources of information or support

1. Legitimate power: potential for influence that derives from being the incumbent of some position or office.
2. Referent power: potential for influence that derives from being liked or respected, personally.
3. Reward power: potential for influence that derives from being able to bestow or withhold valued objects.
4. Coercive power: potential for influence that derives from being able to impose or withhold punitive actions.
5. Expert power: potential for influence that derives from possessing information or skills necessary or valuable to the other.

The study of power (and influence) relations in groups underlies some of the main topical areas in the study of small groups, such as in the study of leadership and conformity.

Nature of leadership

In recent times the focus of leadership research has shifted away from a concern with identifying the leader (as opposed to the follower) or the effective leader (as opposed to the ineffective one)—all largely out of context. The shift has been toward studying the process of leadership itself—that is, studying influence rather than power. Furthermore, the present conviction is that leader, group, task, and situation must be studied concurrently as interacting elements.

One of the most prominent of current theories holds that the kind of leadership style that is most effective depends on the "favourability" of the group-task-situation complex. A situation is favourable to the extent that the leader is liked by his group (referent power), to the extent that he has a strong formal position in the group (legitimate power and perhaps expert power), and to the extent that the group's task is well structured (hence, amenable to the use of reward and coercive power by the leader). In very favourable situations and in very unfavourable ones, a strong or directive or task-oriented leadership style is most successful. In situations of intermediate favourability, in contrast, a more personal-oriented style of leadership seems to be generally more effective.

There is an important competitive line of thought. Early research on leadership focussed on the leader—and often on a search for the traits that made him a leader or a good leader—and the unsuccessful course of that research led many scholars to make an about-face. There is no inherent reason, they thought, why all of the groups must have a singular leader. Indeed, there is considerable evidence that groups often develop more than one kind of leader role. In any case, it is clear that the leader is dependent on his followers to execute tasks necessary to group success. Thus, they may exercise some influence on him, as well as he on them; that is, influence between people is mutual, even when there is a subordinate-superordinate power relationship between them. From this perspective, every man is a leader, in some degree. Hence, it is not fruitful to use leadership as a focal concept; rather, it is more useful to consider the influence process itself.

Nature of conformity

Also related to power and influence is the concept of conformity, which has long been a central object of group research. It was early shown that, when people are influenced by the judgments of others, the direction of influence is toward a common judgment or norm and that the influence persists, later, when the person is again making judgments alone. It was later shown that such social influence was still considerable even when the others were deliberately making incorrect judgments of unambiguous events. These findings triggered an avalanche of research on the antecedents, limiting conditions, and consequences of conformity.

Some of the more systematic research on conformity developed evidence in support of the following network of relationships: physical proximity and other opportunities for encounter increase the probability that communication will take place between any given pair of people. Increased communication leads to positive personal attraction. Personal attraction leads to pressures for uniformity of attitudes, at least on issues relevant to the relationship (that is, conformity to shared attitudes or norms). Deviation of attitudes leads to increased communication, aimed at persuasion. If persuasion is not suc-

cessful in leading to conformity, there will be a shift toward negative attitudes and rejection and a drastic reduction in communication.

Other studies have tended to clarify the complex interdependence of communication, influence, and attraction among group members. Interdependence, here, implies that a change in any one of these will produce compensatory changes in the other two. Thus, increasing communication will tend to increase attraction and influence; increasing influence (such as by increasing a member's power or status) will tend to increase attraction and communication to him; and increasing attraction will tend to increase communication and influence.

The process presumably underlying these phenomena is a tendency for what has been called cognitive balance, or consonance. To take a hypothetical example, when persons A and B are in potential interaction regarding some issue or person X, there is a tendency for one of several balanced states to exist in their pattern of relations. The major balanced state is mutual positive attraction to each other and agreement on X. If A and B are mutually attracted but discover that they disagree on X, this creates an imbalanced state (or a state of dissonance). Dissonance operates as a force toward change. The major modes of such change are: communication to persuade the other; change in one's own attitude toward X (conformity); change in one's own attitude toward B (change in attraction); misperception of the other's disagreement; or a redefinition of X (such as downgrading the importance of X). These mechanisms operate as alternatives to reduce interpersonal imbalance or dissonances. It seems that any given individual will tend to have a preferred mechanism for reducing dissonance and to employ it predominantly.

The ideas of power and influence and of interpersonal dissonance and conformity further imply the idea of conflict. In the main, conflict between persons and groups has been viewed as something "bad," to be avoided or eliminated or at least resolved or managed, by bargaining, negotiation, compromise, conformity, persuasion, or, if all else fails, by withdrawal or by "conquest." It has been pointed out, however, that there are a number of potentially positive social functions of conflict. Conflict between groups tends to bind each group's members to one another. It can bind two rival groups when they are threatened by a common enemy. It also can "clear the air," providing a safety-valve function. A conflict relation is, itself, a structured relation that allows social processes to continue between the contending parties; that is, conflict binds the antagonists to an ordered relationship to one another. Conflict can create associations and alliances that would not otherwise have a reason for being. Finally, conflict can lead to a search for and the generation of new and creative solutions.

Norms and roles. One of the central concepts of social psychology and of small-group research is the concept of norms. The concept has several uses. The term norm is often used simply to mean beliefs, attitudes, or values that are shared by members of a social group. Sometimes, though, the concept of norm carries the further restriction that it be recognizably shared and that the group apply sanctions (rewards and punishments) or at least social pressure to produce conformity to its norms. The idea of a norm, in other words, consists of a shared or common frame of reference, leading to a close agreement in judgments. Many of these judgments are based on social rather than physical reality, which in turn depends on a social consensus as to the meanings of objects, events, and situations. Social norms serve as definitions of social reality for those who share them.

In a sense, a norm is a rule or an agreement or a precedent about behaviour (such as a rule of alternation—"we'll watch your favourite program this week and mine next week"). Once such a rule exists and is recognized, it becomes like a third-party regulator. One can call on adherence to the norm, rather than on informal or personal power, to induce another person to exhibit the indicated behaviour. Moreover, adherence to the norms takes on a moral, or "rightness," quality. When norms have

Nature of conflict

Regulatory effects of norms

developed in a group containing members of unequal power, they bind the stronger as well as the weaker partners of the relationship; thus, norms serve to control and limit the arbitrary exercise of power.

Another basic concept is role, which might best be approached by considering a person's "place" or "location" or "position" in a group. The idea of position is quite clear in formal organizations. One man is director of a division; another man is president of a company; still another is an assistant sales manager. Each of these positions or offices can exist independently of any particular incumbent; and each entails a more or less explicit set of responsibilities and prerogatives. The same kind of concept of position is applicable to the location or status of an individual in informal groups, although such positions are seldom distinguished by formal titles outside of formal organizations.

The idea of position (or office or status) in a group is related to the idea of role. A role is a set of expectations about how the incumbent of one position should behave toward the incumbent of another position. Thus, a role (or role expectation) is a special kind of norm: a shared rule about behaviour, in this case about behaviour between incumbents of particular positions.

In any group, members develop and depend on expectations about how other group members will behave. When these expectations are not fulfilled in a particular role, persons in related roles generate social pressures directed toward fulfillment of these role expectations. There is pressure, in other words, toward conformity.

Role
conflict

Many times the incumbent of a role (or of a set of roles) is faced with conditions that produce role conflict. For one thing, different "others" may hold different and conflicting expectations for his role. The classic example of this case is the first-line supervisor in industry. Management, on the one hand, and his men, on the other, are likely to hold incompatible expectations for his behaviour as a supervisor. A second form of role conflict may arise when multiple expectations within a role are internally conflicting—for example, mothers are to be loving but firm with their small children. In still another case, the expectations for a given role may be unclear or ambiguous—as is often the case for a new role. Any of these and other forms of role conflict can present the individual with difficulties in performing his role and can have harmful effects on his relationships with others and on his self-evaluation.

Creative
solutions
by groups
and
individuals

Individual versus group effectiveness. Generally speaking, it was long thought that groups are more effective than individuals in solving problems, apparently because they provide a wider range of relevant knowledge and perform an error-checking function. This belief even led to the technique of brainstorming, which was alleged to increase creativity. In brainstorming, a set of people try to think of a solution to a stated problem, under rules whereby no one is allowed to evaluate any suggested ideas, although they are allowed to build upon a previously voiced idea. This technique gained considerable popularity as a problem-solution procedure in work organizations, but careful research has indicated clearly that groups do not develop more or more creative solutions under brainstorming than do the same individuals working alone. Indeed, viewed on a man-hours basis, brainstorming in a group is distinctly inferior to working on the same problem alone. This finding is quite compatible with other findings that indicate the negative effects of the presence of others on tasks requiring new responses.

Although groups may be inferior to individuals in generating creative solutions, groups are in fact advantageous for certain kinds of functions. For problems demanding cross-checking of errors; for problems in which the task can be subdivided; for problems requiring many skills, not likely to be found in a single individual; for problems in which sheer numbers of "units produced" are important—in all of these, a group will be superior to a single individual of the same competence. What matters, here, is the way in which the task is organized, as mentioned earlier with reference to member abilities.

But, beyond these considerations, there are certain situa-

tions in which assigning a task to a group rather than an individual is an advantage. For one thing, a group potentially represents a broader pool of knowledge and skills, proportional to its numbers. Often, groups are used as information sources. Moreover, it is almost mandatory that certain kinds of decisions be made by groups, whose membership is in some way representative of conflicting views, because it takes concurrence of such a group (presumably after negotiation and compromise) to lend legitimacy to the resulting decision. Thus, even though group brainstorming is not a guarantee of more and better creative solutions and even though problem solving by groups is partially a waste of man-hours, the performance of tasks by groups, rather than by individuals, is an effective procedure under some conditions and an essential one under others.

As there is considerable difference between individuals and groups, so there is also considerable difference between groups of two members and groups of three or more members. For one thing, a triad, or group of three, is the smallest group in which it is possible for a coalition to form. Furthermore, in triads in which two members hold opposed views, the third member, holding the "balance of power," can exercise considerable influence on group choice. Beyond this, the dyad has only one while the triad has three pair relations, which represent a considerable increase in complexity of group relations and processes.

It is likely that the effects of numbers in a group depend, in part, on what level of manpower is called for by the situation. This involves the question of undermanning versus overmanning. It seems that in cases of undermanning—that is, when the number of persons in the setting is insufficient or barely sufficient to handle the task requirements of the setting—group members tend to become more involved in, committed to, and motivated toward group tasks and goals and experience more success, failure, and satisfactions than do persons in overmanned settings.

Under-
manning
versus
over-
manning

Current problems in small-group study. These tracings of a few of the elements of the small-group field may suggest some of the problems or dilemmas. It should be noted particularly that experience or environment, rather than innate attributes or heredity, have been virtually the whole concern. There have been some proponents of Freudian views who have focussed on innate unconscious motives, and there have been other theorists who have held that group behaviour reflects built-in personality patterns of members. But their views have gained little support and are backed by scant evidence. Recent major advances in genetics, though, may well lead to new support for the importance of innate characteristics in shaping human behaviour in groups.

Another dilemma of long standing involves the relative emphasis on theory and on empirical evidence. The latter, of course, has been getting most of the attention. Indeed, the very success of that emphasis—the development of a highly efficient and sophisticated data-generating technology—is one major element in the current unsettledness of the small-group field. The other major element in that unsettledness is the other side of the same coin—the virtual total lack of emphasis on development of broad or even middle-range theoretical structures. A rebalance of emphasis is clearly indicated for the future.

BIBLIOGRAPHY. The most comprehensive current review of the entire field of social psychology is G. LINDZEY and E. ARONSON (eds.), *The Handbook of Social Psychology*, 2nd ed., 5 vol. (1968–70). The experimental literature is reviewed in a series of volumes edited by L. BERKOWITZ, *Advances in Experimental Social Psychology* (1964–). For collections of articles on small groups, see D. CARTWRIGHT and A.F. ZANDER (eds.), *Group Dynamics*, 3rd ed. (1968); and A. PAUL HARE, E.K. BORGATTA, and R.F. BALES (eds.), *Small Groups*, rev. ed. (1965). Comprehensive reviews of the small-group research literature appear in A. PAUL HARE, *Handbook of Small Group Research* (1962); J.E. MCGRATH and I. ALTMAN, *Small Group Research* (1966); and B.E. COLLINS and H. GUETZKOW, *A Social Psychology of Group Processes for Decision-Making* (1964).

Socialism

Socialism refers to both a set of doctrines and the political movements that aspire to put these doctrines into practice. Although doctrinal aspects loomed largest in the early history of socialism, in its later history the movements have predominated over doctrine, so much so that there is no precise canon on which the various adherents of contemporary socialist movements agree. The most that can be said is that socialism is, in the words of C.A.R. Crosland, a British socialist, "a set of values, or aspirations, which socialists wish to see embodied in the organization of society."

Problems
of
definition

Although it is possible to trace adumbrations of modern socialist ideas as far back as Plato's Republic, Thomas More's *Utopia*, and the profuse Utopian literature of the 18th-century Enlightenment, realistically, modern socialism had its roots in the reflections of various writers who opposed the social and economic relations and dislocations that the Industrial Revolution brought in its wake. They directed their critical shafts against what they conceived to be the injustice, the inequalities, the suffering brought about by the capitalist mode of production and the free and uncontrolled market on which it rested. To the acquisitive individualism of their age they opposed a vision of a new community of producers bound to each other through fraternal solidarity. They conceived of a future in which the masses would wrest control of the means of production and the levers of government from the capitalists.

Although the great majority of men calling themselves socialists in the 19th and 20th centuries have shared this vision, they have disagreed about its more specific ideas. Some of them have argued that only the complete nationalization of the means of production would suffice to implement their aims. Others have proposed selective nationalization of key industries, with controlled private ownership of the remainder. Some socialists insist that only strong centralized state direction and a command economy will suffice. Others advocate a "market socialism" in which the market economy would be directed and guided by socialist planners.

Socialists have also disagreed as to the best way of running the good society. Some envisage direction by the government. Others advocate as much dispersion and decentralization as possible through the delegation of decision-making authority to public boards, quasi-public trusts, municipalities, or self-governing communities of producers. Some advocate workers' control; others would rely on governmental planning boards. Although all socialists want to bring about a more equal distribution of national income, some hope for an absolute equality of income, whereas others aim only at ensuring an adequate income for all, while allowing different occupations to be paid at different rates.

"To each according to his need" has been a frequent battle cry of socialists, but many of them would in fact settle for a society in which each would be paid in accordance with his contribution to the commonwealth, provided that society would first assure all citizens minimum levels of housing, clothing, and nourishment as well as free access to essential services such as education, health, transportation, and recreation.

Socialists also proclaim the need for more equal political rights for all citizens, and for a levelling of status differences. They disagree, however, on whether difference of status ought to be eradicated entirely, or whether, in practice, some inequality in decision-making powers might not be permitted to persist in a socialist commonwealth.

The uses and abuses of the word socialism are legion. As early as 1845, Friedrich Engels complained that the socialism of many Germans was "vague, undefined, and undefinable." Since Engels' day the term socialism has been the property of anyone who wished to use it. The same Bismarck who as German chancellor in the late 1870s outlawed any organization that advocated socialism in Germany declared a few years later that "the state must introduce even more socialism in our Reich." Mod-

ern sophisticated conservatives, as well as Fascists and various totalitarian dictators, have often claimed that they were engaged in building socialism.

ORIGINS OF THE SOCIALIST IDEA

The term socialism, in its modern sense, made its first appearance around 1830. In France it was applied to the writings of Fourier and the Saint-Simonians and in England to those of Robert Owen.

Saint-Simon and Fourier. Comte Henri de Saint-Simon (1760–1825) was an erratic genius with a fertile and yet disorganized mind. His socialist writings revolved around the idea that his age suffered from an unhealthy and unbridled individualism resulting from a breakdown of order and hierarchy. But he held that the age also contained the seeds of its own salvation, which were to be found in the rising level of science and technology and in the industrialists and technicians who had already begun to build a new industrial order. The joining of scientific and technological knowledge to industrialism would inaugurate the rule of experts. The new society could not be equalitarian, Saint-Simon argued, because men were not equally endowed by nature. Yet it would make the maximum use of potential abilities by assuring that everyone would have equal opportunity to rise to a social position commensurate with his talents. By eradicating the sources of public disorder, it would make possible the virtual elimination of the state as a coercive institution. The future society would be run like a gigantic workshop, in which rule over men would be replaced by the administration of things.

Saint-Simon's followers bent the founder's doctrine in a more definitely socialist direction. They came to see private property as incompatible with the new industrial system. The hereditary transmission of power and property, they argued, was inimicable to the rational ordering of society. The rather bizarre attempt of Saint-Simon's followers to create a Saint-Simonian church should not obscure the fact that they were among the first to proclaim that bourgeois-capitalist property was no longer sacrosanct.

François-Marie-Charles Fourier (1772–1837), a lonely and neglected thinker who was more than a little mad, was led to his anticapitalist vision by a loathing for a world of competition and wasteful commerce in which he spent most of his life as a salesman. Possessed by an inordinately wide-ranging imagination, he argued that the regenerated world to come would be characterized not only by social but also by natural and even cosmological transformations. The ocean would be changed into lemonade, and wild animals would turn into anti-lions and anti-tigers serving mankind.

With meticulous and obsessive care, Fourier set forth plans for his model communities, the *phalanstères*, the germ cells of the good society of the future. In these communities men would no longer be forced to perform uncongenial tasks but would work in tune with their temperaments and inclinations. They would cultivate cabages in the morning and sing in the opera in the evening. Fourier's was an antinomian vision in which human spontaneity made outside regulation unnecessary. Whereas Saint-Simon called for the rule of experts, Fourier was convinced that love and passion would bind men together in a harmonious and noncoercive order.

Owenism. The Englishman Robert Owen (1771–1858) held more sober views. Early in his career he became known as a model employer in his textile works in Scotland, and as an educational and factory reformer. Despairing of his fellow capitalists he later turned to the emergent trade union movement. Acutely conscious of the evils of industrialism by which he had acquired his wealth, he thought that the new productive forces could be turned to the benefit of mankind if competition were eliminated and the effects of bad education were counteracted by rational enlightenment. He advocated cooperative control of industry and the creation of Villages of Unity and Cooperation in which the settlers, in addition to raising crops, would improve their physiques as well as their minds. Owenite communities estab-

century

lished in New Harmony and elsewhere in America all failed. His attempts to join the cooperative and the trade union movements in a "great trades union" also proved a failure. Yet he left a lasting imprint on the British socialist tradition; his indictment of the competitive order, his stress on cooperation and education, his optimistic message that men could increase their stature if only the stultifying effects of an unhealthy environment were removed have continued to inform the socialist movement.

Other early socialists. The 1840s saw the rise of a number of other socialist doctrines, particularly in France. Louis-Auguste Blanqui evolved a radical socialist—or, as he called it, communist—doctrine based on a democratic populism and on the belief that capitalism as an inherently unstable order would soon be replaced by cooperative associations. Impatient with theorizing, given to a strong belief in voluntarism and the virtues of revolutionary action, he is remembered for his many attempts at organizing insurrections rather than for his theoretical contributions.

Étienne Cabet, in his influential utopian work *Voyage en Zcarie* (1840), carried on the tradition of Thomas More as well as of Fourier. Louis Blanc is best known for *L'Organisation du travail* (1839), in which he advocated the establishment of national workshops with capital advanced by the government. These workshops would remain free from government control, with workers electing their management. The national workshops he organized in Paris after the revolution of 1848 were soon dissolved by a resurgent middle class. His plans for the "organization of labour" and his pleas for the recognition of the "right to work" were nevertheless a foreshadowing of the modern welfare state.

Pierre-Joseph Proudhon (1809–65) is best viewed as one of the founders of the anarchist tradition. But his attacks against private property and the institutions on which it rests, as well as his championing of a system of human relationships in which reciprocity, equity, and justice would replace what he saw to be rapacity, exploitation, and greed, powerfully stimulated the socialist imagination. His anti-statist and federalist vision of producers' communities provided a counterweight to the centralizing and statist impulses in the socialist tradition.

In England, the first half of the 19th century saw the emergence of a number of writers attacking the inequities of capitalism and basing their indictment of wage labour on radical Interpretations of the thinking of an eminent economist, David Ricardo. Somewhat later, a Christian socialist movement led by Frederick Denison Maurice and Charles Kingsley attempted to combine radical economic views with political conservatism. The radical Chartist Movement of the 1830s and 1840s is better viewed as a political movement of the working class than as a specifically socialist formation, though anticapitalist ideas played a strong part in it.

MARX AND THE RISE OF SOCIAL DEMOCRACY

In the perspective of intellectual history, all of these pre-Marxist socialist thinkers produced ideas of considerable intrinsic worth. But from the viewpoint of the subsequent development of socialism their ideas seem to be tributaries feeding the mighty stream of the Marxist movement that came to dominate the socialist tradition in the last third of the 19th century.

The Communist Manifesto. Karl Marx (1818–83) had a synthesizing mind. He fused German idealistic philosophy with British political economy and French socialism. Marx's earlier writings are discussed elsewhere (see MARXISM). In this article the focus is on his mature thought as first developed in *The Communist Manifesto* (1848), which he wrote in conjunction with Friedrich Engels, his lifelong intellectual companion.

To Marx, society is a moving balance of antithetical forces; strife is the father of all things, and social conflict is the core of the historical process. Men struggle against nature to wrest a livelihood from her. In the process they enter into relations with one another, and these relations differ according to the stage they have reached in their productive activities. As a division of labour emerges in

human society, it leads to the formation of antagonistic classes that are the prime actors in the historical drama. In contrast to his predecessors, Marx did not see history as simply a struggle between the rich and the poor, or the powerful and the powerless; he taught that such struggles differ qualitatively depending on what particular historical classes emerge at a given stage in history. A class is defined by Marx as a grouping of men who share a common position in the productive process and develop a common outlook and a realization of their mutual interest.

Marx, like Hegel and Montesquieu, considered societies as structured wholes; all aspects of a society—its legal code, its system of education, its religion, its art—are related with one another and with the mode of economic production. But he differed from other thinkers in emphasizing that the mode of production was, in the last analysis, the decisive factor in the movement of history. The relations of production, he held, constitute the foundation upon which is erected the whole cultural superstructure of society.

Marx distinguished this doctrine, which he called scientific socialism, from that of his predecessors whom he labelled utopian socialists. He asserted that his teachings were based on a scientific examination of the movement of history and the workings of contemporary capitalism rather than simply on idealistic striving for human betterment. He claimed to have provided a guide to past history as well as a scientific prediction of the future. History was shaped by class struggles; the struggle of contemporary proletarians against their capitalist taskmasters would eventually in a socialist society in which associated producers would mold their collective destinies cooperatively, free from economic and social constraints. The class struggle would thus come to an end.

The First International. *The Communist Manifesto*, which had been written as a program for the Communist League, a group of continental workmen, failed to have an impact on the European revolutions of 1848. For a number of years thereafter Marx and Engels lived in complete isolation from the labour movements developing in England and on the Continent. Socialism in those years was only the creed of isolated sects, often of exiles. In 1864, however, after a gathering in London of continental and English workers' representatives and associated intellectuals, there emerged the International Working Men's Association, commonly known as the First International. Although it encompassed various tendencies ranging from simple trade unionism to anarchism, Marx dominated it from its inception and made it an instrument for the diffusion of his message. Its headquarters were in London, but it never exerted much influence in England, where the labour movement remained impervious to Marxist revolutionary ideology. On the Continent, particularly in Germany, Marxism spread rapidly and soon became the major doctrine of the emerging labour movement.

German Social Democracy. In Germany, Ferdinand Lassalle (1825–64), the architect of the German labour movement, agreed with Marx on the need for autonomous organization of the working class but differed from him in wanting the government to provide the necessary capital for the establishment of producers' cooperatives that would emancipate labour from capitalist domination. To Marx, any appeal to the bourgeois state was out of the question, and he proceeded to organize followers in Germany against Lassalle. In 1869 they created the Social Democratic Party. The division between the followers of Lassalle and those of Marx persisted until 1875, when the two parties united on the basis of a compromise program (which Marx sharply criticized for its Lassallean vestiges).

The German Social Democratic movement grew rapidly, despite Chancellor Otto von Bismarck's attempts to suppress it through anti-socialist legislation and to undercut its appeal by social reforms. In 1877 the Socialists obtained half a million votes and a dozen members in the Reichstag. In 1881 the party claimed 312,000 members, and, by 1890, 1,427,000. After the repeal of the anti-Socialist laws the party adopted the so-called Erfurt Pro-

The growth of organized parties

The idea of class struggle

gram of 1891, eliminating all demands for Lassalleian state-aided enterprises and pledging itself to the orthodox Marxian goal of "the abolition of class rule and of classes themselves."

Revisionism. It soon became apparent that Marx's own thought had gone through a process of evolution so that different disciples could quote chapter and verse in support of fairly divergent political views. In particular, whereas Marx in the late 1840s and early 1850s had asserted that only a violent revolutionary overthrow of bourgeois rule and the emergence of the "dictatorship of the proletariat" would lead to the emancipation of the working class, by the late 1860s his views had considerably mellowed. Writing in England after the second Reform Bill (1867), which had given the vote to the upper strata of the workers, Marx suggested the possibility of a peaceful British evolution toward socialism. He also thought that such a peaceful road might be possible in the United States and in a number of other countries.

Although the leaders of German Social Democracy liked to speak in revolutionary Marxist rhetoric, they had in daily life become increasingly absorbed in parliamentary activities. Under the intellectual guidance of their theoretician Karl Kautsky (1854–1938) they developed a brand of economic determinism according to which the inevitable development of economic forces would necessarily lead to the emergence of socialism. The official Social Democratic platform remained ideologically intransigent, while the party's activities became increasingly pragmatic.

Eduard Bernstein (1850–1932), once a close companion of Engels, challenging prevailing orthodoxy in his famous *Die Voraussetzungen des Sozialismus und die Aufgaben der Sozialdemokratie* (1899; Eng. trans., *Evolutionary Socialism*, 1909), appealed to the party to drop its revolutionary baggage and recognize theoretically what it had already accepted in practice; namely, that Germany would not have to go through revolutionary convulsions in order to reach socialist goals. Ignoring the differences between political conditions in Germany and England, Bernstein urged the party to travel along the English road in hope of gradually transforming capitalism through socialist reforms brought about by parliamentary pressure.

The struggle between Kautsky's orthodoxy and Bernstein's revisionism shook the German party. Bernsteinian doctrine was officially defeated in 1903, but revisionism in fact permeated the party, especially its parliamentary and trade union leaders. At the outbreak of World War I practically all the leaders supported the government and the war, thus ending the party's revolutionary pretensions.

Other Social Democratic parties on the Continent. In France, the Marxists had to contend with rival socialist traditions that had profound roots in French working-class history. The followers of Blanqui and Proudhon played leading roles in the Paris Commune of 1871. In the years that followed, French socialism was torn by conflicting tendencies. The *Parti Ouvrier* founded by Jules Guesde in 1875–76 represented Marxist orthodoxy, but there were other socialist parties that reflected the influence of Blanqui, Blanc, and Proudhon, as well as the 18th-century revolutionary heritage. Even after the various parties amalgamated in 1905, the movement continued to be torn by dissension between its revolutionary and reformist wings. None the less, it continued to grow. At its first congress the unified party claimed 35,000 members, and in the elections of 1906 it won 54 seats in Parliament. By 1914 it had more than 100 members in the Chamber of Deputies. As in Germany, however, revolutionary rhetoric usually went hand in hand with pragmatic action, and the party became in fact a skillful participant in the parliamentary games of the Third Republic. After Jean Jaurès, the great Socialist orator and a principled leader of the peace elements, was assassinated on the eve of World War I, most of the Socialists supported the French war effort.

In the last part of the 19th century, Social Democratic parties generally beholden to Marxist doctrine sprang up

in most of the countries of continental Europe. A Danish Social Democratic Party was founded in the 1870s; the Swedish Socialist movement in 1889. The Norwegian Labour Party (first called the Social Democratic Party) was formed in 1887 but became a major political force only in the early 20th century. In central Europe, Social Democratic parties fairly rapidly assumed a major place on the political horizon. An Austrian Social Democratic Party was founded in 1888. By 1908 it had gained about one-third of the vote cast in the parliamentary elections, to become the strongest Socialist party outside Germany. The Belgian Labour Party, formed in 1885 as an amalgamation of trade union, cooperative, and other groups, rapidly organized thousands of mutual aid societies, built a very strong trade union movement, and led a number of general strikes on behalf of the more liberal suffrage laws. The Dutch Socialist-Democratic Workers Party, founded in 1894, became a significant force only in the years immediately preceding World War I. It held 20 percent of the seats in the lower house of Parliament in 1912.

All of the continental parties were torn by internal tensions. Proposals to enter liberal coalition governments often were defeated by only narrow margins; Marxist orthodoxy prevailed only after sharp struggles. In The Netherlands, for example, a proposal to enter a coalition government was rejected by the close vote of 375 to 320 at the party congress of 1913.

Anarchist tendencies. In the less industrialized parts of Europe, particularly in Italy and Spain, Marxism had to contend with anarchist tendencies mainly rooted in the precapitalist and peasant strata. European anarchism as a political force was created by Mikhail Bakunin, the highly influential Russian libertarian thinker. His Anarchist Federation had belonged to the First International, but quarrels with Marx led to the expulsion of Bakunin and his followers in 1872.

Bakunist and other anarchist strains of thought remained powerful in Spain, despite the founding of the Social Labour Party in 1879. The Spanish socialist movement suffered from the competition of the anarchists throughout its subsequent history, and only after World War I did it become a political force to be reckoned with.

In Italy anarchist tendencies also impeded the growth of a socialist movement. The Italian representatives to the First International followed Bakunin's lead. Not until 1892 was a distinctly Socialist party formed under the leadership of Filippo Turati. In 1913, after the electoral franchise was broadened, the official Socialist Party secured 51 seats in Parliament, and two other Socialist parties that had split from its ranks gained 31 seats. Although it continued to suffer from internal dissension and from anarchist tendencies in the more backward areas of the country, by World War I the Italian Socialist Party had become one of the strongest Marxist organizations in Europe.

The Second International. The First International had brought into being a variety of Socialist movements throughout Europe. When these began to grow roots in their respective political systems, it became apparent that the international movement could no longer be controlled by a single directing centre. After the dissolution of the First International in 1876, Marx and Engels remained father figures whose counsel the movement eagerly sought; but they could no longer direct it. The history of socialism now became largely the history of separate national movements that, for all their ceremonial acknowledgment of Marxist orthodoxy, increasingly tended toward a revisionist and nonrevolutionary line. By the early years of the 20th century socialism had become a powerful parliamentary force in most European countries. Except in Russia, where autocracy still held sway, the Socialists were reformers seeking a transformation of the existing system rather than its violent overthrow. Only left-wing minorities within the various parties still stood for revolutionary orthodoxy.

The Second International, founded in 1889, reflected the changed character of the movement. It was a kind of international parliament of socialist movements rather than the unified and doctrinally pure organization that

the First International had attempted to be. It was dominated by the German party. With traditional Marxist rhetoric, the German delegates stood adamant against proposals to sanction socialist participation in bourgeois governments, and thus appeared to favour a "left" course. But socialist participation in government was not a realistic option in Kaiser William's Germany, and so the German delegates could be intransigent at no cost to themselves. When the issue was put to a vote at the Amsterdam congress in 1904, the Germans sided with those who opposed participation, against Jaurks, and those who condoned it. But Jaurks had the better of it when he pointed out that "behind the inflexibility of theoretical formulas which your excellent comrade Kautsky will supply you with till the end of his days, you concealed . . . your inability to act." As with the issue of government participation, so with the issue of war. The Second International, under its German leadership, issued many moving and stirring manifestoes against war, but when war broke out it disclosed its paralysis. Most of its national components sided with their own governments and abandoned the idea of international working-class solidarity. Almost all of them recognized what they may secretly have believed for a long time: the workers, after all, had a fatherland.

OTHER SOCIALIST TENDENCIES BEFORE WORLD WAR I

The
non-
Marxists

British Fabianism. Although Marxism triumphed in the continental Socialist movement, it did not do so in Great Britain. Henry Hyndman, a radical journalist, founded the Social Democratic Federation on strictly Marxist principles in the 1880s, but it ever remained marginal to the British socialist movement. The Socialist League, founded by the poet William Morris, propounded libertarian-syndicalist ideas and likewise failed to make headway. Fabian socialism, on the other hand, based on non-Marxist ideas, was to have an enduring influence in Britain.

The Fabian Society was organized in the 1880s by a number of young radical intellectuals among whom Sidney and Beatrice Webb, Graham Wallas, Sidney Olivier, and George Bernard Shaw were the most outstanding. It developed an evolutionary and moderate form of socialism. Convinced of "the inevitability of gradualness," the Fabians never endeavoured to become a mass organization but preferred to be a ginger group of intellectuals working to transform society through practical and unobtrusive advice to the men of power. The extremely influential *Fabian Essays* (begun in 1889) contained detailed blueprints for social legislation and reform that influenced policy makers whether they were socialists or not. Through "permeation," which Shaw defined as "wire-pulling the government in order to get socialist measures passed," the Fabians attempted to convince key politicians, civil servants, trade union officials, and local decision makers of the need for planned and constructive reform legislation. Basing their doctrine at least as much on non-Marxist economics as on the continental socialist tradition, they worked for a new order "without breach of continuity or abrupt change of the entire social tissue."

Syndicalism. The syndicalist movement grew out of French trade unionism when it was reconstituted after the bloodletting of the Paris Commune (1871). Convinced of the futility of parliamentary and political activity, the syndicalists stressed that only direct action by workers organized in their unions would bring about the desired socialist transformation. Under the leadership of Fernand Pelloutier the *Fédération des Bourses du Travail* (founded in 1892), which was later amalgamated with the *Confédération Générale du Travail* (1902), was built on the idea that the emancipation of labour would come through a "general strike" that would paralyze the country and deliver power into the hands of organized workers. The unions would become the directing and administering nuclear cells of production.

The syndicalists attracted a number of intellectuals to their ranks, who attempted to provide a philosophical basis for syndicalism and its rejection of the political road to socialism. The most important of their writings, Georges Sorel's *Réflexions sur la violence* (1908; Eng.

trans., *Reflections on Violence*, 1916), has continued to exercise considerable influence on the thinking of revolutionary militants, even though Sorel himself soon shifted his allegiance to the extreme right.

Guild socialism. The guild socialist tradition developed in Britain in the years before World War I. Sharing the general socialist hostility to the wage system and production for profit, guild socialists took from the syndicalists their distrust of the state and their emphasis on producers' control. They looked back to the Middle Ages when independent producers, organized in guilds, controlled the conditions of their employment and took pride in creative work. Aiming at self-government in industry, guild socialists urged that industrial organizations, churches, trade unions, cooperative societies, and municipalities be granted autonomy. They argued that every group in society should carry out its particular functions without control from above, and that individuals should have a say in the direction of all those functional units in which they happened to be interested. Cooperation between functional units would replace direction by the state, which would be restricted to providing needed national services such as police protection. The state would be a functional unit among many others, rather than an all-encompassing sovereign.

Although guild socialism owes its origin to several thinkers, it grew into a mature doctrine only when in 1913 it recruited G.D.H. Cole, a brilliant Oxford don, two of whose early books, *The World of Labour* (1913) and *Self-Government in Industry* (1917), contain the best exposition of guild socialist doctrine. The movement never attained wide popular appeal but has continued to be a source of ideas in the British labour movement, if only as a counterpoint to the bureaucratic and centralizing tendencies of Fabianism.

Socialism in the United States. Socialism never became as influential in the United States as it did in Europe. When the Socialist Party was formed in 1901 it claimed a membership of 10,000 that grew to 150,000 in 1912, in which year the party polled a presidential vote of 897,000, or 6 percent of the national total. Although its strongest roots were among recent immigrants from Europe, it also drew its inspiration from the utopian colonies of the 19th century, from the slavery abolitionists, trade unionists, and agrarian reformers, and from isolated socialist groups of the 1880s and 1890s.

The Socialist Labor Party, a predecessor of the Socialist Party, was formed in 1877 but acquired a distinct outlook only when the journalist and polemicist Daniel De Leon joined it in 1890. De Leon attempted to marry a doctrinaire brand of Marxism to a "labourism" nourished in part on French syndicalist doctrine. He and his followers wished to raise the membership of the unions above "paltry routine business" and prepare them for a successful contest with the power of capital, both at the ballot box and in industrial combat.

The Socialist Labor Party remained a sect. But the Socialist Party developed into a mass movement under the leadership of Eugene Debs, a former union official who had been converted to socialism by reading the works of various socialist writers while in jail. The Socialist Party of Debs was neither centralized nor politically homogeneous. In its ranks it harboured reformists and revolutionaries, orthodox Marxists, Christian ministers, municipal reformers, populists who hated the railroads and the trusts, and Jewish garment workers dreaming of fraternity in the sweatshops. It produced no major theoretical works, but it managed in its undoctinaire way to be an effective voice for the idea of socialism in America. It declined after World War I, its last well-known leader being Norman Thomas.

THE RISE OF RUSSIAN SOCIALISM

The populist tradition. The dominant radical tendency in 19th-century Russia was populism, a doctrine first developed by the author and editor Aleksandr Herzen, who saw in the peasant communes the embryo of a future socialist society and argued that Russian socialism might skip the stage of capitalism and build a cooperative com-

monwealth based on ancient peasant tradition. Herzen idealized the peasantry. His disciples inspired many students and intellectuals to "go to the people" in order to stir them into revolutionary action.

In the 1860s and 1870s, the more radical populists lost their faith in a peasant revolt and turned instead to terrorism. Small groups of student revolutionaries sought to bring down tsarism through terroristic action; their efforts culminated in the assassination of Alexander II in 1881. Sergey Nechayev's *Revolutionary Catechism*, in the writing of which Bakunin had a hand, stressed that the sole aim of the revolutionary is to destroy "every established object root and branch, [to] annihilate all state traditions, orders and classes in Russia." It is one of the ironies of history that Bakunin helped create in Russia an elitist and terrorist movement composed almost exclusively of alienated intellectuals, while in western Europe he appealed to skilled craftsmen and peasants and appeared to be the heir of Proudhon.

Within the broad stream of populism, terrorism was opposed by an evolutionary socialism that put its faith in peaceful propaganda and the education of the masses. While the elitists pursued their campaign of terror, the gradualists stuck to propaganda among the people.

Marxism in prerevolutionary Russia. The father of Russian Marxism was Georgy Plekhanov, who began his socialist career as a populist and was converted to Marxism when he settled in Geneva in 1880; in 1883 he founded the first Russian Marxist organization, the *Osvobozhdenie Truda* (Liberation of Labour Group). Plekhanov thought Russian socialism ought to be based primarily on the growing factory proletariat. Rejecting Herzen's idea that Russia was exceptional, he held that the revolution would be European in character and that Russia's place in it would be determined by its own labour movement. In a variety of books and pamphlets in the 1880s and 1890s, Plekhanov attacked the populists and argued that Marx had shown the objective historical necessity of socialism. The laws of social evolution could not be flouted. A bourgeois revolution in Russia was inevitable in the course of industrial development. The organized working class would know how to take advantage of the bourgeois revolution and push it forward.

Against this German brand of Marxism, Vladimir Ilich Ulyanov (1870–1924), later to be known by his party name of Lenin, argued for a more militant approach to revolution. In *What Is To Be Done?* (1902) he formulated his characteristic doctrine. Socialism would be achieved only when professional revolutionaries succeeded in mobilizing and energizing the masses of workers and peasants. Left to themselves, the workers would get no farther than a trade union consciousness. A militant, disciplined, uncompromising organization of revolutionaries was needed to propel the masses into action.

Lenin's followers parted company with the other Russian Marxists at the second congress of the (illegal) Russian Social Democratic Workers Party held in London in 1903. The anti-Leninist position was formulated by the leader of the more orthodox Marxists, L. Martov, when he declared, "In our eyes, the labour party is not limited to an organization of professional revolutionaries. It consists of them, plus the entire combination of the active, leading elements of the proletariat. . . ."

The two factions within the Russian Social Democratic movement at first cooperated and even held joint meetings; the final split came only in 1912. Individual leaders switched from one faction to another (Plekhanov, who originally sided with Lenin, joined his opponents in 1904). Others, such as Leon Trotsky, attempted for a time to stay free from factional alignments. These disputes were fought out in the West, where most of the leaders of both sides lived as émigrés. Within Russia itself, however, Lenin's opponents (the Mensheviks) mainly attracted the better educated and skilled workers, as well as the Jewish intelligentsia, while his Bolsheviks tended to be most successful among the more backward strata of the working class.

After the February Revolution of 1917 toppled the tsarist regime and installed a liberal and vaguely socialis-

tic leadership, the Bolsheviks managed to extend their organization among the urban masses. When Lenin returned from exile in April 1917, he startled his followers by calling for an entirely new strategy. Previously they had believed that their immediate task was to work within the limits of a democratic republic while preparing for future revolutionary opportunities. Lenin argued instead that they must seek power at once. The desire of the masses for an immediate end to the war, the land hunger of the peasantry, the feebleness of the new regime, he urged, made possible what had not been possible in the abortive revolution of 1905: a socialist revolution led by Bolshevik cadres. Moreover, Lenin argued, a Russian revolution would not be isolated for it would soon be followed by a German revolution.

The soviets (workers' and peasants' councils), which had sprung up spontaneously when the tsarist power collapsed, were the main organizational bases from which the Bolsheviks mounted their assault on the established order. Lenin's slogan "All power to the soviets" found a ready response in the major urban centres. In September 1917 the Bolsheviks won elections for the Moscow and St. Petersburg soviets. These now became centres of "dual power" challenging the official government. It was the St. Petersburg soviet that in October 1917 gave Trotsky the military instrument with which he was able to topple the provisional government and install a revolutionary regime headed by Lenin.

Lenin and the Third International. The Bolshevik seizure of power had been undertaken in the belief that the revolution would soon spread to the rest of Europe. Lenin's perspective had always been internationalist. When most of the socialist leaders of the Second International rallied to their national governments in 1914, Lenin denounced them as traitors to the cause and sought to lay the groundwork for a new organization of revolutionary Socialists. After their seizure of power, the Bolsheviks resolved to create a Third International. By the time the delegates had assembled in Moscow in 1919, a revolutionary uprising in Berlin had been crushed and its leaders murdered. The great majority of the German working class was evidently willing to give the Social Democratic leadership of the new German republic a chance. But to the Russian leaders world revolution still seemed near. Soon after the first congress of the Third International a short-lived soviet republic was proclaimed in Hungary and another in the German state of Bavaria. Communist parties began to be organized in all the major countries of Europe.

When the so-called Communist International (Comintern) met for its second world congress in July 1920, it was no longer a small gathering of individuals or representatives of small sects but a union of delegations from a dozen major Communist parties. The outcome of this meeting was to give the Russian leaders control of the new International, now broken away sharply from the Socialist movement. It adopted 21 conditions for membership in the Comintern, demanding that its adherents reject not only those Socialist leaders who had been "social patriots" in the war but also those who had taken a middle position. It aimed at creating a disciplined and militantly revolutionary world organization patterned after the Russian model, which would accept willingly the direction and unquestioned authority of the Russian leadership.

By 1923 the hoped-for revolutionary tide in Europe had not developed. New uprisings in parts of Germany failed completely in 1923. The Red Army's attempted invasion of Poland had been thrown back. Many Socialists who had for a time joined the Comintern, including the leadership of the Norwegian Labour Party, left-wing Communists in Germany, and Syndicalists in France and Spain, now turned away, rejecting its policy of centralized dictation.

Europe achieved a measure of economic and social stabilization. By the time of Lenin's death in 1924, Moscow was beginning to use the parties over which it still held command as instrumentalities of Russian foreign policy. Although some Comintern leaders like Trotsky still be-

lieved that world revolution was on the agenda, their faith was no longer shared by the majority of the Russian leadership.

SOCIALISM BETWEEN THE WARS

Socialists
and
Com-
munists

The split with the Communists. Communists throughout the world denounced the leaders of the reconstructed Socialist parties as "social traitors" who "objectively" fostered the maintenance of capitalism. They accused them of having repudiated Marxism and betrayed international socialism by collaborating during the war with the bourgeoisie in the defense of their national states. The Socialist leaders retorted by pointing to the dictatorial features of the Soviet state and accusing the Communists of having betrayed the democratic socialist tradition.

The European Socialist movement was irremediably split. In Germany, the Social Democrats united again and succeeded in enrolling the bulk of the working class under their banner; the Communists were reduced to a minority position in the German labour movement. In France, where the Communists at first succeeded in attracting the majority of the Socialist Party, their opponents soon regained ascendancy and the Communists became a minority on the French left. Italian socialism split into Communists and left-wing and right-wing Socialists and thus greatly facilitated Mussolini's march to power. In Great Britain the Communists hardly made a dent in the Labour Party and never became more than a radical sect. European socialism as a whole, as well as socialist movements on other continents, was sharply split between adherents of the Second International and the Communists organized in the Third.

The Comintern followed an erratic course, sometimes veering toward a revolutionary line and sometimes making attempts to collaborate with the more militant strata of the socialists. After the onset of the economic depression in 1929 the Comintern took a sharp leftist turn, expecting the "final crisis" of capitalism to bring proletarian revolution everywhere. It denounced Social Democratic leaders as "social Fascists" and enemies of the working class. In the Prussian Landtag the Communists actually voted with the Nazis to bring down a Social Democratic government, on the theory that the Nazi movement was a passing phenomenon.

At the same time the Socialists gave up in practice, though not always in theory, their commitment to revolutionary doctrine. They became in effect pressure groups trying to extract maximum advantages for the working classes from their respective national regimes. In Germany, in Britain, and in the Scandinavian countries they participated at times in the government. Elsewhere, as in France, they tended to support congenial left-bourgeois regimes. But they lacked, on the whole, a concrete plan of social and economic action, and consequently were ineffective when the world depression unsettled the economies and political regimes of western and central Europe.

Response to the world economic crisis. Nowhere, except in Sweden and Belgium, did the socialists press for comprehensive socialist planning during the depression. Where they were in power they followed orthodox policies of budgetary management and public finance. When they were out of power they contented themselves with a defense of the immediate interests of the workers by demanding more unemployment insurance and opposing reductions in wages.

As the crisis deepened, the Communists gained influence, particularly among the unemployed and those unskilled workers hit most severely by the depression. They did not make deep inroads among other workers.

The rise of Fascism. Hitler's rise in Germany led to the destruction of both the Communists and the Socialists in that country. The Communists had hoped that a Nazi victory would be only temporary, and that afterward they would be called upon to lead the masses of Germany to victory. Their battle cry was, "After the Nazis—We." The Socialists played politics as usual, expecting that the depression would run its "natural" course and that a gradual decline of the Nazi fever would follow. A disunited labour movement proved unable to stay the Nazi

march to power. This disaster led both Communists and Socialists to reconsider their previous policies and to revise their strategy and tactics.

Austrian Socialists, threatened with destruction by the reactionary regime of Chancellor Engelbert Dollfuss, resolved to offer armed resistance in February 1934. The Austrian party had long been regarded as a model for both its theoretical contributions and its concrete accomplishments. It enjoyed the nearly total support of the workers; 500,000 of Vienna's 2,000,000 inhabitants were dues-paying members. But the party was almost completely metropolitan and urban. Consequently the bloody battles of February 1934 remained localized in Vienna. The uprising was suppressed after four days, and the party had to go underground.

Experience in government. Germany. The end of World War I had seen a somewhat reluctant Social Democratic Party installed in the seat of German government. Friedrich Ebert, the head of the party, became the first president of the new republic. But the Socialists were split internally. The "majority Socialists," the right wing of the party, wished to proceed in a cautious and pragmatic manner. The "independent Socialists," led by Kautsky and his former antagonist Bernstein, pressed for fundamental structural reforms. The extreme left, led by Rosa Luxemburg and Karl Liebknecht, wished to organize a revolutionary party and founded the Communist Party of Germany. When younger extremists, overruling Luxemburg and Liebknecht, organized a left-wing *Putsch* early in 1919, they were isolated and easily defeated by the government of the majority Socialists and its allies among right-wing officers. Luxemburg and Liebknecht were assassinated, and the remaining leaders took the group into the Comintern. Another left-wing and Communist *putsch* in Bavaria a few months later was also unsuccessful. In the early 1920s, the independents reunited with the majority Socialists.

In the first election to the new National Assembly in 1919 the majority Socialists obtained a plurality of the votes cast (39.3 percent), and the independent Socialists won another 8 percent. The Socialist government proclaimed the need for socialization of monopolistic industries and other radical measures. But after the elections of June 1920, a non-Socialist cabinet took office. In subsequent years the cabinets were largely non-Socialist in character, though Socialists participated in some of them. The middle classes were again in the saddle, and when President Ebert died in 1925 the conservative nationalist Hindenburg succeeded him. Throughout the turmoil of the first years of the Weimar Republic, the Social Democrats remained a bulwark of republican legality against both the extreme right and the extreme left. In the *Länder* (states), Prussia in particular, they held positions of governmental power and managed to institute a number of reformist welfare measures. But they failed to gain a controlling voice in national politics.

In the May 1928 elections, the Social Democrats emerged as the strongest party in the Reichstag. Although they lacked a majority, their leader Hermann Mueller became chancellor, and their financial expert was named minister of finance. This largely Socialist government, however, proved unable to deal with the economic depression that soon afflicted Germany along with the rest of the world. The government followed an orthodox deflationary policy, pressed for the reduction of unemployment benefits in order to save taxes, and attempted to reduce budget deficits. Unable to stem the tide of depression, it resigned in 1930. This was the last government of the Weimar Republic in which Social Democrats participated. Soon afterward, the Nazis started on their way to power.

England. In the British elections of 1923, the Labour Party, which had adopted a Socialist program only five years earlier, won a plurality; with the support of the Liberals it formed the first Labour government under Ramsay MacDonald in January 1924. Its tenure proved short. After implementing a few modest reform measures, it was ousted by an electorate which, partly because of manufactured fears of a "Bolshevist menace," turned sharply to the right in the elections of October 1924.

Socialists
in office

In June 1929 the Labour Party had its second chance. It won 288 out of 615 seats in the House of Commons and, with the support of the Liberals, formed the second Labour government, again under Ramsay MacDonald. But Labour, like the German Social Democrats, proved unable to deal with the depression, particularly with mounting unemployment. It was pledged to far-reaching social reforms that it was not prepared to carry out. The flight of capital from London assumed catastrophic proportions; business circles demanded a balanced budget and lower unemployment benefits. When MacDonald proposed to accede to some of these demands, the trade unions sharply opposed him. He then split the Labour government and formed a national coalition with the Conservatives and the Liberals. For the remainder of the 1930s the Labour Party was out of power.

Italy. In the Italian elections of 1919, the Socialists won 2,000,000 votes out of a total of 5,500,000. Italy seemed on the verge of revolution; large-scale strikes, mass demonstrations, factory occupations, and spontaneous expropriations of landed estates spread throughout the country. In August 1920, a revolutionary situation developed in the industrial north after a breakdown in wage negotiations; 500,000 workers occupied the factories, kept production going, and prepared for armed resistance. The far left called for an extension of the strike, but a divided Socialist leadership hesitated. The discouraged workers retreated. Mussolini's Blackshirts began breaking up working-class meetings. In 1921, the right-wing Socialists proposed that the party form a coalition government with the Liberals, but the left vetoed the idea. Mussolini's terror squads made further inroads in the large industrial centres. A general strike called by the trade unions proved a dismal failure. Soon afterward Mussolini made his March on Rome (October 1922) and was installed as premier. By 1926 parliamentary government had completely ended in Italy. The Socialists were driven underground.

France. None of the French governments from the end of World War I until the middle 1930s included Socialists. Although the Socialist Party was in fact deeply committed to gradualism, it still clung to its prewar policy of not participating in "bourgeois" governments. Only in the mid-1930s, when militant right-wing groups threatened the Third Republic, did the Socialists change their policy. In June 1936, a government took office representing a Popular Front, ranging from the Communists on the left to Radical Socialists in the centre, and headed by the Socialist leader Léon Blum. The Communists had at last abandoned their doctrine of "social Fascism" and were now willing to enter coalitions with other parties of the centre and left.

The victory of the Popular Front in June 1936 was accompanied by sit-down strikes in the factories; these helped push the government, headed by Léon Blum, in a radical direction. Collective bargaining rights, never recognized before by French employers, were now protected by law; social security and general working conditions were significantly improved; the 40-hour week was made mandatory. The Blum government attempted to institute a French version of the U.S. New Deal. But after the initial enthusiasm had waned, French employers took courage and pressed the government to return to traditional fiscal and budgetary policies. When in June 1937 his middle-of-the-road partners in the coalition refused his demands for emergency fiscal powers, Blum resigned. The Socialists participated in the next government headed by a Radical Socialist, and Léon Blum later formed another Popular Front government that held office for about a month in 1938. When France went to war against Germany in 1939 the Communist Party, which opposed the war, was banned. After France's collapse in 1940, the Socialist Party was dissolved by the Vichy government.

Sweden. Only in Sweden were Socialists successful in their governmental policies. A Swedish Labour government was formed for the first time in 1932. Unlike the other European Socialist parties, the Swedes broke with orthodox budgetary and financial policies and stressed

large-scale intervention by the government in the planning of economic affairs. Extensive public works, financed by borrowing from idle capital resources, helped to reduce unemployment and stimulated the economy; public investment was used methodically to offset the effects of reduced private spending. Unemployment, which had reached 164,000 in 1933, was eliminated by 1938 through a policy of steady economic expansion. The Swedish innovations helped lead the way to the economic policies practiced by almost all Western countries after World War II.

SOCIALISM SINCE WORLD WAR II

The worldwide spread of "socialist" parties. Orthodox Marxists had always assumed that socialism would emerge first in the industrial countries of the world. But a new kind of "socialism" spread rapidly in agrarian societies and backward countries after World War II. In many of these countries Marxism became, despite the intention of its founders, the ideology of industrialization. In the struggle against colonialism the liberation movements, especially the intellectuals and semi-intellectuals who led them, adopted what they conceived to be socialist ideas. It seemed to them that meaningful national independence could be attained only through state direction of the economy. Rapid economic growth, they believed, could be fostered only by restricting consumption and channeling national resources into the building up of productive facilities. In one degree or another the new countries took the Soviet Union as their model for rapid industrialization. All manner of regimes, from totalitarian one-party states to military dictatorships, proclaimed that they were socialist. Only in India and a very few other countries did the ruling party retain the traditional Western socialist vision of social justice, equality, and democracy.

In the meantime, ironically, the Socialists of western Europe were giving up their Marxist views and turning toward the welfare state. During World War II almost all of the Socialist parties had joined governments of national unity. Afterward they sought to become popular parties following the parliamentary road to power and ready to participate in coalition governments with Liberal or Christian Democratic partners. Surrendering the idea that only full state ownership would bring the good society, they aimed at a mixed economy in which public control and a certain amount of planning would bring social benefits for all. This was, in essence, the idea of "the inevitability of gradualism" that the English Fabians and the German revisionists had preached around the turn of the century.

The transformation of western European socialism.

West Germany. The changed orientation of the postwar German Social Democratic Party was expressed in its Frankfurt declaration of 1951, which made no mention of the class struggle and other traditional Marxist doctrine, stating instead that the party "aims to put economic power in the hands of the people as a whole and to create a community in which free men work together as equals." It advocated public control of the economy but rejected comprehensive state ownership. It accepted planning, but stressed that democratic socialist planning had nothing in common with the Communist and totalitarian kind.

A few years later, in its program of principles adopted in Bad Godesberg in 1959, the party shed the last remnants of Marxism. The name of Marx and the words "class" and "class struggle" are not to be found in that program, which even advocates private property in the means of production. It rejects overall central planning and endorses the idea of a competitive free market. The party stands for "as much competition as possible—as much planning as necessary." A "mixed economy" is seen as the ideal. The party no longer claims to possess a universally valid doctrine, but stands for a pluralistic society in which no party seeks to impose its particular philosophy on society as a whole. Thus to all intents and purposes the Social Democratic Party of Germany, which in 1969 formed a government under the leadership of Willy Brandt, has become a reformist party striving for an extension of the welfare state.

New
concepts
of
socialism

From
socialism
to welfare

British Labour. The British Labour Party was never committed to Marxism, and hence found it easier to adjust to the political realities of the postwar world. In 1945 it won a majority in Parliament for the first time. The government of Prime Minister Clement Attlee, during its six years of power, laid the foundations of the British welfare state. A number of basic industries such as coal, railways, road transport, and steel were nationalized. A comprehensive system of nationalized medical care was established. Social services were extended. Full employment was maintained. Although Labour was voted out of office in 1951, its main achievements remained. The steel industry again reverted to private control, but the Conservatives made no effort to undo the other features of the welfare state.

Hugh Gaitskell, who succeeded Attlee in the leadership of the party, wanted to revamp its program by eliminating earlier pledges that the party seek large-scale nationalization of industry. He was not successful, but in practice the party became married to a reformist course aiming at the extension of the welfare state and of pragmatic planning. When the party returned to power in 1965, its leader, Harold Wilson, prime minister until the elections of 1970, pursued a cautiously reformist policy. Harassed by economic difficulties and forced to pay more attention to the balance of payments than to internal reforms, the Labour government made few policy decisions of a distinctively socialist character.

Trends in French and Italian socialism. The French Socialist Party, reconstituted after World War II, participated in leading positions in the first few postwar French governments. It supported nationalization of parts of French industry, especially public utilities, mining, and much of banking and insurance, as well as wide-ranging measures of public control over the economy and structural reforms in the field of social security. But the party had lost much of its prewar support among the workers to the Communists. The Socialists increasingly became a party of civil servants, middle-class professionals, and other white-collar employees. While they made no attempt to recast their program as the German Social Democrats did, their actual orientation was equally moderate.

The Italian Socialist movement split into a number of parties. The largest organization, the Italian Socialist Party under Pietro Nenni, attempted to revive the pre-Mussolini left-wing socialist tradition. It contended that the interests of the working class could best be served by cooperation with the Communists. Of all the Socialist parties of Europe it stood closest to the prewar Marxist tradition of class conflict and "orthodox" Marxism. After the Hungarian revolution of 1956, however, the party increasingly drew away from collaboration with the Communists, finally entering a centre-left coalition government with the Christian Democrats in 1963. Since then it has in practice become indistinguishable from other western European Socialist parties.

The second largest Socialist party of Italy during the post-World War II period has been the Democratic Socialist Party formed under the leadership of Giuseppe Saragat. It was committed to moderate social reforms, and participated in almost every Italian coalition government after 1947. In 1966 the two major Socialist parties merged, but they separated again in the late 1960s.

The welfare state. All the western European Socialist parties have become committed to the welfare state, though they vary in the extent to which they have formally abandoned their Marxist orientation. Some of their theoreticians still cling to the hope that socialism will eventually go beyond the welfare state toward a society in which class distinctions will have been erased and wealth will be more equitably distributed. But while this may be their dream, it no longer informs their political actions.

African socialism. Socialist ideas were carried to North Africa mainly by French-educated African intellectuals; in addition, many French settlers, especially schoolteachers and civil servants, were Socialists or Communists. The various national liberation movements, especially in Tunisia and Algeria, linked the struggle against colonial domination with socialist ideas. When

Algeria became independent its first leader, Ahmed Ben Bella, surrounded himself with French advisers from various Marxist groups.

Collectivization of agriculture and self-management in industry stood high on the agenda of the Algerian national government. When these programs failed, Ben Bella was replaced by Col. Houari Boumedienne, who was pledged to continue "Algerian socialism" but settled in fact for an economy based on state-directed enterprises and private landholdings. The country was, in fact, run by a military dictatorship.

In Tunisia a one-party regime was installed after the liberation of 1956; under its leader, Habib Bourguiba, it proceeded to nationalize the major enterprises. The ruling party, the Destour Socialist Party, permitted no rival political organization; it was committed to modernization through planned development of the economy.

Elsewhere in Africa a variety of "African socialisms" sprang up in the 1950s and 1960s. Pres. Léopold-Sédar Senghor of Senegal advocated a socialist "humanism" based only partly on Marx. Pres. Sékou Touré of Guinea sought to combine Marxist-Leninist ideas with the communal values of precolonial Africa—to "Africanize" Marxism. Pres. Kwame Nkrumah of Ghana proclaimed "consciencism" as the basis for his regime and stated that "only totalitarian measures can preserve liberty"; he was overthrown in 1966.

In Kenya, Tanzania, and other African countries, the ruling elites proclaimed their adherence to one or another version of "African socialism" while in fact being committed above all to rapid industrialization and modernization. Many African socialist writers stressed the need to build their socialism upon African traditions such as communal land ownership, the egalitarian practices of some tribal societies, and the network of reciprocities and obligations that once existed in tribal societies.

Throughout Africa the commitment to socialism was hardly more than lip-service to an ideal. The pressing need was to move from a subsistence to a market economy, to industrialize, and to organize health services, education, housing, and public administration. Autonomous institutions in which men might strive for concerted political and social goals independent of government control scarcely existed in Africa. Hence the prospect for democratic, as distinct from imposed, socialism was remote.

Arab socialism. The "socialist" movements of the Middle East have been led by European-educated intellectuals belonging to a new middle class of civil servants, army officers, and schoolteachers. Trying to appeal to the Arab people as a whole, and without distinction as to class, they have stood for modernization and for the brotherhood of all Arabs.

The major socialist movement has been the Arab Socialist Party, usually called the Ba'ath Party. Founded in Syria, it has rejected tribal or regional loyalties. Ba'ath factions have held power in Iraq and Syria but have not promoted specifically socialist measures or made concrete reforms.

When Gamal Abdel Nasser came to power in Egypt in 1952, his group of young army officers of lower middle class origin had little if any interest in socialism. Nasser was led to socialist ideas in his struggle against the domination of foreign business. By the middle of the 1960s Egypt had nationalized all large industrial and financial enterprises, whether domestic or foreign; it had expropriated large-scale landowners; and it had placed all important sectors of the economy under the control of state planners. But the structure of power remained that of a military dictatorship.

Asian socialism. Representatives of a dozen Asian Socialist parties met in Rangoon in January 1953 for the first Asian Socialist Conference. Some of the delegates had international reputations. The governments of several Asian countries—India, Burma, Ceylon, Indonesia, and Singapore—called themselves Socialist. Yet the Socialist parties soon thereafter lost even the semblance of power and influence. In India, where several Socialist organizations competed, the ruling Congress Party was in fact a national party striving to unite within its ranks

Failure of socialism to take root in Asia

many divergent political and social tendencies. The Burmese Socialist Party was for many years part of a coalition that ruled the country, but it was outlawed in 1962 when Gen. Ne Win seized power. The Indonesian Socialist Party was abolished by President Sukarno in 1960. Except in Singapore, the postwar Socialist parties in Southeast Asia played no major role in the 1960s.

As the influence of the European-style Socialist parties waned, a variety of authoritarian regimes arose speaking in socialist accents. Indonesia's President Sukarno proclaimed Resopim (Revolution, Indonesian Socialism, and National Guidance) his official ideology. The Burmese military dictatorship proclaimed Burma a socialist state. North Vietnam was ruled by a Communist party; in the rest of Indochina, revolutionary movements inspired by Communist ideology battled traditionalist forces supported by the United States. In China, the Communist People's Republic has been in power since 1949.

The Socialist parties of Southeast Asia, after playing a brief role in the struggle for independence, failed to take root in national politics. They were led by European-educated intellectuals, who attempted to emulate European models and were committed to the idea of a democratic road to socialism. But the countries of Southeast Asia were not prepared to follow them; they turned instead to authoritarian regimes that pursued industrial development. Only in Singapore and India were attempts made to combine democracy and socialist planning. In most of Asia, as in Africa, "socialism" has become the ideology of new elites seeking modernization and rapid industrialization.

Japan. Only in Japan, by far the most developed of Asian countries, have traditional socialist organizations become firmly established. The first Socialist Party of Japan, foimed in 1901, was soon dissolved and forced to go underground. During and after World War I socialist organizations again sprang up. In 1936 the Social Mass Party elected 18 members to the Parliament and received more than half a million votes. After World War II, socialist organizations that had been suppressed since 1940 appeared again. In 1946 the Socialist Party won over 90 seats to become the third strongest party. A year later, it gained the largest number of seats in Parliament, and its leader Katayama Tetsu became prime minister in a coalition government. In October 1948, however, the conservatives took office. The Socialists were deeply split between gradualists and revolutionaries. The left wing tended to be sharply anti-American and leaned toward the Soviet Union; the right wing favoured a gradual relaxation of close military and political ties with the United States. The two wings broke apart in the 1950s to form the (left) Socialist Party of Japan and the (right) Democratic Socialist Party. Together they controlled about one-third of the seats in Parliament, but seemed condemned to a permanent minority status. Japanese socialism still awaits a transformation similar to that undergone by western European Socialism in the postwar era.

Other areas and countries. *Australia.* Socialism has deep roots in the British Commonwealth countries of Australia, New Zealand, and Canada. The Australian Labor Party was formed in 1901, when the Australian Commonwealth came into existence. Only three years later its leader, J.C. Watson, became the world's first Labor prime minister. In 1908, and again from May 1910 to June 1913, Labor headed the government. In subsequent years the Labor Party has been frequently in office. It held power throughout most of the 1940s, and again achieved power in the early 1970s.

New Zealand. A loose Liberal-Labor alliance dominated New Zealand politics between 1893 and 1906, but the New Zealand Labour Party, as a social-democratic party committed to the socialization of the means of production, did not emerge until 1913. It grew steadily, coming to power for the first time in 1935. Labour cabinets headed the government from 1935 until 1949, from 1957 until 1960, and from 1972.

The Australian and New Zealand labour movements have been committed to a gradualist and reformist course since their inception. They are strongly tied to the unions,

and though in principle pledged to a Socialist program they are in fact mainly concerned with using governmental control as a means of dealing with immediate problems and expanding social services. The various social security acts that they introduced helped to make Australia and New Zealand modern welfare states, and relatively equalitarian societies, even before World War II.

Canada. Canadian socialism had a slower beginning than its Australian and New Zealand counterparts. Prior to World War I, the Canadian Socialist movement was split between two parties, neither of which managed to win seats in the federal Parliament. During the 1920s various Socialist and Labour parties flourished in different parts of Canada, but only rarely did they send a representative to the federal Parliament. Only with the organization of the Co-operative Commonwealth Federation (CCF) in 1932 did the Socialist movement begin to achieve national importance. Basing its campaigns on the need for "social and economic planning on a bold and comprehensive scale," it gained support in most provincial elections and in June 1944 was able to form a government in the province of Saskatchewan, where it remained in power for 20 years. In 1961 progressive union leaders of the labour congress met with the CCF leadership and formed the New Democratic Party. Whereas the CCF had been largely agrarian in character, the new party had a following in the industrialized parts of the country. In the 1960s it commanded around 18 percent of the vote in elections to the federal Parliament, and played a major role in the politics of such provinces as Saskatchewan, British Columbia, and Ontario. Advocating a planned economy, it stood for increased social security, government employment guarantees, large-scale construction of low-rent housing, and the like. Its policies were similar to those of postwar western European socialism.

Latin America. The historical roots of Latin American socialism are fairly old. Several branches of the First International were established in Argentina in the early 1870s. In Chile and Argentina, and to a lesser extent in other Latin American countries, socialists at times played leading roles, but they were hampered by a variety of splits and by the fact that their following consisted mainly of immigrant industrial workers. They failed to make an impact in rural areas. In Chile, however, they participated in various coalition and popular front governments in the 1920s, 1930s, and 1940s. In the elections of 1958, Chilean socialists supported the Popular Action Front (FRAP) candidate, Salvador Allende. He was narrowly defeated, and defeated again in 1964. In 1970, however, he won by a narrow plurality in a three-way presidential election and became head of a government supported by a popular front ranging from Communists to democratic reformers. His government was pledged to the nationalization of foreign-owned industry and to the planned reconstruction of the country.

THE PROSPECTS OF SOCIALISM

Millions of persons throughout the world cling to the socialist vision of an equalitarian, democratic, fraternal society based on comprehensive planning and public control of the means of production. But the political movement which embodied that vision is fragmented and has lost much of its earlier elan. The socialist spirit was sapped when the Russian Revolution brought forth a totalitarian dictatorship, and further weakened when a variety of authoritarian movements usurped the socialist name. In western Europe and the United States, socialism has come to be equated with the extension of social security and other elements of the welfare state. Few socialist theoreticians ask, "After the Welfare State—What?" Whether socialism will get a second chance is hard to say.

Social Movements

The term social movement is familiar to readers of the popular press and even the most casual students of history. Reform movements, religious movements, revolutions, and the multiplicity of "-isms" loom large in the story of mankind. When the layman speaks of a social movement he usually implies a program or a sequence of actions by a large number of individuals directed toward some social change. Sometimes he may use the term to denote the groups who engage in these actions, saying that someone "joins a movement."

The term signifies also a conceptual tool of social thinkers. The study of social movements is conventionally included in the field of collective behaviour. The subject matter of collective behaviour includes special types of human groupings, referred to in this sense as "collectivities," whose activities and behaviour, emerging from less defined and more problematic situations, are governed by novel or emergent norms rather than by pre-existing, conventional customs and rules. Some scholars seek to explain the novel, spontaneous character of collective behaviour through a theory of emergent norms. Others emphasize psychological mechanisms such as contagion, a form of imitation, or convergence, the simultaneous release of latent predispositions among a number of people. Collective behaviour also includes the study of crowds, large publics, fads and fashions, and mass communication.

CHARACTERISTICS OF SOCIAL MOVEMENTS

Scholarly definitions correspond closely to popular usages. These definitions vary according to their emphasis on the activities of a social movement or the people who engage in these activities. Those that emphasize the nature of the activities tend to focus attention on the conditions that produce movements and the individual motives that prompt large numbers of people to participate in them. Those who view social movements primarily as collectivities tend to shift the emphasis to the structural properties of social movements, the influence of these properties on the behaviour of members, and the interaction between members.

Social movements and social change. All definitions reflect the notion that social movements are intrinsically related to social change. They do not encompass the activities of people as members of stable social groups with established, unquestioned structures, norms, and values. The behaviour of members of social movements does not reflect the assumption that the social order will continue essentially as it is, with individuals being born into a stable society, passing through their own life cycles, and being replaced at death by succeeding generations who will live much the same type of life. It reflects, instead, the assumption that men can change the social order and affect the course of history. It is behaviour based on the faith that men collectively can bring about or prevent social change if they will dedicate themselves to the pursuit of a goal. Uncommitted observers may regard these

goals as illusions, but to the members they are hopes that are quite possible of realization. Asked about his activities, the member of a social movement would not reply, "I do this because it has always been done" or "It's just the custom." He is aware that his behaviour is influenced by the goal of the movement: to bring about a change in the way things have "always" been done or sometimes to prevent such a change from coming about.

The membership. The quixotic efforts of bold, imaginative individuals do not constitute social movements. A social movement is a collectivity or a collective enterprise. The individual member experiences a sense of membership in an alliance of people who share his dissatisfaction with the present state of affairs and his vision of a better order. Like a group, a social movement is a collectivity with a common goal and shared values. Each member is aware that there are other people who share his perception of what is desirable and what is undesirable, what is good and what is bad. While a larger number of people in his society or group may disagree with his definitions, he knows that he is not isolated. The social movement constitutes a new reference group for him.

This sense of membership suggests that the individual is subject to some discipline. In addition to shared values, a social movement possesses norms. These are shared expectations as to how an individual who considers himself a member will behave toward other members and toward members of outgroups. These norms prescribe behaviour that will symbolize the member's loyalty to the social movement, strengthen his commitment to it, and set him apart from nonmembers. The norms prohibit behaviour that may cause embarrassment to the movement or provide excuses for attacks by opponents. Loyalty to a movement may be symbolized by the wearing of badges, by style of dress, or by financial contributions. Commitment is strengthened by participation in group activities with other members and by engaging in actions, individual or collective, that publicly define the individual as a committed member. Engaging in illegal or socially reprehensible activities in response to the demands of the movement may bring the individual to a "point of no return," so that his fate is irrevocably tied to the movement unless he is willing to defect and accept the penalties that will be imposed both by the larger society and by the movement.

A social movement also provides guidelines as to how members should think. Norms of this kind constitute something resembling a "party line"—a definition of the "correct" position for members to take with regard to specific issues. There is subtle pressure on the individual to espouse this position even in the absence of personal knowledge of the arguments for it. At the same time, the movement, through its ideology, provides a justification for the values shared by the members. The ideology is a collective product, produced by the intellectuals of the movement and accepted and shared by the membership. Not every member can be expected to study and think through the philosophy that justified the movement and its values. The ideology provides him with a ready-made presumably authoritative set of arguments. One of the defining characteristics of a social movement is that it is relatively long lasting; the activity of the membership is sustained over a period of weeks, months, or even years, rather than flaring up for a few hours or a few days and then disappearing. A social movement is usually large but, like duration, largeness is only relative. Some social movements, extending over a span of many decades, may enlist hundreds of thousands of members. Some movements take place within the boundaries of a specific secondary group, such as a religious association or a local community, and may include only a few score or a few hundred members. Thus, while a social movement is typically large, long lasting, and widespread, some marginal social movements are relatively limited in scope; but all social movements take place within groups that are large enough to be classified by the sociologist as secondary groups. Furthermore, the exact size of a social movement is impossible to determine exactly, for membership is not formally defined.

The individual in the social movement

The lack
of formal
structure

Indeed, one of the salient characteristics of a social movement is the semiformal character of its structure. It is not informal in the sense that a small, primary group is. At the same time it lacks the fully developed, formal structure of a stable association, such as a club, a corporation, or a political party. The leaders do not possess authority in the sense of legitimized power, and membership is not formal. Even though some of the inner circle of members may go through a ceremony that signifies the act of joining, many members ally themselves to the movement simply by supporting it and "resign" by withdrawing their support. Because of its emergent and developing character, a social movement lacks defined procedures for selecting and identifying members. While it acts collectively in pursuit of some shared goal, it lacks formal procedures for arriving at decisions.

While a social movement does develop some regularities in its modes of activities, these do not constitute a relatively inflexible "standing operating procedure" of the sort that marks a bureaucracy. The movement is not stable and secure in its existence. There is always a state of tension and often one of conflict between it and the larger group or society of which it is a part. Hence its modes of activity are frequently described as strategy and tactics, terms borrowed from military thought. Strategy implies long-range planning for the utilization of all resources available for the attainment of the ultimate goal of the movement. Tactics are procedures for utilizing specific resources to deal with short-term problems or opportunities in a manner that will contribute to the overall goal. Both strategy and tactics must be amenable to change if the course of the struggle indicates that they are not effective. The informal, noncontractual quality of membership, the absence of formal decision-making procedures, and the requirement for flexibility in strategy and tactics place a premium on blind faith and fanatical loyalty on the part of members. While not all members display these traits, the ideal member gives his total, unselfish loyalty to the movement. Since no legal obligation is assumed on becoming a member, either to conform to the movement's norms or to remain a member, commitment to the movement and its values becomes one of the most important sources of member control. The deeply committed member, accepting without question the decisions and orders conveyed by the leaders, sacrificing self, family, and friends if required to do so, is likely to be regarded by outsiders as a fanatic. Some students of social movements, particularly those whose analysis has a psychoanalytic orientation, have suggested that the fanaticism of dedicated members results from individual psychopathological states. An alternative explanation is that the social movement becomes a reference group that provides the member with a new and deviant view of social reality. His basic assumptions about the nature of the social order become so divergent from those of the "normal" members of society that his logic and conclusions are incomprehensible to them. Like them, he is responding to social definitions of reality; but these definitions are derived from a different universe of discourse.

RELATIONSHIPS TO OTHER CONCEPTS

Social movements are intrinsically related to social change; but social change is continuous and not all of it involves social movements. The student of social change may identify social trends that arise out of the uncoordinated actions of many individuals who have no sense of being part of a collective movement but who, nevertheless, modify their culture. In other instances social change is deliberately planned and fostered by agents of change who are assigned the functions of research, development, and planning in stable associations. Social change, whether it results from cultural drift or planned development, generates new problems and new aspirations for members of the society. As a result social movements may arise with the goal of speeding up, redirecting, or blocking ongoing changes in culture.

Comparison with associations, crowds, and publics. The social movement, as a collectivity with a semiformal structure and acting on the basis of emergent norms,

stands in contrast to formal associations with codified norms and established traditions. Yet many of the persons who become members of social movements are, at the same time, members of such associations. Some movements arise within the boundaries of large associations, as when the Protestant Reformation started within the Roman Catholic Church. A movement cuts across the boundaries of associations when segments of the membership of several associations, such as religious denominations, unite in a joint effort such as a peace movement. A movement may include within it entire associations whose members become part of the movement by virtue of their preexisting group memberships. Finally, a social movement that succeeds in having its values accepted and legitimized by the larger society may itself become an association in the formal sense.

Like a social movement, a crowd is a collectivity but more limited in size and duration. The members of a compact crowd are physically together, in sight and hearing of one another. A diffuse crowd includes persons whose communication is indirect; but it is of relatively short duration, for the objectives of a crowd are limited and short-range. Out of the excitement, the imagery, and the sense of unity that exist for a short time in a crowd may grow a more enduring social movement. On the other hand, the tactics employed by a social movement may, with or without design, foster episodes of crowd behaviour by partisans or opponents of the movement.

The public is also a collectivity and one that, like a social movement, is usually diffuse and widespread. It may be distinguished from a social movement by the fact that the public assumes that differences of opinion about an issue legitimately exist and will be debated. The social movement exhibits no such tolerance of divergent opinions. When some members of a public become so persuaded of the righteousness of their cause that they regard disagreement as immoral, they may be transformed into a social movement. Publics also arise in relation to social movements. In such cases the movement itself and its right to exist, rather than the values with which it is concerned, may become the issue for a public. Influencing opinion within such a public may become a matter of great concern to the movement.

Comparison with interest groups and political parties. Interest groups are related both to publics and to social movements. An interest group is a number of people with a deep and continuing interest in a particular issue, who evaluate other current issues on the basis of their implications for this central interest. Thus black Americans, as an interest group, have evaluated American participation in international wars in terms of the significance for Negro rights. An interest group may participate in various publics, or its members may be attracted to a social movement that seems to serve their interests.

Social movements may be regarded as a form of pressure group, though other pressure groups do not act as social movements. The term itself comes primarily from a political context; and the lobby is an example of an institutionalized pressure group, legitimized and regulated by government and supported by an association that it serves.

Some confusion arises in the identification of certain political parties as social movements. In a stable, democratic political system the major parties constitute associations with bureaucratic structures and rules of procedure that function between elections. "New" parties, exemplified in the United States by the term third parties, constitute social movements in their struggle for recognition as regular participants in electoral contests. These new parties have a tentative nature, tend to be concerned with a single issue, and are typically identified with a charismatic leader. Social movements may arise within established parties when a dissident element seeks to displace the "regular" bureaucracy. If a third party succeeds in winning a major election, it is likely to become stabilized as an independent association. Sometimes, however, unsuccessful third parties survive for a long time as movements in which participation, rather than winning elections, is the dominant theme.

Publics
and social
movements

TYPES OF SOCIAL MOVEMENTS

There is no single, standard typology of social movements. As various scholars focus on different aspects of movements, different schemes of classification emerge. Hence any social movement may be described in terms of several dimensions.

Herbert Blumer proposed a broad distinction between *general* and specific social movements, based on differences in structure and goals. A general social movement develops out of a cultural drift and is characterized by vagueness and generality of goals. It lacks organization, and its activities consist of the parallel but uncoordinated behaviour of many individuals. It is not truly a social movement in the sense that a specific social movement is, for the latter has an emergent organization and collectively defined values and norms.

Dimensions
of social
movements

Many attempts at categorization direct attention to the objective of the movement. The social institution in or through which social change is to be brought about provides one basis for categorizing social movements as political, religious, economic, educational, and the like. It may be argued that all movements tend to be either political or religious in character, depending upon whether their strategy aims at changing political structures or the moral values of individuals.

Neil J. Smelser suggests two inclusive types of social movements differentiated according to the level of objective. The norm-oriented movement seeks to bring about changes in the accepted procedures for attaining the values of the society but does not challenge these values themselves. A value-oriented movement stems from a generalized belief that changes should and can be brought about in one or more of the values of the society, as well as in the norms necessary for the implementation of these values.

A commonly used but highly subjective distinction is that between "reform" and "revolutionary" movements. Such a distinction implies that a reform movement advocates a change that will preserve the existing values but will provide improved means of implementing them. The revolutionary movement, on the other hand, is regarded as advocating replacement of existing values. Almost invariably, however, the members of a so-called revolutionary movement insist that it is they who cherish the true values of the society and that it is the opponents who define the movement as revolutionary and subversive of basic, traditional values.

Ralph H. Turner and Lewis M. Killian suggest that social movements may be categorized in terms of what constitutes success for the movement. There are three basic criteria, and every movement incorporates all three to some degree. A value-oriented movement emphasizes the implementation of its program of social change as the measure of its success. A power-oriented movement places greater emphasis on the achievement of power. A participation-oriented movement places the greatest weight on the gratifications that the members gain from participating in the movement, such as a conviction of being "saved."

Some attempts to characterize movements involve the direction and the rate of change advocated. Adjectives such as "radical," "reactionary," "moderate," "liberal," and "conservative" are often used for such purposes. In this context the designations "revolutionary" and "reform" are often employed in a somewhat different sense than that described above, with the implication that a revolutionary movement advocates rapid, precipitous change while a reform movement works for slow, evolutionary change.

Killian advances still another typology based on the direction of the change advocated or opposed. A reactionary movement advocates the restoration of a previous state of social affairs, while a progressive movement argues for a new social arrangement. A conservative movement opposes the changes proposed by other movements, or seeming to develop through cultural drift, and advocates preservation of existing values and norms.

Turner and Killian argue that it is useful at times to categorize social movements on the basis of their public

definition, the character of the opposition evoked, and the means of action available to the movement. This scheme is designed to eliminate the subjective evaluation of goals inherent in such categories as reform and revolutionary. A movement that does not appear to threaten the values or interests of any significant segment of society is publicly defined as respectable. If there is no competing movement advocating the same objective, it is also *nonfactional*. The respectable nonfactional movement must contend primarily with the problems of disinterest and token support, but it has access to legitimate means of promoting its values. A respectable factional movement must contend with competing movements advocating the same general objective, but also has access to legitimate means of extending its influence. A movement that appears to threaten the values of powerful and significant interest groups within the society is publicly defined as revolutionary and encounters violent suppression. As a result, it is denied access to legitimate means of promoting its program. A fourth type of movement is defined as neither respectable nor dangerous but as peculiar; this type, seen as odd but harmless, encounters ridicule and has limited access to legitimate means.

Social movements may also be categorized on the basis of the general character of their strategy and tactics; for instance, whether they are legitimate or underground. The popular distinction between radical and moderate movements reflects this sort of categorization. An obvious difference between types of movements depends upon their reliance on violent or nonviolent tactics. But a nonviolent movement may also be defined as revolutionary or radical because it accepts civil disobedience, rather than legal or parliamentary manoeuvring, as a major feature of its strategy.

There are many other dimensions in which social movements may vary. Some are obviously smaller than others and may be described as cabalistic, reflecting both their limited size and their secrecy. While all movements develop some degree of semiformal organization, they vary in the degree of organization. Some remain loosely organized, others develop a highly structured central leadership group that resembles an association in its continuity and stability.

PROMINENT SOCIAL MOVEMENTS OF RECENT CENTURIES

Historical and scientific accounts make possible the analysis of a formidable number of movements that have arisen during the 18th, 19th, and 20th centuries. Historians such as George Rudé and Eric Hobsbawm have made analyses of the French Revolution, the Chartist and Luddite movements, and various peasant revolts of the 19th and 20th centuries.

The 18th and 19th centuries. The 18th century was marked by two of the great political movements of history: the French and American revolutions. During the same century one of the great religious movements, Methodism, arose in England and spread to the American colonies. Less well known are the peasant revolts that occurred in Italy and Spain.

The 19th century was also an age of revolutions. Political movements swept many European countries in the wake of the French Revolution, signifying the rise of bourgeois nationalism, and across the Atlantic Ocean independence movements arose in several South American countries. In the United States a wide variety of movements emerged. The Abolition movement was countered by the Southern Proslavery and Secessionist movements. The Temperance and the Women's Rights movements were begun, as was Christian Science. Near the end of the century, the ideology of populism supported one of the great third-party movements in U.S. history. The labour movements that extended into the next century in both Europe and America had their inception in the 19th century, which saw the beginnings of the industrial workers' dissatisfaction with bourgeois dominance of economic and political institutions. At the same time, there was an important peasant movement in semifeudalistic Russia. More significantly, the world socialist movement, including Communism, achieved its initial organization and de-

The great
age of
social
movements

veloped its basic ideology. Japan underwent a political movement that resulted in the overthrow of the Tokugawas and the modernization of the nation.

The 20th century. Many social movements that had their greatest impact in the 20th century had their beginnings shortly before the turn of the century. The Communist movement achieved its greatest triumph in the Russian Revolution, but it continued to challenge and sometimes overthrow established regimes in China and in smaller nations around the world. Zionism, the Women's Rights movement, and the Temperance movement all began in the 19th century but achieved their most notable successes in the 20th.

Fascist movements in Italy, Germany, and many smaller European nations, as well as in the United States, rose and fell within the first half of the 20th century, but remnants still exist. The latter part of the century saw the rise of a many-faceted "far right" movement in the United States, which included the revival of the Ku Klux Klan.

The 20th century has seen a new wave of nationalist movements. Colonized peoples in Africa and Asia revolted against European domination in such movements as the Algerian Revolution. In other areas where European or United States influence was subtle and indirect rather than explicit and formal, movements, which combined nationalistic and socialistic themes, developed to challenge existing regimes alleged to be agents of imperialism. The Cuban Revolution overthrew the Batista government and then expropriated United States properties. Arab nationalism developed partly as a response to Zionism, partly as a response to Western economic influence. Other significant nationalist movements arose in Turkey, India, and Iran. Afrikaner nationalism in South Africa and French nationalism in Canada were movements in which people of European ancestry sought political dominance or independence in pluralistic societies.

The Negro protest movement in the United States passed through many phases during the 20th century. The civil rights movement, beginning shortly after the turn of the century under the leadership of the National Association for the Advancement of Colored People, competed with the Marcus Garvey "Back-to-Africa" movement. It was transformed by the strategy of nonviolent direct action inspired by Martin Luther King, Jr., and was subsequently diminished by the Black Power movement and black nationalism. It evoked a countermovement, the resistance movement in the South, and was one of the stimuli for the rise of George Wallace's third-party movement. Movements for self-determination and economic welfare also arose among American Indians and Mexican Americans.

The threat of nuclear war and the involvement of the United States in Viet Nam were met by a peace movement in the United States and were reflected in similar movements in many European countries. Intersecting with the peace movement in the United States was the student movement, which also had counterparts in other nations.

The 20th century has been marked by no great religious movements like those of earlier centuries, but both Protestant and Catholic Christianity have been torn by conflicts between "modernist" and "fundamentalist" movements.

THE DYNAMICS OF SOCIAL MOVEMENTS

As an enduring, sustained collectivity a social movement undergoes significant changes during its existence. This characteristic has led to attempts to formulate a theory of the "life cycle" or "natural history" of social movements. Several scholars, including Rex D. Hopper, have undertaken to identify patterns of developmental change in revolutions. Hopper postulates a preliminary stage of mass excitement and unrest, a popular stage of crowd excitement, a formal stage of formulation of issues and publics, and an institutional stage of legalization and societal organization.

Other scholars question the value of the life-cycle approach to social movements, arguing that empirical studies of numerous movements fail to support the notion of invariant stages of development. Smelser suggests as an alternative a value-added theory, which postulates that while a number of necessary determinants for the occur-

rence of a social movement may be isolated, they need not be added to the situation in any particular order. Some may be present for some time without effect only to be activated later by the addition of another determinant. At most it can be said that the idea of the life cycle permits the discovery of conditions that must be present if any movement is to proceed from one stage to another. It may also help identify the conditions that cause a movement to take one direction rather than another. Still, it can be said that a social movement has a career; for as it endures it always undergoes changes in many of its characteristics, though the sequence of these changes may vary from movement to movement.

Progressive changes in leadership and membership. One of the most apparent changes is a shift in leadership. While social movements are often identified with one outstanding symbolic leader, there is usually a leadership group that includes different types of leaders. In its earliest stages the strongest influence on a movement is likely to be the charismatic leader who personally symbolizes its values. At some point intellectuals play a leadership role by contributing to the developing ideology of the movement. And if a movement endures and grows for any length of time, administrative leaders arise who are concerned with the practical matters of organization and strategy. Influence in the movement may shift between these types. Furthermore, new charismatic leaders may arise to challenge the earlier leaders, suggesting changes in values and strategy and giving rise to factional struggles.

Usually the membership of a movement grows during its career, which introduces an element of greater heterogeneity. In the early stages the followers typically are deeply committed with an almost fanatical dedication to the values. Later, a movement attracts a greater number of other types of members. These include persons disaffected with the social order who need to identify with some unconventional cause. The particular values of the movement are not as important to them as the psychological rewards of participation. Another type, who may be called the "exploiters," see in the movement an opportunity to serve certain private goals. If the movement gains a measure of respectability in some segment of society, members may be acquired who are not deeply committed. They are likely to have significant reservations about the movement and their participation is sporadic. On the other hand, if a movement is publicly defined as revolutionary and subjected to harsh oppression, the membership is likely to be reduced mainly to deeply committed converts or to fanatics who derive some satisfaction from the feeling of being persecuted.

Progressive changes in goals and strategies. The goals rarely remain unchanged. As the movement endures and grows, they are likely to become broader and vaguer than they were at the beginning. Proposals for limited, specific reforms become embedded within programs of general social reform. As the leaders and members begin to acquire a sense of power through early victories, the power orientations of the movement may increase. Acquisition of greater power by the population segment that the movement purportedly represents, rather than the implementation of the values of the movement, then becomes a goal. At the same time, the statement of the movement's aim in acquiring power becomes vaguer and more utopian.

Changes also occur in the strategy, which may tend in either of two general directions. It may emphasize *personal transformation*, bringing about social change by converting a majority of society to implement the values by their actions. Or it may emphasize a strategy of *societal manipulation*, changing social institutions so that the program may be implemented without regard to the number of people favouring the new order. Failure of a movement to gain a large number of converts, combined with indications that it has at its disposal effective means of coercion, leads to a shift to this type of strategy.

Strategy and changes in strategy are strongly influenced by the relationship of the social movement to the larger society and to other social movements. The social struc-

ture and the prevailing belief system may suggest either that change can be brought about by changing the hearts and minds of the individual members or that individuals have little effect on the social order. A public definition of the movement as dangerous and subversive may force it to rely increasingly on a strategy of societal manipulation, including violent tactics. The opposition posed by a countermovement may have the same effect, making attempts at persuasion difficult and dangerous and pushing a nonviolent, noncoercive movement to meet force with force.

RELATIONSHIPS BETWEEN STRUCTURAL ELEMENTS

As a collectivity, a social movement is characterized by an emergent social structure and a culture. The social structure is reflected in the relationship between leaders and followers, the culture in the values and norms.

Unlike an association, a social movement does not possess legitimate leaders in the sense of being endowed with authority through some formal process. Leaders must constantly substantiate their claims to leadership by demonstrating the effectiveness of their influence on the followers. There is a relationship of reciprocal influence. The followers, for their part, lack institutionalized means of making their influence felt, such as referendums, legislatures, or periodic elections of leaders. They have no way of arriving at collective decisions except in occasional crowd situations. It falls to the leaders, therefore, to formulate policies and decisions that will strike a responsive note in their following. Having advanced such proposals, they must rely on either persuasion or coercion to create the illusion that these are collective decisions made by the entire movement. Propaganda thus becomes an important tool of leadership. Occasionally, a leadership group will employ coercion to prevent dissident elements from destroying the illusion that the leaders' decisions are merely statements of what the followers had already decided. The successful leader must, of course, be able to judge the mood and the attitudes of his potential followers in order to evoke a favourable response.

Propaganda is also important for maintaining morale and unity. A social movement lacks both the intimacy of a primary group and the formal boundaries of an association. The speeches and writings of leaders serve, in part, to assure the followers of the size, the strength, and the potential for success of the movement—matters difficult for the followers to observe directly. Movements do utilize interpersonal relations to enhance their unity, encouraging small groups of members to meet frequently in circumstances in which they can form personal ties. Mass meetings and parades, with the accompanying ritual, reduce the feelings of isolation that scattered members may experience. Demanding of members acts that constitute public declarations of allegiance serves as a commitment mechanism, making it difficult for the member to disassociate himself. Of extraordinary value to a movement is the example of martyrs whose fate arouses indignation in the members, symbolizes unreserved commitment, and lightens the burden of sacrifices.

The culture of a movement encompasses norms and values. Norms are standardized expectations of behaviour developed by members. Values include the program and the ideology. The program is the scheme of change, the new social order that the movement proposes to bring about. The ideology is a body of ideas justifying the program and the strategy of the movement. It usually includes a reinterpretation of history, a projection of the utopia that the success of the movement will introduce, a projection of the disastrous consequences of failure, and a reevaluation of population segments in terms of their relationship to the movement.

THE CAUSES OF SOCIAL MOVEMENTS

Both individual psychological states and the characteristics of a society at a particular time may be considered as causes of social movements.

Psychological factors. Individual factors are psychological states that either convince a person to join a movement or so weaken his commitment to conventional

groups that he is willing to risk their disapproval because of his belief in an unpopular cause. Failure to achieve a satisfying status and identity within normal membership groups may be such a factor. The prestige and sense of belonging, which such a person may gain as a member of a social movement, may be even more important to him than the values of the movement. Marginality may be a source of spoiled identity. The marginal man, fitting satisfactorily into no group, may possess a sense of detachment that enables him to be unusually critical of the social order.

Alienation, feelings of powerlessness, hopelessness, and estrangement from society may predispose an individual to participation. Some scholars argue, however, that there are different kinds of alienation. One type leads merely to apathy and resignation. Political alienation, however, reflects a loss of faith in the political community and predisposes the individual to join a movement that challenges it.

Closely akin to these ideas is the theory of Hadley Cantril that participation represents a search for meaning. The need to find meaning in a world that does not seem to make sense might be interpreted as a variation of spoiled identity or alienation.

Deprivation, discontent, and frustration are frequently assumed to be sufficient causes for initiating or joining a social movement. The relationship is not a simple one, however. There is little evidence that the most deprived segments of a population are the most likely to participate in social movements. The concept of relative deprivation has been utilized to explain the fact that persons who could be much worse off than they are but still feel deprived in comparison with even more fortunate groups often play a prominent part in social movements.

Given that discontent and frustration are always present to some degree in every person's life, there must be some basis for the belief that it is possible to change the underlying conditions for a person to cast his lot with a social movement. In addition, there must be a sense that other people share his discontents and his belief in the possibility of change.

Social factors. An important task of the student of social movements is to identify those conditions under which social movements are most likely to arise. While the existence of widespread poverty and suffering might seem sufficient to give rise to efforts at reform, it must be emphasized again that some basis for hope must also exist to stir people to make the effort. Paradoxically, partial alleviation of conditions of deprivation may provide such a basis, serving as the impetus for the formation of a social movement just as things seem to be getting better. The success of other people similarly situated, such as victorious revolutionaries in a neighbouring nation, may be another source of hope.

More general theories of the origin of social movements, such as those of Smelser, Turner, and Killian, suggest that social change may result in strains or conflicts in one or more crucial aspects of the social order. Normative strain arises when changing conditions create a situation in which the established norms no longer lead to the attainment of important, accepted values. Strain in values arises when the values themselves seem to interfere with the satisfaction of important needs of a segment of the society. This sort of strain often arises when different groups, such as immigrants, minorities, or the younger generation, develop values that conflict with those of more established groups. Even with little change in norms and values, changes in social structure reflected in the failure of important functionaries to play their roles adequately may lead to discontent.

Another type of change is a shift in the balance of power within a society. Strain and individual discontent may exist within a social system without leading to a social movement because the distribution of power seems to preclude effective action. A state of accommodation exists; but signs of weakening on the part of the powerful or the acquisition of new resources by the powerless changes the balance of power and gives rise to the hope that, combined with discontent, leads to a social movement.

Interior
structures

Social
movements
and
discontent

Changes in the communications system of a society are of particular importance in facilitating the rise of social movements. A breakdown in communication, blocking the transmission of grievances to functionaries who can act on them, may lead to discontent and political alienation. An increase in the flow of messages between scattered members of a society leads to the socialization of unrest. The growth of mass-communication media, which allows people in many parts of a large society to know what others are thinking and doing, is especially conducive to the development of social movements. By the same token, restrictions on communications, such as censorship, are important techniques for preventing the mobilization of the discontented in social movements.

The general nature of the belief system existing in the culture of a society affects the likelihood that social movements will arise and defines the type that will occur. For example, a system that is essentially fatalistic is less conducive to social movements, particularly those with a strategy of societal manipulation, than one that emphasizes the perfectibility of man and his control over his own fate.

THE FUNCTIONS OF SOCIAL MOVEMENTS

Whatever the specific social factors that give rise to them and the individual factors that cause people to join, social movements have significant personal and social consequences.

Wholehearted commitment to a social movement may produce temporary or even enduring changes in the personality of a member. This may go so far that to his friends and to himself he often seems to have become a quite different person. The mere fact of his belonging may give him a sense of security and importance. Since he is likely to form strong ties with the few with whom he works closely, he receives not only esteem but affection. He also derives a sense of security from the oversimplified version of reality often presented in the ideology; previous doubts and ambivalence are eliminated; he feels that he has found the truth. This fanaticism and single-mindedness makes life simpler for him. Other reference groups decrease in importance, and the difficult decisions required when a person has conflicting group loyalties are minimized. In addition, those who have felt insignificant in the past may find in a social movement opportunities for some degree of leadership. To the extent that a person makes a social movement his most important reference group, he gains a new identity.

In the process, society gains future leaders for whom the social movement has been a training school. Some men who have had their first experience of leadership in a labour movement or a civil rights movement have gone on to become important government officials.

Even when a movement is publicly defined as revolutionary, it has significant effects on public opinion. The socialization and focussing of the discontent of people whose grievances previously have been ignored formulates new issues around which publics develop. Politicians may be forced to take positions on issues that they prefer to avoid. The confrontations that a social movement often precipitates serve to sharpen an issue and lead to the process of polarization. The conflict between a movement and a countermovement may be paralleled by a raging debate in a public consisting of members who are not fully committed to either. In the long run, a social movement may introduce new values into a social order and, even though unrealized, the utopia that it promises may suggest new rights and goals that are cherished long after the movement is ended.

THE CONSEQUENCES OF SOCIAL MOVEMENTS

It has been suggested that the committed participant in a social movement undergoes a psychological reorganization. It is clear that his new sense of security and importance is acquired at the sacrifice of autonomy. As a loyal member he tends to let the leaders do his thinking for him, suppressing doubts as to the validity of the ideology and the wisdom of the leader's decision. He repeats their arguments in a dogmatic fashion; persons who are not in the

movement find it difficult to debate with him since they start from different premises. His perception is selective in a different way from theirs. The ideology, for example, may lead him to view all governmental authorities as villains, while the ordinary citizen views them as legitimate leaders, some good, some bad. The end product of this surrender of autonomy may be an altered world view. Some things taken for granted before becoming part of the movement will never seem the same again, even after leaving the discipline of the movement.

The end products of social movements as collectivities attempting to change the social order cannot be analyzed simply in terms of victory or defeat. Defeat may come as a result of ruthless suppression of the movement or through widespread apathy. A movement may wither away because too few take it seriously and it does not develop enough power to force its program on society. Sometimes the remnants may linger for a long time as a cult, oriented inward toward the gratifications that the members obtain from participation but making no serious effort to change the social order.

Success is most apparent when a movement manages to have its power legitimized as authority. In a successful revolution, the social movement becomes the new source of authority and respectability, and opposition to its values is defined as counterrevolutionary. In other instances, the movement achieves power through secession. Failing to compel acceptance of its values in the larger group or society, the members withdraw into a new social system in which they can attempt to implement the values.

A less obvious form of success is the institutionalization of the values or some important part of them. Accepting the legitimacy of the movement's values, the traditional associations in the society incorporate them into their own values and implement them without a transfer of authority to the social movement. Thus the Socialist Party has seen many of its proposals adopted by the two major political parties and the government of the United States without winning a major election or overthrowing the government. Sometimes, however, the social movement itself is institutionalized by being accorded authority as the legitimate custodian of the new values. The movement is then transformed into a bureaucratic association, as happened with the American labour movement of the early part of the 20th century or the Congress Party of India after the end of British rule.

THE FUTURE OF SOCIAL MOVEMENTS

The rapidity and complexity of social change throughout the world during the 19th and 20th centuries suggest that conditions will be conducive to the multiplication of social movements. The development and diffusion of technology, particularly automation, has made possible the industrialization of an ever-growing portion of the world, changing the living conditions of millions of people. This trend has been accompanied by the urbanization of a growing portion of the world's population. Some become more affluent and find life easier although more impersonal. Others find themselves displaced, poorer than before, and forced to live in the crowded slums of cities so large that they seem to defy efficient management. City governments as well as national governments appear to many people as increasingly bureaucratic, remote and unresponsive to the problems of the ordinary citizen. This may lead to a growth in political alienation and a decline of faith in the efficacy of political systems that purport to be democratic. At the same time, the expansion of radio and television makes possible more rapid and graphic diffusion of the discontent of "the wretched of the earth," to use the phrase of Frantz Fanon.

What are often identified as the two greatest threats to the survival of humanity must be considered in assessing the likelihood of an increase in the number of social movements. One is the population explosion, which leads to physical deprivation among an increasing number of people and presents a growing challenge to prevailing economic systems of distribution. The second is the threat of nuclear holocaust. Some observers of the worldwide youth movement suggest that young people who have

Consequences of success

Effectson members' lives

grown up in a world capable of self-destruction have acquired a different world view from that of earlier generations.

A single major factor must be considered capable of limiting the increase of social movements and leading to the rapid suppression of those that do arise. This is the highly efficient means of social control, physical and psychological, now at the disposal of established political regimes. The totalitarian control of populations, which such means make possible, is not conducive to the rise of social movements.

BIBLIOGRAPHY. H. BLUMER, "Collective Behavior," in A.M. LEE (ed.), *Principles of Sociology*, 2nd ed. (1951), presents a widely accepted definition of the social movement as a form of collective behaviour. R.H. TURNER and L.M. KILLIAN, *Collective Behavior* (1957); L.M. KILLIAN, "Social Movements," in R.E.L. FARIS (ed.), *Handbook of Modern Sociology* (1964); K. and G. LANG, *Collective Dynamics* (1961); and N.J. SMELSER, *Theory of Collective Behavior* (1963), offer general sociological theories of types of social movements and the dynamics of their development. R. HEBERLE, *Social Movements* (1951), develops general sociological theories but focuses on the relationship between social movements and political parties. C.W. KING, *Social Movements in the United States* (1956), develops general principles from the sociological analysis of selected social movements. H. CANTRIL, *Psychology of Social Movements* (1941); H.H. TOCH, *The Social Psychology of Social Movements* (1965); S. MILGRAM and H.H. TOCH, "Social Movements," in G. LINDZEY and E. ARONSON (eds.), *Handbook of Social Psychology*, 2nd ed. (1968); and M. and W.C. SHERIF, *Social Psychology* (1969), represent theoretical approaches, placing greater emphasis on individual motivational and perceptual processes. L.P. EDWARDS, *The Natural History of Revolution* (1927); C. BRINTON, *The Anatomy of Revolution* (1938); and G.S. PETTEE, *The Process of Revolution* (1938), represent attempts to develop general theories of revolution as a type of social movement through the analyses of American and European revolutions. A similar effort based on studies of more recent revolutions in Latin America and the Middle East is found in C. LEIDEN and K.M. SCHMITT, *The Politics of Violence* (1968). There are numerous studies of particular social movements. Representative of those that include theoretical propositions, as well as historical descriptions are E.J. HOBBS-BAWN, *Primitive Rebels* (1959); U.S. title, *Social Bandits and Primitive Rebels*, 1960), a study of archaic forms of social movements in the 19th and 20th centuries; and G.FE. RUDE, *The Crowd in History: A Study of Popular Disturbances in France and England, 1730-1848* (1964), an analysis of crowds in pre-industrial social movements in England and France; C.A. DUBOIS, *The 1870 Ghost Dance* (1939); and K.L.M. BURRIDGE, *Mambu: A Melanesian Millennium* (1960), studies of nativistic movements; sociological analyses of Communism and Nazism in P. SELZNICK, *The Organizational Weapon: A Study of Bolshevik Strategy and Tactics* (1952); and T.F. ABEL, *Why Hitler Came into Power* (1938); essays on the Algerian revolution in F. FANON, *L'an V de la révolution algérienne* (1963; Eng. trans., *Studies in a Dying Colonialism*, 1965); and sociological analyses of social movements in the U.S. in T.H. GREER, *American Social Reform Movements: Their Pattern Since 1865* (1949); L.M. KILLIAN, *The Impossible Revolution? Black Power and the American Dream* (1968); and J.H. SKOLNICK, *The Politics of Protest* (1969).

Social Sciences, History of

The social sciences, which deal with human behaviour in its social and cultural aspects, include the following disciplines: economics, political science, and sociology; social and cultural anthropology, social psychology, and social and economic geography; and those areas of education that deal with the social contexts of learning and the relation of the school to the social order. History is regarded by many of its practitioners as a social science, and certain areas of historical study today are almost indistinguishable from work done in the social sciences. Most historians, however, still consider history as one of the humanities. It is generally thought best, in any case, to consider history as marginal to the humanities and social sciences, since its distinctive insights and techniques pervade both spheres.

During the past quarter of a century, the term behavioural sciences has become more and more commonly used for the disciplines mentioned above. Those who fa-

vour this term do so in part because these disciplines are thus brought closer to some of the sciences, such as physical anthropology, linguistics, law, demography, and physiological psychology, which also deal with the behaviour of man but which do not properly fall among the social sciences. The term is also favoured by many because it carries with it implications of greater methodological rigour, a more definite empirical and behavioral base, and a freedom from moral presuppositions than is the case with the "social sciences," all of which arose in the 19th century when, despite the fashionable quest for scientific character, they were still heavily freighted with traditional philosophical and humanitarian interests. Whether the term behavioural sciences will in time supplant "social sciences" or whether it will, as neologisms so often have before, disappear without trace in a few years is impossible to say. For the purposes of this article, the two terms may be considered synonymous, though the preference throughout will be given to the older and still more universal "social sciences."

The concern in this article is much less with the conclusions and results of the individual social sciences than with their disciplinary identity in modern society. The concern is with the social sciences as vital elements in the aftermath of the two great revolutions, the political and industrial, which opened the 19th century, with the pattern the social sciences assumed in that century, and their extraordinary development in the 20th century. The concern will also be with the intellectual roots of the social sciences and their relation to other areas of thought.

The article is divided into the following sections:

- I. The origins of the social sciences
 - Heritage of the Middle Ages and the Renaissance
 - Heritage of the Enlightenment
- II. The 19th century
 - Themes emanating from the social revolutions
 - The new ideologies and philosophies
 - The development of the separate disciplines
 - Economics
 - Political science
 - Anthropology
 - Sociology
 - Social psychology
 - Social statistics and social geography
- III. The 20th century
 - Marxist influences
 - Freudian influences
 - The changing character of the disciplines
 - Specialization and cross-disciplinary approaches
 - Nature of the research
 - Theoretical modes
 - Developmentalism
 - Social-systems approach
 - Structuralism and functionalism
 - Interactionism
 - Future of the social sciences

I. The origins of the social sciences

Although, strictly speaking, the social sciences do not precede the 19th century—that is, as distinct and recognized disciplines of thought—one must go back farther in time for the origins of some of their fundamental ideas and objectives. In the largest sense, the origins go all the way back to the ancient Greeks and their rationalist inquiries into the nature of man, state, and morality. The heritage of both Greece and Rome is a powerful one in the history of social thought as it is in so many other areas of Western society. Very probably, apart from the initial Greek determination to study all things in the spirit of dispassionate and rational inquiry, there would be no social sciences today. True, there have been long periods of time, as during the Western Middle Ages, when the Greek rationalist temper was lacking. But the recovery of this temper, through texts of the great classical philosophers, is the very essence of the Renaissance and the Age of Reason in modern European history. With the Age of Reason, in the 17th and 18th centuries, one may begin.

HERITAGE OF THE MIDDLE AGES AND THE RENAISSANCE

The same impulses that led men in that age to explore the earth, the stellar regions, and the nature of matter led

Scope of the social or behavioral sciences

them also to explore the institutions around them: state, economy, religion, morality; above all, the nature of man himself. It was the fragmentation of medieval philosophy and theory, and, with this, the shattering of the medieval world view that had lain deep in thought until about the 16th century, that was the immediate basis of the rise of the several strands of specialized thought that were to become in time the social sciences.

Medieval theology, especially as it appears in St. Thomas Aquinas' *Summa theologiae*, contained and fashioned syntheses from ideas about man and society—ideas indeed that may be seen to be political, social, economic, anthropological, and geographical in their substance. But it was partly this close relation between medieval theology and ideas of the social sciences that accounts for the longer time it took these ideas—to achieve what one would today call scientific character. From the time of the great Roger Bacon in the 13th century, there were at least some rudiments of physical science that were largely independent of medieval theology and philosophy. Historians of physical science have no difficulty in tracing the continuation of this experimental tradition, primitive and irregular though it was by later standards, throughout the Middle Ages. Side by side with the kinds of experiment made notable by Roger Bacon were impressive changes in technology through the medieval period and then, in striking degree, in the Renaissance. Efforts to improve agricultural productivity; the rising utilization of gunpowder, with consequent development of guns and the problems that they presented in ballistics; growing trade, leading to increased use of ships and improvements in the arts of navigation, including use of telescopes; and the whole range of such mechanical arts in the Middle Ages and Renaissance as architecture, engineering, optics, and the construction of watches and clocks—all of this put a high premium on a pragmatic and operational understanding of at least the simpler principles of mechanics, physics, astronomy, and, in time, chemistry.

In short, by the time of Copernicus and Galileo in the 16th century, a fairly broad substratum of physical science existed, largely empirical but not without theoretical implications on which the edifice of modern physical science could be built. It is notable that the empirical foundations of physiology were being established in the studies of the human body being conducted in medieval schools of medicine and, as the career of Leonardo Da Vinci so resplendently illustrates, among artists of the Renaissance, whose interest in accuracy and detail of painting and sculpture led to their careful studies of human anatomy.

Very different was the beginning of the social sciences. In the first place, the church, throughout the Middle Ages and even into the Renaissance and Reformation, was much more attentive to what scholars wrote and thought about man's mind and his behaviour in society than it was toward what was being studied and written in the physical sciences. From the church's point of view, while it might be important to see to it that thought on the physical world corresponded as far as possible to what Scripture said—witnessed, for example, in the famous questioning of Galileo—it was far more important that such correspondence exist in matters affecting the nature of man, his mind, spirit, and soul. Nearly all the subjects and questions that would form the bases of the social sciences in later centuries were tightly woven into the fabric of medieval scholasticism, and it was not easy for even the boldest minds to break this fabric.

Then, when the hold of scholasticism did begin to wane, two fresh influences, equally powerful, came on the scene to prevent anything comparable to the pragmatic and empirical foundations of the physical sciences from forming in the study of man and society. The first was the immense appeal of the Greek classics during the Renaissance, especially those of the philosophers Plato and Aristotle. A great deal of social thought during the Renaissance was little more than gloss or commentary on the Greek classics. One sees this throughout the 15th and 16th centuries.

Second, in the 17th century appeared the powerful influence of the philosopher René Descartes. Cartesianism, as his philosophy was called, declared that the proper approach to understanding of the world, including man and society, was through a few simple, fundamental ideas of reality and, then, rigorous, almost geometrical deduction of more complex ideas and eventually of large, encompassing theories, from these simple ideas, all of which, Descartes insisted, were the stock of common sense—the mind that is common to all human beings at birth. It would be hard to exaggerate the impact of Cartesianism on social and political and moral thought during the century and a half following publication of his *Discourse on Method* and his *Meditations*. Through the Age of Reason and down through the Enlightenment in the later 18th century, the spell of Cartesianism was cast on nearly all those who were concerned with the problems of the nature of man and society.

Both of these great influences, reverence for the classics and fascination with the geometrical-deductive procedures advocated by Descartes must be seen from today's vantage point as among the major influences retarding the development of a science of society comparable to the science of the physical world. It is not as though data were not available in the 17th and 18th centuries. The emergence of the national state carried with it evergrowing bureaucracies concerned with gathering information, chiefly for taxation, census, and trade purposes, which might have been employed in much the same way that physical scientists employed their data. The voluminous and widely published accounts of the great voyages that had begun in the 15th century, the records of soldiers, explorers, and missionaries who perforce had been brought into often long and close contact with primitive and other non-Western peoples, provided still another great reservoir of data, all of which might have been utilized in scientific ways as such data were to be utilized a century or two later in the social sciences. Such, however, was the continuing spell cast by the texts of the classics and by the strictly rationalistic, overwhelmingly deductive procedures of the Cartesians that, down until the beginning of the 19th century, these and other empirical materials were used, if at all, solely for illustrative purposes in the writings of the social philosophers.

HERITAGE OF THE ENLIGHTENMENT

There is also the fact that, especially in the 18th century, reform and even revolution were often in the air. The purpose of a great many social philosophers was by no means restricted to philosophic, much less scientific, understanding of man and society. The dead hand of the Middle Ages seemed to many vigorous minds in western Europe the principal force to be combatted, through critical reason, enlightenment, and, where necessary, major reform or revolution. One may properly account a great deal of this new spirit to the rise of humanitarianism in modern Europe and in other parts of the world and to the spread of literacy, the rise in the standard of living, and the recognition that poverty and oppression need not be the fate of the masses. The fact remains, however, that social reform and social science have different organizing principles, and the very fact that for a long time, down indeed through a good part of the 19th century, social reform and social science were regarded as pretty much the same thing could not have helped but retard the development of the latter.

Nevertheless, it would be wrong to discount the significant contributions to the social sciences that were made during the 17th and 18th centuries. The first and greatest of these was the spreading ideal of a science of society, an ideal fully as widespread by the 18th century as the ideal of a physical science. Second was the rising awareness of the multiplicity and variety of human experience in the world. Ethnocentrism and parochialism, as states of mind, were more and more difficult for educated people to maintain given the immense amount of information about—or, more important, interest in—non-Western peoples, the results of trade and exploration. Third was the spreading sense of the social or cultural character of human behaviour in society—that is, its purely historical

and
Cartesianism

Ideas of structure and developmental change

or conventional, rather than biological, basis. A science of society, in short, was no mere appendage of biology but was instead a distinct discipline, or set of disciplines, with its own distinctive subject matter.

To these may be added two other very important contributions of the 17th and 18th centuries, each of great theoretical importance. The first was the idea of structure. First seen in the writings of such philosophers as Hobbes, Locke, and Rousseau with reference to the political structure of the state, it had spread by the mid-18th century to highlight the economic writings of the Physiocrats and Adam Smith. The idea of structure can also be seen in certain works relating to man's psychology and, at opposite reach, to the whole of civil society. The ideas of structure that were borrowed from both the physical and biological sciences were fundamental to the conceptions of political, economic, and social structure that took shape in the 17th and 18th centuries. And these conceptions of structure have in many instances, subject only to minor changes, come down to 20th-century social science.

The second major theoretical idea was that of developmental change. Its ultimate roots in Western thought, like those indeed of the whole idea of structure, go back to the Greeks, if not earlier. But it is in the 18th century, above all others, that the philosophy of developmentalism took shape, forming a preview, so to speak, of the social evolutionism of the next century. What was said by such writers as Condorcet, Rousseau, and Adam Smith was that the present is an outgrowth of the past, the result of a long line of development in time, and, furthermore, a line of development that has been caused, not by God or fortuitous factors, but by conditions and causes immanent in human society. Despite a fairly widespread belief that the idea of social development is a product of prior discovery of biological evolution, the facts are the reverse. Well before any clear idea of genetic speciation existed in European biology, there was a very clear idea of what might be called social speciation—that is, the emergence of one institution from another in time and of the whole differentiation of function and structure that goes with this emergence.

As has been suggested, these and other seminal ideas were contained for the most part in writings, the primary function of which was attack on the existing order of government and society in western Europe. Another way of putting the matter is to say that they were clear and acknowledged parts of political and social idealism—using that word in its largest sense. Hobbes, Locke, Rousseau, Montesquieu, Adam Smith, and other major philosophers had as vivid and energizing sense of the ideal—ideal state, ideal economy, ideal civil society—as any earlier utopian writer. These men were, without exception, committed to visions of the good or ideal society. Their interest in the "natural"—that is, natural morality, religion, economy, or education, in contrast to the merely conventional and historically derived—sprang as much from the desire to hold a glass up to a surrounding society that they disliked as from any dispassionate urge simply to find out what man and society are made of. The fact remains, however, that the ideas that were to prove decisive in the 19th century, so far as the social sciences were concerned, arose during the two centuries preceding.

II. The 19th century

The fundamental ideas, themes, and problems of the social sciences in the 19th century are best understood as responses to the problem of order that was created in men's minds by the weakening of the old order, or European society, under the twin blows of the French Revolution and the Industrial Revolution. The breakup of the old order—an order that had rested on kinship, land, social class, religion, local community, and monarchy—set free, as it were, the complex elements of status, authority, and wealth that had been for so long consolidated. In the same way that the history of 19th-century politics, industry, and trade is basically about the practical efforts of human beings to reconsolidate these elements, so the history of 19th-century social thought is

about theoretical efforts to reconsolidate them—that is, to give them new contexts of meaning.

In terms of the immediacy and sheer massiveness of impact on human thought and values, it would be difficult to find revolutions of comparable magnitude in human history. The political, social, and cultural changes that began in France and England at the very end of the 18th century spread almost immediately through Europe and the Americas in the 19th century and then on to Asia, Africa, and Oceania in the 20th. The effects of the two revolutions, the one overwhelmingly democratic in thrust, the other industrial-capitalist, have been to undermine, shake, or topple institutions that had endured for centuries, even millennia, and with them systems of authority, status, belief, and community.

It is easy today to deprecate the suddenness, the cataclysmic nature, the overall revolutionary effect of these two changes and to seek to subordinate results to longer, deeper tendencies of more gradual change in western Europe. But as many recent historians have pointed out, there was to be seen, and seen by a great many sensitive minds of that day, a dramatic and convulsive quality to the changes that cannot properly be subsumed to the slower processes of continuous evolutionary change. What is crucial, in any event, from the point of view of the history of the social thought of the period, is how the changes were actually envisaged at the time. By a large number of social philosophers and social scientists, in all spheres, those changes were regarded as nothing less than of earthquake intensity.

The coining or redefining of words is an excellent indication of men's perceptions of change in a given historical period. A large number of words taken for granted today came into being in the period marked by the final decade or two of the 18th century and the first quarter of the 19th. Among these are: industry, industrialist, democracy, class, middle class, ideology, intellectual, rationalism, humanitarian, atomistic, masses, commercialism, proletariat, collectivism, equalitarian, liberal, conservative, scientist, utilitarian, bureaucracy, capitalism, and crisis. Some of these words were invented; others reflect new and very different meanings given to old ones. All alike bear witness to the transformed character of the European social landscape as this landscape loomed up to the leading minds of the age. And all these words bear witness too to the emergence of new social philosophies and, most pertinent to the subject of this article, the social sciences as they are known today.

THEMES EMANATING FROM THE SOCIAL REVOLUTIONS

It is illuminating to mention a few of the major themes in social thought in the 19th century that were almost the direct results of the democratic and industrial revolutions. It should be borne in mind that these themes are to be seen in the philosophical and literary writing of the age as well as in social thought.

First, there was the great increase in population. Between 1750 and 1850 the population of Europe went from 140,000,000 to 266,000,000; in the world from 728,000,000 to well over 1,000,000,000. It was an English clergyman-economist, Thomas Malthus, who, in his famous *Essay on Population*, first marked the enormous significance to human welfare of this increase. With the diminution of historic checks on population growth, chiefly those of high mortality rates—a diminution that was, as Malthus realized, one of the rewards of technical progress—there were no easily foreseeable limits to growth of population. And such growth, he stressed, could only upset the traditional balance between population, which Malthus described as growing at geometrical rate, and food supply, which he declared could grow only at arithmetical rate. Not all social scientists in the century took the pessimistic view of the matter that Malthus did but few if any were indifferent to the impact of explosive increase in population on economy, government, and society.

Second, there was the condition of labour. It may be possible to see this condition in the early 19th century as in fact better than the condition of the rural masses at

Effects of population growth

Effects of the democratic and industrial revolutions

earlier times. But the important point is that to a large number of writers in the 19th century it seemed worse and was defined as worse. The wrenching of large numbers of people from the older and protective contexts of village, guild, parish, and family, and their massing in the new centres of industry, forming slums, living in common squalor and wretchedness, their wages generally behind cost of living, their families growing larger, their standard of living becoming lower, as it seemed—all of this is a frequent theme in the social thought of the century. Economics indeed became known as the "dismal science," because economists, from David Ricardo to Karl Marx, could see little likelihood of the condition of labour improving under capitalism.

Third, there was the transformation of property. Not only was more and more property to be seen as industrial—manifest in the factories, business houses, and workshops of the period—but also the very nature of property was changing. Whereas for most of the history of mankind property had been "hard," visible only in concrete possessions—land and money—now the more intangible kinds of property such as shares of stock, negotiable equities of all kinds, and bonds were assuming ever greater influence in the economy. This led, as was early realized, to the dominance of financial interests, to speculation, and to a general widening of the gulf between the propertied and the masses. The change in the character of property made easier the concentration of property, the accumulation of immense wealth in the hands of a relative few, and, not least, the possibility of economic domination of politics and culture. It should not be thought that only socialists saw property in this light. From Edmund Burke through Auguste Comte, Frédéric Le Play, and John Stuart Mill down to Karl Marx, Max Weber, and Emile Durkheim, one finds conservatives and liberals looking at the impact of this change in analogous ways.

Fourth, there was urbanization—the sudden increase in the number of towns and cities in western Europe and the increase in number of persons living in the historic towns and cities. Whereas in earlier centuries, the city had been regarded almost uniformly as a setting of civilization, culture, and freedom of mind, now one found more and more writers aware of the other side of cities: the atomization of human relationships, broken families, the sense of the mass, of anonymity, alienation, and disrupted values. Sociology particularly among the social sciences turned its attention to the problems of urbanization. The contrast between the more organic type of community found in rural areas and the more mechanical and individualistic society of the cities is a basic contrast in sociology, one that was given much attention by such pioneers in Europe as the French sociologists Frédéric Le Play and Émile Durkheim; the German sociologists Ferdinand Tönnies, Georg Simmel, and Max Weber; the Belgian statistician Adolphe Quetelet; and, in America, by the sociologists Charles H. Cooley and Robert E. Park.

Fifth, there was technology. With the spread of mechanization, first in the factories, then in agriculture, social thinkers could see possibilities of a rupture of the historic relation between man and nature, between man and man, even between man and God. To thinkers as politically different as Thomas Carlyle and Karl Marx, technology seemed to lead to dehumanization of the worker and to exercise of a new kind of tyranny over human life. Marx, though, far from despising technology, thought the advent of socialism would counteract all this. Alexis de Tocqueville declared that technology, and especially technical specialization of work, was more degrading to man's mind and spirit than even political tyranny. It was thus in the 19th century that the opposition to technology on moral, psychological, and aesthetic grounds first made its appearance in Western thought.

Sixth, there was the factory system. The importance of this to 19th-century thought has been intimated above. Suffice it to add that along with urbanization and spreading mechanization, the system of work whereby masses of workers left home and family to work long hours in the factories became a major theme of social thought as well as of social reform.

Seventh, and finally, mention is to be made of the development of political masses—that is, the slow but inexorable widening of franchise and electorate through which ever larger numbers of persons became aware of themselves as voters and participants in the political process. This too is a major theme in social thought, to be seen most luminously perhaps in Tocqueville's *Democracy in America*, a classic written in the 1830s that took not merely America but democracy everywhere as its subject. Tocqueville saw the rise of the political masses, more especially the immense power that could be wielded by the masses, as the single greatest threat to individual freedom and cultural diversity in the ages ahead.

These, then, are the principal themes in the 19th-century writing that may be seen as direct results of the two great revolutions. As themes, they are to be found not only in the social sciences but, as noted above, in a great deal of the philosophical and literary writing of the century. In their respective ways, the philosophers Hegel, Coleridge, and Emerson were as struck by the consequences of the revolutions as were any social scientists. So too were such novelists as Balzac and Dickens.

THE NEW IDEOLOGIES AND PHILOSOPHIES

One other point must be emphasized about these themes. They became, almost immediately in the 19th century, the bases of new ideologies. How men reacted to the currents of democracy and industrialism stamped them conservative, liberal, or radical. On the whole, with rarest exceptions, liberals welcomed the two revolutions, seeing in their forces opportunity for freedom and welfare never before known to mankind. The liberal view of society was overwhelmingly democratic, capitalist, industrial, and, of course, individualistic. The case is somewhat different with conservatism and radicalism in the century. Conservatives, beginning with Edmund Burke, continuing through Hegel and Matthew Arnold down to such minds as John Ruskin later in the century, disliked both democracy and industrialism, preferring the kind of tradition, authority, and civility that had been, in their minds, displaced by the two revolutions. Theirs was a retrospective view, but it was a nonetheless influential one, affecting a number of the central social scientists of the century, among them Auguste Comte and Tocqueville and later Max Weber and Émile Durkheim. The radicals accepted democracy but only in terms of its extension to all areas of society and its eventual annihilation of any form of authority that did not spring directly from the people as a whole. And although the radicals, for the most part, accepted the phenomenon of industrialism, especially technology, they were uniformly antagonistic to capitalism.

These ideological consequences of the two revolutions proved extremely important to the social sciences, for it would be difficult to identify a social scientist in the century—as it would a philosopher or a humanist—who was not, in some degree at least, caught up in ideological currents. In referring to such minds as Saint-Simon, Comte, Le Play among sociologists, to Ricardo, the Frenchman Jean-Baptiste Say, and Marx among economists, to Jeremy Bentham and John Austin among political scientists, even to anthropologists like the Englishman Edward B. Tylor and the American Lewis Henry Morgan, one has before one men who were engaged not merely in the study of society but also in often strongly partisan ideology. Some were liberals, some conservatives, others radicals. All drew from the currents of ideology that had been generated by the two great revolutions.

It is important also to identify three other powerful tendencies of thought that influenced all of the social sciences. The first is a positivism that was not merely an appeal to science but almost reverence for science; the second, humanitarianism; the third, the philosophy of evolution.

The Positivist appeal of science was to be seen everywhere. The rise of the ideal of science in the Age of Reason was noted above. The 19th century saw the virtual institutionalization of this ideal—possibly even canonization. The great aim was that of dealing with moral values, institutions, and all social phenomena through the same fundamental methods that could be seen so lumi-

Positivism

nously in such areas as physics and biology. Prior to the 19th century, no very clear distinction had been made between philosophy and science, and the term philosophy was even preferred by those working directly with physical materials, seeking laws and principles in the fashion of a Newton or Harvey—that is, by persons whom one would now call scientists.

In the 19th century, in contrast, the distinction between philosophy and science became an overwhelming one. Virtually every area of man's thought and behaviour was thought by a rising number of persons to be amenable to scientific investigation in precisely the same degree that physical data were. More than anyone else, it was Comte who heralded the idea of the scientific treatment of social behaviour. His *Cours de philosophie positive*, published in six volumes between 1830 and 1842, sought to demonstrate irrefutably not merely the possibility but the inevitability of a science of man, one for which Comte coined the word "sociology" and that would do for man the social being exactly what biology had already done for man the biological animal. But Comte was far from alone. There were many in the century to join in his celebration of science for the study of society.

Humanitarianism, though a very distinguishable current of thought in the century, was closely related to the idea of a science of society. For the ultimate purpose of social science was thought by almost everyone to be the welfare of society, the improvement of its moral and social condition. Humanitarianism, strictly defined, is the institutionalization of compassion; it is the extension of welfare and succour from the limited areas in which these had historically been found, chiefly family and village, to society at large. One of the most notable and also distinctive aspects of the 19th century was the constantly rising number of persons, almost wholly from the middle class, who worked directly for the betterment of society. In the many projects and proposals for relief of the destitute, improvement of slums, amelioration of the plight of the insane, the indigent, and imprisoned, and other afflicted minorities could be seen the spirit of humanitarianism at work. All kinds of associations were formed, including temperance associations, groups and societies for the abolition of slavery and of poverty and for the improvement of literacy, among other objectives. Nothing like the 19th-century spirit of humanitarianism had ever been seen before in western Europe—not even in France during the Enlightenment, where interest in mankind's salvation tended to be more intellectual than humanitarian in the strict sense. Humanitarianism and social science were reciprocally related in their purposes. All that helped the cause of the one could be seen as helpful to the other.

The third of the intellectual influences is that of evolution. It affected every one of the social sciences, each of which was as much concerned with the development of things as with their structures. An interest in development was to be found in the 18th century, as noted earlier. But this interest was small and specialized compared with 19th-century theories of social evolution. The impact of Charles Darwin's *Origin of Species*, published in 1859, was of course great and further enhanced the appeal of the evolutionary view of things. But it is very important to recognize that ideas of social evolution had their own origins and contexts. The evolutionary works of such social scientists as Comte, Herbert Spencer, and Marx had been completed, or well begun, before publication of Darwin's work. The important point, in any event, is that the idea or the philosophy of evolution was in the air throughout the century, as profoundly contributory to the establishment of sociology as a systematic discipline in the 1830s as to such fields as geology, astronomy, and biology. Evolution was as permeative an idea as the Trinity had been in medieval Europe.

THE DEVELOPMENT OF THE SEPARATE DISCIPLINES

Among the disciplines that formed the social sciences, two contrary, for a time equally powerful, tendencies at first dominated them. The first was the drive toward unification, toward a single, master social science, whatever it might be called. The second tendency was toward special-

ization of the individual social sciences. If, clearly, it is the second that has triumphed, with the results to be seen in the disparate, sometimes jealous, highly specialized disciplines seen today, the first was not without great importance and must also be examined.

What emerges from the critical rationalism of the 18th century is not, in the first instance, a conception of need for a plurality of social sciences, but rather for a single science of society that would take its place in the hierarchy of the sciences that included the fields of astronomy, physics, chemistry, and biology. When, in the 1820s, Comte wrote calling for a new science, one with man the social animal as the subject, he assuredly had but a single, encompassing science of society in mind—not a congeries of disciplines, each concerned with some single aspect of man's behaviour in society. The same was true of Bentham, Marx, and Spencer. All these minds, and there were many others to join them, saw the study of society as a unified enterprise. They would have scoffed, and on occasion did, at any notion of a separate economics, political science, sociology, and so on. Society is an indivisible thing, they would have argued; so, too, must be the study of society.

It was, however, the opposite tendency of specialization or differentiation that won out. No matter how the century began, or what were the dreams of a Comte, Spencer, or Marx, when the 19th century ended, not one but several distinct, competitive social sciences were to be found. Aiding this process was the development of the colleges and universities. With hindsight it might be said that the cause of universities in the future would have been strengthened, as would the cause of the social sciences, had there come into existence, successfully, a single curriculum, undifferentiated by field, for the study of society. What in fact happened, however, was the opposite. The growing desire for an elective system, for a substantial number of academic specializations, and for differentiation of academic degrees, contributed strongly to the differentiation of the social sciences. This was first and most strongly to be seen in Germany, where, from about 1815 on, all scholarship and science were based in the universities and where competition for status among the several disciplines was keen. But by the end of the century the same phenomenon of specialization was to be found in the United States (where admiration for the German system was very great in academic circles) and, in somewhat less degree, in France and England. Admittedly, the differentiation of the social sciences in the 19th century was but one aspect of a larger process that was to be seen as vividly in the physical sciences and the humanities. No major field escaped the lure of specialization of investigation, and clearly, a great deal of the sheer bulk of learning that passed from the 19th to the 20th century was the direct consequence of this specialization.

Economics. It was economics that first attained the status of a single and separate science, in ideal at least, among the social sciences. That autonomy and self-regulation that the Physiocrats and Adam Smith had found, or thought they had found, in the processes of wealth, in the operation of prices, rents, interest, and wages during the 18th century became the basis of a separate and distinctive economics—or, as it was often called, "political economy"—in the 19th. Hence the emphasis upon what came to be widely called *laissez-faire*. If, as it was argued, the processes of wealth operate naturally in terms of their own built-in mechanisms, then not only should these be studied separately but they should, in any wise polity, be left alone by government and society. This was, in general, the overriding emphasis of such thinkers as David Ricardo, John Stuart Mill, and Nassau William Senior in England, of Frédéric Bastiat and Jean-Baptiste Say in France, and, somewhat later, the Austrian school of Karl Menger. This emphasis is today called "classical" in economics, and it is even now, though with substantial modifications, a strong position in the field.

There were almost from the beginning, however, economists who diverged sharply from this *laissez-faire*, classical view. In Germany especially there were the so-called historical economists. They proceeded less from the disci-

Effects of
evolution-
ary theory

Unification
versus
specializa-
tion

Classical
economists
and
socialists

pline of historiography than from the presuppositions of social evolution, referred to above. Such men as Wilhelm Roscher and Karl Knies in Germany tended to dismiss the assumptions of timelessness and universality regarding economic behaviour that were almost axiomatic among the followers of Adam Smith, and they strongly insisted upon the developmental character of capitalism, evolving in a long series of stages from other types of economy.

Also prominent throughout the century were those who came to be called the Socialists. They too repudiated any notion of timelessness and universality in capitalism and its elements of private property, competition, and profit. Not only was this system but a passing stage of economic developments; it could be—and, as Marx was to emphasize, would be—shortly supplanted by a more humane and also realistic economic system based upon cooperation, the people's ownership of the means of production, and planning that would eradicate the vices of competition and conflict.

Political science. Rivalling economics as a discipline during the century was political science. The line of systematic interest in the state that had begun in modern Europe with Machiavelli, Hobbes, Locke, and Rousseau, among others, widened and lengthened in the 19th century, the consequence of the two revolutions. If the Industrial Revolution seemed to supply all the problems frustrating the existence of a stable and humane society, the political-democratic revolution could be seen as containing many of the answers to these problems. It was the democratic revolution, especially in France, that created the vision of a political government responsible for all aspects of human society and, most important, possessed the power to wield this responsibility. This power, known as sovereignty, could be seen as holding the same relation to political science in the 19th century that capital held to economics. To a very large number of political scientists, the aim of the discipline was essentially that of analyzing the varied properties of sovereignty. There was a strong tendency on the part of such political scientists as Bentham, Austin, and Mill in England and Francis Lieber and Woodrow Wilson in the United States to see the state and its claimed sovereignty over human lives in much the same terms in which classical economists saw capitalism.

Among political scientists there was the same historical-evolutionary dissent from this view, however, that existed in economics. Such writers as Sir Henry Maine in England, Numa Fustel de Coulanges in France, and Otto von Gierke in Germany declared that state and sovereignty were not timeless and universal nor the results of some "social contract" envisaged by such philosophers as Locke and Rousseau but, rather, structures formed slowly through developmental or historical processes. Hence the strong interest, especially in the late 19th century, in the origins of political institutions in kinship, village, and caste, and in the successive stages of development that have characterized these institutions. In political science, as in economics, in short, the classical analytical approach was strongly rivalled by the evolutionary. Both approaches go back to the 18th century in their fundamental elements, but what is seen in the 19th century is the greater systematization and the much wider range of data employed.

Anthropology. In the 19th century, anthropology also attained clear identity as a discipline. Strictly defined as "the science of man," it could be seen as superseding other specialized disciplines such as economics and political science. In practice and from the beginning, however, anthropology concerned itself overwhelmingly with primitive man. On the one hand was physical anthropology, concerned chiefly with the evolution of man as a biological species, with the successive forms and protoforms of the species, and with genetic systems such as stocks and races in the world. On the other hand was social and cultural anthropology: here the interest was in the full range of man's institutions but confined to those found in fact among existing preliterate or "primitive" peoples in Africa, Oceania, Asia, and the Americas. Above all other concepts, "culture" was the central element of this great area of anthropology, or ethnology, as it was often called

to distinguish it from physical anthropology. Culture, as a concept, called attention to the nonbiological, nonracial, noninstinctual basis of the greater part of what one calls civilization: its values, techniques, ideas in all spheres. Culture, as defined in Tylor's landmark work of 1871, *Primitive Culture*, is the part of man's behaviour that is learned. From anthropology more than from any other single social science has come the emphasis on the cultural foundations of man's behaviour and thought in society.

Scarcely less than political science or economics, anthropology shared in the themes of the two revolutions and their impact on the world. If the data that anthropologists actually worked with were generally in the remote areas of the world, it was the effects of the two revolutions that, in a sense, kept opening up these parts of the world to more and more systematic inquiry. And, as was true of the other social sciences, the cultural anthropologists were immersed in problems of economics, polity, social class, and community, albeit among preliterate rather than "modern" peoples.

Overwhelmingly, without major exception indeed, the science of anthropology was evolutionary in thrust in the 19th century. Edward B. Tylor and Sir John Lubbock in England, Lewis Henry Morgan in the United States, Adolf Bastian and Theodor Waitz in Germany, and all others in the main line of the study of primitive culture saw existing native societies in the world as prototypes of their own "primitive ancestors," fossilized remains, so to speak, of stages of development that western Europe had once gone through. Despite the vast array of data compiled on non-Western cultures, the same basic European-centred objectives are to be found among anthropologists as among other social scientists in the century. Almost universally, then, the modern West was regarded as the latest point in a line of progress that was single and unilinear and on which all other peoples in the world could be fitted as illustrations, as it were, of Western man's own past.

Sociology. Sociology came into being in precisely these terms, and during much of the century it was not easy to distinguish between a great deal of so-called sociology and social or cultural anthropology. Even if almost no sociologists in the century made empirical studies of primitive peoples, as did the anthropologists, their interest in the origin, development, and probable future of mankind was not less great than what could be found in the writings of the anthropologists. It was Auguste Comte who coined the word sociology, and he used it to refer to what he imagined would be a single, all-encompassing, science of society that would take its place at the top of the hierarchy of sciences—a hierarchy that Comte saw as including astronomy (the oldest of the sciences historically) at the bottom and with physics, chemistry, and biology rising in that order to sociology, the latest and grandest of the sciences. There was no thought in Comte's mind—nor was there in the mind of Herbert Spencer, whose general view of sociology was very much like Comte's—of there being other, competing social sciences. Sociology would be to the whole of the social world what each of the other great sciences was to its appropriate sphere of reality.

Both Comte and Spencer believed that civilization as a whole was the proper subject of sociology. Their works were concerned, for the most part, with describing the origins and development of civilization and also of each of its major institutions. Both declared sociology's main divisions to be "statics" and "dynamics," the former concerned with processes of order in society, the latter with processes of evolutionary change in society. Both men also saw all existing societies in the world as reflective of the successive stages through which Western society had advanced in time over a period of tens of thousands of years.

Not all sociologists in the 19th century conceived their discipline in this light, however. Side by side with the "grand" view represented by Comte and Spencer were those in the century who were primarily interested in the social problems that they saw around them—come-

quences, as they interpreted them, of the two revolutions, the industrial and democratic. Thus in France just after midcentury, Frédéric Le Play published a monumental study of the social aspects of the working classes in Europe, *Les Ouvriers européens*, which compared families and communities in all parts of Europe and even other parts of the world. Alexis de Tocqueville, especially in the second volume of his *Democracy in America* (1835), provided an account of the customs, social structures, and institutions in America, dealing with these—and also with the social and psychological problems of Americans in that day—as aspects of the impact of the democratic and industrial revolutions upon traditional society.

At the very end of the 19th century, in both France and Germany, there appeared some of the works in sociology that were to prove most lasting in their effects upon 20th-century sociology. Ferdinand Tönnies, in his *Gemeinschaft und Gesellschaft* (1887; translated as *Community and Society*), sought to explain all major social problems in the West as the consequence of the West's historical transition from the communal, status-based, concentric society of the Middle Ages to the more individualistic, impersonal, and large-scale society of the democratic-industrial period. In general terms, allowing for individual variations of theme, these were the views of Max Weber, Georg Simmel, and Émile Durkheim (all of whom also wrote in the late 19th and early 20th century). These were the men who, starting from the problems of Western society that could be traced to the effects of the two revolutions, did the most to establish the discipline of sociology as it is found for the most part in the 20th century.

Social psychology. Social psychology as a distinct discipline also originated in the 19th century, although its outlines were perhaps somewhat less clear than was true of the other social sciences. The close relation of the human mind to the social order, its dependence upon education and other forms of socialization, was well-known in the 18th century. In the 19th century, however, an ever more systematic discipline came into being to uncover the social and cultural roots of human psychology and also the several types of "collective mind" that analysis of different cultures and societies in the world might reveal. In Germany, Moritz Lazarus and Wilhelm Wundt sought to fuse the study of psychological phenomena with analyses of whole cultures. Folk psychology, as it was called, did not, however, last very long in scientific esteem.

Much more esteemed, and closer to 20th-century conceptions of social psychology, were the works of such men as Gabriel Tarde, Gustave Le Bon, Lucien Lévy-Bruhl, and Émile Durkheim in France and Georg Simmel in Germany (all of whom also wrote in the early 20th century). Here, in concrete, often highly empirical studies of small groups, associations, crowds, and other aggregates (rather than in the main line of psychology during the century, which tended to be sheer philosophy at one extreme and a variant of physiology at the other) are to be found the real beginnings of social psychology. Although the point of departure in each of the studies was the nature of association, they dealt, in one degree or other, with the internal processes of psychosocial interaction, the operation of attitudes and judgments, and the social basis of personality and thought—in short, with those phenomena that would, in the 20th century, be the substance of social psychology as a formal discipline.

Social statistics and social geography. Two final manifestations of the social sciences in the 19th century are social statistics and social (or human) geography. At that time, neither achieved the notability and acceptance in colleges and universities that such fields as political science and economics did. Both, however, were as clearly visible by the latter part of the century as any of the other social sciences. And both were to exert a great deal of influence on the other social sciences by the beginning of the 20th century: social statistics on sociology and social psychology pre-eminently; social geography on political science, economics, history, and certain areas of anthropology, especially those areas dealing with the dispersion

of races and the diffusion of cultural elements. In social statistics the key figure of the century was a Belgian, Adolphe Quetelet, who was the first, on any systematic basis, to call attention to the kinds of structured behaviour that could be observed and identified only through statistical means. It was Quetelet who brought into prominence the momentous concept of "the average man" and his behaviour. The two major figures in social or human geography in the century were Friedrich Ratzel in Germany and Paul Vidal de la Blache in France. Both broke completely with the crude environmentalism of earlier centuries, which had sought to show how topography and climate actually determine human behaviour, and they substituted the more subtle and sophisticated insights into the relationships of land, sea, and climate on the one hand and, on the other, the varied types of culture and human association that are to be found on earth.

In summary, by the end of the 19th century all the major social sciences had achieved a distinctiveness, an importance widely recognized, and were, especially in the cases of economics and political science, fully accepted as disciplines in the universities. Most important, they were generally accepted as sciences in their own right rather than as minions of philosophy.

III. The 20th century

What is seen in the 20th century is not only an intensification and spread of earlier tendencies in the social sciences but also the development of many new tendencies that, in the aggregate, make the 19th century seem by comparison one of quiet unity and simplicity in the social sciences.

In the 20th century, the processes first generated by the democratic and industrial revolutions have gone on virtually unchecked in Western society, penetrating more and more spheres of once traditional morality and culture, leaving their impress on more and more nations, regions, and localities. Equally important, perhaps in the long run far more so, is the spread of these revolutionary processes to the non-Western areas of the world. The impact of industrialism, technology, secularism, and individualism upon peoples long accustomed to the ancient unities of tribe, local community, agriculture, and religion was first to be seen in the context of colonialism, an outgrowth of nationalism and capitalism in the West. The relations of the West to non-Western parts of the world, the whole phenomenon of the "new nations," are vital aspects of the social sciences.

So too are certain other consequences, or lineal episodes, of the two revolutions. The 20th century is the century of nationalism, mass democracy, and large-scale industrialism beyond reach of any 19th-century imagination so far as magnitude is concerned. It is the century of mass warfare, of two world wars with toll in lives and property greater perhaps than the sum total of all preceding wars in history. It is the century too of totalitarianism: Communist, Fascist, and Nazi; and of techniques of terrorism that, if not novel, are to be seen on a scale and with an intensity of scientific application that could scarcely have been predicted by those who considered science and technology as unqualifiedly humane in possibility. It is a century of affluence in the West, without precedent for the masses of people, to be seen in a constantly rising standard of living and a constantly rising level of expectations.

The last is important. A great deal of the turbulence in the 20th century—political, economic, and social—is the result of desires and aspirations that have been constantly escalating and that have been passing from the white people in the West to ethnic and racial minorities among them and, then, to whole continents elsewhere. Of all manifestations of revolution, the revolution of rising expectations is perhaps the most powerful in its consequences. For, once this revolution gets under way, each fresh victory in the struggle for rights, freedom, and security tends to magnify the importance of what has not been won.

Once it was thought that by solving the fundamental problems of production and large-scale organization,

Early
group
studies

Effects of
alienation
and social
isolation

man could ameliorate other problems, those of a social, moral, and psychological nature. What in fact occurred, on the testimony of a great deal of the most notable thought and writing, was a heightening of such problems. It would appear that as man satisfies, relatively at least, the lower order needs of food and shelter, his higher order needs for purpose and meaning in life become ever more imperious. Thus such philosophers of history as Arnold Toynbee, Pitirim Sorokin, and Oswald Spengler have dealt with problems of purpose and meaning in history with a degree of learning and intensity of spirit not seen since perhaps St. Augustine wrote his monumental *The City of God* in the early 5th century when signs of the disintegration of Roman civilization were becoming overwhelming in their message to so many of that day. In the 20th century, though the idea of progress has certainly not disappeared, it has been rivalled by ideas of cyclical change and of degeneration of society. It is hard to miss the currency of ideas in modern times—status, community, purpose, moral integration, on the one hand, and alienation, anomie, disintegration, breakdown on the other—that reveal only too clearly the divided nature of man's spirit, the unease of his mind.

There is to be seen too, especially during later decades of the century, a questioning of the role of reason in human affairs—a questioning that stands in stark contrast with the ascendancy of rationalism in the two or three centuries preceding. Doctrines and philosophies stressing the inadequacy of reason, the subjective character of human commitment, and the primacy of faith have rivalled—some would say conquered—doctrines and philosophies descended from the Age of Reason. Existentialism, with its emphasis on the basic loneliness of the individual, on the impossibility of finding truth through intellectual decision, and on the irredeemably personal, subjective character of man's life, has proved to be a very influential philosophy in the writings of the 20th century. Freedom, far from being the essence of hope and joy, is the source of man's dread of the universe and of his anxiety for himself. Søren Kierkegaard's 19th-century intimations of anguished isolation as the perennial lot of the individual have had rich expression in the philosophy and literature of the 20th century.

It might be thought that such intimations and presentiments as these have little to do with the social sciences. This is true in the direct sense perhaps but not true when one examines the matter in terms of contexts and ambiances. The "lost individual" has been of as much concern to the social sciences as to philosophy and literature. Ideas of alienation, anomie, identity crisis, and estrangement from norms are rife among the social sciences, particularly, of course, those most directly concerned with the nature of the social bond, such as sociology, social psychology, and political science. In countless ways, philosophical, literary, and popular interest in the loss of community, in the search for community, and in the individual's relation to society and morality have had expression in the work of the social sciences. Between the larger interests of a culture and the social sciences there is never a wide gulf—only different ways of defining and approaching these interests.

MARXIST INFLUENCES

The influence of Marxism in the 20th century must not be missed. Currently the works of Lenin have outstripped the Bible in distribution in the world. For hundreds of millions of persons today the ideas of Marx, as communicated by Lenin, have profound moral, even religious significance. But even in those parts of the world, the West foremost, where Communism has exerted little direct political impact, Marxism remains a potent source of ideas. Not a few of the central concepts of social stratification and the location and diffusion of power in the social sciences come straight from Marx's insights. Far more is this the case in the Communist countries—the Soviet Union, other eastern European countries, China, and even Asian countries in which no Communist domination exists. In all these countries, Marx's name is virtually sacrosanct. There is not the same degree of differentiation of social sciences in

these countries that is found in the West. As an example, sociology hardly exists as a recognized discipline in these countries, and by the standards of the West, the other social sciences have little more than a rather rudimentary existence. Economics alone tends to be favoured, and this is, of course, largely Marxian economics—the economics of Marx's *Das Kapital*.

But even though Marxism has had relatively little direct impact on the social sciences as disciplines in the West, it has had enormous influence on states of mind that are closely associated with the social sciences. Especially was this true during the 1930s, the decade of the Great Depression. Today signs are not lacking of a strong revival of interest in Marx that could very well, through sheer numbers of its adherents, affect the nature of the social sciences in the years ahead. Socialism remains for a great many persons an evocative symbol and creed. Marx remains a formidable name among intellectuals and is still, without any question, the principal intellectual source of radical movements in politics. Such a position cannot help but influence the contexts of even the most abstract of the social sciences.

What Marx's ideas have suggested above all else in a positive way is the possibility of a society directed, not by blind forces of competition and struggle among economic elements, but instead by directed planning. This hope, this image, has proved a dominant one in the 20th century even where the influence of Marx and of Socialism has been at best small and indirect. It is this profound interest in central planning and governance that has given almost historic significance to the ideas of the English economist J.M. Keynes. What is called Keynesianism has as its intellectual base a very complex modification of the classical doctrines of economics—one set forth in Keynes's famous *The General Theory of Employment, Interest and Money*, published in 1936. Of greater influence today, however, than the strictly theoretical content of this general theory is the political impact that Keynesian ideas have had on Western democracies. For out of these ideas came the clear policy of governments dealing directly with the business cycle, of pumping money and credit into an economic system when the cycle threatens to turn downward, and of then lessening this infusion when the cycle moves upward. Above all other names in the West, that of Keynes has become identified with such policy in the democracies and with the general movement of central governments toward ever more active and constant regulation of processes once thought best left to what the classical economists thought of as natural laws. True, the root ideas of the classical economists are found in modified form even today in the works of such economists as the American Milton Friedman. But it would not be unfair to say that Keynes's name has become associated with democratic economic planning and direction in much the way that Marx's name is associated with Communist economic policies.

FREUDIAN INFLUENCES

In the general area of personality, mind, and character, the writings of Sigmund Freud have had influence on 20th-century culture and thought scarcely less than Marx's. His basic theories of the role of the unconscious mind, of the lasting effects of infantile sexuality, and of the Oedipus complex have gone beyond the discipline of psychoanalysis and even the larger area of psychiatry to areas of several of the social sciences. Anthropologists have applied Freudian concepts to their studies of primitive cultures, seeking to assess comparatively the universality of states of the unconscious that Freud and his followers held to lie in the whole human race. Some political scientists have used Freudian ideas to illuminate the nature of authority generally, and political power specifically, seeing in totalitarianism, for example, the thrust of a craving for the security that total power can give. Sociology and social psychology have been influenced by Freudian ideas in their studies of social interaction and motivation. From Freud came the fruitful perspective that sees social behaviour and attitudes as generated not merely by the external situation but also by internal emotional needs springing from child-

of social
planning
and
Keynesi-
anism

Freudian
emphases
on the
uncon-
scious
and the
unrational

hood—needs for recognition, authority, self-expression. Whatever may be the place directly occupied by Freud's ideas in the social sciences today, his influence upon 20th-century thought and culture generally, not excluding the social sciences, has been hardly less than Marx's.

THE CHANGING CHARACTER OF THE DISCIPLINES

It is appropriate to turn next to some of the trends and developments that may be seen against these backgrounds.

Specialization and cross-disciplinary approaches. The first point to make about the social sciences of the 20th century is the vast increase in the number of social scientists involved, in the number of academic and other centres of teaching and research in the social sciences, and in their degree of both comprehensiveness and specialization. The explosion of the sciences generally in the 20th century—an explosion responsible for the fact that a majority of all scientists who have ever lived in human history are now alive—has had, as one of its signal elements, the explosion of the social sciences. Not only has there been development and proliferation but there has also been a spectacular diffusion of the social sciences. Beginning in a few places in western Europe and the United States in the 19th century, the social sciences, as bodies of ongoing research and centres of teaching, are today to be found almost everywhere in the world. In considerable part this has followed the spread of universities from the West to other parts of the world and, within universities, the very definite shift away from the hegemony once held by humanities alone to the near-hegemony held today by the sciences, physical and social.

Specialization has been as notable a tendency in the social sciences as in the biological and physical sciences. This is reflected not only in varieties of research but also in course offerings in academic departments. Whereas not very many years ago, a couple of dozen advanced courses in a social science reflected the specialization and diversity of the discipline even in major universities with graduate schools, today a hundred such courses are found to be not enough.

Side by side with this strong trend toward specialization, however, is another, countering trend: that of cross-fertilization and interdisciplinary cooperation. At the beginning of the century, down in fact until World War II, the several disciplines existed each in a kind of splendid isolation from the others. That historians and sociologists, for example, might ever work together in curricula and research projects would have been scarcely conceivable prior to about 1945. Each social science tended to follow the course that emerged in the 19th century: to be confined to a single, distinguishable, if artificial, area of social reality. Today, evidences are all around of cross-disciplinary work and of fusion within a single social science of elements drawn from other social sciences. Thus there are such vital areas of work as political sociology, economic anthropology, psychology of voting, and industrial sociology. Single concepts such as "structure," "function," "alienation," and "motivation" can be seen employed variously to useful effect in several social sciences. The techniques of one social science can be seen consciously incorporated into another or into several social sciences. If history has provided much in the way of perspective to sociology or anthropology, each of these two has provided perspective, and also whole techniques, such as statistics and survey, to history. In short, specialization is by no means without some degree at least of countertendencies such as fusion and synthesis.

Another outstanding characteristic of each of the social sciences in the 20th century is its professionalization. Without exception, the social sciences have become bodies of not merely research and teaching but also practice, in the sense that this word has in medicine or engineering. Down until about World War II, it was a rare sociologist or political scientist or anthropologist who was not a holder of academic position. There were economists and psychologists to be found in banks, industries, government, even in private consultancy, but the numbers were relatively tiny. Overwhelmingly the social sciences had visibility alone as academic disciplines, con-

cerned essentially with teaching and with more or less basic, individual research. All this has changed profoundly, and on a vast scale, during the past three decades. Today there are as many economists and psychologists outside academic departments as within, if not more. The number of sociologists, political scientists, and demographers to be found in government, industry, and private practice rises constantly. Equally important is the changed conception or image of the social sciences. Today, to a degree unknown before World War II, the social sciences are conceived as policy-making disciplines, concerned with matters of national welfare in their professional capacities in just as sure a sense as any of the physical sciences. Inevitably, tensions have arisen within the social sciences as the result of processes of professionalization. Those persons who are primarily academic can all too easily feel that those who are primarily professional have different and competing identifications of themselves and their disciplines.

Nature of the research. The emphasis upon research in the social sciences has become almost transcending within recent decades. This situation is not at all different from that which prevails in the physical sciences and the professions in this age. Prior to about 1945, the functions of teaching and research had approximately equal value in many universities and colleges. The idea of a social (or physical) scientist appointed to an academic institution for research alone, or with research preponderant, was scarcely known. Research bureaus and institutes in the social sciences were very few and did not rival traditional academic departments and colleges as prestige-bearing entities. All of that was changed decisively beginning with the period just after World War II. From governments and foundations, large sums of money passed into the universities—usually not to the universities as such, but rather to individuals or small groups of individuals, each eminent for research. Research became the uppermost value in the social sciences (as in the physical) and hence, of course, in the universities themselves.

Probably the greatest single change in the social sciences during the past generation has been the widespread introduction of mathematical and other quantitative methods. Without question, economics is the discipline in which the most spectacular changes of this kind have taken place. So great is the dominance of mathematical techniques here—resulting in the eruption of what is called econometrics to a commanding position in the discipline—that, to the outsider, economics today almost appears to be a branch of mathematics. But in sociology, political science, social psychology, and anthropology, the impact of quantitative methods, above all, of statistics, has also been notable. No longer does statistics stand alone, a separate discipline, as it did in effect during the 19th century. This area today is inseparable from each of the social sciences, though, in the field of mathematics, statistics still remains eminently distinguishable, the focus of highly specialized research and theory.

Within the past decade or two, the use of computers and of all the complex techniques associated with computers has become a staple of social-science research and teaching. Through the data storage and data retrieval of electronic computers, working with amounts and diversity of data that would call for the combined efforts of hundreds, even thousands of technicians, the social sciences have been able to deal with both the extensive and intensive aspects of human behaviour in ways that would once have been inconceivable. The so-called computer revolution in modern thought has been, in short, as vivid a phase of the social as the physical sciences, not to mention other areas of modern life. The problem as it is stated by mature social scientists is to use computers in ways in which they are best fitted but without falling into the fallacy that they can alone guide, direct, and supply vital perspective in the study of man.

Closely related to mathematical, computer, and other quantitative aspects of the social sciences is the vast increase in the empiricism of modern social science. Never in history has so much in the way of data been collected, examined, classified, and brought to the uses of social

gathering

theory and social policy alike. What has been called the triumph of the fact is nowhere more visible than in the social sciences. Without question, this massive empiricism has been valuable, indispensable indeed, to those seeking explanations of social structures and processes. Empiricism, however, like quantitative method, is not enough in itself. Unless related to hypothesis, theory, or conclusion, it is sterile, and most of the leading social scientists of today reflect this view in their works. Too many, however, deal with the gathering and classifying of data as though these were themselves sufficient.

It is the quest for data, for detailed, factual knowledge of human beliefs, opinions, and attitudes, as well as patterns and styles of life—familial, occupational, political, religious, and so on—that has made the use of surveys and polls another of the major tendencies in the social sciences of this century. The poll data one sees in his newspaper are hardly more than the exposed portion of an iceberg. Literally thousands of polls, questionnaires, and surveys are going on at any given moment today in the social sciences. The survey or polling method ranks with the quantitative indeed in popularity in the social sciences, both being, obviously, indispensable tools of the empiricism just mentioned.

THEORETICAL MODES

It is not the case, however, that interest in theory is a casualty of the 20th-century fascination with method and fact. Though there is a great deal less of that grand or comprehensive theory that was a hallmark of 19th-century social philosophy and social science, there are still those persons occasionally to be found today who are engrossed in search for master principles, for general and unified theory that will assimilate all the lesser and more specialized types of theory. But their efforts and results are not regarded as successful by the vast majority of social scientists. Theory, at its best, today tends to be specific theory—related to one or other of the major divisions of research within each of the social sciences. The theory of the firm in economics, of deviance in sociology, of communication in political science, of attitude formation in social psychology, of divergent development in cultural anthropology are all examples of theory in every proper sense of the word. But each is, clearly, specific. If there is a single social science in which a more or less unified theory exists, with reference to the whole of the discipline, it is economics. Even here, however, unified, general theory does not have the sovereign sweep it had in the classical tradition of Ricardo and his followers before the true complexities of economic behaviour had become revealed.

Developmentalism. Developmentalism is another overall influence upon the work of the social sciences, especially within the past three decades. As noted above, an interest in social evolution was one of the major aspects of the social sciences throughout the 19th century in western Europe. In the early 20th century, however, this interest, in its larger and more visible manifestations, seemed to terminate. There was a widespread reaction against the idea of unilinear sequences of stages, deemed by the 19th-century social evolutionists to be universal for all mankind in all places. Criticism of social evolution in this broad sense was a marked element of all the social sciences, pre-eminently in anthropology but in the others as well. There were numerous demonstrations of the inadequacy of unilinear descriptions of change when it came to accounting for what actually happened, so far as records and other evidences suggested, in the different areas and cultures of the world.

Beginning in the late 1940s and the 1950s, however, there was a resurgence of developmental ideas in all the social sciences—particularly with respect to studies of the new nations and cultures that were coming into existence in considerable numbers. Studies of economic growth and of political and social development have become more and more numerous. Although it would be erroneous to see these developmental studies as simple repetitions of those of the 19th-century social evolutionists, there are, nevertheless, common elements of thought, including the idea of stages of growth and of change conceived as

continuous and cumulative and even as moving toward some more or less common end. At their best, these studies of growth and development in the new nations, by their counterposing of traditional and modern ways, tell a good deal about specific mechanisms of change, the result of the impact of the West upon outlying parts of the world. But as more and more social scientists have recently become aware, efforts to place these concrete mechanisms of change into larger, more systematic models of development all too commonly succumb to the same faults of unilinearity and specious universalism that early-20th-century critics found in 19th-century social evolution.

Social-systems approach. Still another major tendency in all of the social sciences since World War II has been the interest in "social systems." The behaviour of individuals and groups is seen as falling into multiple interdependencies, and these interdependencies are considered sufficiently unified to warrant use of the word "system." Although there are clear uses of biological models and concepts in social-systems work, it may be fair to say that the greatest single impetus to development of this area was widening interest after World War II in cybernetics—the study of human control functions and of the electrical and mechanical systems that could be devised to replace or reinforce them. Concepts drawn from mechanical and electrical engineering have been rather widespread in the study of social systems.

In social-systems studies, the actions and reactions of individuals, or even of groups as large as nations, are seen as falling within certain definable, more or less universal patterns of equilibrium and disequilibrium. The interdependence of roles, norms, and functions is regarded as fundamental in all types of group behaviour, large and small. Each social system, as encountered in social-science studies, is a kind of "ideal type," not identical to any specific "real" condition but sufficiently universal in terms of its central elements to permit useful generalization.

Structuralism and functionalism. Structuralism in the social sciences is closely related to the theory of the social system. Although there is nothing new about the root concepts of structuralism—they may be seen in one form or other throughout Western thought—there is no question but that in the present century this view of behaviour has become a dominant one in many fields. At bottom it is a reaction against all tendencies to deal with human thought and behaviour atomistically—that is, in terms of simple, discrete units of either thought, perception, or overt behaviour. In psychology, structuralism in its oldest sense simply declares that perception occurs, with learning following, in terms of experiences or sensations in various combinations, in discernible patterns or gestalten. In sociology, political science, and anthropology, the idea of structure similarly refers to the repetitive patternings that are found in the study of social, economic, political, and cultural existence. The structuralist contends that no element can be examined or explained outside its context or the pattern or structure of which it is a part. Indeed, it is the patterns, not the elements, that are the only valid objects of study.

What is called functionalism in the social sciences today is closely related to structuralism, with the term structural-functional a common one, especially in sociology and anthropology. Function refers to the way in which behaviour takes on significance, not as a discrete act but as the dynamic aspect of some structure. Biological analogies are common in theories of structure and function in the social sciences. Very common is the image of the biological organ, with its close interdependence to other organs (as the heart to the lung) and the interdependence of activities (as circulation to respiration).

Interactionism. Interaction is still another concept that has had wide currency in the social sciences of the 20th century. Social interaction—or, as it is sometimes called, symbolic interaction—refers to the fact that the relationships among two or more groups or human beings are never one-sided, purely physical, or direct. Always there is reciprocal influence, a mutual sense of

Specific
versus
grand
theory

Influences
of national
growth and
develop-
ment

Emphasis
on pattern
and
interdepend-
ence

"otherness." And always the presence of the "other" has crucial effect in one's definition of not merely what is external but what is internal. One acquires one's individual sense of identity from interactions with others beginning in infancy. It is the initial sense of the other person—mother, for example—that in time gives the child its sense of self, a sense that requires continuous development through later interactions with others. From the point of view of interactionist theory, all one's perceptions of and reactions to the external world are mediated or influenced by prior ideas, valuations, and assessments. Always one is engaged in socialization or the modification of one's mind, role, and behaviour through contact with others.

FUTURE OF THE SOCIAL SCIENCES

What has been covered in the preceding paragraphs may be the most that can be said within restricted compass about the social sciences of the 20th century without turning to the articles on the individual social sciences themselves and on related disciplines (see ANTHROPOLOGY; SOCIOLOGY; ECONOMICS; POLITICAL SCIENCE; PSYCHOLOGY; SOCIAL; GEOGRAPHY; and STATISTICS). The concern here has been with only those major contextual influences, tendencies of overall character, and dominant ideas or theories that the social sciences taken as a whole manifest in one degree or other.

Relation of
social
sciences to
society

There is one final aspect of the subject that must be considered briefly, for how it is resolved will have much effect upon the future of the social sciences in the West. This is the relation of the social sciences to organized society, to government and industry, and other institutional centres of authority. At the present time, there is a significant and undoubtedly growing feeling among social scientists, especially younger ones, that the relationship has become altogether too close. The social sciences, it is said, must maintain their distance, their freedom, from bureaucratized government and industry. Otherwise they will lose their inherent powers of honest and dispassionate criticism of the ineffective or evil in society. Although there may be a certain amount of feeling ranging from the naïve to the politically revolutionary in such sentiments, they cannot be taken lightly, as is apparent from the serious consideration that is being given on a steadily rising scale to the whole problem of social science and social policy.

Since the inception of the social sciences—since, indeed, the time when the universities in the West came into being for the express purpose of training professional men in law, theology, and medicine—man has properly sought, through knowledge, to influence social policy, taking this latter term in the widest sense to include not merely national government but local government, business, professions, and so on. What else, it may be asked, are the social sciences all about if it is not to use knowledge to improve social life; and how else but through influencing of the major institutions can such improvement take place?

So much is true, comes the answering response. But in the process of seeking to influence the great agencies of modern power and function—of what is loosely called the Establishment—the social sciences may themselves become influenced adversely by the values of power and affluence to be found in these great agencies. They themselves may become identified with the status quo. What the social sciences should give, say the partisans of this view, is a continuation of the revolutionary or at least profoundly reformist tradition that was begun in the 18th century by the philosophers of reason who, detesting the official establishment of their day, sought on their own to transform it. What is today called objectivity or methodological rigour turns out to be, say these same partisans, acceptance of the basic values of reigning government and industry.

It is this essential conflict regarding the purposes of the social sciences, the relation of the social sciences to government and society, and the role of the individual social scientist in the society of the 20th century that bids fair at this moment to be the major conflict of the years ahead.

How it is resolved may very well determine the fate of the social sciences, now less than two centuries old.

BIBLIOGRAPHY. The most comprehensive and detailed bibliographical background for the history of the social sciences is to be found in the *Encyclopaedia of the Social Sciences*, 15 vol. (1930–35), still valuable, especially in its historical sections, despite the many years that have passed since its publication; and in the *International Encyclopedia of the Social Sciences*, 17 vol. (1968). The latter is indispensable for its coverage of recent developments in the social sciences. The best individual work, by now a classic in the history of ideas, on the period leading up to the emergence of the individual social sciences, is PRESERVED SMITH, *A History of Modern Culture*, 2 vol. (1930–34, reprinted 1962), it is especially good in its treatment of the circumstances attending the rise of natural science and modern social philosophy. JAMES WESTFALL THOMPSON, *A History of Historical Writing*, 2 vol. (1942), is useful in this respect also; its stress on historians does not prevent its covering areas adjacent to history and closely involved in the roots of the social sciences. On the Enlightenment in France, the age immediately preceding the rise of the social sciences, the best study by far is LESTER G. CROCKER, *Nature and Culture: Ethical Thought in the French Enlightenment* (1963), and *An Age of Crisis: Man and World in Eighteenth Century French Thought* (1959), here recommended to be read or consulted in that order. The best general work on the history of the social sciences and the history of social philosophy back to earliest times in the West is HARRY ELMER BARNES and HOWARD BECKER, *Social Thought from Lore to Science*, 2nd ed., 2 vol. (1952). The first volume deals with the issues and problems of all the social sciences, with major emphasis on the period following the breakup of the Middle Ages; the second volume is primarily concerned with sociology in the 20th century.

Nineteenth century: ERIC J. HOBSBAWM, *The Age of Revolution: 1789–1848* (1962), is an important and fascinating treatment of the social, cultural, and intellectual aspects of the age in which the individual social sciences emerged in western Europe. Its treatment of both the democratic and industrial revolutions, and the problems that they presented to intellectuals and scholars, is incisive and authoritative. ROBERT A. NISBET, *The Sociological Tradition* (1966), although concerned primarily with sociology, deals with the specific ways in which the ideologies and themes of the two revolutions became translated into social theory. The same author's *Social Change and History* (1969), deals in detail with the incorporation of the theory of social evolution into the social sciences of the 19th century and shows the relation of this theory to the earlier idea of progress and its antecedents in Western thought. For the rise and development of the individual social sciences in the 19th and 20th centuries, the following works are recommended: (Anthropology): ROBERT H. LOWIE, *The History of Ethnological Theory* (1937); and MARVIN HARRIS, *The Rise of Anthropological Theory: A History of Theories of Culture* (1968). (Economics): ERICH ROLL, *A History of Economic Thought*, 3rd ed. rev. (1954); and the extremely readable ROBERT HEILBRONER, *The Worldly Philosophers: The Lives, Times, and Ideas of the Great Economic Thinkers*, 3rd ed. (1967). (Political Science): GEORGE SABINE, *A History of Political Theory*, 3rd ed. (1959), has become deservedly a classic. It is best on the three centuries preceding the 20th. FRANCIS W. COKER, *Recent Political Thought* (1934), is excellent for the early 20th century. LEO STRAUSS and JOSEPH CROUSEY (eds.), *History of Political Philosophy* (1963), deals learnedly and penetratingly with aspects of the discipline not ordinarily found in general histories. (Sociology): Barnes and Becker, referred to above, supplies the greatest amount of detailed information on the history of sociology in the 19th and early 20th centuries. Nisbet, also referred to above, deals with the relation between political ideologies and the currents of sociological thought in the late 19th century. LEWIS A. COSER, *Masters of Sociological Thought* (1971), is undoubtedly the best recent general history of sociology in 19th and 20th century Europe and America. (Social Psychology): The best, indeed almost only, account of social psychology in the 19th and early 20th century is FAY BERGER KARPFF, *American Social Psychology: Its Origins, Development and European Background* (1932).

Twentieth century: For authoritative and easily available accounts of very recent developments in the social sciences and their contexts, no single work, not even any few works, will suffice. The reader is advised to turn to the articles in this encyclopaedia on the individual social sciences both for content and for bibliographical sources. The *International Encyclopedia of the Social Sciences*, already referred to above, is indispensable in this respect.

(R.A.N.)

Social Structure and Organization

The terms social structure and social organization are metaphors or analogies, applying to human social relations or conditions certain descriptions that ordinarily would be applied to such things as machines, buildings, or the body organism. The term structure, in particular, was borrowed by social scientists from physics and anatomy. The basic assumption is that there exists in a society—as there presumably exists in a machine or an organism—a functional interdependence of the parts of the whole, all seeking or maintaining an equilibrium. According to the context or the writer, the parts might be social institutions, social groups, obligatory relations, statuses and roles, or other social components. It should be remembered, however, that metaphors or analogies are useful only in their illustration of particular principles. They are intellectual tools, not properties of empirical reality. If pressed in their empirical reality they can become useless and misleading.

In groupings ranging from the state to the mother bearing her child, human beings congregate and disperse, associate and disassociate themselves for a variety of purposes and ends that are to a large extent routinized or institutionalized. They enter into a variety of roles and statuses, more or less hierarchically arranged, and they take up a variety of positions in relation to one another and the offices and institutions of their society. They interact, play their parts, and bring more or less to their parts than they or others had thought possible or usual. In reality, people do not behave or play their parts precisely as the ideal prescribes or even as an observer may state they do. Categories of age, sex, kinship, allegiance, association, class, cooperation, competition, work, play, obligation, and ordination all involve particular kinds of relations between individuals that are ever-changing and subject to a variety of levels of understanding and interpretation. Still, in all this there appears to be more order than muddle and confusion. Activities, rationalizations on those activities, ideas, and statements all seem to have such correspondence that even in strife and discrepancy the human mind can perceive some sort of ordering or pattern in social affairs. The problem is how to realize this pattern—this ordering of concrete activities and rationalizations, or categories of understanding—in some sort of scientific or intellectual mode.

There are various ways of doing this or attempting to do this. Not all the approaches involve use of the term structure or organization per se, but, whatever terms are used, they are used more or less synonymously within the overreaching idea of structure or organization. The remainder of this article considers one by one the major models or approaches.

Culture-pattern model. Three convergent circumstances may be adduced as greatly influencing the development of the culture-pattern model, which was most influential from the 1920s to the 1950s. First, the end of World War I found anthropology at a crossroads. The war had brought to light the fact that while prewar (and especially 19th-century) scholars had been preoccupied with global theories of human social development, very little was known in a scientific way of the ways in which people actually lived, quarreled, and somehow got on together. There was a need for new ideas, ideas that would both stimulate research and discover the determinants of living together in harmony. Second, Sigmund Freud and other psychologists were in their ascendant. It was thought that if anything could rebuild a world shattered and changed out of all recognition by the war, psychology would surely provide the key. Anthropologists began to look to psychology to lead them through and out of their theoretical dearth, and they developed culture-pattern theory as a consequence. Third, the people who advanced culture-pattern theory were mostly Americans, and they were in a rather unique position. Unlike the situation in many other parts of the world, the lives and times of North American native peoples were relatively well documented. They had a discoverable history. Moreover, their geographical circumstances were relatively unusual; the various Indian societies tended to inhabit

distinct ecological zones and form mutually exclusive groups; although they interacted with one another, they were nonetheless physically discernible and bounded groups, each with its own peculiar style of making and doing. The idea of culture as a patterned functioning whole fell in naturally with the circumstances: groups were cultures.

The method used in the culture-pattern approach was essentially to derive a people's culture from an examination of individual people and their personalities. Thus, Ruth Benedict characterized certain cultures on the basis of patterns of institutionalized purposes, motives, emotions and values. Indeed, so direct was the derivation of "culture" from "individual" that a culture, it was thought, could be spun out of the psychoanalysis of a single individual representative.

The model took predominant or basic personality types as the given data, and events in the culture were construed through the lens of such personality types. Clyde Kluckhohn could thus "explain" witchcraft and sorcery as resulting from the interaction between particular events and the given personality type. Furthermore, since culture was derived from the personalities of individuals and since the significance of events depended on predominant types of personality, it was important to find out how this personality was formed—hence the concentration on sexual mores and on the conception, birth, nurture, and upbringing of children. If these practices, taken to be formative of the basic personality, could be changed, then the basic personality would be changed; and this genetic approach could be made to seem historically relevant. Indeed, the shape of history could be made to seem dependent on modes of child nurture. Later developments took status, role, group memberships, and situational determinants into account. Aggression, frustration, conflict, competition, cooperation, motivation, national character, socialization, and character formation were terms frequently encountered in culture-pattern models. Developing a culture pattern for a people was achieved by interrelating some or all of these features. It is a resultant, rather than a predicative, mode of operation.

There is no doubt that culture-pattern studies have made an enormous and valuable contribution to social science, particularly in their close observation and recording of the processes in culture. The mutual mirror image of individual personality and culture, however, has tended to obscure the institutional matrix that individuals with specific economic and political interests have to manipulate to gain their ends. Man's highest cultural achievement, his articulate thought, tends to be lost in a mass of nonverbal behaviour. Changes in economic resources go unnoticed. The conflicts of political and economic interests, whether within the culture or imposed from outside, tend to be subsumed in personality differences.

The structure-function model. The structure-function model, typified in British anthropology, although derived from the French, is the precise opposite of the culture-pattern model. The individual is seen as subordinate not so much to the group as to the categories of collective representation. The collective categories exist and persist; an individual is born into them, manipulates them, and changes them perhaps. But when he dies the collective categories live on. Individuals are not so much personalities in themselves as actors with parts to play. Consequently, role, status, and positional relationships are of paramount importance; so are economic and political interest.

The French sociologist Émile Durkheim was the prime sponsor of this approach. For Durkheim the basic units were the "social facts"—the roles, offices, institutions, or whatever that went on existing independently of the particular individuals who might transiently be occupied with them. These units were thought of as fundamentally centripetal: like an organism, society maintained itself in virtue of the integrative nature of the relations between various parts of the whole. Conformity was necessary to the maintenance of the social order. If there were acts or activities that tended to break down the solidarity

nence of
the social
fact

Structure
and
organiza-
tion
as purely
intellectual
tools

and produce mutually exclusive unities, somehow these unities came to be rebuilt into a larger whole or brought together into necessary mutual alliances immediately or concurrently. The British anthropologist A.R. Radcliffe-Brown asserted that,

the continuity of social structure . . . is not static like that of a building, but a dynamic continuity, like that of the organic structure of a living body. Throughout the life of an organism its structure is being constantly renewed; and similarly the social life constantly renews the structure. (From *Structure and Function in Primitive Society*, 1952.)

The structure-function model seems to have been most successful in application to small-scale societies, in which kinship categories could be made the main components of structure. The kinship categories defined who in a society should be thought of as consanguines and affines; evoked role, status, and positional relationships; generated mutual obligations and expectations of behaviour and attitude; and, further, in small-scale societies could be used to classify the total environment.

The chief British exponents of the structure-function approach, the anthropologists Bronisław Malinowski and Radcliffe-Brown, emphasized the importance of searching for "laws" of social life and society. Only within such laws (or regularities) was social change considered admissible. Critics of the British school have charged that the neglect of change and of history left the model incomplete. But such a charge can hardly be sustained. Much more weighty is the criticism that, being integrationist and wedded to what is permanent, the structure-function model might be able to include minor rebellion and conflict but could not contain revolution, innovative changes, or deep-seated centrifugal or disintegrative tendencies. Furthermore, being normative, it seemed to have few predictive properties.

These criticisms were well founded. Again, it is often said that the model was too intellectualized, too depersonalized. Where are the people in all this manipulation of the categories? Certainly the model is politically conservative and even emasculating: it serves to discover and interpret an unknown but has little or no potential within itself of generating new policies or ideas. It is itself a closed system and can only be adumbrated, developed, and readumbrated in relation to more and more detailed field material.

There was also an American branch of the structure-function proponents, led by such sociologists as Robert K. Merton and Talcott Parsons. It laid less emphasis on kinship patterns and more on various aspects of stratification—role, status, and positional relationships determined by personal qualities, possessions, authority and power, and the like. The shift in emphasis was necessary because there was a shift in the object of study from small-scale to large-scale modern societies. Perhaps, in this, too much was attempted. A model born of and devised for the study of simple and small-scale communities was adapted to the complex organizations of modern civilized society, and in the process the simple coherence of the model was lost in a jumble of jargon, an esoteric maze of words.

The conflict model. The conflict model is grounded in political theory and in attempts to explain the historical process. It generally attempts to predict or, in the words of one of its chief current advocates, the German theorist Ralf Dahrendorf, to "account for the rate and direction of change" (*Conflict After Class*, 1967). It is actually a model that has preoccupied thinkers from earliest times. It involves whole philosophies as to the nature, being, and purpose of man. From Plato and Aristotle through Saint Paul the Apostle, Saint Augustine of Hippo, and numerous Medieval and Renaissance thinkers to men such as John Locke, Thomas Hobbes, Jean-Jacques Rousseau, G.W.F. Hegel, Herbert Spencer, Charles Darwin, Karl Marx, and, indeed, every politician, some model of the locus of conflict and its probable consequences has been essential.

Two major but not necessarily mutually exclusive themes may be identified. First the locus of conflict may be placed squarely in the nature of man; second, it may

be placed in the nature of his social order. Most often the two themes are combined in either of two general ways: (1) In the nature and consciousness of man there is a variety of things (original sin, frustrated sexual drives, the will to dominance or power, competitiveness, territoriality, control of wealth, etc.) that give rise to conflict; these things, or agitants, can be contained, controlled, and rendered nugatory by a particular kind of social order. Nearly all Utopian thought—political, philosophical, or sociological—conforms to this formula. And since the locus (whatever it may be) is inherent in man, few such models can avoid Plato's solution (in *The Republic*) of a dominant corps of guardians to enforce and maintain the harmony. (2) Since the nature and consciousness of man is a product of his social order, conflict results from the contradictions in the social order: the solution to conflict must reside in rearrangements of the social order.

Such models belong mainly to political theory that seeks to promote and bring about certain kinds of change. Hence, both structure and organization are loosely described and subordinated to whatever is deemed the impetus for conflict.

Dahrendorf does present a theory of integration in society, whose social structure is held in equilibrium by certain patterned and recurrent processes; but he joins it to a theory of coercion in which the social structure is held together by force and constraint and contains within itself forces causing an unending process of change. Thus the model becomes a dialectic between stability and change, integration and conflict, consensus and coercion. The model is furthermore focussed on large-scale and complex societies and on class conflict. Unlike Marx, however, he does not identify entities in conflict (such as capital and labour), but identifies conflict in terms of groups and individuals occupying particular roles and exercising power vis-à-vis one another. The roles reflect structure or stasis; the exercise of power and the response to it cause change.

In the model devised by the American sociologist Lewis Alfred Coser, the essential equilibrium is the equilibrium maintained by conflict. What emerges is less a model of structure than a series of propositions about the functions of conflict or what conflict does: it maintains or disrupts cohesion depending upon circumstances; it forms groups and associations, and also destroys them; it is the locus of social dynamics and change, but it also maintains a balance of powers.

In the sense that all conflicts take place within a framework of rules, they do have a structure. The critical situation arises when the parties to a conflict operate under different frameworks of rules—as do members of revolutionary social movements vis-à-vis defenders of the status quo. Here the sociologist should turn historian and attempt to subsume the two sets of rules and relations into an overarching framework. A sociology of revolution, the transformation of one structure into another, however, has so far been elusive. It is not simply a matter of changing the meaning of structure or organization. There are very real conceptual difficulties involved in creating a model capable of transforming itself into another. Adaptations of the Hegelian formula (thesis-antithesis-synthesis) must still suffice.

Physical-science models. Most of the difficulties inherent in physical-science models stem from (1) the nature of social material, (2) basic assumptions and purposes, and (3) language. The empirical realities of physical science may be subjected to innumerable experiments by large numbers of scientists supported and funded by a large proportion of the gross national product. It is questionable whether a comparable effort and investment in social science would obtain comparable results. But since the empirical realities of social life can only be obtained ad hoc, under the artificial conditions of a small group laboratory, or by maintaining an institution very like a concentration camp, it is doubtful whether social scientists would ever have access to the same range of experimental data as do physical scientists. Moreover, in social science there is a moral relationship between investigator and investigated that inhibits an objective analysis and

Integration and coercion

Difficulties in experimenting and securing data

Study of small-scale societies

Emphasis on change in large-scale societies

explanation of social behaviour in physical-science terms. When one of the chief proponents of the physical-science model, the American sociologist George A. Lundberg, states that "human sociology deals with the communicable adjustment technique which human groups have developed in their long struggle to come to terms with each other and the rest of their environment" (*Foundations of Sociology*, 1964, p. 1), he asserts an assumption about human existence with which not everyone would be able to agree.

Moreover, if there could be agreement on the nature of human existence and purpose, there is the additional question of the nature and purposes of sociology, namely, whether it merely analyzes, whether it explains, or both. It is a truism, for instance, that in any interplay of human activities, more energy is expended to reach some goal or conclusion than a rigid physical-science measurement would indicate; that is, most of the empirical reality of social life is totally unnecessary. If the sociologists must explain that all this transparently unnecessary activity appears to be necessary, he raises questions of what is rational and draws in the opinions of his own conscience; as a result, he manipulates more than he observes.

The problem of talking about values and beliefs raises the question of a language that is "value free." The problem is not solved by the invention of new terms and phrases, the creation of new jargon. Such metalanguages, however, are not wholly without value. Hence the present emphasis on using various kinds of computer languages.

Mathematical or logical models. Mathematical and logical models are based on the use of a metalanguage: analyses of empirical realities or rationalizations or categories in terms of the relations of mathematics or logic. From Plato through the Enlightenment until the rise of humanism and the Romantic movement, it had always been an axiom that the cosmos had an underlying harmony that could be expressed in mathematical terms. This was most obvious in the behaviour of celestial bodies, and least obvious in the behaviour of men and women; but, if human behaviour could be expressed in mathematical terms and realized in the forms of social organization or the state, man had perfection in his grasp. Such indeed was the purpose of Plato's *Republic*. Eighteenth-century Humanism and the Romantic movement obscured this ideal. Now, however, it is in process of realization. Primitive as yet, long-winded, and not wholly convincing as explanatory modes, mathematical and a priori logical models are not so much models of structure or organization—though they can be—as analytical modes directed toward the building of a variety of models of structure and organization.

While physical and natural sciences are concerned with the extraction of systematic relationships between sets of empirical data, and social science is mainly concerned with systematic relationships between rationalizations on the empirical data, mathematics and logic are concerned with abstract relations that have no empirical content. They are, like languages, tools whose relational content can be used to bring order to the variety of semantic fields generated by a consideration of data obtained by field research. Myth, kinship, and the decision-making process have been found particularly susceptible to analysis with these tools.

Although there is little doubt that the wedding of mathematics and social science will be fruitful, criticism of such work stems from the fact that sociology was born of, and still carries, a desire to improve society. It is all very well to perform mathematical and logical exercises with ethnographic material, but questions arise over the kinds of policy that will result from them. A first answer resides in the example of physical and natural science: not only do mathematical and logical techniques create a rigour of discipline in the kinds of things that can be said about the data, but the data itself may open further avenues of relations in the abstract terms characteristic of mathematics and logic.

In view of some of the claims of sociology, this would be no small gift. A second answer resides in the work that

has already been done. Given the initial intuitive and intellectual perception of harmony in social affairs, mathematical and logical harmonies may be spun out. And the feedback from such operations will correct the initial perceptions. But at this point one is returned to Plato's problem: what if social relations are basically inharmonious?

General conclusion. Such concepts as social structure and social organization have been guiding notions, basic to the development of sociology as well as social and cultural anthropology. What was once a general term connoting some idea of wholeness, "structure" had attained a certain specificity by the 1940s, mainly because of the work of the British proponents of the structure-function model. But in the course of the subsequent decades it became a general term used to refer to the rules, explicit or implicit, within which any kind of behavioral sequence—verbal, ideational, or physical—could be said to operate. And because structure is a property of any behavioral sequence, the notion of structure is definitely no longer static. It has come to encompass the dynamic aspect, change.

From the 18th century to the present there has been a generalized movement from macromodels to micromodels, from global theories about the nature of human society to micromodels about the nature of specific kinds of situations in particular environments. It is at this point that psychology and sociology or social and cultural anthropology begin to mesh. It is at this point, too, that mathematical and logical models, as well as a variety of investigatory and measuring techniques, are proving to be most useful, both experimentally and when considering the interrelations of small-scale societies. Here lies a growing point whose virtues are only slowly beginning to dawn.

BIBLIOGRAPHY. An early and succinct statement of the notion of system may be found in PÉRE LAFITAU, *Moeurs des sauvages amérindiens comparées aux mœurs des premiers temps*, 2 vol. (1724), though not further developed at the time. Evolutionary theory, particularly in HERBERT SPENCER, *Social Statics* (1850) and *Principles of Sociology*, 3 vol. (1876–96), used the concept, as did Marxist writing. W.H.R. RIVERS, *The Todas* (1906) and *Kinship and Social Organisation* (1914); A.R. RADCLIFFE-BROWN, *The Andaman Islanders* (1922); and BRONISLAW MALINOWSKI, *Argonauts of the Western Pacific* (1922), brought the concept of social structure to the forefront. RUTH BENDICT, *Patterns of Culture* (1934); A. KARDINER (ed.), *The Individual and His Society* (1939); FELIX KESING, *Cultural Anthropology* (1958); and A.F.C. WALLACE, *Culture and Personality* (1961), show the development of the culture-pattern school. The structure-functionalists are well represented by A.R. RADCLIFFE-BROWN, *Structure and Function in Primitive Society* (1952); E.E. EVANS-PRITCHARD, *Witchcraft, Oracles and Magic Among the Azande* (1937), *The Nuer* (1940), and *Nuer Religion* (1956); TALCOTT PARSONS, *The Structure of Social Action* (1937); MEYER FORTES, *The Dynamics of Clanship Among the Tallensi* (1945); R.K. MERTON, *Social Theory and Social Structure* (1949); G.P. MURDOCK, *Social Structure* (1949); and ER LEACH, *Political Systems of Highland Burma* (1954). RAYMOND W. FIRTH, *Elements of Social Organization* (1951); and FREDRIK BARTH, *Models of Social Organization* (1966), offer some of the most influential analyses of organization and structure; and CLAUDE LEVI-STRAUSS, *Anthropologie Structurale* (1958; Eng. trans., 1963); and PIERRE and ELLI KONGAS MARANDA (eds.), *Structural Analysis of Oral Tradition* (1971), reveal the growing distinction between functionalism and structuralism. Conflict models are based on KARL MARX, *Capital*, 3 vol. (1867–79); GEORG SIMMEL, *Soziologie* (1908; 3rd ed., 1923); and MAX WEBER, *Wirtschaft und Gesellschaft*, 2nd ed., 2 vol. (1925; Eng. trans. of pt. 1, *The Theory of Social and Economic Organization*, 1947); for further developments of the conflict model, see GEORGE A. LUNDBERG, *Foundations of Sociology* (1964); LEWIS A. COSER, *The Functions of Social Conflict* (1956); and C. WRIGHT MILLS, *Power, Politics and People* (1963). Mathematical models are illustrated in GEORGE KINGSLEY ZIPF, *Human Behavior and the Principle of Least Effort* (1949); and in IRA R. BUCHLER and HENRY A. SELBY, *Kinship and Social Organization* (1968). General, if necessarily tendentious, reviews are contained in ROBERT H. LOWIE, *The History of Ethnological Theory* (1937); A.L. KROEBER, *Configurations of Culture Growth* (1944); and MARVIN HARRIS, *The Rise of Anthropological Theory* (1968).

Sociology

Sociology is a branch of the science of human behaviour that seeks to discover the causes and effects that arise in social relations among persons and in the intercommunication and interaction among persons and groups. It includes the study of the customs, structures, and institutions that emerge from interaction, of the forces that hold together and weaken them, and of the effects that participation in groups and organizations have on the behaviour and character of persons. Sociology is also concerned with the basic nature of human society, locally and universally, and with the various processes that preserve continuity and produce change.

It is social life that is distinctive in the regulation of behaviour in human beings; the human animal does not have such instincts as serve to guide the behaviour of lower animals, and he is therefore more dependent on social organization than is any other species. Institutionalized social forms therefore are assumed to play the major part in influencing human actions, and it is the task of sociology to discover how these forms operate on the person, as well as how they are established, develop, elaborate, interact with one another, and decay and disappear. Among the most important of such structures is the family, the subject of an important field of sociology. The peer group, the community, the economic and political orders, various voluntary associations, and special organizations such as the church and the military are of particular importance in this inquiry.

Relation
of
sociology
to other
disciplines

Though sociology can be considered as a part of the Western tradition of rational inquiry inaugurated by the ancient Greeks, it is specifically the offspring of 18th- and 19th-century philosophy and has been viewed as a reaction against the frequently nonscientific approaches of classical philosophy and folklore to social phenomena. It was for a time presented as a part of moral philosophy, which covered the subject matter that eventually also became the concern of the various social sciences that are now separate from moral philosophy. Some aspects of other fields remain of interest to the sociologist. Although psychology has traditionally centred its interest on the individual and his internal mental mechanisms, and although sociology has given its major attention to collective aspects of human behaviour, the two disciplines share the subfield of social psychology. The relation of sociology to social anthropology is even closer, and until about the first quarter of the 20th century the two subjects were usually combined in one department, differentiated mainly by the emphasis of the anthropologists on the sociology of preliterate peoples. Recently even this distinction has been fading, as social anthropologists have increasingly added studies of various aspects of modern society to their field of interest. Political science and economics had much of their early development in the practical interests of nations and for a time evolved separately from basic sociology; but recently in both fields an awareness of the potential utility of some infusion of sociological concepts and methods has brought relations closer. A somewhat similar situation has also been developing in respect to law, education, and religion and to a lesser extent in such contrasting fields as engineering and architecture.

Nineteenth-century sociology, influenced by the successes of biology and evolutionary theory, took an interest in resemblances between men and lower animals—in their having, for example, similar instincts—and also in the parallels between biological and social evolution. These interests have declined, but sociology continues to share with the other sciences some interest in ecology, behavioral genetics, and questions of fertility and mortality as they relate to population studies. There is also a conviction among sociologists that contact between physiology and sociology is necessary to avoid errors of ignorance in both fields.

THE BACKGROUNDS OF CONTEMPORARY SOCIOLOGY

Early major schools of thought. The founders of sociology spent decades almost exclusively in the process of finding a direction for their new discipline. In the course

of this groping effort they tried several highly divergent pathways, some suggested by methods and contents of other sciences, others invented outright by the imagination of the scholar.

Social Darwinism and evolutionism. Darwinian evolutionary theory doubtlessly suggested a way in which a science of human behaviour could become academically respectable, and a line of creative thinkers, including Herbert Spencer, Benjamin Kidd, Lewis H. Morgan, E.B. Tylor, L.T. Hobhouse, and others, developed analogies between human society and the biological organism and introduced into sociological theory such biological concepts as variation, natural selection, and inheritance—evolutionary factors resulting in the progress of societies through stages of savagery and barbarism to civilization, by virtue of the survival of the fittest. Some writers also perceived in the growth stages of each individual a recapitulation of these stages of society. Strange customs were thus accounted for on the assumption that they were throwbacks to an earlier useful practice; an example offered was the make-believe struggle sometimes enacted at marriage ceremonies between the bridegroom and the relatives of the bride, reflecting an earlier bride-capture custom.

Social Darwinism waned in the 20th century, but in its popular period it was used to justify unrestricted competition and a laissez-faire doctrine in order that the "fittest" would survive and that civilization would continue to advance.

Determinism: economic, environmental, biological. Except in the philosophy of Karl Marx (whose writings ranged over all the social science fields rather than specifically in sociology), the doctrine of economic determinism never gained a strong foothold in sociology. This was not a consequence of scholarly ignorance; sociologists of all periods have read Marx and have usually read such writers as the historian Charles A. Beard, who emphasized economic self-interest, and Werner Sombart, the German sociologist who had been a convinced Marxist in his early career. But there have been only some adapted reflections of these economic views in the writings of such sociologists as Franklin H. Giddings or Frank H. Hankins who viewed some political and religious doctrines as rationalizations of economic and social interests.

The human geographers—Ellsworth Huntington, Ellen Semple, Friedrich Ratzel, Paul Vidal de La Blache, Jean Brunhes, and others—were also read critically by sociologists but did not make a lasting major contribution to the mainstream of sociological thought, even though there are some who believe that the social morphology of Émile Durkheim, Maurice Halbwachs, and others—that is, their theories about the roles of individuals interacting in a social system—grew in part from this interest.

Aside from the interest in evolution, organismic analogies, and the instinct concept, sociologists have not found biological determination of value to them and have spent more energy in refuting it than in making use of it.

Early functionalism. Following the achievement of a consensus that there should be a place for a science of sociology, there emerged an international effort to define the distinctive character of the subject and especially to clarify its differences from psychology and biology, fields that had also begun to generalize about human behaviour. A Frenchman, Émile Durkheim (1858–1917), was prominent among scholars who considered this question; he argued that there can arise from various kinds of interaction among individuals certain new properties (*sui generis*) not found in separate individuals. These "social facts" as he called them—collective sentiments, customs, institutions, nations—call for study and explanation on a distinctly sociological level rather than on the level of individual psychology. Furthermore, the interrelations of the parts of a society were perceived as cohering into a unity, an integrated system with a life character of its own, exterior to the individual, and exercising constraint over his behaviour. This direction of causation, from group to individual (rather than the reverse as conceived by most biologists of the time) gave encouragement to the scholar

The notion
of stages of
evolution

of the new science. Some writers have designated such a view "functionalism," although the term has in recent years acquired some broader variations of meaning.

Durkheim also pointed out that groups could be held together on two contrasting bases: the sentimental attraction of similarities (mechanical solidarity), such as occurs in friendship groups and among relatives and neighbours, and the organization of complementary differences (organic solidarity), such as occurs in industrial, military, governmental, and other organizations that exist because they have tasks to perform. Other theorists of Durkheim's period, notably Henry Maine and Ferdinand Tönnies, made similar distinctions in different terms—status and *contract* (Maine) and *Gemeinschaft* and *Gesellschaft* (Tönnies)—and conceived of the major trend of civilization as an expansion of the latter and a relative decline of the former.

Some later anthropologists, especially Bronisław Malinowski and A.R. Radcliffe-Brown, developed a doctrine also called functionalism, based on the recognition of the interrelatedness of the parts of a society, in bonds so thoroughly interpenetrating that a change in any single element would tend to produce a general disturbance in the whole. This concept gained a following for a time among many social anthropologists, leading some to advocate a policy of complete noninterference with even the most objectionable practices in a preliterate society (such as headhunting) for fear that control might produce far-reaching disorganization.

William G. Sumner, in his *Folkways*, defined an institution as a "concept and a structure," meaning a purpose or function that is carried out by some systematic organization of persons. Much of the sociology of Max Weber consists of the analysis of societies in such terms. Georg Simmel, sometimes called the founder of the "formal school" of sociology, viewed society as a process ("something functional") that is real and not merely an abstraction, and he built on this idea a statement of sociology consisting of a systematic analysis of social forms.

Modern major directions of interest. The early schools of thought—each presenting a systematic formulation of sociology that implied possession of exclusive truth and that involved a conviction of the need to destroy rival systems—in time gave way to distinguishable directions of interest and emphasis that did not have to be considered inharmonious. These new directions have no dominant leaders and no clearly defined borderlines.

Functionalism and structuralism. Following the main contributions in the earlier theoretical formulations of Charles H. Cooley, such later authors as Pitirim A. Sorokin, Talcott Parsons, Robert Merton, Everett C. Hughes, and others have elaborated on the nature of organizations and their relation to the behaviour of persons and have attempted to build workable conceptualizations of very large social systems, nations, and societies. Sorokin designated his viewpoint as "integralist" and wrote at length about the civilization-cultures that in their balance of values and conditions could be viewed as entities that had distinguishable life cycles, with "ideational," "idealistic," and "sensitive" stages marking their growth and decline, thus following a philosophy-of-history tradition shared by Edward Gibbon, Oswald Spengler, and Arnold Toynbee.

Talcott Parsons has given attention to social systems in a more analytical way, inquiring into the conditions that each system must meet in order to survive (the "functional prerequisites"), the character of the standardized and stable interpersonal arrangements (structures) needed to make each system work, the relations to environmental conditions, problems of boundaries, the recruitment and control of members, and the like. Along with Robert Merton and others, he also worked on the classifications of such structures and on distinctions of function.

The subject matter and methods involved in such structural-functional analysis have indeed become so broad that some authors (such as Marion Levy) have held that it becomes synonymous with scientific analysis in general, or at least with scientific study of the nature of organization.

On a smaller scale, Kurt Lewin and his co-workers pur-

sued somewhat parallel questions, investigating the nature of small groups, families, professional and military units, looking for arrangements and relationships of the parts of each person's "psychological life space" and of the interrelations of these to a "social space" or society's total range of action. The choice of such relatively small units for research made fruitful experimentation possible, and from Lewin's leadership grew the influential research movement that became known as group dynamics. Some writers have also applied the descriptive term *microfunctionalist* to this tradition.

Symbolic interactionism. Sociologists did not for long find the 19th-century instinctivist psychology congenial, and most of them also failed to appreciate the doctrines of classical or Watsonian behaviourism, which sought to be totally objective and experimental. One influential movement in social psychology, however, did take early root and eventually became the largest and most influential field in modern American sociology. In recent years it has become known as "symbolic interactionism," but it was under development for decades before it acquired a name.

Out of early ideas expressed by J. Mark Baldwin and William James, a group of three scholars, John Dewey, George H. Mead, and Charles H. Cooley, built the foundations of a psychology that was to become most useful to sociology. In brief, their contribution was to advance the theory that mind and self are not part of the innate equipment of the human organism but arise in experience and are constructed in a social process—that is, in a process of interaction among persons in intimate, personal communication with one another. The self, or self-concept, as developed by Mead and others, is thus essentially an internalization of aspects of an interpersonal or social process. It exists in imagery and symbolization and is internalized and organized for each person out of his perception of how other persons conceive him. This self-concept, however inexact, fluctuating, and uncertain, nevertheless functions as a guide in social behaviour—that is, persons tend to act in order to preserve the existing or desired image of their self.

William I. Thomas, a sociologist and colleague of the philosopher Mead at the University of Chicago in the early years of the 20th century, regularly taught a course in social psychology based on Mead's conceptions. Thomas was succeeded in 1919 by Ellsworth Faris, himself a psychologist but later a member of the department of sociology, and through his work the tradition was further developed and brought into closer relation to the sociological tradition of Robert E. Park and Ernest W. Burgess, also at Chicago. In this tradition an interest in an appropriate methodology accompanied the growth of substantive knowledge; Thomas particularly emphasized the value of extensive use of personal documents, life histories, and autobiographies. In recent years interest in research on the self and self-conscious behaviour has spread widely, and is now participated in by psychologists, philosophers, and essayists, as well as by a movement within sociology called "ethnomethodology," which investigates areas of symbolic interaction by informal observation, reflection, and skilled interpretation, methods sometimes called *Verstehen* (understanding).

Modern determinism. Economic determinism reflects the interest that a few early sociologists took in views of Karl Marx, such as the idea that differentiation into social classes and conflict between these classes derive from economic factors and the belief that the political system is in large part a product of such social stratification. A residue of this kind of determinism is found among the self-proclaimed "Marxian sociologists." Perhaps the most widely read of these was C. Wright Mills, whose concept of a "power elite" has been extensively and critically examined, with varying resulting judgments on its utility. As Mills saw it, this elite constitutes an integrated ruling group of a capitalistic economic and military system, sometimes called the military-industrial complex, exercising arbitrary power in its own interests. This particular determinism is not supported by most existing objective research, which generally finds a far more pluralistic distribution of political power.

The
concept
of self

A contrasting view of class conflicts was advocated by Karl Mannheim, who saw the cleavages as ideologically produced, as divergences in modes of thought rather than as rational perception of economic interests. Since Mannheim hoped that such conflicts could be resolved, his doctrine should not be considered fully deterministic, but it did stimulate an effort to interpret the relations between ideas and actions that came to be known as the "sociology of knowledge."

Mathematical modelism. A variety of efforts has been made to describe and investigate behaviour mathematically, through measurement and counting and the use of mathematical models. This approach in part characterized the early "sociometry" of J.L. Moreno (although its meaning has greatly drifted and broadened in recent years), the "field theory" of Kurt Lewin, and the investigations by George K. Zipf, John Q. Stewart, and others into the relations of rank and size of political units, the frequency of word use in language, and other simple arithmetic relations. Some of the concepts of game theory, first introduced into economics by its inventors, John von Neumann and Oskar Morgenstern, have also penetrated into sociology. Also the rapidly expanding use of computers has in recent times encouraged the development of various kinds of simulation of behaviour. Some investigations of complex interaction patterns have been carried out by devising games with rules to fit the problem and persons to execute the roles. When specified rules become highly detailed and complex, the outcome may be sought through the use of a computer; thus the game is converted into a simulation. Sociologists have participated, along with other social scientists, in the creation of such simulations of various political and military processes. Extension of these techniques into a variety of interaction processes is to be expected.

METHODOLOGICAL CONSIDERATIONS IN CONTEMPORARY SOCIOLOGY

Much of 19th-century sociology was devoid of systematic method, but late in the period the proliferation of schools of thought, based on speculative sociologies, made evident the need for ways of obtaining verifiable knowledge. Early attempts were crude and unfruitful; such broad surveys as Charles Booth, who produced a monumental series on London, relied mainly on the gathering of masses of facts. Frédéric Le Play in France made extensive studies of family budgets. Herbert Spencer and others assembled vast stores of observations made by other persons, using these to illustrate and support generalizations already formulated.

Early exploitation of statistical materials, such as officially recorded rates of births, deaths, crimes, and suicides, provided only a moderate advance in knowledge, because this approach was too capable of supporting preconceived ideas. Among the most successful of this type of study was research on suicide by **Emile Durkheim**, whose successors in France and elsewhere developed the methodology a considerable way toward scientific adequacy.

After the turn of the century, interest in, and the determination to achieve, a sociological methodology grew steadily. The *Methodological Note*, constituting the greater part of a volume in W.I. Thomas and **Florian Znaniecki's** *Polish Peasant in Europe and America* (5 vol., 1918-20), has been recognized as an important advance, not so much in methodology as in committing sociologists to the task of achieving it.

Park and Burgess studies. Significant advances toward scientific effectiveness occurred at the University of Chicago in the 1920s. Under the stimulation of Robert E. Park, Burgess, and their colleagues a series of studies of the metropolis was conducted. The spirit was inductive, and hypotheses were discovered in rather than imposed on gathered information. Large numbers of students took part in the effort and contributed to both methods and findings. A conspicuous part of the effort consisted of mapping locations of various phenomena: land uses, residences of population categories (racial, ethnic, and occupational), residences of persons who commit various types of crimes or suicide, families becoming divorced or bro-

ken through desertion, and so forth. But along with such information on spatial distributions, data were sought by other means, including participant observation in groups and communities, gathering of life histories and case studies, assembly of relevant historical information, study of the life cycles of social movements and sects, and the like. Attention was explicitly given to the improvement of methodology in all of these efforts, to an extent approximately equal to the attention given to substantive findings. Here for the first time was developed a large-scale cooperative effort in which theory, methodology, and findings evolved together in an inductive process. The influence of this development at Chicago spread rapidly about the United States and in time influenced sociology almost everywhere it was studied in the world.

Statistics. Statistical methods were introduced into sociology from other sciences, and virtually from the start, sociologists have found statistical measures of relationship of great value. Karl Pearson's "coefficient of correlation," for example, has been a popular as well as important statistical concept for the measurement of cause-and-effect relationships among continuous variables. This method reveals the *degree* of causal connection between two variables, though not necessarily the *nature* of the connection. In sociology there are types of data that are relevant to causal inquiry but do not have the characteristics that qualify for the Pearsonian coefficient. Thus, much development work has been done to provide other measures of association involving, for example, *rankings* of groups or individuals or qualitative comparisons (such as whether males and females differ systematically in specified qualities).

Factor analysis, also based on an elaboration of Pearsonian correlation, performs another valuable service to sociology. If there are a large number of variables causally intertwined in a complex way, it is possible that these variables can be reduced to a small number of factors. Fifty different tests of mental ability, for instance, may be in fact fifty different mixtures of only seven or eight dimensions of mental ability. Factor analysis involves reducing such variables to a more limited number of common factors and determining the relative importance of each factor in the original variables. The process has its imperfections and the computations are laborious, but the availability of computers has overcome the latter disadvantage, and in recent years the technique has increased in use.

These statistical methods and many others are applicable to all branches of sociology and are increasingly fruitful in transforming sociology into science (see also **STATISTICS**). In general, the growth of statistical methods has been so rapid that the invention of new techniques has outstripped the ability of scholars to find data worthy of the devices. Thus the rate of progress in the near future may depend to a large extent on improvement in satisfactory data gathering and measurement. Methodologies of data gathering are in fact of major interest in sociology. Techniques of observation—of persons, groups, organizations, communities—have been extensively developed. Important for the same purpose are the various means of quantifying these observations, including scales of various kinds, **sociometric** techniques that make interrelations subject to statistical analysis, content analysis of written materials, and classification of cross-cultural information.

Experiments. Experimental methods, once believed to be inapplicable to sociological research, were extensively applied by psychologists, first on individuals and later on groups. By the 1930s some psychologists—notably Kurt Lewin and his colleagues and also Muzafer Sherif—found means of conducting experiments on social interaction. Sociologists soon followed their example and in time a number of laboratories for such research were established; Robert F. Bales, at Harvard, has made systematic observations on interaction in small, artificial groups and has produced clear and useful results, confirmed in other laboratories. Experiments are also conducted in classrooms, in summer camps, in formal organizations, and elsewhere. In general the success of experimentation has been greatest in simple situations in which the number of

Inductive
research

Harvard
interaction
studies

variables is limited. Complex experiments, however, are possible in **some** circumstances, and the design of complex formal experiments is becoming a developed art in a variety of fields, including sociology.

Data collection. Within the main categories of research methods there are many special problems for which techniques have been devised. Data collection, for example, is effected in many different ways, from unstructured observation, essentially methodless, to sophisticated measurement through special instruments. Some of the basic problems of data collection concern such matters as the most efficient use of terminology, the definitions of units to be measured, and the classifications to be used. In general it is necessary to consider the nature of a specific problem in order to choose the most appropriate unit. For example, in a study of the relation of the size of a city to the cost of operating its local government, the proper unit might well be the population residing within its political boundaries. If the research question, however, is the relation of city size to any of a number of forms of social disorganization, it may be more fruitful to recognize that sociologically the significant unit would include much or all of the settled areas outside the city limits.

In the fields of social differentiation and occupational mobility the matter of definition of specific occupations is critical. If persons are asked in a questionnaire to state their occupation, the usual response is to give only one occupation, and this one is sometimes vaguely defined and made obscure by the tendency to give a euphemistic answer. Persons change occupations; some have more than one; some might claim an occupation that they merely aspire to. The art of obtaining useful answers to such important questions involves carefully designed questions adapted to the specific purposes of the study. General classifications, intended for a variety of studies, have limited utility.

In the process of gathering research data for sociology there are occasional obstacles to direct observation. In such cases indirect indicators may provide crude but useful substitutes. For example, alcoholic consumption in a small village in which the beverage is supposed to be prohibited may be estimated by a count of empty bottles in trash receptacles, or perhaps in the town dump. Library book circulation has been used to estimate the use of television in a community in which withdrawals of books of fiction declined, while nonfiction withdrawals remained as before.

Questionnaires are convenient for obtaining information from large numbers of respondents but involve many methodological problems. Wording of questions must of course be intelligible to uneducated and uninterested persons, must have standard meanings to persons of varying backgrounds, must avoid topics that arouse resistance and refusal to complete the questionnaire, and must avoid being too complex or difficult so that returns are insufficient or constitute a biased sample. Since it is known that slight alterations in the wording of questionnaire items may produce considerable variations in the pattern of responses, the precise wording becomes a matter of some art as well as science. A similar effect occurs in the order of items, since some may suggest or influence responses on later ones.

Similar issues are involved in data gathering through interviewing. It is necessary to control such variables as the appearance, manner, and approach of the interviewer, the specific manner in which questions are asked, ways of avoiding interviewer influence on the responses, and the tendency of some respondents to refuse to answer questions or to discontinue the interview. To meet the problems of resistance on sensitive subjects and inarticulateness about some feelings, various indirect or projective devices may be employed so that a respondent in answering one question provides information he may not realize he is giving about other questions.

Questionnaires and interviews may be so arranged that the patterns of responses form a scale, converting qualitative variations into measures available for statistical treatment. An early scaling method, devised in the late 1920s by a psychologist, L.L. Thurstone, is still widely used in

sociology. It is formed in the following way: a list of questionnaire items is presented to a number of judges who independently relist the items in the order in which they consider them important or of interest. From their decisions are selected items on which there is satisfactory agreement of scale value.

Scaling may also be provided by statements to which a respondent is asked whether he "strongly approves," "approves," is "undecided," "disapproves," or "strongly disapproves." Or the quantitative differences may be introduced through a logical sequence of preference answers—for example, whether the respondent would admit a particular category of person (a) to close kinship by marriage, (b) to his club as a personal chum, (c) to employment in his occupation, (d) to citizenship in his country. Here it is assumed that the later answers imply more desired social distance.

A method or class of methods called sociometry has been under development since its introduction in the middle 1930s by J.L. Moreno. The essence of the method is the collection and tabulation of information about various types of interaction among members of groups of small or moderate size. The interaction may be either actual behaviour or merely anticipated or desired behaviour, and it may consist of preferences for various kinds of association with other persons, such as having them as friends, sitting with them, working with them, and the like. The information may be collected by observation of real behaviour or by interviews or questionnaires with specific items regarding personal choices. After the information is gathered, it is sometimes put in the form of a sociogram, consisting of names of persons enclosed in circles or squares distributed over an area and connected with lines and arrows that indicate both detail of choices and general patterns of relationships. A person receiving many choices is readily seen as the target end of many lines and is sometimes referred to as a "star." A person completely unchosen has no lines pointing toward his name and is called an isolate. Further investigation of persons typed in this fashion may be made by statistical methods, case studies, or otherwise. Overall, it can be said that various improvements and elaborations of the basic sociometric approach have been made, and the method is now less distinctively separate from other social psychology research than it was originally.

Ecological patterning. Ecological methods in sociology were first developed in connection with research on the characteristics of the metropolis, especially in regard to features of a nonsocial character, such as the patterns resulting from the distribution and movements of populations and institutions in the general process of struggling for advantage. A conspicuous part of most early urban studies consisted of mapping such distributions. The patterns of land values, of locations of various types of businesses and industries, of ethnic categories of the population, and of types of behaviour (delinquency and crime, vice, family disorganization, mental disorders, etc.) were all shown to be interrelated in a general urban ecology. This fact was then shown to be related to many aspects of behaviour of city people, and valuable contributions were made to such general sociological topics as social differentiation, migration and vertical mobility, and social disorganization.

In recent years sociological ecology has broadened in meaning and in the elaboration of methods. One modern approach, known as ecosystem theory, consists of tracing general patterns of flow of materials, energy, and information into a system and their transformation during the flow through the system, among other things.

Problems of bias. Since most sociological knowledge is based on the study of samples from some larger universe of items, the possibilities of major errors from sampling bias constitute a methodological issue. Where biases cannot be controlled, the direction and extent may sometimes be estimated, but elimination of biases through use of quotas—or, when possible, random methods—yields the best results. This can be done, for example, by first randomly selecting a number of definable regions and metropolitan areas, then selecting randomly from each such

Sociometry

Questionnaires

Interviewing

area certain urban blocks and rural segments, then further selecting from these segments certain dwelling units, and finally selecting from the dwelling units the specific persons to constitute the sample.

In every stage of the process of discovery in sociology there are possibilities of error, and recognition of these is a part of the progress of sociological methodology. There is continuous creation of technical devices to reduce such errors and to estimate the amount of error that has not been eliminated.

National methodological preferences. All the methods described above are widely used, but their relative popularity in various nations is somewhat related to both the nature of the financial support of research and the field of national interest. Where agricultural problems are of major interest, rural sociology and community studies that can be conducted inexpensively by one or a few investigators are popular. In France, Italy, and several other European nations, industrial sociology is understandably important, much of it based on case studies of industries and the experiences of workers. Sociology in Great Britain, the Scandinavian countries, and Japan covers most of the fields mentioned above.

The broad methodological concepts have varied somewhat according to the country and according to the subfield of sociology. Early in the century there was presumed to be a general difference between the sociologies of European countries and the sociologies of the United States—the former appearing to prefer broad sociological theory based on philosophical methods and the latter showing more inclination toward induction and empiricism. Such differences have declined steadily in recent times, and what differences remain may be in part a result of the differential financing of expensive research.

In the U.S.S.R. and nations under its influence there is much emphasis on the concepts and methods of Marxist sociology, which has only a small following elsewhere. A more important methodological issue divides basic scientific sociology from applied sociology; scholars interested in applied sociology tend to deprecate the methods and findings of the scientific sociologists as being either irrelevant or supportive of an objectionable status quo. Issues of ethics have also in recent years been raised, particularly in regard to observations and experiments in which the privacy of subjects may be felt to be invaded.

STATUS OF CONTEMPORARY SOCIOLOGY

Professional status. The Greek philosophers and the line of European philosophers in the succeeding centuries throughout Western civilization discussed much of the subject matter of sociology without thinking of it as a distinct subject. In the early 19th century all the subject matter of the social sciences was discussed under the heading of moral philosophy. Even after Auguste Comte introduced the word *sociologie* in 1838, the matter was combined with other subjects for some sixty years. Not until the universities undertook a commitment to the subject could a person make a living as a full-time sociologist. This commitment had first to be made by scholars of other fields, of which history was a principal early sponsor.

As early as 1876, at the new Johns Hopkins University, some of the content of sociology was taught in the department of history and politics. In 1889 at the University of Kansas, the word appeared in the title of the department of history and sociology. In 1890 at Colby College, a historian, Albion Small, taught a course called sociology, as did Franklin H. Giddings in the same year at Bryn Mawr College. But the first real commitment to the creation of a field of sociology took place in 1892 at the new University of Chicago, where newly arrived Albion Small asked for and received permission to create a department called sociology—the first such in the world. In the following year or two, departments in the subject were founded at Columbia, Kansas, and Michigan and very soon afterward at Yale, Brown, and many other universities. By the late 1890s nearly all of the educational institutions in the United States either had departments of sociology or offered courses in the subject.

In 1895 the *American Journal of Sociology* began publication at the University of Chicago, in time to be followed by a large number of journals in many other countries. Ten years later the *American Sociological Society* was organized, also to be followed in time by a large number of national, regional, international, and special sociological organizations. These quickly institutionalized the subject and have continuously served to guide its directions and to establish, very roughly, its boundaries. Eventually in 1949 the International Sociological Association was established under the sponsorship of UNESCO, and Louis Wirth (1897–1952) of the University of Chicago was elected its first president.

The rapid growth in numbers of full-time sociologists, along with growth of publications, allowed the content of the discipline to expand rapidly. By 1970 there were more than a dozen important sociological journals and an indefinite number of minor journals in the U.S., as well as a considerable number in other nations. Research grew throughout the 20th century at an accelerated pace, especially since the 1920s, partly as a consequence of strong financial support from foundations, government, commercial sources, and private gifts. Along with this there came a flourishing of research institutes, some affiliated with university departments and some independent. A small but increasing number of full-time sociologists gain their livelihood through full-time research independent of universities.

Similar developments have occurred in various other parts of the world, with variations resulting from special conditions in each case. In France, where Auguste Comte and later Émile Durkheim gave early impetus to sociology, there was early development in many fields of the subject. The two World Wars slowed the development, but after 1945 a strong revival of interest in sociology took place, during which the French government established a number of institutes in the social sciences at the level of institutes in the natural sciences, including several in Paris for sociological research—notably the Centre d'Études Sociologiques, the Institut National d'Études Démographiques, and the Maison des Sciences de l'Homme. These institutes receive government funds and employ many full-time sociologists, some of them among the prominent scholars in the nation. French universities have been somewhat more conservative; the Sorbonne, for example, had in 1970 only one chair officially assigned to sociology. The new University of Nanterre, however, established a department with four professorships. A rich amount of research publication has been produced in France since World War II, particularly in general sociology, theory, methodology, social psychology, industrial sociology, and the sociology of work.

German sociology had a strong base in the late 19th century and afterward, and the writings of Ferdinand Tönnies, Max Weber, Georg Simmel, and others were influential in all parts of the world. By the early 1930s, however, official Nazi hostility had impeded its development and by the time of the Second World War had destroyed it as an academic subject in Germany. Immediately after the war a new generation of scholars, aided by visiting sociologists, imported the new empirical research methods and began the development of a style of German sociology much different from the earlier theoretical and philosophical traditions. At the University of Frankfurt the Institut für Sozialforschung (social research), established by private financing before the war, was revived and has stimulated much research production. West German universities remained conservative for a time, but two newly created universities—the Free University of Berlin and the University of Constance—made sociology one of their major subjects. By 1970 most West German universities had at least one chair in sociology. National needs received special emphasis, including administrative research of use to planning, studies of unemployment, youth problems, and delinquency. A significant amount of research is also published in such fields as rural sociology, political sociology, and the family.

In Great Britain, despite the early prominence of Herbert Spencer and L.T. Hobhouse, sociology was little re-

garded by leading universities until recent years. Before World War II Britain excelled in anthropology, especially in the study of nonwhite societies of the empire. Sociology concentrated on studies of the poor, and much of it was undertaken by persons whose affiliation was similar to that of social workers in the U.S. The major prewar sociology department, at the London School of Economics, had the objective more of social reform than scientific objective research. In the postwar period, however, a considerable revival of sociology took place; Oxford and Cambridge recognized the subject by creating positions for sociologists, and various new universities established chairs and departments. Significant work in Britain has been done in such fields as population and demography, sociology of organization, and general sociology. The Tavistock Institute of Human Relations in London has become world famous and concentrates on human relations in the family, the work group, and organizations.

A parallel growth took place in Canada, Australia, and New Zealand. Canada, with some apparent reluctance, allowed itself to be much influenced by American sociology and has recently built many new departments with sociologists trained in the U.S.

The Scandinavian countries have also to a considerable extent adopted the methods and some of the content of American sociology, and the subject has had rapid development in many of the universities and in research institutes, some of which are connected with universities. There is also a considerable amount of interchange between sociologists in these countries.

Japan has a record of much sociological activity dating back to the 1870s. The Japanese Sociological Society (Nippon Shakai Gakkai), headquartered at the University of Tokyo, was founded in 1923; and by 1960 there were about 150 universities and colleges with courses in the subject. In the early period sociology was nearly all imported; Comte and Spencer, and later Giddings and Gabriel Tarde, were their important theorists. After the Second World War there were rapid changes in sociology in Japan, with empirical research methods largely replacing the earlier philosophical style. Importations from American sociology became abundant. Popular among these were industrial sociology, educational sociology, public opinion research, and the study of mass communications.

Sociology in the Soviet Union was long held back by the perceived incompatibility of the subject with Marxist theory. In recent years, however, it has been permitted to develop, and sociological institutes and chairs of sociology are increasing. By 1970 the Soviet Sociological Association had more than a thousand members. Leading research interests have been such subjects as labour productivity, education, crime, and alcoholism. There remains an apparent tendency to avoid issues that might imply conflict with Marxist thought.

Nations under the influence of the Soviet Union have also from time to time been inhospitable to sociology, but the strong interest of younger scholars has made possible some relaxation of this opposition, and in recent years there has been considerable progress of sociology in Yugoslavia, Czechoslovakia, Hungary, and Poland, with occasional setbacks in some areas, such as Czechoslovakia.

In Israel the dominant department of sociology is at the Hebrew University in Jerusalem, where there are also several research institutes. Israeli sociology maintains continuous close contacts with American sociology, and many of the leading Israeli sociologists have had training or teaching experience in the U.S. Among the specialties in Israel are research in methodology, communication, criminology, and the collective settlements (*kibbutzim*) in which new forms of custom and social organization are observed while under development.

The passing of the Fascist regime in Italy and the relative liberalization in Spain have opened the door to sociology, and academic chairs and research institutes are gradually increasing in these countries. Of particular interest are studies of industrial efficiency and social mobility. The general conservatism of universities, however, may constitute a retarding influence for some time to come.

In Latin America objective sociology has been much

resisted, partly because it has been viewed as a threat to the political and social order, but also because of meagre financial support of research and the low salary level of professors, many of whom must supplement their earnings in the practice of law, in civil service, and other occupations. In the 1960s, however, the number of full-time chairs increased and a number of research institutes, some financed by U.S. funds, were established. Political instability in some countries remains a major hindrance, and in such countries able scholars continue to be forced from their university positions from time to time.

Little by little sociology is penetrating into some of the developing nations. A number of African universities have formed departments, and the subject is gaining in importance in the Philippines, India, Indonesia, and Pakistan.

Scientific status. It is evident that sociology has not achieved triumphs comparable to those of the several older and more heavily supported sciences. A variety of interpretations have been offered to explain the difference—most frequently, that the growth of knowledge in the science of sociology is more random than cumulative. The true situation appears to be that in some parts of the discipline—such as methodology, ecology, demography, the study of social differentiation and mobility, attitude research, and the study of small-group interaction processes, public opinion, and mass communication—there has in fact taken place a slow but accelerating accumulation of organized and tested knowledge. In some other fields the expansion of the volume of literature has not appeared to have had this property. Critics have attributed the slow pace to a variety of factors—the appetite of sociologists for neologisms and jargon, a disposition for pseudo-quantification, and excessive concern with imitation of the methods of natural sciences, overdependence on data from interviews, questionnaires, and informal observations. All these shortcomings can be found in contemporary sociology, but none is characteristic of all areas. In general there has been progress toward efficient terminology and methods and toward more satisfactory data, and conclusions are increasingly based on the harmonious mixture of research methods applied to varied and repeated studies, and therefore are less dependent on the strength of one particular methodological device.

Bias, in more than one direction, is sometimes presumed to be a chronic affliction of sociology. This may arise in part from the fact that the subject matter of sociology is familiar and important in the daily life of everyone, so that there exist many opportunities for the abundant variations in philosophical outlook and individual preferences to appear as irrational bias. Thus critics have expressed disapproval of the sociologists' skepticism on various matters of faith, of their amoral relativism concerning customs, of their apparent oversimplifications of some principles, and of their particular fashions in categorization and abstraction. But skepticism toward much of the content of folk knowledge is a characteristic of all science, and relativism can be interpreted as merely an avoidance of antiscientific ethnocentrism. Furthermore, abstraction, categorization, and simplification are necessary to the advancement of knowledge, and no one system satisfies everyone.

Polarization of views. The dispute about the main purpose of sociology, whether it works to understand behaviour, or to cause social change, is a dispute found in every pursuit of scientific knowledge, and such polarization is far from absolute. Persons differ in the degree to which they regard the value of science as an intellectual understanding of the cosmos or as an instrument for immediate improvement of the human lot. Since even the "purest" scientist conceives of his work as benefiting mankind, the issue narrows to a difference in preference between an *ad hoc* attack on immediate human problems and a long-run trust that basic knowledge, gathered without reference to present urgencies, is even more valuable. Sociologists differ on this issue; in some countries there is much pressure toward early practicality of results; in others, including the United States, the larger number of scholars and the principal sociological associations have shown

Criticisms
of
sociology

preference for "basic science." In very recent times, however, there has emerged a radical movement among students in various countries involving advocacy of complete commitment to action on current political and social problems.

A degree of polarization has also arisen over the proper strategy for research—whether research should take its directions from the needs of society and mankind or from the evolving theoretical corpus of sociology. In nations that allow academic freedom such disputes are usually of low intensity, because each scholar selects his research interests on any basis he prefers, including that of personal taste. In this way presumably the motivation of the investigator is maximized.

The place of values in sociology. Sociologists most interested in action express impatience at the claims of others who prefer to separate their research from personal values. Much of the dispute prevails only because the two sides argue past each other. There can be wide agreement that no human being is without personal values, that research forced to confirm a particular set of values is not good science, and that there can be scientific issues toward which a particular investigator is value-neutral. In research that is susceptible to contamination by the values of the worker, it is generally possible to minimize the damage by employing methodological devices that help to insulate the scientist from his wishes for a particular outcome—such devices as objective observational techniques and measurement methods, independent and blind analysis of results, and so forth.

THE FUTURE OF SOCIOLOGY

Forces that may influence sociology. It would appear that the growth of sociology will accelerate in the visible future. Among present trends suggesting this likelihood are the increase in public appreciation of the subject, the expansion of available funds for both teaching and research, the steady reduction of sectarian opposition to inquiry into social institutions, the improvement in research methods and methods for gathering data that qualify for modern statistical treatment, and the growth of acceptance and support from scientists in other fields. There are possible factors that could inhibit such growth, such as some forms of extreme nationalism and internal conflict, but such conditions so far have impeded development only locally and temporarily.

Furthermore, it appears likely that public interest in the development of sociological knowledge will increase as a consequence of rising awareness of its promise for human safety and welfare. As the expansion of civilization, with its advanced science and technology, progressively conquers the natural hazards that afflict preliterate and preindustrial peoples and diminishes such threats as natural catastrophes, famine, and disease, a wide range of new problems emerges. These are not the menaces of an impersonal nature, but dangers that arise from imperfection in human behaviour, particularly in organized human relations. Wars have shown a tendency to become larger and ever more destructive, and the causes, though far from being understood, clearly lie, in large measure, in the complexities of social organization, in the interaction of great corporate national bodies. There appears to be little hope that politics, unaided by social science among other disciplines, could reverse this trend.

Domestic problems within nations, regions, cities, and towns appear also to become increasing sources of human troubles. There is a general rise in the severity of ethnic hostilities, and of internal conflicts between generations, political factions, and other divisions of the populations. There are also threats to human welfare from various forms of general social disorganization, reflected in the spread of pockets of poverty, crime, vice, political corruption, and family disorganization. In recent times the threats of overpopulation and potential destruction of the ecological environment have added a further reason for public alarm. Contemporary sociology obviously does not yet provide the solutions, but what prospects of human survival there are depend a great deal on the increase of the applicable knowledge of various social sciences, including sociology.

Emerging subfields. Because human behaviour observes no limits in its directions, it is possible for sociologists to extend their inquiries accordingly. The expansion of sociological interests thus has involved some penetration of adjacent traditional academic fields, such as political science, economics, anthropology, psychology, communications, speech, and to some extent even physiology and zoology. Fields within traditional sociology have also broadened their content, producing such expanded subjects as ecology and comparative sociology. Not all this extension is new, however, since much of the 19th century sociology was also very broad, especially the cosmic sociology of one worker, Lester F. Ward, who conceived sociology as the science of sciences, properly covering and organizing all knowledge.

Applications of sociology also appear to be spreading in a variety of directions, and here the possibilities seem unlimited. Sociologists aid industries in obtaining more efficient production; they help unions to increase their power; they organize rebellions of young persons, reform disorganized villages, counsel persons and families, and give or sell services to a wide variety of consumers. To what extent these applied activities will continue to spread will doubtless depend on their effectiveness relative to other means of gaining the same effects.

There is also an expansion of sociology into other than practical applications; for example, there is mathematical sociology, in which mathematical models of social behaviour are developed without systematic observations of behaviour. These efforts are not directed toward immediate human use, but may have value as bases for comparison with real behaviour and thus aid explanation of behavioural causes. A mathematical model of a completely just theoretical process of social mobility, for example, could be useful as a standard for comparing actual mobility at different times and in different nations.

Emerging methodologies. After the easiest sociological questions have been answered, the further progress of research requires ever greater effort and cost, and the proportion of discoveries by individual investigators declines as the necessity for larger teamwork research expands. This foreshadows increasing complexity of the organization of research, as has already taken place in older sciences. Large-scale research in sociology is made possible, and perhaps inevitable, by the availability of expensive computers, elaborate techniques of multivariate analysis, and the storage of information in the form of data banks and the like.

The strongest methodological emphasis in the near future is likely to be on the processes of rigorous testing of generalizations that now appear to be of strategic value in the general structure of sociological knowledge. Complete surprises in the field of human behaviour are less likely than in other sciences, since most of the possible human situations have been familiar in folk knowledge as well as in academic sociology. But the subject contains many inconsistent principles, and few of these have been put to a definitive test, partly from lack of adequate methodology and to some extent from shortage of funds and scientific manpower.

Emerging roles for sociologists. In general the principal employment of sociologists has been in educational institutions, but recently, in various countries, there has been an increasing penetration into other fields of activity. Sociologists, particularly in earlier decades, have been involved in various organized agencies devoted to social work. They have also participated in government work at various levels, from the lower bureaucratic ranks all the way to high administrative responsibility, and in the case of *Thomáš Masaryk*, former president of Czechoslovakia, to the highest office of a nation. In the United States sociologists have been extensively employed in the Bureau of the Census; the Bureau of the Budget; the Institutes of Health; various other sections of the Department of Health, Education, and Welfare; and the office of the president, where they have made contributions to policy.

Other directions of sociological activity include the roles of consultant, social critic, and social activists and even revolutionaries. When the activity diverges far enough

Applications of sociology

from traditional academic sociology, it may cease to be regarded as sociological, but it appears likely that sociologists will continue to spread their activities over the ever-widening region of national or global concern, in the name of their science or otherwise.

BIBLIOGRAPHY. Among older titles of major significance, generally considered classics and still of value today, are: W.G. SUMNER, *The Folkways* (1907, reissued 1940); C.H. COOLEY, *Human Nature and the Social Order* (1902, reissued 1967); G.H. MEAD, *Mind, Self, and Society* ed. by C.W. MORRIS (1934); E. FARIS, *The Nature of Human Nature* (1937); R.E. PARK and E.W. BURGESS, *Introduction to the Science of Sociology* (1921, reissued 1969); and W.F. OGBURN, *Social Change with Respect to Culture and Original Nature*, new ed. (1950; suppl. ch., 1964). A comprehensive summary of early sociological theory is available in H.E. BARNES (ed.), *An Introduction to the History of Sociology* (1948).

The following titles provide excellent coverage of the main directions and subfields of recent and contemporary sociology: R.E.L. FARIS (ed.), *Handbook of Modern Sociology* (1964); R.K. MERTON, L. BROOM, and L.S. COTTRELL (eds.), *Sociology Today*, 2 vol. (1959, reissued 1965); G.D. GURVITCH and W.E. MOORE (eds.), *Twentieth Century Sociology* (1945); J.G. MARCH (ed.), *Handbook of Organizations* (1965); and N.J. SMELSER and J.A. DAVIS (eds.), *Sociology* (1969). Two modern and influential general texts are L. BROOM and P. SELZNICK, *Sociology*, 4th ed. (1968); and G.A. LUNDBERG et al., *Sociology*, 4th ed. (1968).

Leading books treating communities and societies as wholes, as well as the general theory of society and social systems are these: TALCOTT PARSONS, *Societies: Evolutionary and Comparative Perspectives* (1966); I.T. SANDERS, *The Community*, 2nd ed. (1966); R.K. MERTON, *Social Theory and Social Structure*, rev. ed. (1957); G.C. HOMANS, *Social Behaviour: Its Elementary Forms* (1961); G.E. LENSKE, *Human Societies: A Macrolevel Introduction to Sociology* (1970); and A.L. STINCHCOMBE, *Constructing Social Theories* (1968).

The following symposia provide useful coverage of sociological activity in the field of social psychology: E.F. BORGATTA (ed.), *Social Psychology: Readings and Perspective* (1969); C. CORDON and K.J. GERGEN (eds.), *The Self in Social Interaction*, vol. 1, *Classic and Contemporary Perspectives* (1968); and J.G. MANIS and B.N. MELTZER (eds.), *Symbolic Interaction: A Reader in Social Psychology* (1967). Modern technical and statistical methods used in sociology are presented in E.F. BORGATTA (ed.), *Sociological Methodology* (1968); and J.H. MUELLER, K.F. SCHUESSLER, and H.L. COSTNER, *Statistical Reasoning in Sociology*, 2nd ed. (1970).

For special topics and for definitions of sociological terms, consult the *International Encyclopedia of the Social Sciences*, 17 vol. (1968); and J. GOULD and W.L. KOLB (eds.), *A Dictionary of the Social Sciences* (1964).

(R.E.L.F.)

Socrates

Socrates of Athens, who flourished in the last half of the 5th century BC, was the first of the great trio of ancient Greeks—Socrates, Plato, and Aristotle—who laid the philosophical foundations of Western culture. As Cicero said, Socrates "brought down philosophy from heaven to earth"—i.e., from the nature speculation of the Ionian and Italian cosmologists to analyses of the character and conduct of human life, which he assessed in terms of an original theory of the soul. Living during the chaos of the Peloponnesian War, with its erosion of moral values, Socrates felt called to shore up the ethical dimensions of life by the admonition to "know thyself" and by the effort to explore the connotations of moral and humanistic terms.

LIFE

Socrates was born in or about 470 BC, ten years after the Battle of Salamis. His father, Sophroniscus, was a friend of the family of Aristides the Just, founder of the Delian League, from which the empire arose. The tale that his father was a sculptor rests on Plato's reference to the mythical sculptor Daedalus as the ancestor, or work-lineage, of Socrates. Although the philosopher's mother, Phaenarete, acted as a "midwife," this fact implies nothing about her social status.

The memoir writer Ion of Chios mentioned meeting Socrates at Samos in the company of the philosopher Archelaus, a pupil of Anaxagoras (Athens' first philoso-

Socrates, herm with a restored nose probably copied from the Greek original by Lysippus, c. 350 BC. In the Museo Archeologico Nazionale, Naples.

By courtesy of the Soprintendenza alle Antichità della Campania, Naples

pher), presumably during the military operations of 441–439. The connection between the two men is also asserted by the musicologist Aristoxenus, whereas the tradition of commentaries based on Theophrastus, Aristotle's successor, calls Socrates the "disciple" of Archelaus.

Plato and Aeschines the Socratic, both writers of Socratic dialogues, agree with the military historian Xenophon in depicting him as intimate with the leading figures of the Periclean circle (Aspasia, Alcibiades, Axiochus, Callias), then dominant in Athens. Xenophon concurs with Plato in saying that he was well versed in geometry and astronomy, and this representation agrees with the narrative of Plato's *Phaedo* as well as the burlesque *The Clouds*, which was written by the playwright Aristophanes.

Socrates must already have been a conspicuous figure at Athens when Aristophanes and Ameipsias both made him the subject of their comedies in 423, and, because they made a special point of his neediness, he had probably suffered recent losses. (The marked poverty of his old age is said in Plato's *Apology* to have been caused by his preoccupation with his mission to mankind.)

Socrates was married, apparently late in life, to Xanthippe, by whom he left three sons, one an infant. Xenophon speaks of her high temper; there is no evidence, however, that she was a "shrew"; the sons, according to Aristotle, proved insignificant.

Socrates' record for endurance was distinguished. He served as a hoplite, perhaps at Samos (440), and at several stations during the Peloponnesian War. (At Potidaea he saved the life of Alcibiades.) In politics he took no part, knowing, as he told his judges, that office would mean compromise with his principles. Once at least, in 406–405, he was a member of the Boule, or legislative council, of 500; and at the trial of the victors of Arginusae, he resisted, at first with the support of his colleagues, afterward alone, the unconstitutional condemnation of the generals by a collective verdict. He showed the same courage in 404, when the oligarchy of the Thirty Tyrants in Athens, wishing to implicate honourable men in their proceedings, instructed him and four others to arrest Leon, one of their victims. Socrates disobeyed, and he says in Plato's *Apology* that this might have cost him his life but for the counterrevolution of the next year. (For the background to these events see GREEK CIVILIZATION, ANCIENT.)

In 399 Socrates was indicted for "impiety." The author of the proceedings was the influential Anytus, one of the two chiefs of the democrats restored by the counterrevolution of 403; but the nominal prosecutor was the obscure and insignificant Meletus. There were two counts

and
death

in the accusation, "corruption of the young" and "neglect of the gods whom the city worships and the practice of religious novelties," Socrates, who treated the charge with contempt and made a "defense" that amounts to avowal and justification, was convicted, probably by 280 votes against 220. The prosecutors had asked for the penalty of death; it now rested with the accused to make a counterproposition. Though a smaller, but substantial, penalty would have been accepted, Socrates took the high line that he really merited the treatment of an eminent benefactor: maintenance at the public table. He consented only for form's sake to suggest the small fine of one mina, raised at the entreaty of his friends to 30.

The claim to be a public benefactor incensed the court, and death was voted by an increased majority, a result with which Socrates declared himself well content. As a rule at Athens, the condemned man "drank the hemlock" within 24 hours, but, in the case of Socrates, the fact that no execution could take place during the absence of the sacred ship sent yearly to Delos caused an unexpected delay of a month, during which Socrates remained in prison, receiving his friends daily and conversing with them in his usual manner. An escape was planned by his friend Crito, but Socrates refused to hear of it, on the grounds that the verdict, though contrary to fact, was that of a legitimate court and must therefore be obeyed. The story of his last day, with his drinking of the hemlock, has been perfectly told in the *Phaedo* of Plato, who, though not himself an eyewitness, was in close touch with many of those who were present.

Main sources of information. Socrates wrote nothing; therefore, information about his personality and doctrine has to be sought chiefly in the dialogues of Plato and in the *Memorabilia* of Xenophon. As both men were nearly 45 years younger than Socrates, they could speak from firsthand knowledge about only the last ten to 12 years of his life.

Xenophon, whose relations with Socrates seem not to have been close, has even been suspected of drawing from Plato. His admitted deficiencies in imagination and capacity for thinking do not make him the more faithful exponent of a philosophical genius. Moreover, Xenophon's apologetic purpose calls for some discounting. His most valuable statements are those that appear to be most at variance with his main thesis, viz., that the prosecutors of Socrates were mistaken even from their own point of view.

Plato's more vivid picture has been suspected on the grounds that he used Socrates as a "mouthpiece" for speculations of his own: the theory of "Ideas" or doctrine of "Forms" is thus held to have been originated by Plato. There are serious reasons for denying this assumption, though they have not yet convinced many scholars; in any case, to employ it, without investigation, to discredit Plato's testimony begs the question.

In some important respects, Plato's testimony is confirmed by the extant writings of Aeschines Socraticus. *The Clouds* of Aristophanes yields valuable information about Socrates in his middle 40s, though allowance must be made for the work's character as a burlesque. It should be compared carefully with the autobiographical statements put into the mouth of Socrates in the *Phaedo*, which, though not "contemporary evidence," are clearly meant to express Plato's bona fide belief about his master's intellectual history. Whichever way the evidence is interpreted, however, a Platonic view of Socrates is available in the *Dialogues* that is valuable in its own right; hence the following discussion will draw heavily upon the *Dialogues* as the primary source for the portrait of Socrates.

Personal characteristics. Though Socrates was a good fighting man, his outward appearance was grotesque. Stout and not tall, with prominent eyes, snub nose, broad nostrils, and wide mouth, he seemed a very Silenus. But, as his friends knew, he was "all glorious within," "the most upright man of that day" (Plato, *The Seventh Letter* [324e]). His self-control and powers of endurance were exemplary; "he had so schooled himself to moderation that his scanty means satisfied all his wants."

But Socrates was no self-tormenting ascetic: he "knew both how to want and how to abound" and could be the soul of the merriment at a gay party. He had no sympathy with the slatternliness of his friend Antisthenes nor with the godly dirtiness often affected by the followers of Pythagoras (the philosopher of number). There was nothing of the complacent self-righteousness of the Pharisee nor of the angry bitterness of the satirist in his attitude toward the follies or even the crimes of his fellow-men. It was his deep and lifelong conviction that the improvement not only of himself but also of his countrymen was a task laid upon him "by God," not to be executed, however, with a scowling face and an upbraiding voice. Like St. Francis Xavier, he understood that to win men's souls one must be "good company." Conscious of his own infirmities, he felt a profound sympathy for the intemperate.

Socrates was a true patriot who felt that he could best prove his devotion to Athens by setting his face resolutely against the attractions of specious, and popular but deadly, false theories of public and private morality. When the city brought him to trial and threatened him with death, his sense of civic duty forbade him to escape into exile either before or after the trial. It was his very patriotism that made him an unsparing critic of the Athenian "democracy" and so led to his being condemned to death.

Nothing was more marked in his character than an unusually keen appreciation of the comic in human nature and conduct that protected him at once against sentimentality and against cynicism. This is what his opponents in Plato call his "irony" and treat as an irritating affectation. "Intellectually the acutest man of his age, he represents himself in all companies as the dullest person present. Morally the purest, he affects to be the slave of passion" (W.H. Thompson). No doubt, in part, this irony was "calculated"; it "disarmed ridicule by anticipating it." But its true source is the spontaneous sense of fun that makes its possessor the enemy of all pretentiousness, moral or intellectual. And it is certain that, though the purity of Socrates is beyond question, he really had an ardent and amorous temperament.

Religious beliefs. Socrates was clearly a man of deep piety with the temperament of a mystic. He regarded mythology, with its foolish or immoral tales about gods, as a mere invention of the poets. But he found it easy to combine his own strong belief in God as ruler of the world with the view that, in practice, one could worship God in the way prescribed by "the usage of the city." God's existence is shown, he held, not only by the providential order of nature and the universality of the belief in him but also by warnings and revelations given in dreams, signs, and oracles. The soul of man partakes of the Divine; and, as Plato argued in the *Phaedo*, Socrates believed in the soul's immortality. Aristophanes makes Socrates combine the parts of "infidel" physicist and hierophant of a mysterious private faith and, in *The Birds*, presents him as presiding at a fraudulent séance. He was regular, says Xenophon, in prayer and sacrifice, though he held that, because only the gods know what is good for a man, his prayer should simply be "give me what is good." It is clear from Plato that Socrates was quite familiar with Pythagorean and Orphic religious ideas—with the doctrine of the divine origin and destiny of the soul, for example—though he regarded the ordinary Orphic mystery monger with healthy contempt.

The evidence that Socrates had a markedly "mystical" temperament is abundant. Plato tells of his curious "rapt," in one of which he stood spellbound for 24 hours in the trenches. The accounts of the philosopher's "divine sign" tell the same story. This, according to Plato, was a "voice" often heard by Socrates from childhood. It forbade him to do things but never gave positive encouragement. According to Plato, it merely gave prognostications of good or bad luck, and the occasions of its occurrence were often "very trivial." Thus, it was neither an intuitive conscience nor a symptom of mental disorder but an interior psychic audition.

Mode of life. Socrates seemed to spend all his time in the streets, the marketplace, and, more particularly, the

The Socratic irony

Plato's depiction of Socrates

The test
of the
Delphic
oracle

gymnasia. He cared little for the country. Though he frequented by choice the society of young men of promise, he also talked freely to politicians, poets, and artisans about their various callings, their notions of right and wrong, the familiar matters of interest to them. The object of all this dialogue was to test the famous oracle of Apollo at Delphi, which had pronounced him the wisest of men. This pronouncement was made before Socrates had become conscious of his mission to his fellowmen: even at that early date, it is implied, he had the highest of reputations in circles interested in wisdom. (This early date is attested by the fact that the Eleatics from Megara and the young pupils of the Pythagoreans from Thebes and Phlious who were attached to Socrates must have formed their connection with him before the Peloponnesian War.)

Socrates set himself to convict "the god" of falsehood. But finding that those who thought themselves wise were unable to give any coherent account of their wisdom, Socrates had to admit that he was wiser than others, just because he alone was aware of his own ignorance. This account is plainly tinged with the usual "irony." Socrates took the Delphic oracle seriously enough to probe into its real import. He believed himself charged with a mission from God to make his fellowmen aware of their ignorance and of the supreme importance of knowledge of what is for the soul's good. This is proved by his declaration that he was more than ready to face instant death rather than to neglect his commission.

The poverty in which this mission had involved him and the austerity of the rule of life that it entailed were notorious. Summer and winter, Socrates' coat was the same; he had neither shoes nor shirt. "A slave who was made to live so," the Sophist Antiphon said, "would run away." This self-imposed life of hardships was the price of his spiritual independence.

His message, however, was variously received. Some of those whose false pretensions were exposed by his trenchant criticizing regarded him with ill will; many thought him an officious busybody. Among the younger men, many merely thought it good sport to see their elders silenced. Others, such as Alcibiades and Critias, deliberately attached themselves to him for a time "for private ends," believing that to learn the secret of so acute a reasoner would be the best preparation for success in the law courts, the council, and the assembly. Others sincerely hoped by associating with him to become good men and true, capable of doing their duty by house and household, by relations and friends, by city and fellow citizens. Finally, there was an inner circle that entered more deeply into Socrates' principles and transmitted them to the next generation. But these were not "disciples" united by a common doctrine. The bond of union was a common reverence for a great man's intellect and character. It was, in the main, this group—many from states that had been enemies of Athens in the recent war—that collected around Socrates on the day of his death.

The accusation and its causes. The explanation of the attack made on Socrates is simple. He had been on terms of close friendship with the two men whose memories were most obnoxious to the democrats: Critias, the fiercest spirit among the extremists of the "terror" of 404; and Alcibiades, whose self-will had done so much to bring about the downfall of the Athenian empire. The charge of "educating Alcibiades" was made prominent in the pamphlet written a few years after the trial by the Sophist Polycrates, in justification of the verdict. More than half a century later, the orator Aeschines reminds his audience that Socrates had been put to death because he was believed to have educated Critias. In point of fact, it was absurd to make Socrates responsible for the ambitions of Alcibiades, and, as he reminded his judges, he had disobeyed an illegal order from Critias and his colleagues at the risk of his life. But it is natural that he should have had to suffer for the crimes of both men, the more so because he had been an unsparing critic of democracy and of the famous democratic leaders and, furthermore, had not, like the advanced democrats, withdrawn from Athens during the "terror."

Socrates was, in fact, suspected of using his great abilities and gifts to pervert his younger associates from loyalty to the principles of democracy, and the convinced democrats who had recovered the city in 403 were unwilling, as J. Burnet has said, "to leave their work at the mercy of reaction." The motives of Anytus, an upright, unintelligent democrat, are thus quite explicable: from his point of view, Socrates would be at the best a moderate oligarch, and democrats who remembered the career of the statesman Theramenes, who had tried to mix oligarchy and democracy, could not be expected to make a fine distinction between the moderate oligarch and the traitor.

The real grounds for the attack could not be disclosed in the indictment because of the amnesty that had terminated the struggle, of which Anytus himself had been a main promoter. Hence, the charge took the form of a vague accusation of "corruption of the young." Probably for the same reasons, Anytus was ashamed to appear as the principal in the matter and put forward the obscure Meletus, who might venture on "indiscretions" more openly. If this was the same Meletus who prosecuted Andocides on the same charge of "impiety," he must have been a half-witted fanatic—and this may explain why the charge of irreligion was added. Xenophon suggests that the allusion was to the "divine sign," but this cannot be correct. Meletus said nothing about the "sign" at the prosecution, and Socrates is speaking with his "usual irony" when he pretends to guess that the mention of "religious novelties" in the indictment referred to the "sign." In the *Apology*, Socrates says that the prosecution is, no doubt, relying on memories of Aristophanes' *The Clouds*, where he had been made to talk "atheism" as part of the burlesque on men of science.

But there must have been more behind the charge. It seems likely that the prosecution of Andocides revived the old scandal of the "profanation of the mysteries" that had thrown Athens into a ferment on the eve, in 415, of the Sicilian expedition. The two chief victims, Alcibiades and his uncle Axiochus, had both been among the intimates of Socrates, and there is reason to think that others of his friends were affected. If this is what lay behind the charge, it can be understood why its real meaning seems never to have been explained: for in view of the terms of the amnesty, the matters in question were not within the competence of the court.

Socrates himself treats the whole matter with contempt. His defense consists in narrating the facts of his past life, which had proved that he was equally ready to defy the populace and the Thirty in the cause of right and law, and in insisting on the reality of his mission from God and his determination to discharge it, even at the cost of life. The prosecutors had no desire for blood. They counted on a voluntary withdrawal of the accused from the jurisdiction before trial; the death penalty was proposed to make such a withdrawal certain. Socrates himself forced the issue by refusing at any stage to do anything involving the least shade of compromise. The prosecution had raised the question whether he was a traitor or, as he held himself to be, an envoy from God; Socrates was determined that the judges should give a direct verdict on the issue without evasion. This is not only what makes him a martyr but also what forbids us to call Anytus a murderer.

DOCTRINE AND METHOD

Socrates was a man of the Periclean age, which witnessed one of the periodic "bankruptcies of science." Cosmological speculation, which had been boldly pursued from the beginning of the 6th century, seemed to have led to a chaos of conflicting systems of thought. The Rationalist Parmenides of Elea had apparently cut away the ground from science by showing that the real world must be quite unlike anything that the senses reveal and that, consequently, the interpretation of the world by familiar analogies is inherently fallacious; and his pupil Zeno of Elea seemed to have shown that even the postulates of mathematics are mutually contradictory. Thus, the ablest men, such as the Sophists Protagoras and Gorgias, had turned away from the pursuit of science and concerned them-

Socrates' early interest in "natural science"

selves not with truth but with making a success of human life.

Socrates, as a young man, was enthusiastically interested in "natural science" and familiarized himself with the various current systems—with the Milesian cosmology with its flat Earth and the Italian with its spherical Earth and with the mathematical puzzles raised by Zeno about "the unit" (*i.e.*, the problem of continuity). There was a complete lack of critical method. For a moment, Socrates hoped to find salvation in the doctrine of Anaxagoras that "Mind" is the source of all cosmic order because this seemed to mean that "everything is ordered as it is best that it should be," that the universe is a rational teleological system. But on reading the book of Anaxagoras, he found that the philosopher made no effective use of his principle; the details of his scheme were as arbitrary as those of any other.

The Socratic "hypothesis." After this disappointment, Socrates resolved from then on to consider primarily not "facts" but logoi, the "statements" or "propositions" that one makes about "facts." His method would be to start with whatever seemed the most satisfactory "**hypothesis**," or postulate, about a given subject and then consider the consequences that follow from it. So far as these consequences proved to be true and consistent, the "hypothesis" might be regarded as provisionally confirmed. But one should not confuse inquiry into the consequences of the "hypothesis" with proof of its truth. The question of truth could be settled only by deducing the initial "hypothesis" as a consequence from some more ultimate, accepted "hypothesis."

The doctrine of Forms. According to Plato, Socrates next proceeded to take it as his own fundamental "hypothesis" that every term (such as "good," "beautiful," "man") that has an unequivocal denotation directly names a selfsame object of a kind inaccessible to sense perception and apprehensible only by thought. Such an object Socrates calls an Idea or Eidos; *i.e.*, a Form. The sensible things on which a man predicates beauty, goodness, humanity, have only a secondary and derivative reality; they become this or that for a time, in virtue of their "participation" in the Form.

Scholars in the 19th century usually assumed that this doctrine of Forms was consciously devised by Plato after the death of Socrates. The chief argument for this view is based upon the observation of Aristotle that Socrates rightly "did not separate" the universal from the particular as, it is apparently implied, Plato did. He might equally have meant, however, that the doctrine of the *Phaedo* does not itself involve the kind of "separation" to which he objects in the Platonic theory. On the other side, the doctrine is expressly said in the *Phaedo* to be a familiar one, which Socrates "was always" repeating; and, if untrue, it is hard to see what could be the point of such a mystification and harder to understand how Plato could have expected it to be successful, especially as most of the personages of the *Phaedo* were certainly still alive. If true, however, one must be prepared to admit the possibility that he is also reproducing the thought of Socrates in the *Symposium* and *Republic*, in which he speaks of a supreme Form, that of Beauty, or Good, the vision of which is the far-off goal of all intellectual contemplation. Unfortunately, no complete separation of the Socratic and the Platonic is possible.

Logical methods. On the logical side, both Plato and Xenophon bear out the remark of Aristotle that Socrates may fairly be credited with two things: "inductive arguments" and "universal definitions." The "universal definition" is an attempt to formulate precisely the meaning of a universally significant predicate—*i.e.*, to apprehend what the *Phaedo* calls a Form. And it is from the practice of Socrates, who aimed at the clarification of thought about the meaning of moral predicates as the first indispensable step toward the improvement of practice, that the theory of logical division and definition, as worked out by Plato and Aristotle, has arisen.

The "inductive arguments" mean the characteristic attempts to arrive at such formulations by the consideration of simple and striking concrete illustrations, the per-

petual arguments about "shoemakers and carpenters and fullers," which the fashionable speakers in Plato profess to think vulgar. Induction, on this view of it, is not regarded as a method of proof; its function is that of suggestion: it puts the meaning of a proposed "definition" forcibly and clearly before the mind. The justification of the definition, then, has to be sought in a consideration of the satisfactoriness of the "consequences" that would follow from its adoption. Socrates himself sought for his "definitions" principally in the sphere in which he was most interested: as Aristotle says, he concerned himself with the "ethical," character and conduct, both private and public, not with "nature" at large.

Ethics and politics. With Socrates the central problem of philosophy shifted from cosmology to the formulation of a rule of life, to the "practical use of reason." As the *Apology* relates, the specific message from God that Socrates brought to his fellowmen was that of the "care" or "tending" of one's "soul," to "make one's soul as good as possible"—"making it like God," in fact—and not to ruin one's life, as most men do, by putting care for the body or for "possessions" before care for the "soul"; for the "soul" or psych? is that which is most truly a man's self.

Socrates' view of the soul stands in sharp contrast with the Homeric and Ionian view of the psych? as "the breath of life," which is given up when the man "himself," his body, has perished, and also with the view prevalent in circles influenced by Orphic-type religions, according to which the soul is a sort of stranger loosely inhabiting the body, which "sleeps while the body is active, but wakes when the body sleeps"; instead, the soul came in the 4th century to be viewed as the normal walking personality, the seat of character and intelligence, "that," as Socrates says in Plato, "in virtue of which we are called wise or foolish, good or bad." And as this usage of the word first appears in writers who are known to have been influenced by Socrates (Isocrates, Plato, and Xenophon), it may fairly be ascribed to his influence. Thus the soul is the man.

A man's happiness or well-being, in Socrates' view, depends directly on the goodness or badness of his soul. No one ever wishes for anything but true good—*i.e.*, true happiness. But men miss their happiness because they do not know what it is. For real good they mistake things that are not really good (*e.g.*, unlimited wealth or power). In this sense, "all wrong-doing is involuntary." Men need to know true good and not confuse it with anything else, so as to keep from using strength, health, wealth, or opportunity wrongly. If a man has this knowledge, he will always act on it, since to do otherwise would be to prefer known misery to known happiness. If a man really knew, for instance, that to commit a crime is worse than to suffer loss or pain or death, no fear of these things would lead him to commit the crime. To the professional Sophist, "goodness" is a neutral "accomplishment" that can always be put to either of two uses, a good one or a bad one. To Socrates, in contrast, knowledge of good is the one knowledge of which it is impossible to make an ill use; the possession of it is a guarantee that it will always be used properly. Thus, Socrates becomes—as against the relativism of Protagoras—the founder of the doctrine of an absolute morality based on the conception of a felicity that is the good not of Athenians or Spartans or even of Greeks but of man as man, as part of universal humanity.

Politics, from this point of view, is the task of "tending" the souls of all his fellow citizens and making them "as good as possible." The knowledge of good is also the foundation of all statesmanship. The radical vice of ancient democracy, according to Socrates, is that of putting society in the hands of men without true insight and with no adequate expert knowledge. His main criticism, however, is that, though in some departments democracy takes the advice only of a qualified expert, on questions of morality and justice it treats any one citizen's opinion as of equal value with another's.

Even a Themistocles or a Pericles plainly had no knowledge of true statesmanship: they gave the populace the things that tickled its taste, such as a navy and a commerce; but they were no "physicians of the body politic,"

His original view of the soul

Whether the Forms are Socratic

His political philosophy

for they did not promote "righteousness and temperance," the spiritual health of the community. Socrates maintained that he alone deserved the name of statesman, because he understood, as the men of action did not, that knowledge of the absolutely good is the necessary and sufficient condition of national well-being and felicity. Indeed, Plato's *Republic* may fairly be viewed as a picture of life in a society governed by this Socratic conviction. How far any of the special regulations of the *Republic* embody actual convictions of Socrates is more than can be said, though it is significant that the *Aspasia* of Aeschines represents Socrates as maintaining one of Plato's "paradoxes," the capacity of women for war and for politics.

Socrates exerted a temporary influence on a group of men who have come to be known as "the minor Socratics," among whom the most important were Antisthenes of Athens and Euclides of Megara, with whom the Cynics and the Megarian school were connected. It was mainly through his influence on Plato, however, who took up the thought of Socrates and continued it in his own life's work, that Socrates' efforts bore their full fruit for subsequent ages (see PLATO and PLATONISM AND NEOPLATONISM).

BIBLIOGRAPHY

General studies: The most thorough and balanced introduction to Socrates and recent scholarly discussion is W.K.C. GUTHRIE, *A History of Greek Philosophy*, vol. 3, *The Fifth-Century Enlightenment*, pp. 323-507 (1969). Socrates' cultural and philosophical context is concisely described in F.M. CORNFORD, *Before and After Socrates* (1932; paperback ed., 1960); and in W.K.C. GUTHRIE, *The Greek Philosophers: From Thales to Aristotle*, ch. 4 (1950), on the reaction toward humanism. Older classical accounts by JOHN BURNET, *Early Greek Philosophy*, 4th ed. (1930); A.E. TAYLOR, *Socrates* (1932); and CONSTANTIN RITTER, *Sokrates* (1931, in German), ascribe to Socrates himself much of Plato's formal theory of Ideas while also giving sympathetic portraits of his personality and thought.

The historical Socrates: Many studies centre on the historical value of the principal informants about Socrates: Plato and Xenophon, Aristotle and Aristophanes. The main source materials and problems are presented by R.L. LEVIN and JOHN BREMER, *The Question of Socrates* (1961); a brief informative survey of positions comes from C.J. DE VOGEL, *Philosophia*, pt. 1, *Studies in Greek Philosophy*, ch. 5 (1970); and some useful principles for understanding and using the Socratic sources are furnished by EMILE DE STRYCKER, "Les Témoignages historiques sur Socrate," *Mélanges Henri Grégoire* (1950). Reliable accounts are given of the Socrates-Plato relationship by G.C. FIELD, *Plato and His Contemporaries*, 3rd ed. (1967); and of Socrates' last days by COLEMAN PHILLIPSON, *The Trial of Socrates* (1928). Historical facts are skeptically regarded and the functions of myth and political polemic on the part of the sources are stressed by O. GIGON, *Sokrates: Sein Bild in Dichtung und Geschichte* (1947); A.H. CHROUST, *Socrates, Man and Myth: The Two Socratic Apologies of Xenophon* (1957), with special criticism of Xenophon and Antisthenes; and the two reporting dissertations by V. DE MAGALHAES-VILHENA: *Le Problème de Socrate* (1952) and *Socrate et la légende platonicienne* (1952). There are some scholarly defenses and methodological interpretations of the historicity of the major Socratic sources: AUGUSTE DIES, *Autour de Platon*, 2 vol. (1927); T. DEMAN, *Le Témoignage d'Aristote sur Socrate* (1942); K.J. DOVER's introduction and commentary to his edition of Aristophanes, *Clouds* (1968); and HUGH TREDENNICK's introduction to his translation of Xenophon, *Memoirs of Socrates and the Symposium (The Dinner Party)* (1970).

Socrates in history: The personality, ideals, and examples of Socrates are a perennial inspiration for subsequent thinkers and traditions. His influence is visually manifested in the many illustrations and texts of MICHELINE SAUVAGE, *Socrate et la conscience de l'homme* (1956; Eng. trans., *Socrates and the Human Conscience*, 1960); as well as in the collection of testimonies gathered by HERBERT SPIEGELBERG in *The Socratic Enigma* (1964). His educational impact is measured by W.K. RICHMOND, *Socrates and the Western World* (1954), while his deep impress upon Christian religious awareness and Existential thinking is affirmed in ROMANO GUARDINI, *Der Tod des Sokrates* (1943; Eng. trans., *The Death of Socrates*, 1948 and 1962). Three samples of Socrates' relationships with modern philosophy are: SOREN KIERKEGAARD, Om

Begrebet Ironi med stadigt Hensymtil Socrates (1841; Eng. trans., *The Concept of Irony, with Constant Reference to Socrates*, 1968), reformulating his view of irony in terms of Romanticism and Hegel; LEONARD NELSON, *Socratic Method and Critical Philosophy* (1949, reprinted 1965), giving a Neo-Kantian interpretation of his maieutic method; and LASZLO VERSENYI, *Socratic Humanism* (1963), showing Socrates' implications for reflective and Existential humanisms today.

(A.E.Ta.)

Sodium and Potassium Products and Production

Sodium and potassium are both soft, silvery-white metals. When freshly cut they have a brilliant lustre, but since they are among the most reactive of the metallic elements, they tarnish in contact with air, turning a dull, gray colour. They also react vigorously with water, decomposing it and forming sodium hydroxide or potassium hydroxide and liberating hydrogen. The hydrogen may ignite, and sometimes the reaction is slightly explosive. Potassium is more reactive than sodium and is likely to flame spontaneously in moist air. Both must be kept under a liquid containing no oxygen and handled very carefully because they are extremely caustic to all tissues. (For further information on the physical and chemical properties of these two elements, see ALKALI METALS AND THEIR COMPOUNDS.)

Because they are extremely reactive chemical elements, sodium and potassium are not found in nature in the free state (as metals) but are widely distributed in combined form as compounds. The most familiar compound is sodium chloride—ordinary salt. Other salts of sodium and potassium are found in nearly all soils and terrestrial waters and in many rocks. The rocks and soil are richer in potassium, but the oceans contain only about 1/30 as much potassium as sodium. Sodium and potassium are the sixth and seventh most abundant elements in the Earth's crust, of which they constitute 2.8 percent and 2.6 percent, respectively. Both elements are important in nutrition; their compounds are contained in most plant and animal tissues, and potassium compounds are important fertilizers.

History. The histories of sodium and potassium are as closely related as their chemical natures. Some of the earliest civilizations knew and used materials containing compounds of both sodium and potassium, and as these compounds were similar, they did not distinguish between them. Records originating in lower Mesopotamia and dating from the 17th century BC mention saltpetre (potassium nitrate) for making glazes. The Egyptians used native sodium carbonate as early as the 16th century BC for making glass.

Both sodium carbonate and potassium carbonate were termed alkali and were prepared from early times by passing water through the ashes of burned plants and evaporating the water from the solution. The term soda was applied at first to either alkali and later only to the ashes of sea plants; the term potash, however, was restricted to the ashes of land vegetation, and the term originated from the use of large pots from which the solutions were evaporated. The two alkalies, soda and potash, were successively designated as natural and artificial and as mineral and vegetable; but finally, in the 18th century, it was found that the so-called mineral alkali occurred in the ashes of sea plants and the so-called vegetable alkali occurred in a number of minerals; then the terms soda and potash were assigned to specific substances.

In 1807 the brilliant English chemist Sir Humphry Davy decomposed both alkalies, obtaining first the metallic potassium and then sodium. He coined the names potassium and sodium, latinized versions of potash and soda. Among the strongest reducing agents known, sodium and potassium cannot be isolated by ordinary chemical reduction, so it is not surprising that they were only prepared after electric current was discovered in 1800 and electrolytic methods were developed.

Sources. *Sodium.* Sodium occurs in the form of halides, silicates, carbonates, sulfates, and nitrates. The prin-

Early methods of preparation

principal source of sodium, of such importance that it outweighs all others, is sodium chloride, particularly rock salt deposits, but also salt evaporated from brine from underground salt deposits and salt obtained from seawater by solar evaporation. (For mining and recovery, see SALT AND SALT PRODUCTION.)

Sodium is disseminated throughout the rocky crust of the Earth in the form of soda feldspar (*i.e.*, as silicate of sodium) and in other sodium-containing rocks. Sodium carbonate is also widely dispersed in nature, forming constituents of many mineral waters and occurring as the principal saline component in natron or trona (hydrated sodium carbonate, sodium bicarbonate) lakes, as efflorescences, and as solid crusts found at the bottom of certain salt lakes. Gaylussite is a double salt, $\text{Na}_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 5\text{H}_2\text{O}$, occurring in Colombia.

Sodium sulfate occurs in an anhydrous condition as thenardite and in a hydrated condition, Glauber's salt. Glauberite is a double sulfate of sodium and calcium. Cryolite is a fluoride of aluminum and sodium, mined extensively for industrial purposes.

Potassium. Potassium occurs in many silicate rocks and minerals. The most important source is salt deposits, but a small percentage is obtained from plant and animal sources. Only a small fraction of the forms of potassium are economical to recover, those compounds that are water-soluble, *viz.*, potassium chloride and potassium sulfate; they are frequently found in mixtures with magnesium salts, both as dry mineral deposits and in brines. Their solubility allows them to be easily extracted, and they are readily amenable to chemical operations. Although nearly as abundant as sodium, potassium is less accessible; the relatively few workable deposits contain saline residues formed by the evaporation of inland seas of past geological eras.

All plants are potential sources of potassium compounds. The proportion of potassium present in organisms varies widely; but in higher animals and most vegetation, except some marine plants, the potassium content is greater than that of sodium. Sugarcane and sugar beets contain significant quantities of potassium salts, 90 percent of which is extracted with the sugar. Soluble potassium salts are drawn into the roots of plants from fertile soil and accumulate in the plant structure, where some of them are metabolized into organic salts, such as tartrates and oxalates. If, however, the plants are burned, the organic potassium salts are converted into potassium carbonate.

Recovery of the metals. When Davy first isolated potassium and sodium in 1807, he did it by electrolysis of the fused hydroxides. A modification of his method, called the Castner process, was long used commercially to prepare sodium, but it was not entirely satisfactory for the more difficult potassium reduction. Most sodium is now prepared by the Downs process, in which a fused mixture of sodium chloride and either calcium chloride or sodium carbonate is electrolyzed to yield chlorine as well as the metal. Pure molten sodium chloride is not used because at the high temperature required to melt it (801° C, or 1,474° F) the vapour pressure of sodium metal is dangerously high, and sodium is appreciably soluble in the molten salt. With the fused mixture, a lower temperature (in the vicinity of 600° C, or 1,100° F) may be used.

Potassium metal was obtained in 1808 by chemists Joseph-Louis Gay-Lussac and Louis-Jacques Thenard of France by reduction of the hydroxide with iron; they packed the hydroxide and iron wire or turnings into a gun barrel, which was coated with clay and heated to white heat. During the same year, François-René Curaudeau prepared potassium by reducing potassium carbonate with carbon. During the following 50 years, various chemists studied this reaction to devise methods of separation and rapid cooling of the products; such methods were necessary to prevent the explosive compound $\text{K}_6\text{C}_6\text{O}_8$ from forming.

The processes that evolved were the forerunners of reduction methods using metals, such as magnesium and aluminum, or using compounds, such as calcium carbide,

hydride, or silicide. After high-vacuum techniques were developed, calcium could be used to reduce potassium to the pure metal in a vacuum; sodium vapour has been used similarly as a fairly successful reducing agent for potassium.

Electrolytic methods of preparing potassium entail decomposing the fused hydroxide, the cyanide, or a potassium oxysalt dissolved in a fused potassium halide.

Uses of the metals and their alloys. *Sodium.* Metallic sodium is used to manufacture sodium chemicals of technical importance, particularly sodium peroxide, sodium cyanide, sodium amide, sodium hydride, sodium azide, and sodium borohydride. Sodium is also used extensively in synthetic chemistry; *e.g.*, as a reducing agent and a drying agent.

Because sodium exhibits the photoelectric effect to a marked degree, emitting electrons when exposed to light, it has been used in the manufacture of photoelectric cells. Because of its relatively high heat capacity and high heat conductivity, sodium is used as a heat-transfer medium. In some types of nuclear reactors, molten sodium carries heat from the core of the reactor to a boiler for generation of steam. Metallic sodium is also being investigated as an electrical conductor, when properly protected from air and moisture.

Sodium-vapour lamps, in which gaseous sodium is made to glow inside a tube by an applied voltage, give a yellow-coloured light of good illumination characteristics and are extensively used for street and road lighting.

Potassium. Metallic potassium has few uses, the most important being the synthesizing of potassium compounds, such as potassium superoxide, KO_2 , used in protective breathing equipment. In the rebreather gas mask, the superoxide reacts with exhaled air to liberate oxygen and remove carbon dioxide and water vapour.

During the first half of the 19th century, metallic potassium was used to produce aluminum by the reduction of the chloride; magnesium, boron, and silicon were produced by a similar method. In 1854 it was found that sodium, which is cheaper, serves as well as potassium, and sodium was used for these purposes until electrolytic processes were developed. Sodium also replaced potassium in many other industrial processes. Potassium, however, still plays a role in certain organic syntheses.

A radioactive isotope of potassium, K-40, has been used to estimate the age of the Earth and some of the Moon rocks.

Alloys. Alloys of sodium and potassium serve as heat-transfer media, such as are described above for sodium alone. An alloy of 77.2 percent potassium and 22.8 percent sodium has been suggested as a liquid coolant for nuclear reactors. A potassium-sodium alloy takes part in the reduction of titanium tetrachloride to the metal.

Sodium-lead alloy often is substituted for metallic sodium as a reducing agent or a drying agent and is also employed in the manufacture of tetraethyllead, a common constituent of antiknock gasoline.

Compounds and their uses. *Sodium compounds.* Sodium chloride (common salt) is the most abundant form and the most important source of sodium. It is the main salt present in seawater, of which it comprises about 80 percent of the dissolved matter. Throughout the world there are extensive deposits of sodium chloride, which probably originated when prehistoric seas evaporated. It is a white, cubic crystalline salt, very soluble in water; the large crystals are transparent. Present in all body fluids, sodium chloride is essential to human and animal nutrition, and it is a food preservative and seasoning. Sodium chloride is important in the manufacture of soaps, dyes, ceramic glazes, leather, and other sodium-containing chemicals. (See also SALT AND SALT PRODUCTION.)

Sodium hydroxide, or caustic soda, the most important industrial caustic, is a white, deliquescent (moisture-attracting) solid that may be obtained from a solution of sodium chloride by electrolysis. It is highly corrosive to animal and vegetable tissue. The alkaline solutions it forms when dissolved in water neutralize acids in various commercial processes: in petroleum refining, it removes

chloride

sulfuric and organic acids; in soapmaking, it reacts with fatty acids. In the making of cellophane, paper, viscose rayon, and other products, its alkaline solutions enter into the treatment of cellulose and into the manufacture of many chemicals.

Sodium carbonate is a crystalline white salt soluble in water; in the technical grade, the anhydrous form is known as soda ash, and the decahydrate is known as washing soda. Its first industrial-scale manufacture was by the historic Leblanc process, which has since been supplanted by the Solvay process, or by electrolysis. (For descriptions of these processes, see CHEMICAL INDUSTRY.) A general cleaner, sodium carbonate has many industrial applications, and in medicine it is used to treat skin inflammations and to cleanse body orifices.

Sodium bicarbonate (sodium hydrogen carbonate), household baking soda, is a white crystalline powder or granular salt soluble in water; it is prepared principally from sodium carbonate. A source of carbon dioxide gas, sodium bicarbonate goes into the manufacture of effervescent beverages and baking powder and is a component of fire extinguishers. Medically, it counteracts urinary and stomach acidity, cleanses mucous membranes, and dresses burns.

Sodium sulfate, in water-soluble white powder or crystalline form is usually called mirabilite or thenardite when obtained from deposits or brines; the name Glauber's salt refers to the decahydrate $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$. Its uses include the dyeing and printing of textiles and the manufacture of glass and paper.

Sodium nitrate, a soluble crystalline white salt, occurs naturally in the impure form of Chile saltpetre (caliche) or is manufactured from sodium carbonate and nitric acid. It goes into the manufacture of chemicals, fertilizer, glass, pottery, enamels, matches, explosives, and dyes. It also serves as a meat-pickling agent.

Sodium peroxide, a yellowish-white powder made by heating metallic sodium in dry air, is an oxidizing agent for bleaching paper, cloth, wood, ivory, and sponges, and for purifying air in confined spaces, such as submarines and airplanes. Although not explosive in itself, sodium peroxide is dangerous and may react explosively with combustible substances, particularly if moisture is present.

Sodium sulfide, prepared by heating sodium sulfate with coal, is important in the manufacture of sulfur dyes and rubber. It is an intermediate compound in the production of other chemicals and a laboratory reagent.

Sodium fluoride is made from sodium carbonate and hydrofluoric acid. An insecticide and pesticide, it is poisonous and may be fatal to human beings if ingested; but when added in minute amounts to municipal water supplies, sodium fluoride reduces the incidence of dental caries.

Sodium alkyl sulfates are important intermediate chemicals that may be derived from petroleum; they are essential in the synthetic-detergent industry, in the dye industry, and in the processing of a number of different oils.

Sodium thiosulfate (sodium hyposulfite) is in the "hypo" solution with which photographers fix developed negatives and prints; it acts by dissolving the unchanged silver salts. It is also used to remove traces of chlorine from bleached paper and textiles.

Water glass is sodium silicate of varying composition; it may be in the form of dry powder, an amorphous mass, or a syrupy liquid. It is a binder in the manufacture of abrasive wheels, grindstones, glass, and porcelain. As a water solution, it was formerly used to preserve shell eggs. In the paper and textiles industries, water glass is used as a protective coating and fireproofing agent.

Sodium amide (sodamide) is a reagent used in the chemical industry to introduce amino groups into molecules, particularly in dye production. Made directly from sodium and ammonia, sodium amide is used in turn along with carbon at red heat to prepare sodium cyanide.

Sodium cyanide solution readily dissolves gold and silver metals in the presence of air and is used to extract these metals from their ores. A violent poison, it is also

used as an insecticide and as a source of the fumigant hydrogen cyanide. Sodium cyanide is an intermediate compound in the preparation of other useful chemicals, particularly for the manufacture of dyes, pigments, and nylon.

Sodium hypochlorite is a salt that is unstable, except when it is mixed with sodium hydroxide. Used in solution, it is a bleach, being used in the manufacture of paper, textiles, and other products, as well as in the household.

Potassium compounds. Potassium chloride, a white crystalline solid or powder, is the most abundant of the naturally occurring salts of potassium and closely resembles sodium chloride. Potassium chloride is used in various pharmaceutical preparations, as a fertilizer, and as a starting material in the manufacture of many important potassium compounds, including the hydroxide and the carbonate.

Potassium hydroxide, the caustic potash of commerce, is a white solid that can cause severe burns to human tissue. It dissolves in water to give a strongly alkaline solution. Deliquescent (moisture-attracting), it sometimes serves as a drying agent. Potassium hydroxide may be produced from a solution of potassium chloride by electrolysis. Formerly, it was prepared by reacting wood ashes (potassium carbonate) with slaked lime (calcium hydroxide), and from this primitive alkali, soap was made. Essentially, this was also the standard industrial method for manufacturing potassium hydroxide until the end of the 19th century, when it was superseded by the electrolytic process. Because it is more expensive than sodium hydroxide, the use of potassium hydroxide is somewhat limited, but it does go into the manufacture of soap, particularly liquid soap, and chemicals.

Potassium carbonate (potash) is essential to the production of Bohemian glass, soft soaps, fertilizers, and many inorganic chemicals. The first industrial-scale process for manufacturing this salt was an adaptation of the Leblanc sodium carbonate process, since replaced by a number of modern processes.

Potassium bicarbonate (potassium hydrogen carbonate), a white soluble salt, like sodium bicarbonate, is a source of carbon dioxide gas. It is used in baking powders and fire extinguishers and medically as a buffer for stomach and urinary acid.

Potassium sulfate is a constituent of a number of saline minerals. The colourless or white, hard rhombic crystals are used in fertilizers, in the manufacture of glass and alums, and as a laboratory reagent.

Potassium nitrate, also called **nitre**, or saltpetre, is a soluble crystalline white salt. As the quantity obtained from natural deposits is limited, it is prepared either from synthetic nitric acid and potassium hydroxide or from naturally occurring potassium chloride and sodium nitrate. It is a valuable fertilizer and has many other uses: in the manufacture of fireworks, matches, blasting powders, explosives, fluxes, and glass, and in the food industry for curing meats and pickling.

Potassium bromide, a white crystalline salt, is used in photography to make gelatin papers and plates, and in medicine as a sedative and an antiepileptic.

Potassium dichromate is a soluble, bright orange-red crystalline salt prepared from chrome iron ore. It is an important oxidizing agent in leather tanning, and in the chemical, paint, and dye industries. A corrosive poison internally, its dust is caustic to human tissue.

Potassium permanganate, a deep purple crystalline salt, dissolves in water to give beautiful purple oxidizing solutions, that are used as bleaches, deodorizers, dyes, and reagents in laboratory analyses. Medically, it is used as a topical astringent, antiseptic, and antidote for some poisons.

Sofia

The capital and the dominant political, economic, and cultural centre of the People's Republic of Bulgaria, Sofia (Bulgarian *Sofiya*) owes much to its crossroads location, a favourable site, good economic conditions, and mineral springs. Though it had an ancient foundation, centuries of Ottoman domination impeded its full development until 1878, when the town began to flourish following liberation from Turkish rule. A major transformation occurred after World War II and the advent of a Bulgarian Communist government. The city and immediate region had become the home of some 1,000,000 people by the time of the census of 1975. New housing projects and parks have added a modern flavour to a city once dominated by minarets, and Sofia has become one of the most attractive of Balkan cities.

The city lies in the southern portion of the Sofia Basin of the mountainous central western portion of Bulgaria and commands the geographical centre of the whole Balkan region. To the north lie the Balkan Mountains (Stara planina in Bulgarian). The Lyulin Mountains rise to the immediate west; the Lozen Mountains to the southeast; and the Vitosha Mountains, intimately linked with the territorial growth of the town, to the south. Although situated in a basin (the scenery of which adds much to its charm), Sofia is not isolated; convenient passes in the mountains encircling the basin, together with the deep gorges of the Iskŭr River, make communications with the rest of the country easy. Important routes connecting the Adriatic and central Europe with the Danube, the Black Sea, and the Aegean cross the mountain passes.

History. Traces of Neolithic settlements of the 4th millennium BC have been unearthed within the modern city limits, and in this respect Sofia is one of the oldest of European urban communities. The Serdi (or Sardi), a Thracian tribe, established a settlement near the hot mineral springs as early as the 8th century BC. This community was conquered soon after 29 BC by the Romans, who named it *Serdica* (Greek *Sardica*). During the reign of the emperor Trajan (98-117) it became the administratively autonomous town of *Ulpia Serdica*, and in the late 2nd century the community was strengthened by fortress walls and towers.

Inside the walls, the streets ran north-south and east-west according to a grid pattern and were paved with stone that covered a complex drainage and water supply system; in the centre of the community, monumental and richly ornamented public buildings arose. From the 3rd century, the town was the main centre of the Roman province of Inner Dacia (Dacia Mediterranea) and possessed the important privilege of issuing its own coins. Parts of the surviving Church of St. George date from the 4th century.

The community reached its greatest height under the

emperor Constantine the Great, and in 342 or 343 it was the site of an important meeting of Christian bishops, the Council of Sardica. From the later 4th century it was part of the Eastern Roman Empire, centred on Byzantium, and it was plundered by Attila and the Huns in 441-447. During the 6th century, Byzantine influence increased under the emperor Justinian, and the restored Church of St. Sofia, which later gave the town its name, survives from this period. In 809 the Bulgarian khan Krum seized the town and incorporated it in the Bulgarian state; it was given the Slav name *Sredets* (meaning "Middle," or "Centre"), and Byzantine authors began to refer to it as *Triaditsa*, the Greek equivalent. The community became a strong Bulgarian fortress and an important strategic and administrative centre. From 986 its walls were besieged by Byzantine troops, to which it fell in 1018. The town remained part of the Byzantine Empire till 1185 when the Second Bulgarian Empire was established.

From the 12th to the 14th century, *Sredets* was a developed handicrafts centre, with a brisk trade in goldsmiths' and ironsmiths' products, arms, and ornamental table pottery; toward the end of this period the town acquired the name of *Sofia*, from its reconstructed church. It fell to the Turks in 1382; the Ottoman governor of Rumelia (the name given by the Turks to the conquered Byzantine lands) took up residence there, and the town gradually acquired a distinctive Oriental appearance. By the time of the Crimean War, in the mid-19th century, it had declined to the status of a minor provincial community. The population nevertheless took an active part in the long national struggle for Bulgarian liberation and an independent Bulgarian church. Finally, in 1870, Vasil Levsky founded a revolutionary committee in the city. Sofia was liberated from Ottoman rule by Russian troops on January 4, 1878. Designated the Bulgarian capital on April 3, 1879, the town subsequently grew in both area and population, and its citizens headed the political struggles of the late 19th and earlier 20th centuries. The capital later played a leading role in the anti-Fascist movements of World War II; it was the headquarters of all the main resistance organizations, became the centre of the first zone liberated by the resistance forces, and became the seat of the coalition government set up in 1944. Reconstruction followed in the 1940s and '50s, and renewed expansion and development followed the adoption of a general urban plan in 1961.

The contemporary city. *Site and administration.* The modern city extends across the terraces of the Iskŭr River and its tributaries, the Vladayska, Perlovska, and Lesnovska, at the foot of the Vitosha and Lyulin mountains. The average altitude is 1,800 feet (550 metres), but it reaches almost 2,300 feet (700 metres) in the Vitosha foothills.

Sofia has a moderate continental climate, with a warm summer, a dry and pleasant autumn, a cold winter with substantial snowfall, and a cool, rainy spring. Fog occurs in the colder half of the year.

The city occupies a 65-square-mile (167-square-kilometre) area in the Sofia *gradska obshtina* (city municipality), divided administratively into seven sections. It is also the centre of the *okrŭg* (district) of Sofia and, in its function as administrative centre of the municipality, an *okrŭg* in its own right. The municipal People's Council (315 members) and its executive and administrative organ, the Executive Committee (17 members), headed by a president, direct the affairs of the city. The council and the committee are elected every two and a half years. The city proper population was 966,000 in 1975, that of the greater metropolitan area 1,000,000.

Economic life. Since the establishment of Communist government in Bulgaria in 1947, the social, economic, and cultural life of the city, as well as its physical appearance, have been transformed. More than half the working population is engaged in industry, the building trade, and transportation. Almost 15 percent of Bulgaria's workers and almost the same percentage of the country's large industrial enterprises are found in the city, which accounts for nearly 18 percent of Bulgarian

industrial output. The engineering and metalworking industries, with products ranging from locomotives to medical instruments, are the most developed, followed by ferrous and nonferrous engineering (including the Kremikovski metallurgical combine) and plants producing electronic components and equipment. The food industry (processing meat, flour, sugar, confectionery, as well as cigarettes and wine) is next in importance, together with the textile and clothing industries. Rubber, footwear, furniture and woodworking, paper, and chemical industries are also well represented. About three-quarters of the national printing industry is located in the city, including the plant in which eight of the 13 Bulgarian dailies are printed. There are television and radio stations.

An agricultural zone, characterized by fruit and vegetable growing and dairy farming, surrounds the city, and it is connected with neighbouring settlements by roads. An Outer Ring road, completed in the mid-1970s, greatly alleviated the traffic congestion in the city centre. Sofia is also the centre of Bulgarian air traffic and has scheduled flights to some 35 other countries; the city's railway stations handle more than 5,000,000 tons of goods and more than 25,000,000 passengers annually. Local transport needs are served by tramways, trolleybuses, and buses, while several cable lifts ascend the neighbouring Vitosha Mountains.

Sofia is also a growing commercial centre, with many specialized shops, hotels, and restaurants catering to local needs and to the growing number of tourists. Most commercial, administrative, and cultural life is carried on in the historic central core of the city, while new, multi-storied housing developments and industrial plants rise up on the periphery.

Cultural life, recreation, and health. Sofia is the home of the Bulgarian Academy of Sciences, the Academy of Agricultural Sciences, the Sofiiski Universitet "Kliment Ohridski" (University of Sofia)—the oldest establishment of higher learning in Bulgaria, founded in 1888 as the Sofia Higher Institute—and a number of other institutions of higher learning, serving, in all, some 30,000 students. The city also contains the Cyril and Methodius National Library, the National Art Gallery, the Ivan Vazov National Theatre and Opera House, an astronom-

ical observatory, and a number of museums. In addition to the restored St. George, Boyana, and St. Sofia churches, historical monuments include two mosques, one housing a fine archaeological collection, and the Alexander Nevsky Cathedral, erected to commemorate the gratitude of the Bulgarian people to the Russian liberators of 1878. The headquarters of the Bulgarian Communist Party and the mausoleum of the statesman Georgi Dimitrov are also noteworthy.

Recreational and health facilities include modern sports grounds and mineral baths and sanatoriums. The nearby beauty spots of the Pancharevo and Iskŭr gorges are popular tourist attractions, whether for weekend trips or summer vacations, and settlement is spreading to the foothills of the equally scenic Vitosha and Lyulin mountains. In the city itself, the parks add touches of greenery to the clean lines of the modern thoroughfares and buildings.

(D.Ko./Ed.)

Soft Drinks

Soft drinks are a class of nonalcoholic beverage, usually but not necessarily carbonated, containing a sweetening agent, edible acids, and natural or artificial flavours. Natural flavours are derived from fruits, nuts, berries, roots, herbs, and other plant sources. Coffee, tea, milk, cocoa, and undiluted fruit and vegetable juices are not considered soft drinks.

The term obviously was originated to distinguish the flavoured drinks from hard liquor, or "spirits." Soft drinks were recommended as a substitute in the effort to change the hard-drinking habits of early Americans.

The cola beverages, lemon, lime, orange, grape, and other fruit flavours, as well as ginger ale and root beer, are popular in most countries. Carbonated beverages without flavouring or sweetening are known as soda water, club soda, sparkling water, etc.; these may contain mineral salts.

There are many specialty soft drinks. Kava, made from roots of a bushy shrub, *Piper methysticum*, is consumed by the people of Fiji and other Pacific islands. In Cuba

people enjoy a carbonated cane juice; its flavour comes from the unrefined syrup. In tropical areas, where diets frequently lack sufficient protein, soft drinks containing soy-bean flour have been marketed. These provide a pleasant, inexpensive way to add protein to one's diet. In Egypt, carob or locust bean extract is used. In Brazil a soft drink is made using mat6 as a base. The whey obtained from making buffalo cheese is carbonated and consumed as a soft drink in North Africa. Some eastern Europeans enjoy a drink prepared from fermented stale bread. Honey and orange juice go into a popular drink of Israel.

HISTORY

Carbonated beverages and waters were developed from European attempts to imitate the popular and naturally effervescent waters of famous springs, with primary interest in their reputed therapeutic values. The effervescent feature of the waters was recognized early as most important. Jan Baptista van Helmont (1577–1644) first used the term gas in his reference to the carbon dioxide content. Gabriel Venel referred to aerated water, confusing the gas with ordinary air. Joseph Black named the gaseous constituent fixed air.

Numerous reports of such experiments and investigations were included in the *Philosophical Transactions* of the Royal Society of London in the late 1700s, including the studies of Stephen Hales, Joseph Black, David Macbride, William Brownrigg, Henry Cavendish, Thomas Lane, Joseph Priestley, and others. Duplication of the waters of Bad Pyrrnont, a spa in Germany near the city of Hameln, was one of the major objectives, probably because of the popularity of the spa and because of the relatively simple nature of the mineral content of the waters there.

Priestley's
contribution

In 1772 Joseph Priestley published *Directions for Impregnating Water with Fixed Air*. He had obtained fixed air for his experiments from a brewery near his house. In 1773 Priestley received the Copley Medal from the Royal Society of London for his reports concerning fixed air and mixture of waters with it. His reports emphasized the alleged medicinal value of artificially carbonated water.

Meanwhile, other European scientists were active in the field. Studies by Torbern Bergman, a Swedish chemist, were published in the reports of the Royal Swedish Academy of Sciences in 1775. Carl Wilhelm Scheele of Sweden was similarly engaged. Antoine Lavoisier, in France, identified the fixed air of Priestley as a combination of carbon and oxygen, which he called *gaz acide carbonique*. In England John Mervin Nooth developed special apparatus for preparing small quantities of effervescent waters. His report appeared in 1775 in the *Philosophical Transactions* of the Royal Society.

Improvements in the Nooth device were made by João Jacinto de Magalhães in 1777. In 1781–83 the English chemist Thomas Henry described apparatus for the production of carbonated waters on a commercial scale. Many others followed, and factories and bottling plants opened in Geneva, Paris, London, Dublin, Dresden, and several other European cities during the period 1789–1821.

U.S. investigators also were interested in carbonated water and its health values. As early as the summer of 1807, in New Haven, Connecticut, Benjamin Silliman of Yale College began producing bottled soda water on a commercial scale and opened a public establishment for dispensing it. In Philadelphia artificially carbonated waters were bottled and sold commercially by Joseph Hawkins, with machinery of his own invention. The firm was known as Shaw and Hawkins. Hawkins received a U.S. patent for preparation of imitation mineral waters in 1809, the first of record in this field.

PRODUCTION

All ingredients used in soft drinks must be of high purity to obtain a quality beverage. These include the water, carbon dioxide, sugar, acids, and flavours.

Water. Although water is most often taken from a safe municipal supply, it usually is processed further to ensure uniformity of the finished product; the amount of im-

purities in the municipal supply may vary from time to time. In some bottling plants the water-treatment equipment may simply consist of a sand filter to remove minute solid matter and activated carbon purifier to remove colour, chlorine, and other tastes or odours. In most plants, however, water is treated by a process known as superchlorination and coagulation. Here, the water is exposed for two hours to a high concentration of chlorine and to a flocculant, which removes such organisms as plankton (minute plants and animals); it then passes through a sand filter and activated-carbon purifier.

Carbon dioxide and carbonation. Carbon dioxide gas gives the beverage its sparkle and tangy taste and prevents spoilage. While it has not been conclusively proved that carbonation offers a direct medical benefit, carbonated beverages are used to alleviate postoperative nausea when no other food can be tolerated, as well as to ensure adequate liquid intake.

Carbon dioxide is supplied to the soft drink manufacturer in either solid (Dry Ice) or liquid form maintained under approximately 1,200 pounds per square inch pressure in heavy steel containers. Lightweight steel containers are used when the liquid carbon dioxide is held under refrigeration. Here, the internal pressure is about 325 pounds per square inch. As the carbon dioxide is used the liquid changes into a gas in which form it can be dissolved in water.

Carbonation (of either the water or the finished beverage mixture) is effected by chilling the liquid and cascading it in thin layers over a series of plates in an enclosure containing carbon dioxide gas under pressure. The amount of gas the water will absorb increases as the pressure is increased and the temperature is decreased.

Flavouring syrup. Flavouring syrup is made from sugar, either granulated or as a 67 or 76 percent solution known as liquid sugar. The sugar is dissolved or diluted with processed water. Desired flavouring substances are then added, along with edible acids and colouring. In some cases preservatives protect the beverage from rancidity or microbiological spoilage.

Finishing. There are two methods for producing a finished beverage. In the first, the syrup is diluted with water and the product then cooled, carbonated, and bottled. In the second, the maker measures a precise amount of syrup into each bottle, then fills it with carbonated water. In either case, the sugar content (51–60 percent in the syrup) is reduced to 8–13 percent in the finished beverage.

The blending of syrups and mixing with plain or carbonated water, the container washing, and container filling are all done almost entirely by automatic machinery. Returnable bottles are washed in hot alkali solutions for a minimum of five minutes, then rinsed thoroughly. Single-service or "one-trip" containers are generally air- or water-rinsed before filling. Automatic fillers service from 30 to over 1,000 containers per minute.

Pasteurizing noncarbonated beverages. Noncarbonated beverages require ingredients and techniques similar to those for carbonated beverages. However, since they lack the protection against spoilage afforded by carbonation, these are usually pasteurized, either in bulk or by continuous flash pasteurization prior to filling, or in the bottle.

Powdered soft drinks. These are made by blending the flavouring material with dry acids, gums, artificial colour, etc. If the sweetener has been included, the consumer need only add the proper amount of plain or carbonated water.

Iced soft drinks. The first iced soft drink consisted of a cup of ice covered with a flavoured syrup. Today's sophisticated dispensing machines blend measured quantities of syrup with carbonated or plain water to make the finished beverage. To obtain the soft ice, or slush, the machine reduces the beverage temperature to between 22° and 28° F (–5° and –2° C).

PACKAGING AND VENDING

Soft drinks are packaged in glass bottles, tin or aluminum cans, plastic bottles, treated cardboard cartons, or in large stainless steel containers.

Vending of soft drinks had its modest beginning with the use of ice coolers over a half-century ago. Nowadays,

Superchlorination
and coagulation

most drinks are cooled by electric refrigeration for consumption on the premises. Vending machines dispense soft drinks in cups, cans, or bottles. There are two methods of vending soft drinks in cups. In the "pre-mix" system, the finished beverage is prepared by the soft drink manufacturer and filled into five- or ten-gallon stainless steel tanks. The tanks of beverage are attached to the vending machine where the beverage is cooled and dispensed. In the "post-mix" system the vending machine has its own water and carbon dioxide supply. The water is carbonated as required and is mixed with flavoured syrup as it is dispensed into the cup.

ECONOMIC IMPORTANCE

The soft drink consumption pattern throughout the world is unknown. However, it is believed that the United States and Canada are the leaders in consumption of this type of beverage. In the U.S. some 2,970 (1970) soft drink plants produce in excess of 72,000,000,000 carbonated soft drinks on an eight-ounce size basis per year. This amounts to more than 355 per person per year. Currently in the United States 55 percent of carbonated soft drinks are sold in returnable bottles, 30 percent in one-trip containers, and 15 percent through cup vending machines and fountains. In other parts of the world soft drinks are sold mainly in returnable bottles. Canned soft drinks are becoming popular in countries such as Australia, Canada, the Philippines, and England.

Soil Mechanics, Applications of

Soil mechanics is concerned with the use of the laws of mechanics and hydraulics in engineering problems related to soils. Soil is a natural aggregate of mineral grains, with or without organic constituents, formed by the chemical and mechanical weathering of rock. It consists of three phases: solid mineral matter, water, and air or other gas. Soils are extremely variable in composition, and it was this heterogeneity that long discouraged scientific studies of these deposits. Gradually, the investigation of failures of retaining walls, foundations, embankments, pavements, and other structures resulted in a body of knowledge concerning the nature of soils and their behaviour sufficient to give rise to soil mechanics as a branch of engineering science.

History. Little progress was made in dealing with soil problems on a scientific basis until the latter half of the 18th century, when the French physicist Charles-Augustin de Coulomb published his theory of earth pressure (1773). In 1857 the Scottish engineer William Rankine developed a theory of equilibrium of earth masses and applied it to some elementary problems of foundation engineering. These two classical theories still form the basis of current methods of estimating earth pressure, even though they were based on the misconception that all soils lack cohesion, as does dry sand. Twentieth-century advances have been in the direction of taking cohesion into account; understanding the basic physical properties of soils in general and of the plasticity of clay in particular; and systematically studying the shearing characteristics of soils—that is, their performance under conditions of sliding.

Both Coulomb's and Rankine's theories assumed that the surface of rupture of soil subjected to a shearing force is a

plane. While this is a reasonable approximation for sand, cohesive soils tend to slip along a curved surface. In the early 20th century, Swedish engineers proposed a circular arc as the surface of slip. During the last half century considerable progress has been made in the scientific study of soils and in the application of theory and experimental data to engineering design.

A significant advance was made by the German engineer Karl Terzaghi, who in 1925 published a mathematical investigation of the rate of consolidation of clays under applied pressures. His analysis, which was confirmed experimentally, explained the time lag of settlements on fully waterlogged clay deposits. Terzaghi coined the term soil mechanics in 1925 when he published the book *Erdbau-mechanik* ("Earth-Building Mechanics").

Research on subgrade materials, the natural foundation under pavements, was begun about 1920 by the U.S. Bureau of Public Roads. Several simple tests were correlated with the properties of natural soils in relation to pavement design. In England, the Road Research Board was set up in 1933. In 1936 the first international conference on soils was held at Harvard University.

Today, the civil engineer relies heavily on the numerical results of tests to reinforce experience and correlate new problems with established solutions. Obtaining truly representative samples of soils for such tests, however, is extremely difficult; hence there is a trend toward testing on the site instead of in the laboratory, and many important properties are now evaluated in this way.

Engineering properties of soils. The properties of soils that determine their suitability for engineering use include internal friction, cohesion, compressibility, elasticity, permeability, and capillarity.

Internal friction is the resistance to sliding offered by the soil mass. Sand and gravel have higher internal friction than clays; in the latter an increase in moisture lowers the internal friction. The tendency of a soil to slide under the weight of a structure may be translated into shear; that is, a movement of a mass of soil in a plane, either horizontal, vertical, or other. Such a shearing movement involves a danger of building failure.

Also resisting the danger of shear is the property of cohesion, which is the mutual attraction of soil particles due to molecular forces and the existence of moisture between them. Cohesive forces are markedly affected by the amount of moisture present. Cohesion is generally very high in clays but almost nonexistent in sands or silts. Cohesion values range from zero for dry sand to 2,000 pounds per square foot for very stiff clays.

Compressibility is an important soil characteristic because of the possibility of compacting the soil by rolling, tamping, vibration, or other means, thus increasing its density and load-bearing strength.

An elastic soil tends to resume its original condition after compaction. Elastic (expandable) soils are unsuitable as subgrades for flexible pavements since they compact and expand as a vehicle passes over them, causing failure of the pavement.

Permeability is the property of a soil that permits the flow of water through it. Freezing–thawing cycles in winter and wetting–drying cycles in summer alter the packing density of soil grains. Permeability can be reduced by compaction.

Capillarity causes water to rise through the soil above the normal horizontal plane of free water. In most soils numerous channels for capillary action exist; in clays, moisture may be raised as much as 30 feet by capillarity.

Density can be determined by weight and volume measurements or by special measuring devices. Stability of soils is measured by an instrument called a stabilometer, which specifically measures the horizontal pressure transmitted by a vertical load. Consolidation is the compaction or pressing together of soil that occurs under a specific load condition; this property is also tested.

Site investigation. Soil surveys are conducted to gather data on the nature and extent of the soil expected to be encountered on a project. The amount of effort spent on site investigation depends on the size and importance of the project; it may range from visual inspection to elabo-

Collection
of samples

rate subsurface exploration by boring and laboratory testing. Collection of representative samples is essential for proper identification and classification of soils. The number of samples taken depends on previously available data, variation in soil types, and the size of the project. Generally, in the natural profile at a location, there is more variation in soil characteristics with depth than with horizontal distance. It is not good practice to collect composite samples for any given horizon (layer), since this does not truly represent any one location and could prove misleading. Even slight variations in soil characteristics in a horizon should be duly noted. Classification of the soil in terms of grain size and the liquid and plastic limits are particularly important steps.

An understanding of the eventual use of the data obtained during site investigation is important. Advance information on site conditions is helpful in planning any survey program. Information on topography, geological features (outcrops, road and stream cuts, lake beds, weathered remnants, etc.), paleontological maps, aerial photographs, well logs, and excavations can prove invaluable. Geophysical exploration methods yield useful corroboratory data. Measurement of the electrical resistivity of soils provides an insight into several soil characteristics. Seismic techniques often are used to determine the characteristics of various subsurface strata by measuring the velocity of propagation of explosively generated shock waves through the strata. The propagation velocity varies widely for different types of soils. Shock waves also are utilized to determine the depth of bedrock by measuring the time required for the shock wave to travel to the bedrock and return to the surface as a reflected wave.

Dependable subsurface information can only be obtained by excavation. A probe rod pushed into the ground indicates the penetration resistance. Water jets or augers are used to bring subsurface materials to the surface for examination. Colour change is one of the significant elements such an examination can reveal. Various drilling methods are employed to obtain chips from depth. Trenches or pits provide more complete information for shallow depths. Pneumatic or diamond drilling may be required if hard rock is encountered. At least a few of the boreholes should exceed the depth of significant stress that is established for the structure.

Avoidance of structural disturbance of the samples is not critical for some tests but is very important for in-place density or shearing strength measurements.

Complete and accurate records, such as borehole logs, must be prepared and maintained, and the samples themselves must be retained for future inspection.

Foundations. A foundation distributes the loads due to its own weight, the weight of the superstructure, and any forces acting upon them. The loads are distributed over the soil surface in such a manner as to avoid excessive stresses in the soil. Such stresses could induce rupture of the supporting soil, causing differential settlement and cracking of the structure.

Structural foundations may be divided into two categories: spread and deep. Each of these may be classified in various ways. Spread foundations include: spread footings, mats, and floating foundations. Deep foundations are of two main types: piles and caissons.

Spread foundations. Spread footings are small compared with the total area of the structure and are used to support individual columns or bearing walls. Factors governing their settlement include load size, depth below original grade, and groundwater level. A mat foundation generally consists of a thick reinforced concrete slab beneath all, or a major portion, of the structure. It provides support for structures containing heavy, widely distributed loads, as would be the case in bins or silos. Mats are not suited to buildings with large, open floor spaces owing to the unfavourable bending effects produced. A true floating foundation is boxlike in construction and extends to a depth below the ground surface such that the weight of the excavated earth equals the gross weight of the structure; thus, the contact pressures approximate the intensity and distribution of pressures exerted by the soil mass prior to excavation. Floating foundations are gener-

ally quite rigid, with the exterior foundation walls, and often the interior cross walls, integrated with the base slab. This entire substructure constitutes the floating foundation. Such foundations are normally employed when the soil has negligible bearing capacity or shearing strength.

Deep foundations. Piles, which are driven into the ground, are of two types: end bearing and friction. End-bearing piles are driven to the load-bearing stratum—e.g., bedrock. They are assumed to derive all their vertical support from the strong formation in which the lower end is embedded and none from the overlying material by which they are surrounded. In friction piles, on the other hand, the load is transmitted to the adjacent soil along the full length of the pile through friction and surface adhesion. Hence, the compressive stress in the pile itself decreases with depth, permitting the use of tapered piles, whose configuration helps transmit the loading to the soil. To support concentrated loads, a group of piles with a cap is often used, since it is impractical to locate and drive a pile precisely as required. Piles are commonly made of timber, concrete, or steel.

Caissons, being larger than piles, are constructed in excavations. A belled caisson is essentially a concrete pile cast in place in an excavation. It has an enlarged section or bell at the bottom of the shaft. Caissons of this type transmit the load to the bottom stratum, in the same way as a footing. Socketed or drilled-in caissons extend for a short distance into the rock formation, which has been excavated to form a socket. When excavating in soft or flowing formations, a casing may be used that later can be retrieved.

Sometimes it is necessary to add permanent support to an existing foundation, either to provide additional load-bearing capacity or greater depth. This is termed underpinning, and is most prevalent in urban areas. When the excavation for a new building is deeper than the adjoining structures, underpinning of those structures usually is required. It may also be necessary because of increased floor capacity in a building or addition of more stories, changes in subsurface stability (due to such factors as vibration or lowering of water level), or inadequate footing capacity during initial construction. Settlement invariably accompanies underpinning, but usually it is within tolerable limits. Precautions need to be taken to ensure that settlement is uniform throughout the building. During the operation, the bracing of both the underpinning and the building against lateral movement is of the utmost importance. Underpinning designs are similar to those for other foundations.

Slopes, embankments, and dams. Any ground surface that is inclined to the horizontal constitutes an unretained earth slope. Crustal movements or the processes of weathering, erosion, sedimentation, and transportation create natural slopes, whereas man-made slopes are formed by excavation or filling. Slopes used for engineering purposes include highway or railroad cuts, canal banks, open-pit mines, trenches, mill-tailing piles, levees, earth dams, and embankments for highways, railroads, and airfields.

All slopes are continually being degraded or flattened. This may occur imperceptibly by creep or erosion, or it may occur catastrophically as in a landslide. Surface soil particles are maintained in static equilibrium by the downward pull of gravity and by friction, cohesion, and other passive restraining forces. This equilibrium is readily disturbed by any increase in the downslope forces or decrease in resistance to sliding. Both may be accelerated by water. When the mass that has broken away from the main slope remains relatively intact, it is termed a mass slide. Some soils, especially clays, suddenly change from a relatively firm consistency to a nearly liquid state, causing flow slides. This change is generally induced by the presence of a critical amount of water. In granular soils, flows may occur due to liquefaction induced by vibratory motion.

Stability analyses are performed to determine the factor of safety of slopes. A factor of safety of 1.0 is assigned to a slope on the brink of failure. It is defined as the ratio of

Under-
pinningFloating
foundation

Deter-
mining
stability
of slopes

the restraining forces to the forces inducing motion; 1.0 indicates exact equilibrium. Generally, safety factors of 1.5 to 2.0 are employed, although values of 1.1 are acceptable for highway and railroad cuts, where failure would not present major hazards. For rotational slides—*i.e.*, slides along a curved surface—the trace of the failure surface may be approximated by a circular arc. Translatory slides—*i.e.*, slides along a flat or nearly flat plane—occur along a weak layer in the strata. The slope is considered as consisting of a block and wedges subjected to appropriate gravitational and resistance forces.

Improving drainage is often the first step in enhancing the stability of slopes. Although gravity flow is preferable, pumping occasionally is used. To protect against potential mud flows, it is essential to prevent entry of water into both surface and subsurface strata. Plant growth on a clay surface improves stability. Proper grading helps to provide positive runoff. Flattening of the slope increases slope stability but this may not be adequate protection in itself, especially against translatory slides.

Stability procedures used for slopes are generally applicable to embankments; however, an embankment induces a considerable loading on the existing soil. If the load distribution due to an embankment is known, it is possible to make an analysis of the stress conditions in the foundation so that the magnitude and direction of the principal stresses can be determined at strategic locations. Traditional photoelastic stress analysis techniques may also be employed. On the basis of these studies, the embankment design can be altered to reduce the undesirable stresses. Foundations of embankments may be stabilized by slope flattening, water drainage, compaction, grouting (injection of stabilizing substances, such as cement), or excavation and replacement by a selected material. It is imperative that the nature and magnitude of settlement be determined prior to initiation of construction, since these may affect the shape of the embankment and increase the cost of stabilization.

Embankments constructed for the purpose of creating reservoirs or diverting streams are referred to as earth dams or levees. The watertightness requirements for dams vary considerably with the purpose for which they are built, but in no case should the seepage be allowed to threaten the stability of the structure. Instability can result from seepage through the dam or from rapid drawdown (lowering of the water level on the upstream side of the dam).

Dams generally are designed with several distinct components. The central core consists of impervious material to minimize seepage. Sometimes a cutoff trench filled with impervious material is also located in the foundation. Occasionally, a concrete cutoff wall is provided in the core, and either this or sheet piling may extend into the foundation. The slopes of the dam are formed with pervious material; these are called shell sections. On the upstream side, the shell protects against the effects of rapid drawdown, while downstream it prevents deterioration due to seepage. Between the core and shell, transition sections of an intermediate grade material are placed. This material acts as a filter, preventing desilting or lateral movement of the fines (fine soil particles) from the core. Rock is often placed at the downstream slope and is covered with **riprap** (irregular rock fragments) to prevent damage by wave wash (see also DAM).

Pavements. Pavements are required for roads, highways, and airfield runways and taxiways. They are generally constructed on natural soil formations or fills. The load-carrying capacity and service life of such structures are governed both by pavement construction and the nature of the underlying soil. Many special methods of evaluating subgrade soils and selecting pavement materials have been developed.

Pavement construction generally begins with the preparation of the subgrade, which is accomplished by grading the ground to obtain the desired cross section and profile. Since the subgrade is the local material on which the pavement is built, no selection of material is possible. Limited modification takes the form of compaction and drainage. Subgrades have inadequate bearing capacity for

modern vehicles, and the capacity deteriorates due to weather, hence, the need for paving. Pavements may be classed as rigid or flexible, depending on the manner in which they distribute loads. A rigid pavement has sufficient strength in flexure to distribute a concentrated load over a considerable supporting area. Portland cement concrete pavements are considered to function in this manner. Such pavements may rest directly on the subgrade, but generally they rest on a base course of sand, gravel, or stone. Flexible pavements are flexurally weak but are designed with sufficient thickness so that the stresses on the subgrade are relatively low. These pavements have two components: a base course of granular material and a specially treated wearing course. The lowermost layer may be referred to as the subbase. The wearing course, which is abrasion resistant and provides weatherproofing, may consist of crushed stone bound with asphalt. The nature of the subgrade, pavement loading, traffic volume, and climate determine pavement thickness (see also ROADS AND HIGHWAYS).

Underground excavations. The methods used to make underground excavations or tunnels depend on the nature of the soil or rock in which the facility is to be located and its intended purpose. Excavation methods may be classified as hard rock, soft ground, immersed tube, and cut-and-cover.

Hard rock. Although some hard rock tunnels are now driven with tunnelling machines or "moles," most of them are still excavated using drilling and blasting techniques. Machine tunnelling results in a smoother wall surface, which, since it has fewer stress concentrations, makes possible the use of a thinner lining. When blasting is employed for large tunnels, often a small pilot heading or "monkey drift" is driven ahead of the main excavation. In addition to providing an extra free face for rock breakage, it permits accurate geological studies.

Soft ground. In soft ground tunnelling, machines are used more commonly. The drilling and blasting method, however, is also employed. When tunnelling through a stiff clay, for instance, a method known as the liner-plate method may be used. Light liner plates, strengthened by steel ribs, are installed to support the clay before the concrete lining is placed. The shearing strength of the clay and the width of the tunnel are important considerations when using this method. The unit pressure on the footing for the temporary lining is dependent on tunnel width, and if it exceeds the shear strength, intolerable settlement or even failure may occur. Compressed air may be used during construction to reduce the pressure on the clay until a permanent lining is installed. This technique is also very useful in restricting the flow of water into the tunnel, but is most successful only in the smaller diameter tunnels. In tunnels of larger section it is preferable to employ the shield.

In the shield tunnelling method, a metal shield is forced forward into the ground by means of a set of hydraulic jacks located around the periphery of the shield. The stroke of the jacks is made equal to the width of each ring of lining. After the shield has been thrust forward, the jacks may be relieved of pressure and the lining segments positioned. These then serve as the reaction frame for the next thrust forward. The shield prevents loss of ground radially, and the face soil is allowed into the shield through openings in the face of the machine.

Immersed tube. Immersed tube techniques are best for underwater tunnelling. A trench is dredged, with slopes depending on soil characteristics and prevalent current velocities. Then a series of tunnel shells, built of steel or reinforced concrete, with ends closed by temporary bulkheads to permit flotation, are towed into position and sunk. The shell sections are then joined.

Cut-and-cover. In the cut-and-cover method of excavation, frequently used in subway construction, a long trench is dug, the tunnel lining is put in place, and the tunnel is covered over. It is an economical method, especially for shallow tunnels. Sheet piling and other appropriate measures need to be taken to prevent flow of material into the trench, which could cause settlement of adjoining ground and buildings.

Base
course

Dam
com-
ponents

Since the full weight of the overburden comes to bear on the tunnel lining only some time after construction, the permanent lining must be designed to support this full weight (see also TUNNELLING AND UNDERGROUND EXCAVATION).

(M.M.S.)

Soil Organism

The soil, often considered to be lifeless and inert, contains vast numbers of living organisms, which range in size from microscopic single cells to small mammals. One square metre of rich soil may contain more than 1,000,000-000 organisms.

IMPORTANCE OF SOIL ORGANISMS

As decomposers. Soil organisms are important because they improve soil fertility by breaking down plant and animal tissues; during this process, the nutrients that are released and the minerals that are fixed are incorporated into the soil. Soil flora and fauna break down dead plant material into a finely divided organic complex called humus; the exact composition of humus is unknown, but it probably contains a small proportion of water-soluble organic substances, many phenolic compounds, some organic phosphates, and a polyuronoid substance containing complex sugars. It consists of about 60 percent carbon; the ratio of carbon to nitrogen is about 10 to 1 (*i.e.*, the nitrogen content is about 6 percent). Soil animals incorporate the humus into soil, where it is gradually broken down by micro-organisms that release its constituents for plant nutrition.

As pests. Some soil organisms are pests of crops or animals. Growth of a single crop favours the proliferation of specific soil animals that feed on roots; these organisms then become pests and may kill the plants or cause decreased crop yields. Among the soil animals that feed on, or in, roots are nematodes, slugs and snails, symphylids, beetle larvae, fly larvae, caterpillars, and root aphids. Millipedes and springtails may occasionally attack growing roots, although normally they feed on decaying matter. Some soil organisms cause rots such as those in potato wart disease and potato blight (see DISEASES OF PLANTS). Some soil micro-organisms release substances that inhibit the growth of higher plants, and some soil animals are intermediate hosts for organisms that cause animal diseases, particularly those caused by nematode or helminth parasites.

Pesticides and other soil pollutants affect the populations of many soil organisms. Some soil invertebrates are susceptible to pesticides. The active predatory species often are killed first, allowing the numbers of their prey to increase; for example, populations of springtails increase when their mite predators are killed by DDT. Other agricultural practices decrease the populations of soil organisms. Although the ecological balance of the soil is changed by pesticides, the total numbers or weight of soil organisms is not always decreased. Persistent pesticides affect the fauna over long periods of time. Herbicides, which may kill the soil microflora, often affect the soil fauna indirectly by killing some of their plant foods.

GENERAL FEATURES OF SOIL ORGANISMS

Types of soil organisms. *Protists.* Many of the micro-organisms in the soil participate in breaking down organic matter, in soil formation and fertility, and in returning mineral elements to the soil. The smallest and most numerous soil micro-organisms are bacteria; these spherical, rod-shaped, or spiral cells usually reproduce by simple division and survive unfavourable periods as resistant spores; they are more numerous in alkaline than in

acid soils. The actinomycetes resemble both bacteria and fungi; actinomycete spores, although similar to those of bacteria, germinate into very fine colourless mycelia (or threads) that resemble those of fungi. Such fungi as molds, mildews, or mushrooms are usually larger and more variable in form than either bacteria or actinomycetes; they prefer acid soils. They also have resting spores, which germinate into actively growing, straight or branched, white or colourless mycelia (threads) that produce fruiting bodies on which spores develop. There are also algae, which are found as motile single cells or non-motile filaments and contain pigments (*e.g.*, chlorophyll); they are most abundant near the soil surface (see Figure 1).

Microfauna. The soil microfauna, which are usually defined as animals less than 100 microns long, include single-celled protozoans, some smaller nematodes, small flatworms, rotifers, and tardigrades (eight-legged arthropods); the microfauna feed on micro-organisms. The abundant soil protozoans range from the shapeless amoeba to forms with whiplike flagella or tiny hairlike cilia; all protozoans have a nucleus, multiply by cell division, and form resting cysts. Much of the microfauna is confined to water films in litter and soil.

Mesofauna (Meiofauna). Other soil animals, somewhat larger than microfauna, have been placed in a heterogeneous group called the mesofauna. Many of them are nematodes, which are bisexual, survive unfavourable conditions as eggs in resistant cysts, and feed on micro-organisms, other soil animals, decaying organic matter, or living plants. The mites (Acarina), which are the most numerous arthropods in soil, have eight legs when adult and feed on plant or animal material; some are important in breaking down organic matter. Springtails (Collembola), which are wingless insects commonly found in soil, feed on decaying organic matter and micro-organisms; collembolans that live near the soil surface have a springing organ, which enables them to leap. Small, wingless, insect-like organisms called proturans lack antennae and eyes and probably feed on fungi; members of another arthropod group, the paupods, have nine pairs of legs when mature and feed on decaying plant material.

Macrofauna. The most common soil animals in the group known as the macrofauna are potworms (Enchytraeidae), small, white, segmented worms that feed on fungi, bacteria, and decaying plant material. The myriapods include the small white symphylids, which have 12 pairs of legs and feed on plant roots or decaying material; the centipedes (Chilopoda), which are many-legged, long, slender arthropods that prey on other soil animals; and the millipedes (Diplopoda), which have many legs arranged in pairs and feed principally on decaying plant material. Among the other macrofauna are slugs and snails, which eat mostly plant tissues and organic debris. Among the soil-inhabiting insects are fly larvae, and beetles and their larvae; some of these are predatory but most feed on decaying matter.

Megafauna. The megafauna are the largest soil organisms and include the larger earthworms, which pass both soil and organic matter through their guts, and several vertebrates (*e.g.*, moles, mice, hares, rabbits, badgers, gophers, snakes, lizards), whose food habits vary. The earthworm is important in maintaining soil fertility.

Vertical distribution of soil organisms. The vertical distribution of soil organisms is not uniform; most of them are concentrated in the litter layer and the top two inches of soil in woodlands. It has been calculated that as much as 90 percent of the soil fauna may be in this upper stratum. Many soil invertebrates move up and down through the soil either daily, seasonally, or in response to changes in temperature or moisture in the upper soil. Some invertebrates penetrate deep into the subsoil, usually moving through cracks and fissures. The vertical distribution of micro-organisms follows that of organic matter; as a result, much of the soil microflora is concentrated close to the soil surface.

THE ROLE OF MICRO-ORGANISMS IN SOIL

The most important functions of soil micro-organisms are to break down plant and animal organic matter and to

Humus

Effects of pesticides

Movement through soil

Figure 1: Types of soil organisms

help convert it into a form usable by plants. **Heterotrophic** soil micro-organisms, which derive their carbon and energy from organic materials, are concerned mainly with the breakdown of organic matter, the carbon cycle, and nitrogen fixation. Autotrophic micro-organisms, which obtain carbon from carbon dioxide and energy from the oxidation of simple organic compounds, form nitrites and nitrates and oxidize sulfur and iron compounds. Most micro-organisms produce carbon dioxide, which dissolves in water to form a weak acid (carbonic acid); this carbonic acid dissolves relatively insoluble soil minerals, which thereby makes these minerals available to plants as nutrients.

Since most functions of soil micro-organisms are beneficial, soils with large populations are usually naturally fertile. Micro-organisms are more numerous and more active in woodland soils than they are in pasture soils; these in turn have a greater microbial activity than fallow or cultivated soils.

The carbon cycle. One of the most important functions of soil micro-organisms is to recycle the carbon that is bound as complex substances in decaying plant and animal matter. Green plants convert carbon dioxide and water into organic plant substances. Animals eat these plants and convert their constituents into animal tissues. When plants and animals die, micro-organisms begin the decay process and complete the carbon cycle by liberating carbon dioxide to the atmosphere. They also liberate miner-

als (for example, nitrogen and sulfur) and such complex molecules as proteins, polysaccharides, and nucleic acids into the soil.

The nitrogen cycle. Nitrogen, because it is an important component of proteins, is an indispensable element for the growth of micro-organisms, plants, and animals. The availability of nitrogen in soil, in a form that is useful to plants, quite often influences natural vegetation and crop yields.

One essential role of soil micro-organisms in the nitrogen cycle is to break down complex nitrogenous compounds (e.g., proteins, polypeptides, nucleic acids) in soil and humus to simple inorganic compounds (ammonium ions, nitrite, and nitrate) that can be used by plants. Proteins can be decomposed by certain bacteria and fungi. Bacteria usually are most active in alkaline soils, whereas fungi are more active in acid ones. Micro-organisms may release nitrogen in the form of ammonium ions (ammonification); these ions may be oxidized to nitrates by other micro-organisms in a process that is known as nitrification.

Some micro-organisms (e.g., *Nitrosomonas* species) reduce nitrates to nitrites; others (e.g., *Nitrobacter* species) convert nitrites to ammonium ions; still others convert nitrites or ammonium ions back to gaseous nitrogen (denitrification). Soils may be depleted of their nitrogen in this way if no organisms are present to convert the nitrogen back into compounds useful to plants.

Nitrogen
fixation

Another essential role of soil micro-organisms in the nitrogen cycle is to return (or fix) nitrogen from the atmosphere; this can occur either by the activity of free-living micro-organisms or as a result of a symbiotic association between plants and micro-organisms.

Free-living micro-organisms capable of utilizing atmospheric nitrogen include bacteria (e.g., *Azotobacter*, *Clostridium*) and blue-green algae (e.g., *Anabaena*). Since many of these bacteria also can use ammonium ions and other nitrogenous compounds as nitrogen sources, they fix nitrogen only when alternative sources are not available. Their transformations are not as important as the symbiotic associations between plants and bacteria described below.

The genus *Rhizobium* causes the formation of root nodules on suitable leguminous plants as well as some trees and shrubs. The roots of the plants secrete substances that stimulate growth and multiplication of *Rhizobium* in the soil around the roots. During nodule formation, atmospheric nitrogen is fixed by these bacteria.

The sulfur cycle. Sulfur is an essential component of plant and animal tissues. Although abundant in nature, as much as three-fourths of soil sulfur may be bound in a form that is unavailable to plants. The most important forms of sulfur for plant nutrition are sulfate salts, although some sulfur in the atmosphere may be taken into plants through the leaves as sulfur dioxide gas. Soil micro-organisms release sulfur from organic compounds and form inorganic compounds; hydrogen sulfide, for example, is released into the atmosphere. Some autotrophic micro-organisms oxidize inorganic forms of sulfur into elemental sulfur, then to sulfurous acid, and, finally, to sulfuric acid.

Sulfates formed by the combination of sulfuric acid and calcium, magnesium, sodium, and potassium provide food for plants. Sulfates may be reduced to sulfites by specific bacteria in transformations that are similar to those that occur in the nitrogen cycle. In well-aerated soil, sulfates are formed readily; in oxygen-depleted soils, however, as are often common in swamps, hydrogen sulfide is produced.

(For additional information about biogeochemical cycles, see BIOSPHERE.)

Adverse effects of soil micro-organisms. Although most soil micro-organisms are beneficial, some are harmful. There are pathogens that cause root rots of higher plants; in greenhouses, for example, "soil sickness" may result from large populations of pathogenic organisms.

Micro-organisms sometimes compete with higher plants for available nutrients, particularly nitrogen and phosphorus. The addition of carbon-rich organic matter to soil often causes significant increases in the numbers of micro-organisms, which utilize the nitrates available in the soil, thus depriving higher plants of nitrogen.

Toxins

Another harmful effect of soil micro-organisms is their production, particularly under oxygen-poor conditions, of substances that inhibit or prevent the growth of higher plants and other micro-organisms. These toxic substances (e.g., methane, hydrogen sulfide, phosphine, skatole, indole, various organic acids) are found most commonly in woodland soils and in lesser amounts in pastures and plowed and cultivated soils.

Their concentrations are highest in summer and autumn and lowest in the spring. Soil can be detoxified by washing or flooding, by adding lime, by using fertilizers, and by cultivating frequently.

THE ROLE OF ANIMALS IN SOIL

Animals are usually not important in maintaining the fertility of agricultural soils. In woodlands, however, soil animals are essential; they maintain the cyclic breakdown of organic material, return organic matter to the soil, and improve soil structure. Soil animals feed on decaying organic matter, living plants, animal excreta, or other animals. The number of animals in a given area of soil is dependent on the availability of food, temperature, moisture, and the degree of aeration and drainage; several hundred million animals (with a fresh weight of as much

as a ton) are probably a valid estimate for the number of animals in an acre of soil (see Figure 2).

Figure 2: Characteristics of populations of soil organisms.

Formation of humus. Although they contain micro-organisms when they fall, leaves usually are unpalatable to soil animals until they have weathered for several weeks in a litter layer. During this period, after water-soluble materials (e.g., polyphenols) are leached out of the leaves, they are invaded by fungi and other microflora (called primary micro-organisms) and become damp and soft in texture. These changes render the leaf tissues palatable to various soil animals.

A period of intense invertebrate activity occurs; the invertebrates that attack litter at this early stage have been called primary soil animals (see Figure 3). They include millipedes, wood lice, fly larvae, springtails, oribatid mites, enchytraeid worms, and earthworms. Earthworms are important; the burrowing species, such as the "night crawler" (*Lumbricus terrestris*), break up large quantities of leaves before pulling them down into their burrows as food. During this fragmentation of the litter, the invertebrates initiate the conversion of leaf material into a medium suitable for the growth of microflora; for example, invertebrates increase the surface area of leaf tissues by feeding on them. The organic constituents of leaf tissues do not undergo much change, however, as they pass through the invertebrate intestines.

Some chemical changes occur during fragmentation of the litter by soil animals. A few complex molecules are broken down into simpler molecules; for example, certain invertebrates, with the help of symbiotic organisms in their guts, can break down complex substances such as cellulose, keratin, and chitin. The leaf litter and the feces of the animals are now suitable substrates for the growth of other micro-organisms, and a second wave of microbial activity occurs. These micro-organisms act on the organic matter to make it palatable to other soil animals (the secondary decomposers), which flourish only on pre-digested material.

The secondary animals, which feed on this and also on micro-organisms, include springtails, oribatid mites, and enchytraeid worms. Some secondary animals may also be primary decomposers, but different species usually are

Figure 3: Formation of humus.

involved. The arthropods produce distinctive feces in the form of fine pellets, and enchytraeid worms produce amorphous black feces. During this stage algae, protozoans, nematodes, and rotifers invade the fine water films that form on the surfaces of leaf fragments and animal feces. (Many activities of the soil fauna and flora are dependent on moisture; if the litter layer dries, many soil organisms encyst or enter a resting stage.)

The roles of the soil fauna and microflora in decomposing organic matter are complementary and interrelated. If soil animals are numerous, bacteria also are abundant. Consumption, digestion, and excretion of leaf litter by soil animals alternates with increases in the population of micro-organisms; as a result the proportion of humic sub-

stances in the litter increases and mixes thoroughly with other materials.

The soil fauna ultimately destroy the mesophyll tissues of the leaves, leaving only veins and toughened leaf margins. The rate at which destruction of the mesophyll continues is dependent on the moisture and temperature of the litter layer; destruction is rapid when the litter is moist and temperatures are high.

The organic matter of leaves, therefore, is continuously eaten and excreted by soil animals, acted upon by micro-organisms, and mixed with other soil materials. As this process proceeds, the cellulose, protein, and sugar content of the humus diminishes; the ratio of carbon to nitrogen decreases as starches and sugars in the litter are broken down to carbon dioxide and water. Mineral elements such as sodium, potassium, and magnesium are leached away gradually; eventually the humic substances that remain may represent as little as one-fourth of the organic matter in the original leaf tissues. The remainder of the content of the humus at this stage is lignin (a substance related to cellulose) and protein; fats, waxes, and other residual materials also are present.

Humus increases the porosity and the water holding capacity of soil and also acts as a reservoir for essential plant nutrients; these substances, released gradually, are made available to plants by the action of soil micro-organisms.

Soil fertility and structure. After the formation of humus, soil animals play an important role in soil fertility and structure. The incorporation of humus from litter into soil is a gradual process dependent on the activities of soil animals. In soil that contains small animals and a few micro-organisms, most of the leaves and wood fragments are not decomposed and lie on the soil surface; below the surface is a distinct humus layer, and soil horizons are defined; such a soil is said to be in a mor, or raw humus, condition.

When the soil flora and fauna are abundant, however, decomposition of plant material is rapid, and the humus is mixed into the soil so that layers or horizons are hard to define; such a soil is classified as a mull humus form.

The earthworms are important soil animals in temperate soils; they create the mull condition by turning over the soil—i.e., taking organic matter deep into the soil and bringing subsoil to the surface as "casts" (i.e., excrement). Estimates as to the amount of soil turned over in this way by earthworms vary from 3 to 24 tons per acre per year, with an average of 11 tons. This is equivalent to completely turning over all the soil on the earth to a depth of one inch every ten years.

Soil also is turned over by earthworm species that do not burrow or cast soil to the surface. Moles, which feed mainly on earthworms, also turn over large quantities of soil as they tunnel. In tropical soils, termites, as they construct mounds or gallery systems, are more important than earthworms in turning over soil. Many other animals distribute soil by tunnelling; in particular millipedes, wood lice, ants, and mollusks can turn over large amounts. An important aspect of soil turnover by animals is that it distributes micro-organisms to suitable substrates.

Soil animals also aerate and drain the soil as they dig their tunnels or burrows. Earthworms, termites, ants, wood lice, millipedes, centipedes, and mites break open soil that has been compacted and improve its aeration as they move through it.

Soil without animals lacks "aggregates." Mineral soil particles (particularly clay and lime) and organic matter are cemented together as they pass through the intestines of soil animals; when these substances are excreted they are in the form of water-soluble aggregates; millipedes, wood lice, and earthworms are particularly valuable in forming such aggregates.

Soil animals contribute to the turnover of soil nitrogen; their feces contain nitrogen in forms such as ammonia, urea, uric acid, and other compounds that are readily converted to substances that plants can utilize. It has been calculated that the amount of nitrogen excreted by an

Turnover
of soil

average earthworm population is about equal to the amount removed by an average crop of hay—i.e., about 50 pounds of nitrogen per acre; however, soil micro-organisms contribute much greater quantities of nitrogen. Organic matter bound in the tissues of soil animals is perhaps as much as a ton per acre, expressed as fresh weight. This is a reservoir of nutrients that is released gradually to the soil as the animals die.

Soils

Soil may be defined as the fine earth covering land surfaces that has the important function of serving as a substratum of plant, animal, and human life. Soil acts as a reservoir of nutrients and water, and absorbs and oxidizes the injurious waste substances that plant growth accumulates in the rhizosphere (i.e., the root zone). These functions of soil are possible because it contains clay minerals and organic substances (clay and humus form the finer part of soil) that absorb both ions (electrically charged atoms) and water.

Soil usually consists of a sequence of chemically and biologically differentiated layers, called horizons, that have been formed by the action of natural forces on the unconsolidated residue (regolith) of rocks and minerals on the Earth's surface. The regolith itself is the result of weathering of the original massive rocks at the surface and may be considered to be incipient soil. In the process of weathering, fracturing occurs along planes of weakness in the rocks and their mineral components react chemically with water, oxygen, and organic, carbonic, nitric, and sulfuric acids that are derived from the atmosphere and living organisms. Through the continuation of these chemical, physical, and biological actions and reactions, the regolith material is transformed into soil that exhibits one to four master horizons called, from the surface downward A, B, and C horizons (the soil profile), and the underlying consolidated rock, R.

Surface and subsurface horizons are distinguished by the differences in conditions at various depths. Some materials accumulate in the soil and some substances decompose or are dissociated to release compounds that may be dispersed, dissolved, or transported from one horizon to another; they may even be carried away from the immediate locality. Solutions are present in the soil layers, and these vary in composition and concentrations, and thus in the chemical changes they effect. These several conditions determine the abundance and variety of living organisms, from microscopic ones to vertebrates, which in turn influence the further development and the properties of the soil. In the soil profile that results, the horizons differ from each other in characteristics such as colour, chemical composition, particle sizes and distribution, and structure (i.e., arrangement of the particles in groups, aggregates, or independent units).

The A horizon extends from the ground surface to the unmodified regolith or consolidated rock. It is the horizon in which weathering is most intense, with partial removal of the resulting products and a zone of accumu-

lation of organic material. In a typical high-productive soil, the A horizon is rich in humus (more than 1 percent carbon) to a depth of 15 centimetres (6 inches) or more; it contains the greater part of immediately available plant nutrients. Soils of low productive capacity tend to have A horizons that are poor in humus and plant nutrients. The B horizon lies immediately beneath the A horizon and may reach a depth of 25 to 36 inches (64 to 91 centimetres). It is a zone of more moderate weathering in which there is an accumulation of many of the products removed from the A horizon. Sometimes the B horizon is very clayey and impermeable, constituting a serious impediment to plant growth. In a productive soil water, air, and root penetration is easy to a depth of 75 centimetres (30 inches) or more and the water-holding capacity of the entire layer is 15 centimetres (6 inches) of available water, or more. The C horizon contains the parent materials, from which the A and B horizons are formed. The R layer is not part of the soil proper; it is an underlying layer that has properties much different from those of the C horizon immediately above it and that influences the soil by its position. Because of soil development factors that will be discussed in following sections of this article, some master horizons can be missing in certain soil profiles. For example, erosion may remove the A horizon; shortness of time or absence of key factors may preclude development of a B horizon; a shallow, weathered layer may be transformed completely into A and B horizons, so that no parent materials are left to constitute a C horizon; or conversely a deep regolith can screen the A layer to the point that the latter does not influence the properties of the overlying soil horizon.

There are many functions provided by soil that are important to man. Agriculture and animal husbandry produce more than 90 percent of man's food; together with forestry these soil-connected activities produce many other materials needed by man, such as wood, cellulose, textile fibres, and leather. The utilization of soil by agriculture, animal husbandry, and forestry is often termed "soil exploitation." Soil is necessary for dwellings, highways, airports, and recreation areas, and it also provides road fill and material for water retention structures and many other essential functions.

This article will treat soil formation and the influential factors involved, soil profiles, soil properties and their dependence on geographic factors, soil classification, and the geographical distribution of soil. Soil-plant relations and engineering properties are treated in the articles ECOSYSTEM and SOIL MECHANICS, APPLICATIONS OF, respectively. For coverage of the processes of rock weathering and the products involved, see WEATHERING and CLAY MINERALS. Certain special soil types are principally treated in the articles LOESS and DURICRUSTS, and the interaction of soils and climate is discussed in MICROCLIMATES. (See also HYDROLOGIC CYCLE for the role of soils in the world's water system.)

PROCESSES OF SOIL FORMATION

Clay formation. The most fundamental soil forming process is weathering. During the weathering process the crystals of feldspars and other silicate minerals are broken up, releasing chemical compounds such as bases, silica, and oxides of iron and aluminum (specifically the sesquioxides: Fe_2O_3 and Al_2O_3). Leaching (i.e., washing or draining away by percolation of water through the soil) removes most of the bases and some of the silica, and the remaining silica combines with alumina and forms crystalline clays.

The kind of crystalline clay produced depends on leaching intensity. Rapid leaching leaves little silica to combine with alumina and results in what are known as 1:1 clays consisting of a tetrahedral (silica) and octahedral (alumina) layer; slow leaching leads to the formation of 2:1 clays, consisting of one octahedral (alumina) layer sandwiched between two tetrahedral (silica) layers. In neither case is the result solely one of the two types, but 1:1 clay is predominant after rapid leaching, and 2:1 clay more abundant when leaching is slow (see Figure 1).

Ions are atoms or groups of atoms that have become

The weathering process

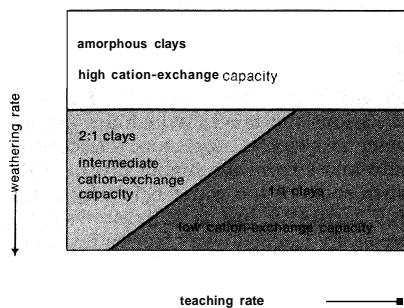

Figure 1: Influence of weathering and leaching rates on clay mineralogy and cation-exchange capacity; rates increase in the direction shown by the arrows (see text).

electrically charged through the loss or gain of electrons; ions of positive charge are cations and those of negative charge, anions. The phenomenon known as cation exchange is the result of the differences in the force with which clay holds different cations. The surfaces of clay minerals contain many negative charges, which are balanced electrically by the adsorption (*i.e.*, taking up on the surface, as opposed to taking up and distributing throughout the body of an absorbent) of cations. The tightness with which the soil holds cations varies; it is greatest for hydrogen cations and decreases for other cations in the following order: calcium, magnesium, potassium, sodium. Because of the differences in attractive forces, adsorbed cations may be removed and replaced by other cations. Because clay formation is very slow, for long time periods the silica and alumina constitute an amorphous (structureless) clay that has a cation-exchange capacity several times greater than that of crystalline clays. Alumina-rich 1:1 clays have low cation-exchange capacity. Silica-rich 2:1 clays have higher cation-exchange capacity, but lower than that of amorphous clays. Thus young soils and lower horizons that have undergone little weathering have high cation-exchange capacities per unit of clay, as do volcanic soils, because their weathering has been so rapid that clay formation has not had time to take place. Such capacity is lower in old soils in dry or cold climates, and it is lowest in tropical soils.

The most significant aspect of weathering is its relationship to clay crystallization or leaching, rather than its rapidity. Minerals differ greatly in their weatherability, and they have been classified in this respect. Clay crystallization seems to be accelerated by a basic medium, especially magnesium. Leaching is an irreversible process (see Figure 2), and thus the effect of a humid season cannot be undone by a dry season. What is important is leaching rainfall, *Ln.*, which is the difference between rainfall and potential evapotranspiration (*i.e.*, return to the air by direct evaporation or by transpiration of vegetation, or both) during the humid season. Leaching rainfall is low in temperate countries, even when they are humid (as in London and Moscow), and high in tropical countries, even when they have a long dry season (as in Kano, Nigeria). The prevalence of 1:1 clays in tropical countries is more directly the result of leaching rainfall (see Table 1) than of the great age of the rocks.

Rocks subjected to weathering, young soils, and soils formed from easily weatherable materials (*e.g.*, volcanic ashes, lava, or basalt) are rich in amorphous clays of high cation-exchange capacity. Such amorphous clays are mixed with 1:1 clays or 2:1 clays, depending on leaching intensity. Old soils and soils formed from materials that weather with difficulty are poor in amorphous clays and rich in 1:1 clays or 2:1 clays according to whether leaching is rapid or slow. Soil usually contains a great variety of clays that differ in their relative proportions.

In addition to the absorbing capacity for water and ions, which is the most important soil property, clay mineralogy affects such physical properties of soil as its structure and permeability to air and water. A soil rich in amorphous clays has a low apparent density and is very permeable to air and water; decay of organic matter is slow and humus content is unusually high. Soils rich in

1:1 clays usually have a stable structure and swell very little when moistened; on the other hand, a soil rich in 2:1 clays, mole especially montmorillonite, has a weak structure, low permeability, and swells easily when moistened.

Tropical soils are usually dominated by 1:1 clays, whereas those of temperate countries contain chiefly 2:1 clays. But pedology, the study of soils, began in temperate countries and is consequently based on what is observed in soils with 2:1 clays; it was some time before the fundamental difference between tropical and temperate soils was realized and understood. For analogous reasons, and because amorphous clays were lost when preparing clay sample for analysis, understanding of volcanic soils has been much delayed. It is only recently that they have been recognized as a special group. Even now the volcanic soils of dry climates are little known.

Mica is a platy silicate mineral that is directly altered (*i.e.*, changed in mineralogical composition) to clays. The first clays formed have high cation-exchange capacity; later 2:1 or 1:1 clays dominate, so that the foregoing outline of the weathering process is applicable to soils formed from materials rich in mica.

Experiments show that weathering is more rapid in a medium containing organic acids. Hence, when soil is covered by raw humus, as in podsol regions, amorphous clays are formed as a result of the rapid weathering.

By eluviation (the transposition of soil material from one horizon to another) an illuvial horizon is formed by the deposition of materials leached out of an overlying layer. The illuvial horizon of podsoles, called

Figure 2: Water movement in the soil. In general, water moves in the soil in only one direction—it descends. While descending it is absorbed by plant roots, and the substances it contains precipitate; in this way various substances are transported from the higher layers (horizons) to the lower ones. Under moderate rainfall, the quantity of water that is lost by drainage is little, if any, and only very soluble substances are eliminated.

the spodic horizon, is rich in amorphous clays and resembles **ando** (volcanic ash) soil in many respects.

Clay mineralogy is usually studied by X-rays and techniques of differential thermal analysis, which provide information on structural changes during heating. Soils may be classified on the basis of the relationship between cation-exchange capacity and clay content. Gradations between **ando** soils and those rich in the clay mineral kaolinite have cation-exchange capacity similar to those of soils dominated by 2:1 clays, but when conditions favour the formation of 2:1 clays, or the soil is young, volcanic soils exhibit very high cation-exchange capacities.

Humification. Second only to clay in importance as a soil constituent is organic matter, which contributes significantly to soil absorbing capacity. Roots die continuously, vegetation and crop residues fall on the soil surface and decay, and the organic leaching products enter the soil. Part of these residues is mixed with soil by organisms living in the soil or by tillage operations; some algae produce organic matter that also is added to soil.

All these residues are transformed by micro-organisms into a mixture of organic substances called **humus**. Two kinds of humus may be distinguished: (1) mild humus is dark in colour, well saturated with bases, especially calcium, rich in humic acids (of high molecular weight), and serves to stabilize clay; (2) raw humus is more red in colour, less basic, rich in fulvic acids (of low molecular weight), and favours dispersion of clay. Soil also contains organic matter that has not yet been humified and in certain cases peat, which is more or less carbonized material that still retains its original structure.

Vegetation determines the kind of humus a soil contains. Grasses produce mild humus rich in humic acids, and conifers produce raw humus rich in fulvic acids. But the base content of soils is also important in determining humus type; for example, calcium-rich soils produce milder humus than do hydrogen-saturated soils. Water-logging also has an effect, favouring production of raw humus. Root growth is more abundant near the soil surface, and aerial residues accumulate on the surface; thus, organic-matter content decreases with depth.

The effects of leaching. Except for the amount that is immediately evaporated from the surface, rainwater moves through the soil in only the downward direction, and

while descending it is absorbed by plant roots. Excess water may be eliminated by drainage, so that even in dry climates the upper layers of soil are somewhat leached. Leaching decreases with depth (see Figure 2). Descending water dissolves various substances, which are precipitated when the water is absorbed by roots. Descending water transports substances from the higher layers to the lower ones, and when some of the water is lost by drainage, the substances it carries are lost as well. More soluble substances are more easily leached away from a layer and are accumulated at greater depth. All chlorides and sodium, potassium, and magnesium sulfates are more soluble than gypsum, which is in turn more soluble than calcium and magnesium bicarbonates.

When there is no drainage, all substances remain in the profile, stratified according to their solubility (see Figure 3)—chlorides and sulfates at the lowest part of the **rhizo-**

Figure 3: Influence of leaching rainfall (Ln) on soil formation. Leaching rainfall increases from left to right, as shown by the arrow. D.P., desert pavement; A'e, surface horizon poor in humus and eluvial; Bt, textural B; ca, lime accumulation; sa, salts accumulation; Ah, surface horizon rich in humus; Ae, eluvial surface horizon; Eu, eutrophic upper soil; Dys, dystrophic upper soil (see text).

sphere (root zone of plants), gypsum above them, and calcium carbonate at a higher level. With more leaching the profile deepens, salts are leached away, gypsum accumulates in the lowest part of the rhizosphere, and lime above it. Still further leaching removes first the gypsum, while the lime accumulates in the lower part of the **rhizosphere**; then it removes the lime, and the soil becomes acidified. Because silica is less soluble than lime, 1:1 clays are usually formed in an acid medium, and are usually acid. But an acid soil may later be basified, and 1:1 clays are sometimes inherited from parent material, as in the case of **allochthonous** soils (*i.e.*, those transported from other environments).

Dispersion mechanisms of soil constituents. Biological transport of elements. Plants absorb various elements from the profile and deposit them, with their residues, on the soil surface, a process that counteracts leaching. In soils rich in bases leaching is more important. This accounts for the fact that base saturation and pH (the standard measure of acidity, related to the concentration of hydrogen ions; a pH value of 7.0 is neutral, whereas that from 1.0 to 7.0 is acid and that from 7.0 to 14.0 is alkaline) usually increase with depth. In acid soils, leaching is difficult because cations are firmly retained by soil colloids, and biological transport to the surface prevails; base saturation decreases with depth. In the **kaolisols** of the humid tropics, the upper 25 centimetres (ten inches) of soil often contain more bases than the rest of the profile to a depth of 150 centimetres (five feet). The process is selective, however; *e.g.*, sodium and magnesium are less absorbed by plants than are potassium and calcium.

Base
saturation
acidity

Types
of humus

Addition of constituents by running water and wind. Floodwaters always contain salt, and soil, when flooded, may become saline (*i.e.*, high in chlorides and sulfates of sodium, potassium, calcium, and magnesium) unless some of the water is lost by drainage. Floods sometimes deposit fine earth or coarse materials on the soil surface. Sea winds often bring salts, and some soils, such as those of New Zealand and the Falkland Islands (Islas Malvinas), have probably been salinized in this way. In other cases winds bring dust or volcanic ash, additions that may counteract leaching and modify the soil profile.

Subirrigation. In some soils there is a water table one to two metres below the rhizosphere. During the dry season water rises by capillary action from this water table to the rhizosphere, where it is absorbed by plant roots, and the substances it contains accumulate. In this way a horizon of salts, gypsum, lime, silica, or iron accumulation is formed, depending upon the substances that are contained in subirrigation water. When the accumulation takes place in a layer poor in clay, the lime, silica, or iron are deposited on the surface of sand or gravel and may cement them, forming a hardpan (cemented layer impenetrable by roots). Many calcareous horizons, duripans, fragipans, and iron pans have this origin, but they also may be cemented by substances that descend in the profile. When the water table is shallow, the hardpan may reach the soil surface.

Solonization. Sodium clay is easily dispersible, and in sodium soils it is transported from the surface to some depth. Sodium soils swell when moistened, however, which impedes clay movement, so that clay illuviation takes place near the surface rather than at depth. This process is called solonization, or solonetization, and results in sodium-saturated soils (solonetz) that have a richer clay horizon at depth than at the surface.

Leaching activated by vegetation, however, produces organic acids and transports calcium from the lower layers to the surface. Sodium then is replaced by calcium or hydrogen in the eluvial layer and the upper part of the illuvial one. Clay illuviation thus takes place at a greater depth, and soil becomes planosol or solod (calcium- or hydrogen-saturated soils with considerable difference in clay content between the eluviated surface and the clay illuvial horizon).

Planosols can also be formed directly from a slightly sodium-saturated soil; low sodium saturation is sufficient to facilitate clay dispersion and permits clay movement to greater depth. Solonetz are often formed from sodium-saline soils, and planosols from easily weatherable materials, such as volcanic ash, under conditions that impede leaching (*e.g.*, dry climate or poor drainage or both).

Iron and clay illuviation. Fulvic acids react with iron and may cause its eluviation and that of clay. For that reason, soils formed under forest vegetation, which produces humus rich in fulvic acids, are often leached; there is a difference in clay content between the surface horizon and the B horizon in which the clay is illuviated. Moreover, such soils are relatively rich in free iron, and a difference in free iron content is often observed between the surface horizon, which is poorer, and a lower enriched horizon. Because dispersed iron is easily precipitated by bases or concentration of soil solution, soils developed under conditions that favour the formation of fulvic acid-rich humus are usually rich in iron that is finely precipitated with organic matter, which gives them a brown colour (brunisollic soils).

Podsolization. Weathering in a strongly acid medium produces an eluviation of the sesquioxides (Fe_2O_3 and Al_2O_3) released by weathering. Because weathering is very rapid amorphous clays of high cation-exchange capacity are formed. The soil formed has an upper horizon rich in unweathered minerals (sand), and an illuvial one rich in amorphous clays ("spodic" horizon). Such soils are called podsoils. Although vegetation and other conditions may favour the accumulation of raw humus, its acidity is neutralized when soil contains lime or when weathering releases bases in sufficient quantity. Podsollic weathering is therefore observed in sandy materials rich in quartz and other minerals of low weatherability. The

organic matter that produces eluviation of clay or sesquioxides decays and cannot accumulate in the illuvial horizon; but when this horizon is waterlogged or when its temperature is very low, an accumulation of organic matter takes place and a humus illuvial horizon is formed. Such soils are called humus podsoils.

Rubification. When soil is thoroughly dried from time to time, precipitates of iron and organic matter cannot accumulate and the organic matter disappears by decay, causing irreversibly dehydrated iron sesquioxides to form. This process is known as rubification, and the resulting soils, called cinnamonic, are rich in fine crystallites of dehydrated iron sesquioxides.

Ferrugination. Iron sesquioxides adhere firmly to sand grains and gravel, give them a red colour, and may cement them to form an iron pan. This process is most common in soils that have been formed from materials that release much iron upon weathering and leave much sand, whereas humic horizons are seldom ferruginized, probably because organic acids and reductive processes remove the iron coating from sand grains. Fulvic acids favour iron eluviation and the formation of ferruginized horizons at some depth; thus, fragipans and other iron-cemented pans are common in podsoils and brunisollic soils. The ferruginous horizons of tropical soils are formed similarly, fulvic acids contributing to their formation, but reductive processes can also be responsible for iron eluviation. Periodic soil drying may consolidate iron coatings, especially in climates in which a humid and a dry season alternate. It seems that iron coatings protect sand and gravel grains from weathering, and they are the cause of many "stone lines" parallel to soil surface.

Segregation of iron. In soil that is rich in iron and poor in 2:1 clays that retain it, iron tends to segregate, forming irregular concretions and nodules. After repeated moistenings and dryings, the nodules become as hard as stone and may form a pan cemented with iron and gravel (laterite). Waterlogging seems to further iron segregation, and alternative moistenings and dryings harden the nodules or pan. This process resembles ferrugination, the difference being in degree of segregation.

Gleization. Under waterlogging conditions, iron becomes ferrous and has a valence of 2+. (Valence is an expression of the combining power of an element, which is determined by the number of electrons in its outer or valence shell of electrons; valence is represented by a number that corresponds to the number of electrons an atom of the element can accept [if the number is positive] or donate [if the number is negative]). Ferrous soil has gray-blue colours, is called gley, and the process is called gleization. When waterlogging is less severe and transitory, ferrous iron is oxidized (*i.e.*, loses an electron, with a resulting change in valence to 3+, which is that of ferric iron, Fe^{3+}), and ruggy mottles (spots) are produced in the soil. Because ferrous iron is more mobile than ferric iron, gleization favours iron eluviation, resulting in a leached upper horizon; iron accumulates at a lower depth or is leached away. Or the iron may ascend by capillarity from the water table to the lower part of the rhizosphere.

Development of soil characteristics. Soil profile and horizons. Humification, leaching, clay eluviation, and other soil-forming processes all create differences between soil horizons. Soil profiles vary considerably in horizon types and their thicknesses.

Soil properties. Both water-holding capacity and cation exchange depend on clay content, clay mineralogy, humus content, kind of humus, and nature of absorbed ions. Mineral constituents larger than clay also have some water-holding capacity, and in some cases silt exhibits considerable ion exchange capacity. This may be attributed to its formation by aggregates of amorphous clays or by amorphous clay that adheres to silt particles.

Soil texture (*i.e.*, the relative proportion of mineral constituents classified according to their size) determines to a considerable extent soil porosity and, consequently, permeability to air and water, which are essential for root life and many processes that take place in soil. A high content of coarse constituents usually increases porosity.

But clay and humus bind single soil grains together in increasingly larger aggregates.

Soil has a "structure" on which its porosity-permeability depends greatly. Soil structure is built up by alternate moistening and drying, and plant roots contribute greatly by opening pores between soil aggregates; it is undone by waterlogging. The stability of aggregates increases with humus content, especially humus that originates from grass vegetation (forest humus is less effective).

Calcium and hydrogen soils have structural stability, whereas sodium soils lose stability easily. Soils rich in amorphous clays are very porous and permeable, and their apparent density is exceptionally low. Soils rich in 1:1 clays are also permeable. High content of 2:1 clays, however, is usually associated with low permeability because the soil swells when moistened and the pores close. The clay type is very important; montmorillonite is the worst in this respect. Water movement in 2:1 clayey soils is chiefly through cracks produced when soil dries, and water movement in pores between small aggregates is very slow. Soils rich in coarse constituents are usually permeable. Soils with a high fine-sand content, however, have low permeability, poor aggregation, and small pores between single grains of fine sand; moreover, they are not extensible, and they resist root penetration.

Because soil horizons vary in texture, humus content, and absorbed ions, soil properties vary from horizon to horizon. This fact should be taken into consideration in evaluating the soil as a whole. Distinction must be made between intrinsic qualities—such as texture, clay mineralogy, the nature of absorbed cations, and their variation along the profile—and the secondary qualities that are consequences of the first and are more or less transitory—such as structure and permeability. Humus content and soluble salts are intermediary; they can be modified by management, added, or leached away.

From an agricultural point of view, the most important soil qualities are cation-exchange and water-holding capacities, the nature of absorbed cations, richness in assimilable plant nutrients and certain other substances (e.g., lime, free aluminum), permeability, structure, humus content, and waterlogging. For engineering uses, texture, clay mineralogy, humus content, swelling capacity, capacity to corrode metals, structure (which can be modified), permeability, and waterlogging (chiefly extrinsic), are important.

Horizon nomenclature. Usually the upper horizon, which is generally richer in humus and may be eluvial, is called A; it may be "humic" (Ah), eluvial (Ae), or "bleached" (A₂). The horizon in which clay has been illuviated is called Bt; that of amorphous clays produced by podsolization ("spodic" horizon) Bir (from iron, which was considered the most important illuviated substance); and that of humus illuviation Bh. Weathered material that has not been sufficiently enriched in humus to be humic and has not had important illuviation of clay or humus is called C. Underlying consolidated rock is called an R horizon.

A horizon of lime accumulation is usually called ca, but the term can be extended to all horizons that give effervescence with an acid. An accumulation of gypsum is indicated as cs; a horizon unusually rich in easily soluble salts by sa; cn designates an accumulation of ferruginous concretions and nodules; mf a ferruginous hardpan; mc a calcic hardpan; x a fragipan (fragil hardpan cemented with iron); G denotes strong gleying; g moderate gleying.

According to clay mineralogy a horizon may be allophanic, illitic, kaolinitic, or superkaolinitic, the diagnosis being chiefly based on the relation between cation-exchange capability (CEC) and clay content. According to base saturation, a horizon may be acid, neutral, natric, magnesian, or calcic. Fifteen percent sodium saturation is sufficient to make a horizon "natric." The terms acid and neutral are replaced by dystrophic and eutrophic (poor or rich in nutrients) in the case of kaolinitic and organic soils in which the relation of absorbed cations to clay content is a better diagnostic indicator than base saturation. Many of these terms are poorly defined in the literature, and definitions vary from author to author.

Rates of soil formation. Rates of soil formation vary enormously according to the process involved, and for the same process according to conditions. Weathering varies according to the weatherability of the material, and minerals may be classified in this respect. Weathering of a consolidated rock is usually slow at the beginning, accelerates as the rock breaks up and more surface area is exposed to attack, and then becomes increasingly slower as weatherable minerals disappear. It is accelerated by plant roots and by the accumulation of raw humus, and also by a rapid removal of the bases by leaching.

Weathering is more rapid than is usually thought. In experimental leaching of coarse gravel of basalt with pure water at 20° C (68° F), 0.45 percent of the silica was eliminated in 11 months. Leaching with water containing acetic acid (pH 2.5, which is a common acidity value in the vicinity of roots and decaying organic matter) accelerated the process by a factor of 21. Volcanic ashes weather sufficiently to support vigorous vegetation in a few decades.

Tombstones and other man-made structures weather more slowly because they are not in contact with plant roots or decaying organic matter, and, moreover, the surface of attack is very small.

Humification is a very rapid process. Experiments and agricultural practice all over the world have shown that soil organic matter can be doubled or reduced to half in 5–50 years. Podsolization is also rapid, and it has been reported that soils planted with conifers have been podsolized in a century. Salinization and desalinization are also rapid because of the higher solubility of salts less soluble than gypsum. Decalcification and acidification with water containing carbon dioxide are intrinsically slower but may be accelerated when produced by water containing organic acids, which is usually the case.

There is less information concerning clay eluviation, but experiments show that this is a relatively rapid process because water often moves through soil cracks, carrying much clay per unit of water. The formation of argillic (clay illuvial) horizons has been estimated to require between 550 and 5,250 years. In many cases the age of soil that has been formed in previously glaciated areas, newly formed terraces, or from recent volcanic material, is known; but it is not always possible to ascertain whether clay eluviation required all this time. In any case, existing evidence and the fact that soils correspond well to present climatic conditions indicate that soil formation processes are relatively rapid.

FACTORS INVOLVED IN SOIL FORMATION

Basic types of factors. *Climate.* The amount and kind of clay that is formed, soil depth, base saturation, and the formation and depth of saline, gypsic, or calcic horizons all depend on leaching intensity. Consequently, the significant factor is leaching rainfall (see Figure 3). The soils of temperate climates are rich in 2:1 clays, whereas those of tropical countries are rich in 1:1 clays. But in both cases when the soil is young, or has been formed from volcanic ashes, it contains considerable amorphous clays, which increase its cation-exchange capacity.

Temperature is another influence in soil formation. Because the solubility of silica increases with temperature, high temperatures favour the formation of 1:1 clays, which is another reason for the abundance of such clays in tropical soils. Water penetration and root penetration depend on leaching rainfall, so that the depth of weathering and of soil increase with Ln. Soils of tropical countries are usually very deep; those of cold or dry climates, or of both, shallower. Temperature is also important. At high latitudes and altitudes the lower layers of soil are very cold, even in summer; consequently, weathering and soil depth are limited, which is important in the case of autochthonous soils (i.e., formed in the original location) developed from consolidated rocks. Permafrost limits both soil depth and drainage. In very dry climates no water is lost by drainage. In dry climates substances formed by weathering accumulate in the profile, stratified according to their solubility, and as leaching increases the lower horizons disappear, and the profile becomes deep-

er. Finally, there are insufficient bases in the soil to neutralize the organic acids produced by decay of roots and organic matter. Solution in the soil then tends toward acidity, the soil is leached with acid water, and hydrogen ions replace other ions. The result of this cycle is an increasingly more acid soil. Acidification, however, also depends greatly on vegetation type, temperature, and waterlogging. In addition to the above direct influences, climate greatly affects vegetation, which is one of the most important factors in soil formation.

Drainage and topography. Leaching is impossible without drainage; thus, impeded drainage has to some extent the same effect as drought. Impeded drainage may result in the formation of soils with 2:1 clays, well saturated with bases, saline, gypsic, or calcareous horizons. It also causes gleization and may result in the formation of a water table, which has various influences, especially salinization and formation of various pans—petrocalcic horizons, duripan, ironstone, fragipan, laterite, etc. (see Figure 4). Topography greatly influences erosion, drainage, flooding, and subirrigation, which have a profound influence on soil formation, as has been discussed. Soils on slopes are usually shallow and stony (lithosols), and those in the valleys are alluvial.

Vegetation and living organisms. Vegetation largely determines the kind of humus that is formed. Some trees, especially conifers, usually produce raw humus that may cause podsolization. Other trees produce weakly acid humus capable only of producing iron mobilization and clay illuviation. Such soils are brown (brunisollic) and more or less leached. Grasses produce mild humus rich in acids that stabilize clay. The distribution of humus along the profile also depends on the type of vegetation. Grasses have numerous roots that decay rapidly and enrich soil in

humus to considerable depth. Tree roots contribute little to soil humus; thus, the humic horizon of forest soils is usually shallow (see Figure 5).

Vegetation protects soil from the sun's rays and retards organic matter decay; it absorbs calcium, potassium, and phosphorus from the lower soil layers and counteracts their leaching; and it protects soil against erosion. Erosion, even hydraulic, is severe in deserts because there is no vegetation to protect the soil. Living creatures within the soil such as earthworms and termites mix the various soil horizons and counteract their differentiation; they also mix soil plant residues on the soil surface and contribute to organic matter decay and humus formation. A certain mixing also occurs when old trees are uprooted by wind.

Parent material. Soil is parent material that has been altered by various processes, and its ultimate nature depends upon its original composition. In soils formed from unconsolidated sedimentary rocks, much of the clay is inherited from parent material. Materials rich in lime are difficult to decalcify, acidify, or podsolize. Materials rich in iron usually give red soils.

Time. Although in geological terms soil formation is rapid, in human terms it requires many decades or centuries. Soil age has a great influence on soil properties. The age of a soil usually is measured from the time the rock was first exposed to the surface or from the time the alluvial material was deposited. The time factor is not always clear because erosion and deposition are continual processes. Moreover, clay is often much older than the deposition, having been formed in one place and transported to another.

Young soils commonly have an undifferentiated profile. Saline, gypsic, and calcic horizons are formed more rapidly than those of clay accumulation, whereas a humic horizon may be formed in a few decades. Young soils are richer in amorphous clays and, under conditions that favour acidification, are less acid than old ones; pH increases with depth in young soils, and it decreases with depth in old ones.

Interaction of factors **and** processes. Any effect that each factor has on soil formation depends on the other factors; for example, the effect of climate depends on drainage, parent material, time, etc., and the other factors are similarly interdependent. Different soils are formed under the same climatic conditions according to drainage, parent material, time, vegetation, and other relevant influences; in like manner, different soils may be formed from the same parent material. Because soil is the result of various processes and each factor acts on several of them, it is better to relate soils to processes, and through processes to factors. The environment under which a soil is formed may vary during its formation: drainage may improve or deteriorate; exposure to such factors as erosion, flooding, or subirrigation may be ended or initiated; or there could be a change in vegetation. Thus soil does not always reflect the conditions under which it is encountered.

Climatic changes are very slow, and to affect soil formation appreciably they must be radical. A change in drainage will impede leaching, just as will a very drastic reduction of leaching rainfall; waterlogging may cause the formation of raw humus that produces podsolization in a warm climate, that otherwise favours organic matter decay and excludes podsolization, when drainage is normal. Little leaching rainfall is needed to leach a coarse soil; a great deal of rainfall is needed to leach a clayey soil. Acidification is faster and more extensive when parent material is poor in bases. For all these reasons, caution should be used when attributing the properties of a soil to climatic changes or, still more, when explaining climatic changes on the basis of pedologic evidence.

There are cases, however, in which such evidence is convincing. In Australia and Africa, soils rich in 1:1 clays are found in the desert; they have certainly been formed under a considerably more rainy climate. Because allitic weathering (that producing chiefly 1:1 clays) is deep, subsequent erosion and deposition merely transport

Figure 5: Influence of vegetation and humus on soil formation. such soils from one place to another. In some cases 1:1 clays have been transported great distances from where they were formed: in the delta of the Paraná, near Buenos Aires, there are soils with clays that came from the centre of Brazil, and many soils of northern India have 2:1 clays that have been formed in the Himalayas.

The frequent variation in conditions during soil formation, resulting in polygenetic soils, usually is more closely related to topography than to climate; also, the clay found in a soil may have been formed in past time or at a distant site.

SOIL GROUP CLASSIFICATION AND NOMENCLATURE

Observation of natural categories. The question of soil classification is a controversial one, but there is no doubt that classification should be based on categories that exist in nature, rather than on arbitrary creations of a classification system.

In a natural classification, groups are recognized and subsequently arranged in a system; the system may change, but the groups will pass almost unchanged from one system to another. Pedologists have approached soil classification in such a manner. Observing that some soils have an ashy surface horizon, resting on another darker in colour and richer in fine earth, pedologists called them **podsoils** (ashy soils). Other soils with a deep, dark horizon rich in organic matter and well saturated with calcium were termed **chernozems** (black soils). Soils of rather undifferentiated profile and of red colour were named **krasnozems** (red soils). In this way, groups of soils have been recognized and arranged in classification systems; although opinions differ as to how these groups should be arranged within a classification system, essentially the same groups exist for all pedologists.

The soil continuum. Because soils form a continuum, it has been difficult to follow the example of other scientists in categorizing on the basis of clear distinctions between groups. The same processes are involved in the formation of various soils, with the result that a soil may have the essential features of **ando** soils (amorphous clays) and those of **chernozemic** soils (deep humic horizon, dark and well saturated with bases) and thus be both **ando** and **chernozemic**. Soils may reflect many such heterogeneous conditions—for example, **chernozemic** (mollic) and **gleisolic**, **gleisolic** and **podsol**, and the like. Accordingly, soil classification must be manifold, recognizing that the same soil may belong to various groups. When this necessity is understood, the problem of soil classification is simplified, and the major categories shown in Table 2 may be recognized (see Figure 6).

Supplementary descriptions. Various other terms, denoting special features, also may be precisely and simply defined and included in soil nomenclature. For example: clay, loam, sand (referring to soil texture); lithosol (stony, gravelly); **regosol** (sandy); aeolian (formed by wind, dune); **hammada** (stony desert); and rock outcrop. Acid (H s.), natric (Na s.), magnesian (Mg s.), Ca soil, eutrophic, and dystrophic all refer to absorbed cations. Takyr and lunettes are special kinds of saline soils. Roof clays and sulfate saline clays (cat clays) are special kinds of clays. Gray-brown podsol, noncalcareous brown, **gray-wooded**, red-yellow podsol, and lateritic podsol are different kinds of **lessivé** soils; the first three have 2:1 clays, the later two are kaolinitic. Sod and humic are used for soils unusually rich in humus for their groups. Prairie, chestnut (**kastanozems**), and reddish chernozemic are different kinds of **chernozemic** soils. Podsolized, leached, or degraded **chernozems** are types of **brunisol** or leached soils or both. **Claypan planosols** are **planosolic** clays. **Serozems** are **rendzinas** lacking humic horizon. **Rubrozems** are **kaolisols** with a deep humic horizon. Red desert are mini-planosols (thin horizons). Mini-planosols, mini-solonet, and mini-podsols are **planosols**, **solonet**, or **podsoils** with thin horizons. Arctic browns are **brunisol** permafrost rankers. Terra rossa is a cinnamonic soil from hard limestone. Terra roxa is an **ando-kaolisol** intergrade soil. Terre de barre is a eutrophic latosolic kaolisol. Low humic gley is an acid gleisolic soil. Humic gley is a gleisolic chernozemic soil. Desert crust is an accumulation of products of weathering in virtual absence of leaching. Alluvial, desert, forest, forest-steppe, grassland, groundwater, lowland, mangrove, meadow, mountain, paddy, paramo, prairie, tropical, and tundra are environmental, nontaxonomic terms often used in soil nomenclature.

Seventh Approximation System. A system based on measurable soil properties rather than on theories of soil formation, the 7th American Approximation System, was introduced in 1960 and has expanded continuously by supplements. It is the first approach to precise definition of soil groups and pedologic terms, and, moreover, it has implicitly adopted manifold classification: adjectives (mollic, spodic, andic, etc.) are used to show relationships with other groups; names are formed by aggregation of formative elements that denote special characteristics, and consequently groups. Many of the groups named in the preceding section correspond in 7th Approximation to several taxa the nomenclature of which includes the corresponding formative element. For example, **andepts** and **andic** correspond to **ando**; **histosols** to **organic**; **spodosols** to **podsoils**; **vertisols** to dark clays. The formative element **aqu** denotes gleisolic; **natrarg**, **solonet**; **rend**, **rendzina**; **sal**, **saline**.

Indication of soil properties. Some formative elements show soil properties: **acr** denotes extreme weathering; **allic**, free aluminum; **anthr**, man-made soil; **arenic**, sandy; **calci**, calcic; **chrom**, high chroma (red colours); **dys** or **dystr**, dystrophic; **eu** or **eutr**, eutrophic; **gibbs**, presence of gibbsite; **hydr**, saturated with water; **lithic**, stony; **pale**, old (soil); **pell**, dusky colour; **psam**, sandy; **rhod**, red; **sal**, saline; **sider**, rich in free iron; **sombri**, dark colour; **thapto**, a buried soil is included in the profile; **vermi**, wormholes, worm casts, or filled animal burrows; **vitr**, **ando** rich in unweathered volcanic glass.

Identification of horizons. Other formative elements denote presence of certain horizons: **abruptic**, abrupt textural change; **alb**, albic horizon; **cumulic**, thickened humic horizon; **dur**, **duripan**; **ferr**, B horizon rich in free iron, or iron concretions or nodules; **frag**, **fragipan**; **glossic** or **gloss**, horizon **A₂** is tongued; **hapl**, typical profile; **hum**, unusually deep humic horizon, or humus podsol B horizon; **ochr**, light-coloured A horizon; **pachic**, thick **A**; **petrocalcic**, petrocalcic horizon; **plac**, thin pan; **plinth**, **laterite**; **ruptic**, broken (discontinuous) horizon; **stratic**, stratified horizon; **superic**, **laterite** in the surface; **umbr**, deep nonchernozemic humic horizon. Other formative elements of the nomenclature indicate the manner in which the material has been deposited: **fluv**; **alluvial**; **limnic**, **lacustrine**.

Table 2: Major Soil Types

Ando rich in amorphous clays	Organic extremely rich in organic matter; may have peaty and/or organic horizon
Brunisolic 2:1 clays; braunified or acid horizons	Podsoils eluviation of alumina and iron, usually producing ashy sandy surface horizon and illuvial horizon rich in amorphous clays
Chernozemic 2:1 clays; deep neutral dark humic horizons	Planosols clay eluviation produced by sodium; illuvial horizon not natric
Cinnamonic 2:1 clays; reddish colour; rich in dehydrated iron oxides	Rankers 2:1 clays; humic horizon resting on rock or permafrost
Dark clays 2:1 clays; rich in expanding clays; well saturated with bases	Raw 2:1 clays; undifferentiated soil profile
Gleisolic gray-blue colours or mottles due to waterlogging	Rendzinas high lime content
Kaolinitic tropical; rich in 1:1 clays; may have undifferentiated profile, or horizons rich in iron concretions or laterite	Solonchaks rich in salts such as chlorides, sulfate, etc.; related to gypsisols, rich in gypsum
Lessivé clay illuviation produced by organic matter	Solonet clay illuviation produced by sodium; natric illuvial horizon

Figure 6: Fundamental characteristics of some soil groups.

Specifications referring to reaction (acid, neutral) and to type of clay refer to the whole profile. Aa, albic (ashy) surface; Bir, iron podsol B (spodic); Ah, humus rich surface h; Ae, eluvial surface h; Bt, textural (clay illuvial) B; br, braunified; ru, rubified; G, gley; R, rockbed; Eu, eutrophic (rather well provided with bases) soil; Cn, ferruginous concretions and nodules; Lt, laterite; Dys, dystrophic (poor in bases) upper soil.

Climatic elements of the system. Although soil temperature and moisture are not intrinsic soil properties, they are used as diagnostic features in the 7th Approximation; i.e., soils are classified according to the climate in which they are encountered. Such formative elements include: bor, boreal; cryo, very cold; pergelic, permafrost; torri, torrid (usually dry); trop, small annual range of temperature; ud, usually humid; ust, dry but not long dry seasons; xer, long dry seasons.

The 7th Approximation System demonstrates that soil description, classification, and nomenclature may be achieved with few symbols that, in combination, can represent the enormous variety of soils existing in nature.

GEOGRAPHIC DISTRIBUTION OF SOILS

Because soil formation depends so much on climate, topography, vegetation, and parent material, soils vary in association with other geographic features, and soil regions may be distinguished in the same manner as climatic and vegetation regions. Such soil regions lend themselves to being further subdivided or combined into higher groups. Each region contains a variety of soils, many of which are also encountered in other regions, but the distribution of soils follows a definite pattern.

The concept of soil region is important from both a theoretical and a practical point of view. Theoretically, soil distribution is often the key to answering many questions about soils. From a practical viewpoint, it is difficult and costly to prepare detailed maps of soil locations, which can vary in short distances—sometimes within a few metres.

Polar regions. *Tundra.* Vegetation is scarce in tundra regions (see Figure 7) and consists of herbs and grasses that do not produce very acid humus. Rainfall in the tundra is low and leaching rainfall (Ln) is still lower: 40 millimetres (one in. equals 25mm) in Baker Lake, Northwest Territories; 20 in Eureka, Alaska; 60 in Resolute, Northwest Territories, Canada; 30 in Barrow, Alaska; 40 in Anadyr, 70 in Bulun, 50 in Nizhnekolymsk, and 40 in Russkoye Ustye, Siberia. The bases leached from the surface accumulate in the lower part of the profile and circulate in it through plants and by capillarity (soil surface is often humid and soils are shallow); moreover, drainage is often impeded by permafrost. Acidity is not sufficient to produce podsolization, but it reacts with iron to produce complexes that result in brunisolic soils. The soils formed, arctic brown, are relatively shallow; the pH increase with depth is more rapid than usual; and there is a tendency

The function of soil maps

cold dry

Figure 7 Distribution of soil regions with associated vegetation according to temperature and leaching rainfall (see text).

toward the formation of a humus-rich horizon on the surface of permafrost. In the drier parts of tundra, the lower horizons are often calcareous.

Waterlogging is frequent in tundra because of the presence of permafrost, resulting in the accumulation of organic matter, a prevalence of reducing conditions and peat formation. Gleisolic and organic (half bog) soils are frequent. The general pattern of distribution is arctic brown in well-drained sites to gleisolic and half-bog mini-podzols in depressions. Alternate freezing and thawing results in a patterned surface (polygonal).

Subglacial desert. In the subglacial desert vegetation is almost absent, weathering is very slow, and the soils formed are very shallow (lithosols, etc.). The limits of tundra and subglacial desert soil regions correspond rather well with the homonymous climatic regions.

Podsol regions. With a short summer and conditions not too frosty for forest, so that an evergreen coniferous forest prevails, a raw, highly acid humus is produced and podsolization takes place. The soils formed in well-drained sites are iron podzols.

In waterlogged sites organic matter accumulates, reducing conditions prevail, and gleisolic soils, sometimes organic, are formed. When there is no drainage, bases cannot be eliminated from the profile and soil is less acid, a condition common in the drier podsol regions. When there is a slow drainage, however, soil is acidified and becomes humus podsol, somewhat gleisolic and peaty. Such soils usually have heath or sphagnum vegetation.

Humus podzols are more common in atlantic regions because of their higher rainfall, than in continental regions. Hardpans are more common in atlantic regions. Some regions of Central Siberia have permafrost that interferes with drainage; moreover leaching rainfall is low, with the result that iron leaching is incomplete and the eluvial horizon is yellow rather than ashy. The yellow podzols may be considered as intergrades to arctic brown.

Brunisol regions. With a longer summer, deciduous forest prevails, which produces milder, less acid humus that forms brunisol soil, more or less leached. Where leaching rainfall is low and parent materials are calcareous or basalt, soils are neutral (braun erde); in the opposite rainy condition, soil is acid (brun acide).

The most important brunisol regions are in western Europe, the eastern United States, the state of Washington, and the adjacent Canadian coast. In western Europe, there are many small regions with calcareous materials, basalt, or loess, and low leaching rainfall. Braun erde abound; some of them are chernozemic or have a calcareous horizon at some depth or both. In the transition zone to the chernozemic region of North America, chernozemic braun erde (brown earth) and chernozemic lessivé (prairie) are common, and in the Appalachian Mountains, brun acide.

Chernozemic regions. A grassland vegetation with chernozemic soils occurs when spring is not dry, winter is relatively cold, and leaching rainfall is low. Calcareous,

gypsic, or salic horizons are frequent. Solonchaks, solonetz, and planosols—more or less gleisolic and chernozemic—are common in poorly drained depressions.

The most important chernozemic regions of the world are the Danube Basin and the southern Soviet Union in Eurasia, the Great Plains of the United States and the prairies of Canada, and the Pampas region of Argentina. But there are some differences among them. The parent materials of Russian chernozems are more calcareous and the leaching rainfall is lower (for the same humidity index). Consequently, soils are richer in lime; effervescence with hydrogen chloride begins immediately below the humic horizon or within it; clay eluviation and planosolic chernozems are not common; and the humic horizon is, in general, deeper and richer in organic matter. In the North American Great Plains, parent materials are less calcareous, lime is encountered at greater depth or not at all, clay eluviation is more frequent, planosolic chernozems more common, and the humic horizon is in general shallower and poorer in organic matter. In Argentina, parent materials are chiefly volcanic; cation-exchange capacity is unusually high (andic chernozemic); much sodium is released by weathering; clay eluviation is frequent; and planosolic chernozems, solonetz, and solonchaks are common.

The general pattern of soil distribution in chernozemic regions, is chernozemic soils in well-drained areas, with planosols, solonetz, and solonchaks, more or less chernozemic and gleisolic, in areas of deficient drainage.

Cinnamonic regions. In climates with dry seasons where soil is dried thoroughly to considerable depth, fine crystallites or irreversibly dehydrated iron sesquioxides are formed, giving reddish colours and cinnamonic soils. In cinnamonic soils organic matter decays rapidly and does not accumulate on soil surface. Humus originates chiefly in roots and it is well distributed along the profile. Many cinnamonic regions have a Mediterranean climate. Those with a monsoon climate are usually transitional to brunisol, chernozemic, desertic, or kaolinitic regions. Except for Australia, a Mediterranean climate is associated with mountainous topography and high frequency of limestones and volcanic materials; moreover, leaching rainfall varies considerably from zero to very high figures. Brown cinnamonic (bruns mediterraneans) and red cinnamonic (rouges mediterraneans) are common in areas with high leaching rainfall or ferruginous materials or both. They are sometimes acid and rich in 1:1 clays, being intergrades to kaolinsols (krasnozems).

Desert regions. Vegetation is very scarce in the desert, and soil erosion is very severe from wind and occasional rains; weathering is slow and shallow, and leaching is almost absent. Soils are very poor in organic matter and do not have a humic horizon.

Because sodium elimination is difficult, autochthonous soils are usually planosols and solonetz with very thin horizons (mini-planosols and mini-solonetz); a calcareous horizon usually underlies the B horizon. Soil is often covered by coarse material (desert pavement), which partly results from wind erosion and protects the soil. In such absolute deserts as the Chilean desert, however, products of weathering remain in the place of their formation and a loosely cemented desert crust is formed. Materials eroded from higher land accumulate in depressions, forming dunes and alluvial soils. Where waters accumulate, planosolic, solonetzic, and saline soils abound, and "salares" also are frequent. There are many good alluvial soils, however (rendzinas, chernozemic, etc.), and some of them are gleisolic.

The general pattern of soil distribution may be summarized as follows: high plateaus and plains areas exhibit autochthonous soils, mini-planosols, mini-solonetz, and solonchaks with salares (salt accumulations); slopes exhibit lithosols; and depressions exhibit dunes and alluvial soils, with many solonetz, solonchaks, serozems, and gleisolic soils with salares.

A distinction may be made between American (North and South), Asian, and African deserts. American deserts received much volcanic ash from active volcanoes, and mini-solonetz, mini-planosols, and duripans are plentiful.

The three chernozemic regions

Drained and water-logged conditions

Occurrence of mini-horizons

In Asia, calcareous materials abound, and raw (undifferentiated) soils that produce effervescence with hydrogen chloride are common. In Africa and Australia, palaeosols formed from kaolinitic materials are frequent.

Kaolinitic regions. The high leaching rainfall of tropical countries, even though there may be a long dry season, results in formation of 1:1 clays. Soils are usually acid in the lower horizons, whereas the upper horizon may be eutrophic. The difference between eutrophic and dystrophic soils, which is important from an agricultural point of view, seems well associated with the presence or absence of a dry season. A dry season, even a short one, activates decay of organic matter, favours fires, and interferes with the production of acid humus, which is the principal factor of acidification, several times more effective than water mixed with carbon dioxide.

In soils rich in 1:1 clays, waterlogging produces segregation of iron in the form of concretions or nodules. For that reason laterite is common in waterlogged areas, and, because it is impermeable, aggravates waterlogging and may reach the surface. In granite, gneiss, and similar materials, very common in Africa, the iron released by weathering may adhere to sand or gravel surfaces and cover them with a red coating. When soil is thoroughly dried periodically, such coatings become irreversibly dehydrated, protect the particle or gravel from further weathering, and a ferruginous horizon is formed. Such protection is insufficient in the upper horizon, where organic acids abound, and also in the lower horizons, which are waterlogged continuously; as a result, the ferruginous horizon is encountered at some depth. Some of the iron may come from the waterlogged horizons.

It is of interest that concretions of gravel and laterite contain unweathered material imprisoned in iron sesquioxides. Such material is virtually absent in the overlying and underlying horizons, indicating that both ferruginous horizons and laterite are formed at an early stage of weathering. This also indicates that stone lines of geologic origin may contribute to the formation of ferruginous horizons. It is, however, difficult to believe that there was a stone line parallel to soil surface each time a ferruginous horizon was formed. Ferruginous horizons and laterite are seldom found in soils formed from easily weatherable materials such as basalt, fine sand, and in continuously humid climates.

Young soils from volcanic ash are naturally ando in type. With time amorphous clays crystallize, cation-exchange capacity decreases, and soil becomes first terra roxa (intergrade ando-kaolinitic) and then kaolinitic. Terra roxa, however, is often made up of young soils formed from basalt and abound in basaltic slopes, where erosion does not permit soil to become old (Misiones, Argentina; coffee region, Brazil).

Mountainous regions. Erosion is the main characteristic of mountainous regions. The soils are usually young, consisting of lithosols and rankers in slopes and alluvial soils in the valleys and surrounding the mountain plains.

Three kinds of mountainous regions may be distinguished: humid-temperate, dry, and humid-tropical. In humid-temperate climates organic matter accumulates and there is an abundance of brunisolic soils (braun erde, brun acide). There are also lessivk and podsols, but many podsols do not have an ashy horizon. The spodic horizon, rich in amorphous clays, is overlain by a gray-brown horizon (brown podsols), and limestones often form lithosolic rendzinas. Acid humus and peaty soils, more or less gleisolic, are common in depressions.

In dry but not desertic mountains, grassland vegetation, sometimes scattered with woody plants, is common. Lithosols and other raw soils and rendzinas, basically cinnamonic and chernozemic, are widespread, with saline, solonetzic, planosolic, and organic, relatively gleisolic soils in depressions.

In humid-tropical mountains the growing season is longer and the growth index much higher; soils are deeper and richer in organic matter (some giant podsols have been found); otherwise they resemble those of humid-temperate climate of the same summer type. At lower altitudes kaolinitic weathering begins and forms kaolinitic

soils; erosion, however, results in soils remaining younger than in the lowlands, eutrophic soils and terra roxa are more frequent, and soils are also richer in organic matter. These characteristics partly account for the higher density of population in mountainous regions.

Intermediate and modified regions. Passage from one type of soil region to another is gradual, and intermediate regions can be recognized. Moreover, preponderance of allochthonous alluvial soils, waterlogging, or presence of a particular material justify separation of some regions from the main type.

In the transition belt from podsolic to brunisolic regions, the prevailing soils are podsols and lessivk (gray-brown podsolic), and the distribution is chiefly determined by parent material. In the transition between podsolic and chernozemic regions, Soviet authors recognize a forest-steppe zone with gray-wooded soils (lessivé with somewhat ashy horizon, better saturated with bases, and sometimes calcareous at some depth). Near this forest-steppe region are many sod-podsols (podsols with rather well developed humic horizon), attributed to cropping. An analogous transitional region in Canada occurs between the podsolic and chernozemic region.

The prairie soils in the United States are characteristic of the transition between chernozemic and brunisolic regions and may be considered as chernozemic lessivk or chernozemic braun erde. They are also found in the Danube Basin and other parts of Europe, and combine characteristics of both the chernozemic and brunisolic, or lessivé groups. The region of red-yellow podsolic soils of the southeastern United States may be considered as a transitional kaolinitic-brunisolic region with soils usually lessivé and very acid, usually low in cation-exchange capacity in comparison to their clay content. In other parts of the world, the transition between brunisolic and kaolinitic coincides with mountainous topography or special parent materials. The transition between brunisolic and cinnamonic regions in Europe is marked by cinnamonic-brunisolic intergrades (brun mediterraneans, southern braun erde, etc.); that between chernozemic and cinnamonic regions in the United States by reddish chernozems. The transition between cinnamonic and desertic regions in the United States is marked by reddish brown soils. Comparable soils are encountered in many parts of Asia, Africa, and Australia. Planosolic, solonetzic, and saline soils are common in these transitional regions.

In the transition between cinnamonic and kaolinitic regions, materials rich in easily weatherable minerals give soils with 2:1 clays, whereas 1:1 clays predominate in the opposite case, a condition that prevails in many parts of the Mediterranean Basin with high leaching rainfall and mild winters (e.g., Portugal). In Africa and Australia, however, many kaolinsols of such a transitional region are palaeokaolinsols.

Volcanic regions. Volcanic ashes have such great influence on soil formation that volcanic regions constitute a special group. Ando soils are frequent in volcanic regions. A distinction may be made between humid volcanic regions with acid ando, often deficient in phosphorus, and dry volcanic regions with soils well provided with bases, often chernozemic. Planosolic, solonetzic, and saline soils, and duripans or calcareous horizons, are frequent in dry volcanic regions and still more so in desertic ones, where planosols and solonetz become mini-planosols and mini-solonetz. Ando soils are usually fertile, and as a result settlements grow around volcanoes in spite of dangers. The most important volcanic soil regions of the world are: The Cordillera (mountain ranges) of North, Central, and South America; the entire Pacific Coast of these regions; the Great Basin of North America between the Cordillera and the Rocky Mountains, Mexico, and Central America; all the Cordillera of South America, the plains to the north and west, and many lands to the east; all of Patagonia, the Pampas region of Argentina, and to a certain extent the Chaco; many parts of the Mediterranean Basin, especially in Italy; Indonesia, the Philippines, Japan, and Kamachatka; and some parts of Ethiopia, Kenya, Uganda, Rwanda, Burundi, and Cameroon.

Nature of transition belts

Humid and dry volcanic soils

Water-logging and iron concretions

Alluvial and waterlogged regions. Some regions have alluvial soils of materials that came from regions of different climate. The most conspicuous examples are the alluvial region of northern Italy, one of the better agricultural regions of the world, and those of northern India and Indochina, which nourish a dense population or export much food. In Australia, and to a certain extent in Africa, are regions in which the soils have been formed from kaolinitic materials developed under different conditions; these regions may be called palaeokaolinitic.

In some regions waterlogging is so common that the soils may be called gleisolic. Some of them are podsollic, for example the southwestern coast of Hudson Bay in Canada, most of Finland, and most of northern Soviet Union. Others are chernozemic, as the "Pampa Deprimida" of Buenos Aires, Argentina. Still others are found in the transition region between chernozemic and kaolinitic soils of southern Brazil, Uruguay, and Corrientes, Argentina. Soils vary as a consequence: gleisolic humus podsoles and peat in the first case; gleisolic chernozemic planosols and solonetz in the second; chernozemic lessivé (prairie), chernozemic gleisolic (humic gley), dark clays (vertisols), planosols, acid gleisolic (low humic gley), kaolinitic podsollic (red-yellow podsollic), with krasnozems and terra roxa on basaltic hills in the third.

Some tropical regions have relatively young soils, many of which have been formed from calcareous materials. This is the case in the Yucatán Peninsula of Mexico, in the West Indies, and on the coral islands of Oceania. Their soils are predominantly brunisolic-kaolinitic.

Solar System

The solar system consists of the Sun and the complex assemblage of bodies, gas, and dust particles revolving

around it in closed orbits under the dominating influence of its gravitational attraction. For a detailed treatment of the various members of the solar system see SUN; INTERPLANETARY MEDIUM; PLANET, MINOR; COMET; METEOR; METEORITE; MOON; and articles about the planets under their individual names. Apart from the Sun, the known constituents of the solar system are the major planets; the planetary satellites (number for each planet shown in Figure 1); thousands of minor planets, mostly between Mars and Jupiter, of kilometre size and smaller; thousands or perhaps millions of comets with smaller mass still, most of them in elongated orbits; meteorites; and very tenuous dust and gas. A brief survey of the solar system as a whole is given here.

The solar system is usually defined as extending to the orbit of the outermost known planet, Pluto, about 40 astronomical units from the Sun. (The astronomical unit is equal to the semi-major axis of Earth's orbit, 93,000,000 miles, or 150,000,000 kilometres; see also below.) The solar system is sometimes considered to extend to the aphelia (the points of their orbits most distant from the Sun) of the comets with nearly parabolic (open) orbits, however, or to the edge of the roughly spherical region known as the solar cavity (the solar cavity is the volume of space, centred on the Sun, that contains the extremely tenuous interplanetary dust and gas). Then, the extent of the solar system is much larger, perhaps hundreds of astronomical units.

The Sun comprises more than 99 percent of the mass of the solar system. The rest consists of almost empty space traversed at wide intervals by bodies of relatively insignificant mass. These bodies may be grouped into two solar families: (1) the nine major planets (possibly ten, if the existence of a suspected planet beyond Pluto is confirmed), with 32 satellites attending six of them, and almost 1,700 known bodies of kilometre size called minor planets (formerly asteroids); and (2) several thousand or more comets, a horde of meteors and meteorites, and a thin cloud of interplanetary dust and gas. It has been estimated that there are 40,000 minor planets bright enough to be photographed with a 100-inch telescope. A long search with a large telescope might reveal still more satellites, especially of Jupiter and Saturn. New comets are discovered at the rate of several per year on the average. But it is very doubtful if any unknown distant major planets brighter than the 16th magnitude exist.

The solar system was thought for centuries to be the centre of the universe. Up to the 16th century, two conflicting theories were held. Some early Greek philosophers reasoned that the then known five inner planets revolved around the Sun, but this idea was later supplanted by the geocentric theory in which the Earth, not the Sun, was placed at the centre. As observations improved in accuracy, more complicated schemes became necessary to account for the motion of the planets. These in turn became inadequate; and, by the 16th century, the foundations of the theory of gravitation were laid.

Gravity controls the solar system, the motions of all bodies being consistent to a high degree of accuracy with the effects of gravitational attraction of the Sun and the other bodies. The planets are the only bodies massive enough for their effects to be appreciable, and their presence complicates the calculations; in practice the effects are comparatively small and are only included in computing the orbits of bodies that approach a planet closely. Usually only comets or minor planets in highly elongated orbits are affected, but a celebrated 19th-century case of investigation of the perturbation of one planet, Uranus, by another, then unknown, led to the discovery of the latter planet, Neptune.

The Sun. The Sun is the only star close enough so that its surface details can be viewed from Earth. All other stars are so distant that they appear merely as points of light even in the largest telescopes. In a sense Earth is in actual contact with the Sun since the solar wind, a stream of electrons and ionized atoms from the Sun (see below), passes through the Earth's orbit. Compared with the average star, the Sun is slightly more luminous, slightly larger and more massive, and slightly less dense. Its diam-

The two
solar
families

Relative sizes of the planets, arranged in order of distance from the Sun (but not according to their respective distances from each other), and the numbers of their satellites.

eter is 109 times the diameter of the Earth, and it is 333,000 times as massive. The temperature at the surface of the Sun is about 6,000° K and is believed to increase to perhaps 20,000,000° K at the centre. Although the density of material near the centre of the Sun is eight times the density of lead, it is gaseous throughout.

The Sun radiates at the rate of about 9×10^{25} calories per second, emitting enough energy to melt a 3,000-foot layer of ice surrounding it in 90 minutes. It heats the planets and other bodies that have only small or no internal heat sources of their own. This energy is derived from thermonuclear processes involving the transformation of hydrogen into helium. Although the Sun loses 4,000,000 tons of hydrogen per second in this process, it is believed that the Sun will continue to radiate at essentially its present rate for hundreds of millions of years.

The material lost by the Sun streams outward continuously (the quiet component) with additions (active component) from bursts of activity on the Sun's surface. This streaming, called the solar wind, can be detected in several ways well beyond the Earth's orbit. The outgoing radiation affects the direction of the gaseous tails of comets so that they turn away from the Sun. The magnetic lines of force around the Earth and Jupiter are also affected, being compressed on the side nearest the Sun and greatly elongated on the side away from it; this effect was first predicted by theory and later confirmed by direct measurements from space probes.

The active component of the solar wind comprises plasma (ionized gas) clouds that move out from flare regions on the Sun's surface at speeds reaching 2,000 kilometres (about 1,000 miles) per second. The material reaches the Earth a day or so later. Interactions with the particles and magnetic fields in the upper atmosphere produce aurorae and geomagnetic storms. Cosmic ray particles from very large flares have been detected also at ground level.

Size of the solar system. Distances within the solar system are measured in several units, usually in miles or kilometres or in astronomical units. Distances to the stars are much larger and are measured usually in light-years (the distance travelled by light in one year) or in parsecs (the distance at which half the difference in the direction of a star seen against the background of faint stars changes by one second of arc in six months). The six-month baseline for the measure of the direction of the star is the distance across the Earth's orbit—i.e., two astronomical units. Simple geometry relates the astronomical unit and the parsec. The astronomical unit serves as the link between the large stellar distances and the distances measurable on the Earth; knowledge of the scale

of the solar system is essential for connecting the larger and smaller units (see PARALLAX, ASTRONOMICAL).

The distance from the Sun to the outermost known planet, Pluto, is 39.4 astronomical units, whereas the distance to the nearest star is 1.33 parsecs (4.35 light-years). Highly elongated cometary orbits may extend to hundreds or thousands of astronomical units; but beyond Pluto there are vast volumes of almost empty space, so that the sparsely populated solar system is surrounded by even emptier space. Compared to the size of the Galaxy, of which it is part, it is an insignificant point; and it would be difficult, even from the nearest star, to detect the presence of any part of it except for the Sun itself.

The solar system is located just outside the galactic plane, or Milky Way, about two-thirds of the way out from the centre of the Galaxy. Its distance from the centre is about ten kiloparsecs. For comparison, one kiloparsec is 1,000 parsecs; one parsec is 3.26 light-years, or 206,265 astronomical units. The astronomical unit is equivalent to 150,000,000 kilometres.

The major planets and their satellites. *Basic properties.* The known major planets in order of increasing distance from the Sun are Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, Neptune, and Pluto. The terrestrial planets are Mercury, Venus, Earth, and Mars; the giant planets are Jupiter, Saturn, Uranus, and Neptune. Pluto, the outermost, is believed to be about 0.45 times the size of Earth, and its orbit crosses the orbit of Neptune. There are reasons for believing that Pluto may once have been a satellite of Neptune that escaped from its gravitational control. The terrestrial planets are of about the same size and mass as the Earth and are of high density, between about three and six times that of water. The giant planets have from 15 to 318 times the volume of Earth but have only about 20 percent the density of the terrestrial planets. Saturn is so light that an average piece of it, if available, would float in water. The high density of the terrestrial planets is attributed to their large metallic content. The giant planets are believed to consist mostly of the lightest elements, hydrogen and helium, which, deep in the interior, are probably in a solid or even metallic state.

Comparisons among the planets. A separate article on each planet describes individual characteristics. The following section deals with comparisons among them.

The Earth and Venus have been described as sister planets because their sizes, masses, and densities are roughly the same. Both have extensive atmospheres, but the composition of these are not the same. Venus has no moon. It is difficult to take the comparison further owing to observational difficulties caused by the extensive cloud cover

The
solar
wind

The
inner or
terrestrial
planets

on Venus. Surface relief and the existence of at least one probable mountain range have been discovered by radar. Oceans cannot exist on Venus because of the high surface temperature of about 700° K, and evidence is still poor regarding the existence of other features similar to geological ones on Earth.

Mars, though smaller than Earth, has some similarities, and more extensive photographic coverage in the 1970s is beginning to show the presence of many features on Mars that may have similar origins to those of their counterparts on Earth. Results from space probes sent to Mars and from radar studies in the early 1970s have allowed some direct comparisons between planetary details. Many Martian features suggest glaciation and erosion, possibly in long-past ages; they also suggest possibly still-active volcanism. Large areas resembling groups of calderas and craters have been photographed. Further, rifts and cracks in long double and single nearly straight lines and areas of intersecting sets of parallel rift systems have been found on Mars. All these can be matched on Earth. Many large height differences (up to several kilometres) have been found to exist on Mars.

Many Martian craters have counterparts on the Moon, which also shows large-scale systems of apparently tectonic lineaments (rills, raised ridges in intersecting sets of parallel systems).

Detailed knowledge of the outer planets and cross comparisons of the data may become possible during the 1980s. Pioneer 10, launched on March 2, 1972, is expected to pass close to Jupiter in December 1973. Jupiter is the only planet other than Earth that is known to have an appreciable overall magnetic field. Like Earth, it also has a surrounding magnetosphere.

The natural satellites. A satellite is defined as a body that revolves around a planet. It is thus distinguished from a planet by its motion rather than by any physical property. Mercury, Venus, and Pluto have no known satellites; Earth has one, Mars two, Jupiter 12, Saturn ten, Uranus five, and Neptune two. Some satellites are only a few miles in diameter, as in the case of the two tiny moons of Mars and the outer satellites of Jupiter. A few satellites are about the size of Mercury and Mars, as in the case of satellites Ganymede and Callisto of Jupiter, Titan of Saturn, and Triton of Neptune, each of which is about 3,500 miles in diameter.

Other constituents of the solar system. *Minor planets or asteroids.* The orbits of more than 1,600 asteroids have been computed since the discovery of the first asteroid in 1801. The size of these minor planets ranges from approximately 500 miles (800 kilometres) in diameter to one mile or less. Their total mass is estimated at only $\frac{1}{3000}$ that of Earth. Almost all of the asteroids revolve around the Sun between the orbits of Mars and Jupiter; but a few exceptional ones have elongated orbits that extend from Mercury to Mars, in the case of the minor planet Icarus, and from Mars to Saturn, in the case of the minor planet Hidalgo. Some of the exceptional asteroids, such as Hermes and Eros, have come within a few million miles of Earth.

Comets. Comets are bodies of great size but small mass. They are popularly pictured as bright stars flashing erratically across the sky, followed by long luminous tails. But few comets become bright enough to be seen without a telescope. Only those that approach the Sun closely enough have tails, and their motions are not erratic but, as with the planets, are in accordance with the law of gravitation. Apparent slight deviations from gravitational motion observed in a few comets, such as Encke's, may be caused by the action of forces within the comet's nucleus. The extremely tenuous material in the tails is deflected away from the Sun by repulsive forces stronger than gravity; such forces are caused by the solar wind and radiation pressure from the Sun.

In contrast to the nearly circular orbits in which the planets and most of the asteroids move, most comets revolve in greatly elongated orbits. Cometary orbits may also be inclined at any angle to the ecliptic (the plane of the Earth's orbit). The comets of short period, less than 100 years, move in orbits of moderate inclination. Hal-

ley's Comet is the only periodic comet that moves in a retrograde direction. A few comets revolve in nearly circular orbits.

Meteors and meteorites. A meteor, or "shooting star," refers both to the flashes of light occasionally seen darting across the night sky and to the objects that produce the light. Meteors may be solid objects no larger than a grain of sand or a pea. The glow is produced by collisions between the atoms of the meteor and the molecules of the air. Such meteors are consumed in the atmosphere of Earth at altitudes of about 60 miles (95 kilometres). Some solid bodies, having a mass of a few ounces to many tons, reach Earth. They are called meteorites. Micrometeorites a few microns in diameter sift through the atmosphere and reach Earth as dust particles.

When the Earth encounters a swarm of meteors moving in an orbit around the Sun, there occurs a meteor "shower," during which the number of meteors counted per hour may amount to several dozen or more. Very seldom does a display resembling a real shower occur. But there have been a few times when meteors appeared to stream from the sky as thickly as snowflakes. The orbital elements of some meteor swarms are so similar to those of certain comets that there can be no doubt that the comets and meteor showers are related. The meteoric material evidently originates from debris left behind by the disintegration of some comets.

Interplanetary material. Under favourable conditions a wedge-shaped glow may sometimes be seen along the ecliptic extending upward from the western horizon after sunset or from the eastern horizon before sunrise. This is the zodiacal light, which apparently originates from a swarm of dust particles surrounding the Sun in the plane of the Earth's orbit, or ecliptic, and extends out beyond the orbit of the Earth. The total quantity of dust must be very small, as it does not noticeably interfere with the motion of the inner planets.

Another phenomenon attributed to dust or meteorites is the gegenschein, or "counterglow," which may sometimes be seen as a faint hazy patch of light in the night sky always directly opposite the Sun. It is variously attributed to light reflected from meteorites or dust trapped by magnetic or electrical forces in the tail of the magnetosphere around the Earth in the direction away from the Sun.

Regularities in the solar system. So far as can be ascertained, there is not only a regular progression of diminishing surface temperature outward with distance from the Sun but also a change of chemical composition. The number of known satellites also varies in a possibly significant way (see the Table). The greatest number of satellites is found around planets near the minor-planet belt. Some of Jupiter's outer satellites may be captured minor planets; more than 40 of these little bodies, the Trojan planets, share Jupiter's orbit but are at some distance from the planet in two groups. The groups lie near one corner of two equilateral triangles, each of which has Jupiter and the Sun at the other corners.

The sizes of the planetary orbits, including the mean path of the minor planets as one, follow a curious rule, the Titius-Bode law, which has sometimes been considered to have evolutionary significance. This rule is as follows: If a series of fours be written down and three added to the second, 3×2 to the third, 3×2^2 to the fourth and so on, the sums are 4, 7, 10, 16, 28, 52, 100, 196, 338, 772, and so on. These numbers divided by 10 give a fair approximation to the planetary distances expressed in terms of the Earth's distance (one astronomical unit) up to the distance of Uranus, if the average size of the minor planet belt is taken as 2.8 astronomical units. It can be seen that five quantities called parameters are needed for the rule: the numbers 4, 3, and 2, the device of dropping the second term for Mercury (equivalent to making the power of 2 to be minus infinity for this planet), and the device of starting the series proper at Venus. Nevertheless, eight planets (counting the minor-planet belt as one) fit the rule, and it received much acclaim in the early 19th century when it led to the discovery of Ceres.

The relative sizes of the planetary orbits may have been determined largely by the local density of the primordial

material from which the planets formed. What is equally difficult to explain is why only one planet formed in each orbit. It may be that this was due to a local increase in density that served as a gravitational nucleus.

Movements
of the
planets

The nine major planets from Mercury to Pluto revolve around the Sun in the direction customarily referred to as direct. They move in elliptic orbits that depart only slightly from circles. The orbits lie nearly in the plane of Earth's orbit, which is used as a reference plane. Except for the orbit of Pluto, which has a tilt of 17°, no other planet has a tilt to this plane greater than 7°. The Sun also rotates on its axis in the direction in which the planets revolve around it. Most of the planets also spin about their own axes in the same direction as they rotate about the Sun. The exceptions are Uranus, the axis of which, nearly in the plane of the ecliptic, is tilted over so far that it revolves in a retrograde, or reversed, manner, and Venus, the retrograde motion of which is extremely slow. The direction of spin, if any, of the belt of minor planets between the terrestrial and giant planets is not known. Earth's Moon, the two satellites of Mars, eight of the 12 satellites of Jupiter, and nine of the ten satellites of Saturn revolve in this same direction. But four of the small satellites of Jupiter and the outermost satellite of Saturn revolve in a retrograde direction. These tiny bodies may be captured asteroids. This explanation is not so plausible, however, in the case of a large satellite of Neptune that also revolves in the retrograde direction.

All of the 1,700 asteroids for which orbits are known revolve around the Sun in the same direction as the planets and in about the same plane. Most of the asteroids also move in nearly circular orbits. As already noted, there are a few exceptional asteroids that move in elongated orbits, as do most of the comets. But there are also several comets that move in nearly circular orbits, like the majority of the asteroids.

Interactions among various bodies. Direct interaction among the planets does not now seem possible; but the paths of some of the smaller bodies, such as the minor planets, are easily perturbed, and comets are even more easily influenced by a close approach to one of the larger planets, particularly Jupiter. In this way, a small body could be deflected into a new path bringing it close to a large planet. Several of the minor planets, such as those named Icarus, Eros, and Geographos, have very elongated paths that bring them inside the Earth's orbit. Many comets have made close approaches, and in 1910 Earth passed (unnoticeably for most people) through the enormous but very diffuse tail of Halley's Comet. The chances of a direct hit are very low indeed, perhaps once or twice in the history of the solar system. Two unusual events in Siberia, however, at Sikhote Alin in 1947 and at Tunguska in 1908, have been attributed to the fall of a minor planet and of a comet, respectively. In each case, great explosions of unknown origin that devastated large, forested areas occurred. The arrival of meteors and meteorites is less rare, but a few records of damage to houses or persons due to the fall of meteorites are known.

Theories of the origin of the solar system. The orderly arrangement and motion of the planets and asteroids are impressive evidence that they form a true solar system. It seems impossible that such a system could have resulted from chance encounters between these hundreds of bodies. Another significant factor is the extreme isolation of the solar system. The nearest star is 60,000 times as far away as Pluto. The evidence is thus overwhelming that the members of the solar system had a common origin. Theories of the origin of the solar system have been of two general types: (1) origin by an orderly process of evolution, and (2) origin by catastrophe.

The classic example of the first type is the nebular hypothesis advanced by the French mathematician Pierre-Simon Laplace in 1796. He postulated a vast disc-shaped mass of cold gas in slow rotation, extending beyond the orbit of the farthest planet. As this nebula contracted under the mutual gravitation of its parts, its rate of rotation necessarily increased to conserve angular momentum. The angular momentum of a body rotating around a centre is the product of its mass, velocity, and the radius connecting it with the centre. It can be proved that the angular momentum of a closed system cannot change. If, for example, the radius decreases, the velocity increases proportionately so that the product remains the same. Eventually the rate of rotation increased so much that the centrifugal force at the periphery of the nebula exceeded gravitation, causing a ring of material to separate from the main mass. As contraction continued, other rings broke off at successively smaller distances from the centre.

Laplace's
nebular
hypothesis

These rings were not of uniform width all the way around. The densest portion gradually drew material to it and condensed into a planet. The satellites were formed by condensation from the contracting planets. The comets and meteors were presumably formed from material left over between the planets. Today the Sun is all that remains of the primeval nebular mass.

Laplace's nebular hypothesis was one of the most successful theories in the history of science. For a century it was practically unchallenged. About 1900, however, it encountered criticism that caused it to be discarded. The chief objection to the nebular hypothesis is the peculiar distribution of angular momentum found in the solar system. The planets, which possess less than 1 percent of the mass of the solar system, by some means have been able to acquire 98 percent of its angular momentum. Scientists cannot conceive of a natural physical process during which the angular momentum of a system could have been so unequally distributed. It is also more likely that matter would have separated from the nebula particle by particle rather than in the form of a ring.

One way to get a large amount of angular momentum into the planets is to put it there. This could be done by having the necessary energy forcibly injected from outside the system. A theory of catastrophe supplies the needed omission. Accordingly, the theory assumes that the Sun suffered a collision or near-collision with a passing star.

As the star approached, great tides were raised on the Sun. If the star came close enough, there was not merely a tidal bulge but also an ejection of matter from the Sun in the form of a long filament. The end of the filament tended to follow the star into space, causing it to move in a curved direction around the Sun. Some of the material also fell back on the Sun and started it rotating in the same direction as the revolution of the filament around it. According to this theory, the filament broke into separate parts that ultimately condensed into the planets. Again, the asteroids, comets, and meteorites consist of debris left over between the planets.

Objections
to the
catastrophe
theory

This theory sounds fairly plausible, but the calculations indicate that the ejected filament, instead of revolving around the Sun, would probably have followed along behind the passing star into outer space. To meet this objection the theory has been modified by assuming that the Sun was originally a double star and that the collision was with the Sun's companion. The colliding stars could have gone off in different directions, leaving the central part of the filament torn from them nearly motionless near the Sun. But highly heated material dragged from the interior of a star would be more likely to explode and form a thin atmosphere around the Sun, rather than condense into planets. The most serious objection to any encounter theory is the great distance between the stars, which makes the probability of two stars colliding practically nil. In an attempt to circumvent this difficulty it has been assumed that the filament was formed when a companion of the Sun exploded, becoming a nova.

Modern theories of the origin of the solar system generally reject catastrophic processes and prefer as their starting point a primeval mass of cold gas, as in the old nebular hypothesis. There would be considerable turbulence in such a large mass, with currents forming and dying down and forming again. Eventually this mass would break up into gas clouds or protoplanets. The material at this time would have been cold; but eventually, with contraction, the central mass would have become hot enough to radiate. The radiation would have caused the planets to lose much of their mass into space by evaporation. In this way the difficulty in connection with angular momentum is avoided.

It should be emphasized that no theory of the origin of the solar system has won general acceptance. All involve highly improbable assumptions. The difficulty is in trying to find a theory with any degree of probability at all.

Possible uniqueness of the solar system. With the largest telescopes a planet even as large as Jupiter cannot be detected revolving around the nearest stars. Hence there is no direct knowledge of any stellar planetary systems involving small planets. Stellar associations are common in the Milky Way. Probably more than half of the "stars" are actually binaries or systems of higher multiplicity. At least one star exists with a companion only 0.016 as massive as the Sun, or 17 times the mass of Jupiter. It seems reasonable to suppose, therefore, that many stars are accompanied by bodies of planetary dimensions.

BIBLIOGRAPHY. GEORGE ABELL, *Exploration of the Universe*, 3rd ed. (1975), contains chapters on the solar system written at an elementary level. Popular accounts include: FL. WHIPPLE, *Orbiting the Sun: Planets and Satellites of the Solar System* (1981); JONATHAN LEONARD and CARL SAGAN, *Planets* (1966); and WERNER VON BRAUN and FREDERICK I. ORDWAY III, *New Worlds: Discoveries from Our Solar System* (1979). V.I. MOROZ, *Physics of Planets* (NASA TT F-515, 1968; orig. pub. in Russian, 1967), deals mainly with planetary atmospheres; and W.M. KAULA, *An Introduction to Planetary Physics* (1968), deals with orbits and the solid bodies of the inner planets. *The Solar System*, ed. by G.P. KUIPER and B.M. MIDDLEHURST, 4 vol. (1953-63), contains much data that are still valid; reviews of recent work are given in the *Annual Review of Astronomy and Astrophysics*.

(D.G.R.)

Solid State of Matter

Matter in bulk may have several states or phases; the most familiar of these being the gas, liquid, and solid states. Each of these general types of phases can be further subdivided into groups based on particular types

of properties. Thus, solids may be divided into crystalline (e.g., sodium chloride) or non-crystalline (e.g., glass), into metallic (e.g., copper), ionic (e.g., sodium chloride), covalent (e.g., germanium), or molecular (e.g., solid argon). These classifications are not exact. The properties of the solids depend on the properties of the atoms that form the solid, on the arrangement of atoms in the solid, and on the conditions (such as temperature and pressure) under which the solid is examined.

The wide variety of behaviour exhibited by solids is a direct result of the type of bonding that holds the atoms of the solid together and of the structural arrangement of the atoms. Classification of solids based on their structures can be developed at various levels of magnification, ranging from the scale of centimetres to angstroms (10^{-8} centimetre). As might be expected, the earliest structural studies were based on features that could be seen by the unaided eye. Thus, speculations on atomism by the ancient Greeks (e.g., Democritus, at about 400 BC) were based on observations of the textures of ceramic materials and visual observations of the fractured surfaces of ceramics and bronzes. In the 19th century the etching of metals with acids and their subsequent examination with low-magnification optical microscopes was extensively carried out and revealed microstructural features of solids on the scale of what is presently known as the grain structure (about 10^{-3} centimetre). This work grew out of much earlier work by metalsmiths in many parts of the world, who revealed the macrostructure of objects such as swords and armour by differentially polishing, scraping, or etching with naturally acidic liquids. These processes revealed the distribution of hard and soft constituents of the metals and gave rise to the beautiful and remarkable patterns on the Japanese and Damascus swords.

Early
recognition
of solid
structure

Parallel to the developing understanding of the microstructure of solids, mineralogists had been examining and classifying crystals of naturally occurring minerals. By the 19th century many of the crystallographic features of crystals and their symmetry properties were known as a result of such studies, since the shapes of natural crystals often reflect the atomic arrangements. It was not, however, until the discovery of X-ray diffraction from crystalline solids in 1912, following a suggestion by Max Theodor von Laue, a German physicist, that the atomic structure of crystals began to be understood. By this time the atomic nature of matter was accepted, and it was the patterns produced by the diffraction of X-rays from the regular arrangement of atoms in crystals that resulted in an understanding of the structure of solids on an atomic scale (about 10^{-8} centimetre). Resolution by different methods of examination has improved, and today, with the use of the electron microscope and the field ion microscope, individual atoms in a solid can be resolved and studied. As understanding of the structure of solids has progressed, it has become clear that imperfections in the arrangements of atoms in solids have a major effect on the properties of solids, and a wide variety of these imperfections has been studied.

The solid state of matter cannot be understood without knowledge of the atomic structure of matter, details of which are treated fully in the articles ATOMIC STRUCTURE, MOLECULAR STRUCTURE, and others that are referred to below. Here, only a brief summary of this knowledge can be made.

In most general terms, each of the chemical elements consists of a characteristic type of atom that is composed of subatomic particles arranged in a specific fashion. The nucleus of every atom consists of neutrons, particles with no electrical charge, and protons, particles with a single positive charge; this positively charged nucleus is surrounded by electrons, particles with a single negative charge, arranged in a structure according to the force of attraction between opposite charges and the force of repulsion between similar charges. The lightest element, hydrogen, has only one proton in the nucleus and a single electron; the heaviest naturally occurring element, uranium, has 92 protons and 92 electrons; between these are 90 other elements. The number of neutrons also increases, but not in such an orderly manner. The electrons around

General
view of
atomic
structure

a nucleus may be thought of as occupying positions in a series of concentric shells. Some of these configurations are less stable than others, and the distribution of energy is such that the electrons tend to arrange their positions to attain the most stable arrangements. Thus, some atoms tend to donate electrons and others to accept them in chemical reactions; frequently, an exchange produces charged atoms, or ions, which may then form one of the chemical bonds that hold together compounds. Some atoms may share electrons in a chemical reaction, a bonding process in the formation of compounds. The electrons involved in chemical reactions are called the valence electrons, and they may occupy one or more of the outer shells. Changes in the states of matter (gas, liquid, solid) also involve bonds among atoms through their electron structures.

Many topics in this article are treated elsewhere in much greater detail, specifically the articles **CHEMICAL BONDING**; **CRYSTALLIZATION AND CRYSTAL GROWTH**; **IONIC CRYSTALS**; **METALS, THEORY OF**; **MOLECULAR STRUCTURE**; **POLYMERS**; **SEMICONDUCTORS AND INSULATORS, THEORY OF**; **MAGNETISM**; **ELECTRICITY**; **DEFORMATION AND FLOW**; **ELASTICITY**. The solid state has been most important in focussing scientific attention on properties of matter.

This article is divided into the following sections:

- I. General structure and properties of solids
 - Classification of solids based on the type of bonding
 - Ionic solids
 - Covalent solids
 - Metallic solids
 - Molecular solids
 - Hydrogen-bonded solids
 - Crystal structures
 - Mechanical properties of solids
 - Elastic and plastic properties
 - Thermal properties
- II. Electrical and magnetic characteristics
 - Electronic structure and properties of solids
 - Conductors
 - Insulators
 - Semiconductors
 - Thermoelectricity
 - Electron emission
 - Liquids and amorphous solids
 - Magnetism in solids
 - Paramagnetism and diamagnetism
 - Ferromagnetism
 - Soft magnetic materials
 - Hard magnetic materials
- III. Interaction of radiation with matter
 - Behaviour of solids illuminated with radiation
 - Generation of electromagnetic radiation

I. General structure and properties of solids

CLASSIFICATION OF SOLIDS

BASED ON THE TYPE OF BONDING

Role of
energy in
formation
of solids

Solids form from either the liquid or the vapour state, because the energy of the atoms (more properly, the thermodynamic variable called free energy) decreases when the atoms take up a relatively ordered, three-dimensional structure. The decrease in energy on forming the solid from the vapour phase is termed the cohesive energy and results from two types of interactions: a repulsive action (or term) that prevents the atoms from moving too close together and an attractive, or bonding, term that stabilizes the crystal against separation of the atoms. The origin of these energy terms serves as one basis for classifying solids into five groups: ionic, covalent, metallic, molecular, and hydrogen-bonded solids. In discussing real materials, it is important to realize that many cases occur in which the type of bonding falls into two or more of the above ideal classes. Thus, the compounds gallium arsenide, indium antimonide, and aluminum phosphide are examples of materials that have both covalent and ionic contributions to the atomic bonding, and the elements bismuth and antimony are examples of materials that have a partially metallic and partially covalent type of atomic bonding.

Ionic solids. Ionic bonding occurs between strongly electropositive (with weak affinity for electrons) elements, such as the alkali metals (lithium, sodium, etc.),

which form positive ions, and strongly electronegative (with strong affinity for electrons) elements, such as the halogens (fluorine, chlorine, etc.), which form negative ions. In this type of solid, electron transfer occurs between atoms, from electropositive to electronegative, and the solid consists of the resulting positively and negatively charged atoms or ions. For simple ionic solids such as sodium chloride, lithium fluoride, and cesium chloride, this electron transfer results in each ion having a closed electronic shell. The charged ions arrange themselves in space so that the coulombic attraction (a term for the attraction or repulsion between charges) between unlike charged ions equals the coulombic repulsion of similarly charged ions. While many different crystal structures can result from ionic bonding, three commonly occurring crystal structures are cesium chloride, sodium chloride, diamond, and zinc sulfide, types shown in Figure 1. It should be noted that in these crystal structures each ion has oppositely charged ions as its nearest neighbours, as a result of the coulombic forces acting between the ions.

Figure 1: Examples of crystal structures.

(A) Cesium chloride; (B) sodium chloride; (C) diamond; (D) zincblende.

The major contributions to the cohesive energy are electrostatic in origin and are called the Madelung energy. In calculating this energy, coulombic interactions between all the charged ions are summed. For a stable atomic arrangement, this energy must be attractive. The electrostatic, or coulomb-interaction, energy is calculated as the product of the charges on each ion, $\pm q$, divided by r , the distance between the ions, this quantity having the form q^2/r . Thus, as the separation becomes less, the interaction increases, and the closely packed crystal structures in which each ion is surrounded by nearest neighbours having opposite charges lead to a total electrostatic energy that is negative; i.e., energy decreases on forming the crystal from dissociated ions. As the spacing between ions decreases, the crystal energy becomes increasingly negative, due to the $1/r$ dependence of the coulomb interaction. At small ionic separations, however, the closed electron shells of the adjacent ions begin to overlap in space, resulting in a rapid increase in energy as the ionic separation decreases. (The basic cause of this repulsion is accounted for by the Pauli exclusion principle, which states that no two electrons can have the same quantum numbers.) Equilibrium separation of ions of the crystal corresponds to the minimum energy position and is equal to about three angstroms (3×10^{-8} centimetre). The

Calculating
electro-
static
interaction

properties of ionic crystals are largely determined by the charge transfer that takes place. For example, when an electric field is applied, the current is carried by the motion of the charged ions and therefore depends on the diffusion of negatively charged ions toward the electrode carrying a positive charge or the positive ions toward a negative electrode or both. The electrical conductivity of a crystal therefore increases exponentially with temperature (since the increased thermal energy causes an increased rate of atomic jumping) at a rate that reflects the rate of diffusion of the ions.

Covalent solids. Covalent bonding (also known as homopolar bonding in organic chemistry) occurs when the valence (or outer) electrons of neutral atoms are shared between nearest neighbours in the crystal. This atomic arrangement allows each of the atoms to achieve a closed outer electron shell by sharing electrons with its neighbours. Covalent bonds generally contain two electrons, one from each neighbouring atom, and, since eight electrons are required for a closed electron shell, the arrangement of the atoms is such that each has four nearest neighbours. This results in a tetrahedral (having four faces) arrangement of atoms in space, and covalently bonded solids often have the diamond structure shown in Figure 1. The covalent bonds are highly directional, with the bonding electrons being predominantly located along the directions between nearest neighbour atoms; *i.e.*, the atoms that provide the two electrons forming the bond. One of the parameters describing the energy state of the electron is the direction of its own spin, and, when the electrons of the bonding pair have opposite spin, the interaction between them is attractive. The energy of the associated atoms of the solid system is decreased from the energy of the atoms when they are free by the sharing of electrons between nearest neighbours (to allow a completed electron shell for each atom), and the decrease provides the cohesive energy for the system.

This ideal picture of the covalent solid is applicable to the bonding of the Group IV elements in the periodic table, such as carbon (when it occurs in the form of diamond), silicon, and germanium. Each of these has four valence electrons, which are shared in four tetrahedral covalent bonds. Other elements, however, also can exhibit covalent bonding. The two atoms of molecular hydrogen (H_2) are covalently bonded. Compounds of Group III and Group V elements such as gallium arsenide (GaAs) or indium antimonide (InSb) have at least partial covalent bonding, with the Group III element, gallium or indium (Ga, In), contributing three and the Group V element, arsenic or antimony (As, Sb), contributing five valence electrons to the covalent bonds. In these compounds the atomic structure is termed the zinc-blende structure, which differs from the diamond structure only in that each atom (*e.g.*, gallium) is surrounded by nearest neighbours of unlike atoms (*e.g.*, arsenic). Some of the elements of Groups V, VI, VII of the periodic table (such as arsenic, antimony, tellurium, iodine, and bromine) form complex crystal structures in which the bonding is at least partially covalent. In these less simple solids, covalent bonding occurs between atoms with fewer than four nearest neighbours arranged in sheets, chains, or molecules. The bonding between these sheets, etc., is the result of the induced displacement of the electrons and nuclei of neighbouring atoms and is called the van der Waals force; it is much weaker than covalent bonding.

The properties of crystals in which the bonding is predominantly covalent are determined largely by the localized nature of the electrons forming the bonds. These materials include electrical insulators such as diamond (room-temperature conductivity of about 10^{-14} [ohm-centimetre] $^{-1}$) and semiconductors such as germanium (room-temperature conductivity of about 40 [ohm-centimetre] $^{-1}$). In both cases, the electric current is carried by electrons that have been thermally excited (*i.e.*, their energies have been raised by heat) from their localized configuration (*i.e.*, basic position in the normal atom) to a more energetic state, or state of higher energy, in which they are nonlocalized and can move in response to an

outside electric field. This excitation of electrons from the valence band (*i.e.*, electrons involved with bonding forces) to the conduction band (*i.e.*, electrons with enough energy to overcome local bonds and move through the spaces among the atoms if an electrical force is applied) leads to an electrical conductivity that increases exponentially with temperature. The various covalently bonded crystals differ in the amount of energy required to excite an electron to the conduction band, the value being about 160,000 calories per mole (*i.e.*, per 6.02×10^{23} electrons) in diamond and 28,000 calories per mole in silicon.

Metallic solids. Bonding of solids formed from elements such as copper, aluminum, beryllium, sodium, and the many others classified as metals arises from the non-localized nature of the valence electrons in these solids. When an atom is brought into a metallic crystal, those properties of the valence electrons that are called its wave functions are altered because of the proximity of the valence electrons and the positively charged ionic cores (*i.e.*, the electrons that do not function in the chemical bond because they are held so firmly by the nucleus) of the other atoms in the structure. The resulting valence-electron wave functions are associated with the entire volume of the metal, and therefore each valence electron can no longer be associated with a particular ion core. The average energy of these nonlocalized valence electrons, which is partly kinetic energy of motion through the solid and partially potential energy due to interactions with the ionic cores and the other valence electrons, is reduced on forming the solid, thus providing the cohesive energy. It is the nonlocalized or free-electron nature of the valence electrons in metals that results in their characteristic properties. In some cases, however, the electrons can still retain much of their localized nature. Thus, many of the properties of the transition elements in the periodic table (*i.e.*, those with unfilled d shells in the structure of orbitals arranged according to energy distribution among the electrons; *e.g.*, iron, vanadium, chromium, zirconium, molybdenum) are determined by the behaviour of these d electrons in the solid. The d electrons remain largely localized around the ionic core; *i.e.*, they are not free to move through the solid but still contribute to properties such as the cohesive energy and magnetic properties.

Metallic crystals have characteristically high electrical conductivity (about 10^6 [ohm-centimetre] $^{-1}$ for a metal such as copper) due to the free-electron character of the valence electrons. They can move away when an electrical field is applied without requiring any thermal activation; *i.e.*, without having to be thermally excited (heated) into a conduction band, as in covalent crystals. In these cases, however, the motion of the electrons is limited; they are scattered when they meet imperfections in the crystal and when they approach atoms that are vibrating due to heat energy. The electrical conductivity, therefore, decreases as the temperature is increased, because an increase in the magnitude of thermal vibrations of the atoms obstructs the movement of free electrons.

Molecular solids. Rare-gas solids (such as argon, krypton, and xenon) and some molecular solids (*e.g.*, methane, CH_4 ; hydrogen, H_2 ; chlorine, Cl_2) exhibit weak van der Waals or molecular bonding in the solid state. Since the bonding occurs between atoms that have completely filled outer electron shells or non-ionized molecules, the crystals are only weakly bonded and are stable only at low temperatures. The van der Waals bonding results from the displacement of the atomic nuclei from the centres of the electron charge distribution in each atom, the displacement resulting when neutral atoms or molecules are brought close to each other. This induced charge displacement creates an electric dipole (*i.e.*, a body with two poles oppositely charged) that interacts with the adjacent induced dipoles to reduce the energy of the crystal and provide a small cohesive energy. The attractive interaction energy between the induced electric dipoles is of very short range and varies as the distance between atoms to the -6 power (or $1/\text{distance}^6$). It is balanced by the repulsive interaction that occurs as the filled electron shells of the atoms begin to overlap on

Valence and conduction bands

The role of electron spin

Heat and metallic conductivity

bringing the atoms closer together, a consequence of the increase in energy due to electrons having the same energy; *i.e.*, the same four quantum numbers, which account for all the energy of an electron relevant to that electronic structure, occupying the same volume. (According to the Pauli exclusion principle, no two electrons of an atom may have the same four quantum numbers.) The nature of this type of molecular bonding leads to electrons that are localized at each atom and therefore to molecular solids that do not conduct electricity. They are insulators. Very large amounts of energy are required to excite an electron in such a solid from a localized state to a nonlocalized one. Due to the low cohesive energy of these crystals, significant electron excitation does not occur in the temperature range in which they are solid.

Hydrogen-bonded solids. Hydrogen bonding is of great significance in organic solids and in certain molecular solids such as ice, hydrogen fluoride, and potassium hydrogen phosphate. The single valence electron of hydrogen allows it to form a covalent bond with only one other atom, as with another hydrogen atom in the hydrogen molecule, H_2 . In some solids containing strongly electronegative atoms, such as nitrogen, oxygen, or fluorine, hydrogen can form a bond between two of the electronegative atoms. In these cases, the hydrogen is at least partially positively ionized (*i.e.*, its electron has been partially removed) and serves to bond two negatively charged ions. Such bonding is of significance in many polymeric materials and in organic solids such as DNA (deoxyribonucleic acid), where it acts to bond the strands of the DNA molecule.

As was previously stated, solids rarely exhibit a single idealized type of atomic bonding. In general, ionic and covalent bonding is very strong, leading to high heats of vaporization and melting points; molecular bonding is very weak; and metallic bonding occupies an intermediate position. The type of bonding also places some constraints on the structures in which the solids crystallize; however, the variety of crystal structures observed is much greater than might be suspected from the few simple types of atomic bonding described above.

CRYSTAL STRUCTURES

While it has been recognized since about the 17th century that crystalline solids consist of a regular array of repetitive units, the three-dimensional periodic arrangement of atoms that form crystals was first established in the early 20th century. In 1912 M. Laue developed the theory of diffraction of X-rays from a periodic arrangement of atoms, and in 1913 W.L. Bragg used X-ray diffraction to establish the structures of some ionic crystals, such as sodium chloride and potassium bromide, potassium chloride, and potassium iodide. Since then, the diffraction of X-rays, electrons, and neutrons has been used to determine the structure of a myriad of simple and extraordinarily complex structures, ranging from the relatively simple structures of the elements to the structures of proteins and DNA. While the nature of the atomic bond may place certain constraints on the structure of the solid, it does not determine it, and, as shall be indicated below, a wide variety of crystals is formed from materials of the same class of atomic bonding.

Atoms in a crystalline solid are arranged in a repetitive three-dimensional arrangement termed a lattice, and the position of any point in the lattice is determined relative to a set of crystal axes. Both the lattice and the axis system are mathematical fictions used to describe the actual atomic positions in space. Nonetheless, they facilitate the description of many crystalline properties, and a standard set of axes and lattices has been developed. (The details of crystal structure are fully treated in the articles CRYSTALLOGRAPHY and CRYSTALLIZATION AND CRYSTAL GROWTH.) The arrangement of points forming these unit cells is the basic repetitive unit of the lattice that is formed by translation of the unit cells along each of the three crystal axes. The magnitude of the basic translation distance in the unit cell is about three to eight angstroms (3 to 8×10^{-8} centimetre). It has been conventional to describe the crystal structures using seven crystal axes

(triclinic; monoclinic; orthorhombic; tetragonal; cubic; trigonal, or rhombohedral; and hexagonal) and 14 unit cells. While those choices are not unique, all possible repetitive arrangements of points in space (*i.e.*, all lattices) can be described by one of these 14 conventional unit cells, which are called Bravais lattices.

A description of the crystal structure requires that the positions of all atoms be established relative to the Bravais lattice. In the simple cases there is one atom per lattice point; *e.g.*, the structure of copper is face-centred cubic, with one copper atom at each point, while iron (at room temperature) has a body-centred cubic unit cell with one atom per lattice point. Most crystals have a rather more complex structure, with several atoms per lattice point. Thus, the diamond structure, which is characteristic of many covalently bonded elements (shown in Figure 1), has two atoms per lattice point in the face-centred cubic lattice; and the sodium chloride structure (shown in Figure 1), which is characteristic of many ionic crystals, has two ions, Na^+ and Cl^- , associated with each lattice point of a face-centred cubic lattice. Many more complex structures are known where the number of atoms per lattice point is large. For example, the element manganese has a crystal structure below $742^\circ C$ ($1,368^\circ F$) that is simple cubic with 58 atoms per unit cell, another structure from $742^\circ C$ to $1,095^\circ C$ ($1,368^\circ$ to $2,003^\circ F$) that is simple cubic with 20 atoms per unit cell, a third structure between $1,095^\circ C$ and $1,133^\circ C$ ($2,003^\circ$ to $2,071^\circ F$) that is face-centred cubic with four atoms per unit cell, and a fourth structure from $1,133^\circ C$ ($2,071^\circ F$) to the melting point that is body-centred cubic with two atoms per unit cell.

Crystal symmetry determines the dependence of many of the macroscopic properties on direction in the crystal. Thus, properties such as electrical conductivity, magnetic susceptibility, elastic constants, and dielectric constants reflect the symmetry of the crystal structure. As a result, cubic crystal structures such as sodium chloride are isotropic (*i.e.*, their properties, such as dielectric constant, are independent of the direction in which they are measured) while quartz, having a trigonal crystal structure, has two independent dielectric constants, and the experimentally measured value depends on the direction of measurement. As a consequence of these crystal symmetry elements, a cubic crystal (copper, germanium, sodium chloride, etc.) has three independent elastic constants, while for a hexagonal crystal (zinc, cadmium, magnesium, etc.) there are five independent elastic constants.

Atomic bonding limits the variety of crystal structures possible in the case of covalent, ionic, and hydrogen bonding. For example, as a result of the nature of the coulombic interaction, ionic crystal structures are limited to those in which each ion has oppositely charged ions as nearest neighbours. Simple monovalent ionic solids in which positive ions have small radii crystallize in the sodium chloride structure, and the same crystal structure is characteristic of some simple divalent ionic solids. The cesium chloride structure is characteristic of monovalent ionic structures in which the positive ionic radius is relatively large. A variety of ionic crystals crystallize in the zinc sulfide structure, in which the positive and negative ions are tetrahedrally coordinated and the structure is similar to the diamond structure. Much more complicated crystal structures are formed when the atoms in the molecule are ionically bound and the molecules themselves are arranged in layered structures with bonding between layers arising through van der Waals forces.

The covalently bonded elements form in the diamond structure, which allows tetrahedral coordination of the atoms. In covalently bonded compounds, which generally also exhibit at least partial ionic nature, the structure formed is the zinc sulfide structure. Hydrogen bonding places severe restrictions on the structures of organic crystals such as proteins and DNA. These crystalline constraints are of great importance in molecular genetics. Metallic bonding places relatively few constraints on the crystal structure, and consequently a wide variety is observed.

While some of the polymeric materials crystallize in

regular three-dimensional structures, these are not nearly as perfect as more normal crystalline solids. The basic polymeric unit (or mer) consists of covalently bonded carbon and hydrogen atoms (with the possibility of other atoms, such as oxygen, fluorine, or other covalently bonded groups of atoms, added in particular polymers). These basic units, or monomers, are covalently bonded into long chains that may consist of thousands of repeating units. The angles between the covalent bonds along this chain are limited to discrete values by the nature of the covalent bonding. Polyethylene is an example of a simple polymer: the basic mer is a three-atom group linked by single bonds—hydrogen—carbon—hydrogen, or H—C—H, which is repeated in a sequence by single bonds between the carbon atoms:

These chains may be thousands of units long (for details see POLYMERS).

Crystal-line defects

Macroscopic solids are far from being perfect crystals. In general. They usually contain a variety of crystalline defects, some of which are shown in Figure 2. Solids usually consist of a set of smaller three-dimensional volumes called grains, in each of which the crystal axes have a constant orientation but between which the crystal axis orientation varies. The surfaces separating the grains are termed grain boundaries. Inside each grain the perfection of the crystalline lattice is perturbed by line imperfections termed dislocations, which correspond to a local change in the atomic arrangement. The simplest of these, the edge dislocation, corresponds to the insertion of a partial atomic plane into the lattice. A number of crystal defects exist at individual points in the lattice. Some of the atomic positions may be occupied by foreign atoms; these atoms may either substitute for host atoms on the regular crystal sites or occupy small interstices between the normal atomic positions. Vacancies (called Schottky defects) and small clusters of vacancies are formed by removal of atoms from their normal lattice positions, leaving them vacant, and self interstitials can be formed by inserting the atoms in between the normal sites. In ionic crystals these point defects are often charged and tend to occur in small clusters in order to preserve electrical neutrality. Such ionic point defects are often associated with "colour centres," or defects that absorb light causing a colouring of the crystal.

A number of other primary imperfections can be described in addition to these crystalline defects. One of these is the phonon, a quantum of lattice vibrational energy. In analogy to a photon, the phonon can be treated as a wave or a particle. Its characteristics determine certain properties of solids such as heat capacity, thermal conductivity, and optical absorption. In insulators and covalent crystals, free electrons and holes (regions of positive electrical charge) can be introduced by ionizing radiation, thermal excitation by phonons, or high electric fields. A bound electron-hole pair can form and is termed an exciton.

MECHANICAL PROPERTIES OF SOLIDS

Elastic and plastic properties. Many of the uses of solids depend on their ability to support stresses (applied load divided by the area of application); indeed, the ability of a solid to support normal loads (loads applied perpendicular to a surface) and shear loads (loads applied parallel to the surface) distinguishes a solid from a gas or liquid. The deformation (change of shape of the solid) that results from the application of a stress may be divided into three general types: elastic, plastic, and anelastic. These may be best defined with reference to the dependence on the rate at which the stress is applied and the permanence of the deformation when the stress is removed.

Elastic deformation is an instantaneous shape change in response to an applied stress and is completely and immediately recovered when the stress is removed; *i.e.*, there is

no permanent "set." In contrast to this, plastic deformation results in a permanent shape change that depends on the rate at which a stress is applied and that is not recovered on removal of the stress. Anelastic deformation, occupying a middle ground between these two extremes, is a recoverable deformation that depends on the rate of application of the stress and on the time during which it remains applied. These three types of deformation have been commonly experienced in the stretching of a steel spring or of a rubber band (elastic deformation), the bending of a paper clip (plastic deformation), and the decreasing amplitude of vibration of a plucked violin string (caused by anelastic deformation). Unfortunately for the investigators of these phenomena, it is not easy to separate these three classical types of behaviour, and the overall result of the application of a stress is a combination of all these types.

Thermal properties. The excitation of lattice vibrations and electrons on increasing the temperature of a solid has a major effect on many properties of solids. Attempts at understanding these thermal effects have played a central role in the development of solid-state physics. The early quantitative experiments on the specific heat of solids in the 18th century were interpreted as the introduction of heat as a "caloric fluid" that had properties such as weightlessness and transparency and that seeped from hot to cold. It was not until 19th-century work on the behaviour of gases that heat was interpreted as the motion of molecules and that the kinetic molecular theory stating this in specific terms became accepted. The application of principles that had been developed for gases to an understanding of the thermal properties of solids was not possible in the context of classical physics, and the attempt provided some motivation for the development of quantum mechanics early in the 1900s.

The two major thermal phenomena in solids are the specific heat (or heat capacity: the quantity of heat that will raise the temperature of a unit mass 1°) and the conduction of heat. Based on the understanding of gases, it was realized that each atom stored energy in its vibrational modes (frequency and amplitude) as kinetic en-

Early theory of heat

Types of deformation

ergy (energy of motion) of the atom and as potential energy of the distorted bonds that join the atom to its nearest neighbours. The amount of energy per mode in the temperature range where the solid behaved classically—*i.e.*, where the atomic motion can be described without the use of quantum mechanics—was one-half of the product of Boltzmann's constant, k (3.3×10^{-24} calorie per degree Kelvin) and the absolute temperature, T (degrees Kelvin): $\frac{1}{2} kT$. Since the vibration of each atom in a solid can be described as motion in three independent directions (*i.e.*, three kinetic and three potential energy modes), the classical energy of a mole of atoms in a solid is three times the product of Boltzmann's constant, k , the temperature, T , and Avogadro's number, N , 6×10^{23} (the number of atoms in the atomic weight in grams of an element): $3 NkT$. The heat capacity, the rate of change of energy with temperature, is $3Nk$ (or about six calories per mole). In addition to energy stored as lattice vibrations (phonons), excitation of electrons to higher energy states may also occur. In metals this electronic specific heat increases linearly with temperatures and is small compared to the lattice vibration term.

Conduction of heat along a temperature gradient in a solid can involve the transport of energy by electrons, by phonons, or by both. Transport of heat by electrons accounts for the majority of the thermal conductivity in metals at room temperature and above. The thermal currents due to electron and phonon transport, however, are additive and at low temperatures the heat conductivity is due solely to phonons. Motion of phonons and electrons through the lattice is limited by scattering from crystalline defects such as impurities, grain boundaries, external surfaces, dislocations, etc. and from other phonons and electrons. These scattering processes determine the thermal conductivity of the solid.

II. Electrical and magnetic characteristics

Materials display a wide range of electrical behaviour, typified by the electrical conductivity of such elements as aluminum, silicon, and phosphorus, which are neighbours in the periodic table of elements. Wires made of each of these materials about the size and length of wires in a lamp cord and connected across the terminals of a 12-volt auto battery would conduct greatly different currents. Through the aluminum wire a current of about 100 amperes would flow, through the silicon wire a current many times smaller would flow, about 10^{-6} ampere, and through the phosphorus wire a current of only about 10^{-15} ampere would flow.

This wide range of electrical behaviour among aluminum, a useful metal, silicon, a widely used semiconductor, and phosphorus, a good insulator, typifies the enormous variety of electrical applications of materials now possible. Why should the adjacent elements, aluminum with 13 electrons, valence 3, silicon with 14 electrons, valence 4, and phosphorus with 15 electrons, valence 5, behave so differently? The answer requires understanding of the basic characteristics of electrons in solids.

ELECTRONIC STRUCTURE AND PROPERTIES OF SOLIDS

The general structure of matter has occupied the attention of scientists for centuries, but the present view of the electronic structure has been developed rather recently. The discovery of the electron and its properties in the early part of the 20th century and the invention of quantum mechanics in the 1920s led to development of a detailed theory of the electronic structure of solids in the 1930s. The theory is rather good, overall, even though some fine details are not yet clear. This lack has not prevented technical application of knowledge of the electronic structure of solids; indeed, the rapid development of solid-state devices has its basis in the close interplay among the developing theory, basic experiments, and practical applications.

Conductors. Wide variability of electrical behaviour is not limited to the three examples just described; rather, this variability is common as is illustrated for a number of materials in Figure 3. The group of materials at the bottom, the metals, are good conductors. The individ-

ual atoms in the metals are assumed to have lost electrons (the valence electrons) to the entire solid. These free electrons move as a group in an electric field and hence conduct current. Indeed, early in the 20th century a quantitative theory of conductivity was developed to explain electrical conductivity in terms of the number of free electrons, their charge, and their degree of mobility. Later refinements were added by application of quantum mechanics, but the basic principles still apply.

Free electrons in metal. Description of the free electrons in a metal can be made by application of fundamental features of quantum theory. First, only the valence electrons of the atoms of the metal can become free. The inner electrons remain bound to the nucleus of the individual atoms and form with the nucleus a charged entity called the ion core. Second, the free electrons are subject to the constraints of the fundamental precepts of quantum mechanics—the Pauli exclusion principle and the Heisenberg uncertainty principle. The first of these requires that no two electrons may move in the same direction in the crystal with the same speed. The second defines the words "the same"; *i.e.*, it fixes the direction and velocity intervals permitted the various electrons. Consideration must also be given to electron spin; this feature and a more precise statement of the two principles are given in the article METALS, THEORY OF.

Detailed application of these principles of quantum mechanics yields the following picture of the free electrons: the electrons indeed have access to all parts of the metal. Their speed of movement through the crystal ranges from near zero to a few million metres per second, about 1 percent of the velocity of light. Their wavelength (*i.e.*, their de Broglie wavelength; see ELECTRON) ranges between the actual size of ordinary solids (a few feet, say) to a lower limit of about five to ten angstroms. They have a mass about the same as that of an electron in a vacuum (*i.e.*, what is called the rest mass) but not precisely this

mass, and interactions with the lattice ions can cause variation.

The range in velocity is not the most convenient way of describing the motion of the electrons. A more useful description is their range in energy—the sum of their kinetic energy of translation or displacement through the crystal and their residual energy of association with the ion cores, an association that is not completely lost even when the electrons become free. For example, when sodium atoms condense to form solid sodium, not much change occurs in the inner states (those electron orbitals designated as $1s$, $2s$, and $2p$) of the ion core. But the outermost state (the $3s$ orbital) is broadened into a band of closely spaced energy levels, some occupied by electrons, some empty (see Figure 4). The energy of the highest occupied states, called the Fermi energy, lies about 2.5 electron volts (or eV; defined below) above the bottom of the band for sodium. The spacing of the levels at the Fermi energy is exceedingly small; adjacent levels are only about 10^{-8} electron volt apart for a few cubic centimetres of sodium. Electrons can easily be excited into these empty levels by electric fields, by heat energy, and by light. It is this easy excitation of electrons into empty levels that makes metals good conductors of electricity and heat, makes metals opaque to visible light, and gives them their characteristic lustre.

Figure 4: The energy levels of sodium and silicon for both isolated atoms and the solid material. The energy levels are not to scale; the $1s$ level, in particular, should lie much deeper than is shown (see text).

The electron volt

The unit of energy universally used in consideration of electrons is the electron volt. It is the energy acquired by an electron when it moves through a potential difference of one volt. The electron striking the screen of a television tube has a kinetic energy of about 20,000 electron volts. It is a very small unit; a mosquito buzzing about may have a kinetic energy of perhaps 100,000,000,000 electron volts. Even so, a few electron volts is a great deal of energy in terms of events that happen in solids.

No net electric current flows in a metal if no electric field exists; an electron moving in one direction with a certain speed is paired off with one moving in the opposite direction with that speed. This pairing off is altered slightly when an electric field is applied, however. All electrons experience a force in the same direction because of the field and are accelerated to higher velocities (*i.e.*, they go into some of the higher energy states). Since all are accelerated in the same direction, they provide a net flow of electric charge—*i.e.*, an electric current. The current does not become infinitely large, however, because the increase in velocity of the electrons is limited by collisions with the ion cores; the electrons must pick their way through a dense cloud of ions whose electric fields deflect and scatter them. A steady-state condition is

established when the extra energy gained from acceleration in the field is just balanced by the loss of energy in the collisions. Detailed analysis of this situation yields the equation known as Ohm's law (see **ELECTRICITY**).

The excess velocity the electrons gain in fields of ordinary size is not very large compared to their intrinsic velocity of a few million metres per second. In the lamp filament of a flashlight, for example, the electrons drift along only a few centimetres per second under the influence of the electric field produced by the battery.

Effect of alloying on conductivity. Metals tend to heat up when they carry an electric current. The electrons gain kinetic energy in the electric field. This kinetic energy is transferred to the metal ions by the collisions, increasing the vibrational energy of the atoms of the metal and hence increasing the temperature of the metal. In fact, an extension of the mathematical treatment which gives Ohm's law yields Joule's law, which relates the heat generated to the number of conduction electrons and to their mobility in the metal and to the electric field imposed.

The resistivity of metals and alloys has a range of about 100 times from that of silver to that of the stainless steels. This range is certainly not caused principally by differences in the number of conduction electrons. Rather, it is caused mainly by differences in mobility. Consider the example of nickel and Nichrome (*i.e.*, the heating element in an electric stove, 80 percent nickel and 20 percent chromium): Nichrome has a resistivity about 20 times greater than that of pure nickel, even though the two materials have nearly the same number of free electrons. The difference in resistivity must be caused by a greater probability of collisions of electrons in the Nichrome, hence a lower mobility of the electrons. Alloying nickel with chromium atoms increases the lattice irregularities, making collisions of electrons with the lattice atoms more likely.

Effect of heat on conductivity. Increasing the temperature of a metal also increases the probability of collisions and thus increases the resistivity. For example, the resistivity of the tungsten filament of a 100-watt incandescent lamp increases by about 20 times when the lamp is heated from room temperature to its operating temperature of about 2,500° C (4,500° F). The ions in the solid oscillate more vigorously at higher temperatures, increasing the chance that collisions with electrons will occur. These two examples, one the effect of alloying and the other the effect of temperature, are a general feature of metallic conductors; theory, in fact, predicts and experiments show that atoms in a pure, perfect crystal should not impede the motion of the electrons at all. The resistivity of a metal should disappear completely if collisions of the electrons with the ions of the crystal could be eliminated. Thus, the resistivity of the pure metals tends toward zero near the temperature of absolute zero (−273° C [−460° F]). But, even more, below a certain temperature (called the critical temperature) the electrical resistivity of a certain group of materials called superconductors is actually zero; they become infinitely good conductors of electricity. Thousands of metals and alloys are known to show superconductivity; all must be cooled to extremely low temperatures to show the effect. This limits their practical use, of course, but they are beginning to be technologically important. Since they can carry immense currents without loss, they are useful in generating high magnetic fields and have tremendous potential in electrical-power transmission (see the article **SUPERCONDUCTIVITY**).

Insulators. The electrical insulators are at the other extreme of the electrical-resistance scale; they conduct poorly (see Figure 3). A number of the pure elements are good insulators, among them phosphorus, sulfur, boron, and carbon (in the form of diamond); however, an immense number of compounds are insulators, among them many oxides and salts, a wide variety of glasses and other ceramic materials, and most plastics. They are useful mainly for two reasons. Their poor conductivity makes them useful as electrical insulators for conducting metals and semiconductors, and they can be used to increase the storage capacity of electrical condensers.

Variations in resistivity

Types of insulators

The valence electrons of these solids are tightly bound to the ion cores; thus, they do not readily become free, as do the valence electrons in a metal. This in turn means that they cannot conduct much current in an electric field; that is, these solids are electrical insulators. As an example, consider a crystal of diamond. An energy of about five electron volts is required to free a valence electron; at room temperature virtually none of these electrons is free, fewer than one in 10^{40} (*i.e.*, a sphere of diamond about 100 miles in diameter would have only a single free electron from thermal excitation). Thus, the capability of diamond or of the other good insulators to conduct current by free electrons is exceedingly small. It is so small, in fact, that most of the conduction of electricity at ordinary temperatures is caused by migration of the ions themselves.

Though good insulators have very few free electrons, they cannot remain insulators if the electric field is made indefinitely large. Eventually, breakdown occurs and a spark jumps, oftentimes destroying the dielectric. Most solid insulators break down at about 500,000 volts per inch (air and gas mixtures at somewhat lower fields).

Electrons in insulators are bound to the ions rather firmly, but they are indeed influenced by an electric field. They and the ions (which are charged positively) are displaced relative to each other a small amount by the presence of a field and hence form a minus-plus, or $-+$, pair, called an electric dipole. Since all electron-ion pairs are aligned parallel to each other, the entire solid possesses an overall dipole that is simply the vector sum of all the individual dipoles. Though the strength of each little dipole is so small that it is measurable only by the most special and sensitive techniques, a piece of solid—*e.g.*, a cubic centimetre—contains so many dipoles that the dipole strength of the overall solid can be appreciable. This, combined with the higher breakdown strength of solid insulators relative to that of air, has important practical application. For example, the capacitor in the power supply of an alternating-current radio is about a centimetre in diameter and a few centimetres long. If the metal oxide that serves as the heart of that capacitor were to be replaced by air, reasonable manufacturing tolerances would require that the air capacitor be a volume many metres in each direction.

Dielectric materials

This phenomenon, which produces these dipoles, called the dielectric effect, is actually possessed by all solids, but the only materials for which it is significant are the insulators. Mica and quartz have long been important practically. The oxide of aluminum, Al_2O_3 , and more recently that of tantalum, Ta_2O_5 , are important in high-capacitance condensers of small physical size of miniature electronic circuits. Oil, waxed paper, glass, and plastic and films are also dielectric materials of great importance.

Semiconductors. The semiconductors are partway between the insulators and the metals in terms of electrical conductivity (see Figure 3). They possess more free electrons than the insulators but not as many as the metals: whereas the best insulators have fewer than one free electron per cubic centimetre at room temperature, and metals have 10^{22} , germanium, a widely used semiconductor, has about 10^{14} , and silicon has about 10^{10} . The mobility of the free electrons in these semiconductors is about the same as that for electrons in the metals; in fact, it is a little larger, so the lower conductivity of semiconductors (compared to the metals) is directly a result of the smaller number of free electrons. The practical value of semiconductors lies not in the precise number of free electrons for pure materials, however, but in the easy control of the number of free electrons made possible by alloying. Thus, the conductivity of semiconductor alloys can be rather completely controlled (see SEMICONDUCTORS AND INSULATORS, THEORY OF).

Experiments that measure not only the number of free charges responsible for current flow but also the sign of the charges show an additional curious feature. Current in some semiconductors is carried by motion of negative charges—*i.e.*, electrons—but in some others by motions of positive charges. The explanation is based on detailed

examination of the electronic structure of semiconductors and the process of electron excitation.

Atoms of a semiconductor such as silicon are bound together in the solid in a covalent-bonding arrangement of the valence electrons, of which there are four per atom. All of the valence electrons are required to fill these bonding states, and no electrons are left over in this valence band to be free (see Figure 4). Thus, without electron excitation, the number of free electrons is zero, and the conductivity is low; in fact, it would be zero. When excitation of an electron does occur—say, by a thermal fluctuation—not only does the electron become free, but an empty state is left in the covalent group of bonding electrons. This empty state, called a hole, can itself move through the crystal. It acts like a free positive charge.

Some semiconductors have equal numbers of free electrons and holes; *e.g.*, pure silicon and pure germanium. These materials are called intrinsic; their properties are determined by the inherent character of the pure, perfect material. Other semiconductors have an excess of electrons and are called *n*-type; examples are pure silicon alloyed with a little phosphorus and pure germanium alloyed with a little antimony or arsenic. Still others have an excess of holes, and these are called *p*-type; examples are silicon alloyed with a little boron or aluminum and germanium with a little indium or gallium. The examples illustrate the principle that *n*-type material is formed from silicon or germanium (valence 4) alloyed with an element of valence 5, which provides an extra free electron per alloying atom. Material of *p*-type is formed by alloying with elements of valence 3, which provides an extra hole per alloying atom.

The use of semiconductor materials in devices is based on two technological capabilities: (1) Through alloying chemistry, the material can be made either *n*-type or *p*-type. This control of the amount of alloying element extends to control of the number of charge carriers, thus to control of the level of conductivity. (2) Layered arrangements can be made in which *p*-type and *n*-type material butt against each other in the same chip of semiconductor crystal. It is these multilayered sandwiches of alternate *p*-type and *n*-type material, the layers having carefully controlled chemistry and thickness, that make possible devices such as rectifiers, transistors, integrated circuits, junction lasers, and switches.

Uses of semiconductors

Thermoelectricity. The article to this point has described both the fundamental nature of electrons in solids and the effects produced by an electric field applied externally; *i.e.*, a gradient, or change, in the voltage from one point to another. Other kinds of external fields can be introduced, however, an important one being a temperature difference or a gradient in temperature along a solid. Such a gradient leads to an effect called thermoelectricity. This effect has long been known and has several practical applications.

The maximum energy of electrons in solids, the Fermi energy, varies from material to material. Therefore electrons on the two sides of an interface formed when two materials are in contact will not be at the same energy, and electrons will flow across the interface in one direction or the other to occupy empty states of lower energy. For differences of Fermi energy of sizable amounts—*e.g.*, an electron volt—the expectation would be that large fractions of the electrons in one solid would transfer to the other, but that is not the case. Another phenomenon enters when charge is transferred; a potential difference—that is, a voltage—is set up because of a growing unbalance of total charge (ions plus electrons) in each piece of the solid. This potential difference opposes the transfer of electrons beyond a certain point. At the point of equilibrium the potential difference is called the contact potential difference. It can be a sizable effect; for example, between gold and aluminum, 0.6 volt, and between copper oxide and cadmium sulfide, 0.4 volt.

This contact potential difference cannot easily be measured, as with a voltmeter. In a series of interfaces—*e.g.*, copper to nickel to iron and back to copper—all contact voltages cancel out. The laws of thermodynamics require it; that is, if the temperature of the entire circuit is con-

stant. If two junctions are not at the same temperature (e.g., the copper–nickel and the nickel–iron in the example just described), then a voltage may indeed be developed around the circuit, a thermoelectric voltage. It develops because the Fermi energy of different materials varies differently as temperature is changed; hence, the contact potential difference of a given type of junction varies with temperature.

The thermoelectric voltage developed at junctions in circuits consisting of a series of dissimilar metals, when the junctions are held at different temperatures, is small. For example, the thermoelectric voltage developed between one junction of iron and copper at 0° C (32° F) and another at 100° C (212° F) is only about 0.001 volt. Certain combinations of alloys give somewhat higher voltages, up to 0.010 volt for the same temperature range, and some combinations of materials partway between the metals and semiconductors, the semimetals, yield even higher values. Even so, the effect is a small one, though a cascade of junctions, called a thermopile, can be used to produce higher voltages.

Two chief uses are made of thermoelectric circuit voltages: (1) to measure temperature; (2) to convert heat to electric power with no moving parts other than the electrons. Unfortunately, the efficiency is low, at most around 10 percent (compared to an efficiency of about 45 percent for a steam-turbine generating plant), and therefore they are not widely used for generation of electric power.

A related effect occurs in a circuit containing a thermoelectric junction when a current is passed through the circuit, as from a battery. Depending on the nature of the junction and the direction of current flow, heat is absorbed or liberated at the junction. This phenomenon, called the **Peltier effect**, again is not large, but it does have one practical application: such a junction can be used as a refrigerator whose only moving parts again are the electric charges themselves. Because of the high cost of suitable materials and low efficiency, it is not now a practical substitute for the conventional rotary-compressor-type of refrigerator.

Electron emission. The free electrons in a metal have kinetic energy ranging from near zero to several electron volts. Nevertheless, their interaction with the ion cores is still sufficiently large so that they must have appreciably more energy before they can leave the solid. That is, an energy barrier a few electron volts in size exists at the surface of a solid. Electrons are indeed emitted from solids, and this additional energy is available from several sources.

Thermionic emission. Electrons may gain the required energy from lattice phonons—emission resulting from this source is called thermionic emission. It occurs because electrons are occasionally excited to higher energy states by collisions with the lattice ions. Although the chance of an excitation large enough to overcome the surface barrier is small, it is not zero at any temperature. Furthermore, the chances increase as the temperature is raised. For example, cathodes in television tubes emit about 10^{15} times more electrons per second at their operating temperature than they do at room temperature. The current is large enough to be useful.

Photoelectric emission. Electrons can also be emitted from a solid by the action of electromagnetic radiation, a phenomenon called the photoelectric effect. Photons (the quanta of energy associated with electromagnetic waves) of visible light have ample energy to cause this emission from most solids, but radiation of a wavelength longer than infrared is insufficient to cause emission of electrons.

Field emission. Finally, emission can occur even at room temperature if an applied electric field is high enough. This phenomenon, called field emission, is caused by a purely quantum-mechanical effect called tunnelling. A strong electric field of at least 1,000,000 volts per centimetre is applied to a metal surface. This field causes the surface barrier to become exceedingly thin (like a semitransparent sieve), so that the electrons can penetrate through the barrier without need of enough energy to surmount it, hence the term tunnelling. Fields of this size are conveniently formed by sharpening a

metal electrode to a fine tip, just as a high electric field is formed at the point of a lightning rod.

Currents produced off sharp tips can be very large, as much as millions of amperes per square centimetre. Even though the tip is commonly much sharper than the point of a pin, the power produced by the electron stream can be hundreds of watts. Thus, it can act as the source of electrons for a high-power "flash" X-ray tube. It can also serve as the source for a high-magnification microscope, a device with magnification so large that it can resolve the individual atoms themselves.

Liquids and amorphous solids. Continued reference to the motion of electrons in crystals does not mean that liquids do not conduct electricity. Liquid mercury, for example, is widely used in electrical switches. The wonder is that liquid metals are as good conductors as they are; their conductivity at the melting point differs little from that of metals at room temperature. Somehow the electrons are able to pick their way through the helter-skelter collection of disordered ions that form the liquid without being continuously scattered.

A related kind of material, amorphous solids, may also conduct electricity well. Amorphous, meaning noncrystalline, metals and semiconductors are something of a laboratory curiosity at this time, but they may become important technically. Most promising, perhaps, is the prospect that amorphous semiconductors may be important in devices. Many elements, among them silicon, germanium, arsenic, antimony, selenium, tellurium, and some mixtures of them, can readily be solidified in an amorphous state. They are usually semiconductors in this amorphous, glassy state, but little filamentary islands of crystalline material of good conductivity can be made to form under certain circumstances. The entire phenomenon is not well understood nor are its applications fully evident (see GLASSY STATE).

MAGNETISM IN SOLIDS

Few subjects in science are more difficult to understand than magnetism. A magnetic field is invisible, it can be detected only by its effect on moving charges or on other magnetic fields, and the state of magnetization of a particular piece of material is not easy to measure. Yet magnetism is important technologically for such devices as motors, relay armatures, electrical transformers, and speakers for communications systems, and many natural phenomena are a result of magnetism, such as sunspots, the Van Allen radiation belts, and the Northern Lights (see EARTH, MAGNETIC FIELD OF).

One of the obstacles to understanding magnetic solids is the difficulty of making measurements on them. Since lines of magnetic force cannot be seen and in fact are simply a convenient way of thinking about magnetic interaction, indirect methods of observing magnetic fields must be used; for example, the torsional, or twisting, effect on a permanent magnet. A magnetic field is produced by a coil of wire when a current flows through the coil. If the coil has 50 turns per metre and carries a current of one ampere, the magnetic field at the centre of the coil is said to be 50 ampere-turns per metre. This is about the average size of the Earth's magnetic field and is rather small. If an iron rod is inserted inside the coil, though, a much higher field results, perhaps 10,000 times as much. Such a field, 500,000 ampere-turns per metre, is large enough to be extremely useful. A field of this size is large enough to drive an electric motor, to activate an electric-power generator, or to power a loudspeaker.

Paramagnetism and diamagnetism. Not all materials inserted into the coil would increase the magnetic field by such a large amount. Some, called paramagnetic solids, would increase the field only slightly. Such solids include aluminum, sodium, manganese, chromium, magnesium, potassium, titanium, and many others. Another large group would actually decrease the strength of the field but again only slightly; they are called diamagnetic. They include copper, zinc, germanium, silver, gold, and bismuth. Neither the paramagnetic nor the diamagnetic materials are technically important, but it is instructive to examine the reason for their behaviour.

Liquids as conductors

The Peltier effect

Observing the magnetic field

Paramagnetism occurs in matter because small magnetic dipoles on the individual atom are slightly aligned by a magnetic field. (A magnetic dipole of an atom can be considered to be a tiny permanent magnet.) The effect is small; the increase in magnetic field produced by paramagnetic materials is commonly only about one part in 100,000, at the greatest.

Diamagnetism is caused by a change in the orbital motion of electrons that occurs upon application of a magnetic field. The change causes formation of induced dipoles that are aligned opposite to the applied field; hence, they reduce the overall strength of the field. All materials possess some diamagnetic characteristics, even those that are paramagnetic or ferromagnetic; in these last cases, the positive effects overwhelm the negative diamagnetic features. Even at its strongest, the diamagnetism of most materials is very weak; for copper, silver, and gold the influence is only a few millionths of the external field.

Ferromagnetism. The strong magnetic effect that is called ferromagnetism is by far the most interesting. It exists in a number of metals and alloys, but by far the most important are the elements iron, cobalt, nickel, and their alloys. The first magnetic materials known to man were not these pure metals and alloys, however, but lodestone, a type of iron oxide. This material, which occurs in nature in great quantity, was known for its magnetic qualities at least as early as 600 BC. Modern alloys of this same kind, called ferrites, are exceedingly important.

Just as the conduction of electric current is a property of the electrons (*i.e.*, their charge), so is magnetism a basic property of the electrons. Each electron behaves like a small permanent magnet of a certain size, a fundamental unit given the name Bohr magneton. This tiny dipole is an inherent characteristic of the electron, and no magnetic field is required to produce it. Whereas the electrical conductivity of solids is caused by the motion of the free electrons, the electrons important to ferromagnetism in solids are the ion-core electrons. In fact, not all of them contribute, since they partly cancel each other. The ferromagnetic materials (*e.g.*, iron, cobalt, and nickel) are those for which the cancellation is not complete and the effects of some of the inherent dipoles add. Furthermore, dipoles interact so as to align themselves parallel to each other in certain directions, even in the absence of a field. Since different materials have different numbers of uncompensated dipoles, the strength of magnetic materials differs. For example, cobalt and iron have about the same strength, nickel only about one-third as much.

Notions about the origins and details of magnetism developed gradually, culminating about 1910 in a theory by the French physicist Pierre-Ernest Weiss. His theory of magnetization and demagnetization utilizes the concept of domains, small regions in which dipoles on adjacent ions spontaneously align themselves parallel. Direct observation of domains required another two decades of work, but they were observed in the 1930s by Francis Bitter, an American physicist. By now, a great deal is known about the structure of domains and the details of the magnetization process.

Ferromagnetism disappears above a certain temperature, called the Curie temperature. The self-alignment capability of the dipoles gradually disappears as the temperature goes up, because the increasing energy of the thermal vibrations misaligns the dipoles. Finally, the dipoles lose their self-aligning capability completely, and the solid is no longer ferromagnetic. The Curie temperature of nickel is 358° C (676° F), of iron, 770° C (1,418° F), and of cobalt, 1,131° C (2,068° F). Alloys of these elements have intermediate Curie temperature in general; obviously, a ferromagnetic material must have a Curie temperature higher than any temperature at which it is actually used.

Soft magnetic materials. Soft ferromagnetic materials become demagnetized easily when the external field is removed. Hard magnetic materials become magnetized and demagnetized with great difficulty. The most widely used soft magnetic material is transformer steel, an alloy of iron with a few percent of silicon. Another group consists of

iron-nickel alloys, one of 50–50, the other around 20–80, both being called Permalloys. A third alloy, with certain characteristics superior to either of these groups, has a composition of around 78% nickel, 18% iron, and 4% molybdenum; appropriately, it is called Supermalloy.

Magnetic materials made from metals become useless at high frequencies, because energy losses caused by eddy currents are too high to be tolerated. The problem is solved through use of magnetic insulators, mainly oxides of iron. One important group of these oxides (called ferrites) is based on the iron oxide compound Fe_3O_4 . This is the natural magnetic material that constitutes lodestone.

An interesting and promising material is a special group of magnetic iron oxides having the garnet structure. A typical example is yttrium iron oxide, $\text{Y}_3\text{Fe}_5\text{O}_{12}$. Tiny cylindrical domains can be formed across thin strips of this material, the direction of magnetization in a domain being opposite to that of the material surrounding it. These little cylinders behave like tiny magnetic "bubbles"; they are stable in size and can be moved about very rapidly by a small magnetic field. The bubbles are so small, about 0.001 millimetre in diameter, that their density in a sheet can be very high, perhaps 1,000,000 per square inch. They can also be made to step from site to site about 1,000,000 times per second with expenditure of very small energy. They have potential use as high-density, rapid access memory systems for computers.

Hard magnetic materials. Striking as are the advances that have been made in soft magnetic materials, advances in the hard magnetic materials for permanent magnets are just as startling. Three periods characterize the development of permanent magnets in the last century. The first, from about 1880 to 1930, saw a development of special steels; the magneto of the early automobiles and the old telephone receiver got their size and shape from the quality of these steels. In the second period, from 1930 to 1960, the Alnicos (*i.e.*, alloys of iron with copper, titanium, aluminum, nickel, and cobalt) were supreme, yielding smaller, stronger magnets, though so brittle and hard that they could not be fashioned by machine. Finally, after 1960, the ceramic magnets and alloys of the rare earths have been developed. The successes achieved in these three periods depend on a particular characteristic of magnetic materials.

The word permanent applied to magnets means "not easily demagnetized." This characteristic is measured by the size of field necessary to reduce the magnetization of a permanent magnet to zero, called the coercive field. Good permanent magnets must have coercive fields of 50,000 ampere-turns per metre or more. Such quality was first achieved by use of physically hard tool steels (a typical alloy had 71% iron, 17% molybdenum, 12% cobalt), which produced large magnetic fields because they contained large amounts of iron and cobalt. They also contained many finely dispersed carbides that impede motion of the domain walls. Thus, they were not easily demagnetized; domain walls separating domains of opposite polarity could not easily move through the material.

The permanent-magnet tool steels were replaced by materials whose high coercive force comes from the actual shape of magnetized regions in the alloys. The alloy Alnico is typical. It consists of extremely fine needlelike particles of magnetic material imbedded in a nonmagnetic binder. When solidified and heat-treated in a magnetic field, the long particles tend to line up with the field, yielding a strong magnet. If the particles are fine enough, domain walls cannot form in them, and the individual particles cannot be readily demagnetized.

Small-particle theory in the 1950s led to attempts to produce permanent magnets by dispersing fine suspensions of iron in plastic or a metallic binder. Several products were made and sold, but manufacturing problems are difficult, and these magnets are not of great commercial importance.

The third phase of permanent-magnet development has used a property known as crystalline anisotropy. Simply put, certain directions in a crystal are magnetically pre-

The
ferrites

Electrons
and
magnetism

Aniso-
tropy

ferred over others. For iron, the cube edge is preferred; for nickel, the cube diagonal; and, for cobalt, the axis normal to the hexagonal plane. In switching the direction of magnetization from one preferred direction to another, parts of the crystal will be at one time or another in a higher energy state—hence, a large coercive force is required to change the direction of magnetization.

Attempts have been made for many years to find alloys that would utilize this strong directional preference. Until recently, they were largely unsuccessful. Work on ferrites, though, led to discovery of a hexagonal oxide of iron, $\text{BaFe}_{12}\text{O}_{19}$, that has high coercive force. Like the cubic ferrites based on the Fe_3O_4 structure, however, it does not produce the highest magnetic fields, since much of its volume is taken up by nonmagnetic ions. Even so, many ceramic magnets are made from this material.

Strenuous attempts were made in the 1960s to find a metallic alloy with hexagonal structure, large anisotropy, and large density of a high-moment ion. Thus, it would be a strong magnet to give high field and a hard magnet to resist demagnetization. Such a group of materials has been found, a hexagonal compound of cobalt with some of the rare-earth metals. A compound of cobalt with samarium, Co_5Sm , makes a permanent magnet more than ten times as strong as the best Alnico.

III. Interaction of radiation with matter

The electromagnetic spectrum covers an immense range of frequencies. That part most commonly used, visible light, is but a tiny part of the known range. Even so, this discussion is concentrated on the interaction of the visible spectrum with matter (see also the articles RADIATION EFFECTS ON MATTER; ELECTROMAGNETIC RADIATION).

Electromagnetic waves are pulsations of electric and magnetic fields. In a vacuum they travel with a velocity of 300,000 kilometres per second (186,000 miles per second). Their frequency, ν , and wavelength, λ , are related to their velocity, c , by a simple equation in which the velocity equals the product of wavelength and frequency: $\nu\lambda = c$. A stationary observer who could detect the electric field of the waves as it passed by would find that its strength, E , would have some maximum amplitude, A , and would vary with time in a very regular fashion. Furthermore, the electric field is maximum at right angles to the direction of motion of the wave.

The energy of electromagnetic waves is quantized; that is, the energy comes in discrete, well-defined units called photons, the size of which is given by the product, $h\nu$, of a universal number called Planck's constant, h , and the frequency, ν , of the wave. Strong radiation fields contain more photons than weak ones, but all photons of a given frequency have the same energy.

Thus, electromagnetic waves have four essential features: (1) they travel with a certain speed, 186,000 miles per second in vacuum but less in solids, liquids, or gases; (2) each wave has a particular frequency that is determined by the manner in which it is excited; (3) the wave consists of electric and magnetic fields at right angles to the direction of propagation, and these fields vary sinusoidally (*i.e.*, their values when charted follow a sine curve) with time as observed by a stationary observer; (4) the energy of the wave is packaged into individual units, called photons, whose energy has magnitude $h\nu$.

For all the value of materials as building materials, for all their value in electrical and magnetic uses, nothing about materials is more important to mankind than this relationship to electromagnetic radiation. The infrared in the sun's rays provides warmth; more detailed information is provided by sight than by any other sense; food and clothing come ultimately from chemical interactions of plants with radiation. The sections that follow deal with the way materials behave when they are illuminated with radiation, the changes in the internal structure induced by the energy of incoming waves, and the way radiation is generated in materials.

BEHAVIOUR OF SOLIDS ILLUMINATED WITH RADIATION

Most materials do not emit light of their own; mostly, they simply reflect light, transmit it, or absorb it. How

matter behaves when illuminated depends on what the electrons do. If the light photon has a frequency such that its energy matches the energy needed to excite an electron to a higher state, then the photon may be absorbed. The electron, which may be an ion-core electron or one of the free electrons in a solid, may return to its initial state from this higher energy excited state by re-emission of the photon of the same frequency ν . Detection of this photon permits viewing of an object by reflected (that is, by re-emitted) light. The process of absorption and re-emission of photons is very selective. If the energy of the incoming photon does not closely match the required excitation energy, no excitation occurs. The sharpness of absorption lines for gas atoms can be noted by observation of the dark lines observed in spectra of nebulae and stars, including the sun (see ASTRONOMICAL SPECTROSCOPY, PRINCIPLES OF). Radiation falling on solids and liquids must meet this same requirement of energy matching, called resonance, but solids have such an abundance of frequencies of excitation possible that excitations may exist in broad ranges of frequency.

Ice is transparent to visible light because no excitations exist whose energy matches photons in the visible part of the spectrum. Excitation levels do exist in the ultraviolet, so ice is opaque to ultraviolet. Radiation in this part of the spectrum has wavelengths shorter than 4,000 angstrom units; *i.e.*, frequencies greater than 10^{15} hertz (or cycles per second). Photons of this frequency have energies of about 1.6×10^{-19} calorie; *i.e.*, about four electron volts. This is the energy required to free a valence electron in the ice crystal. Ice (liquid water as well) also absorbs photons with frequencies in the infrared; were it not so, all lakes and rivers might be frozen permanently.

The warming of ice and water by infrared radiation shows another feature of excitation of electrons by photons. Energy of excitation in solids and liquids need not be re-emitted as the same type of photons—the energy may be transferred to thermal vibrations (that is, into heat), or it may produce other physical or chemical changes in matter.

Insulators such as glass, quartz, diamond, and rock salt crystals are transparent to visible light for the same reason as ice. No excitation resonances exist in the visible spectrum, because the valence electrons are so tightly bound that photons with energy in the ultraviolet are required to free them. Addition of impurities with resonances in the visible range, however, reduces the transparency and may give the crystal a colour. Crystalline aluminum oxide, corundum, is transparent to visible light; addition of a little chromium gives it a red colour to produce the gemstone ruby; addition of titanium and iron produces the blue sapphire (see GEMSTONES).

Metals are opaque to visible light; they also reflect light with little loss. This reflection comes entirely from the free electrons. These electrons are able to move so freely that no electric field may be propagated in the solid, and light penetrates only a few hundred angstroms. The motion of the electrons, in fact, causes the light to be re-emitted; indeed, if the surface of the metal is smooth, the re-emitted radiation from all parts of the surface is in phase, and the surface acts like a mirror.

Metals are excellent reflectors of radiation not only in the visible part of the spectrum but also for radiation of longer wavelength, far into the infrared ($\lambda = 1$ to 500 microns). Gradually, the depth of penetration of the wave increases, and transformation of the incident energy to heat increases. Power lines conducting electric current alternating at 60 cycles per second to heat a lamp filament are supplying radiation of wavelength 5,000,000 metres to the metal. All of this energy is absorbed in the filament; none is reflected (neglecting inductive effects of the tiny coil). Waves with even lower frequency have been detected in nature by geophysicists using sensitive magnetometers. These waves (of wavelength up to 10,000,000,000 metres) are thought to penetrate deeply into the earth—far down into the molten metallic core.

Optical properties of semiconductors lie between those of metals and those of insulators. They are commonly

insulators

Essential
features of
electro-
magnetic
waves

transparent at radio frequencies and down into the infrared. In the visible region they are opaque like metals; incident photons are absorbed by the excitation of valence electrons into higher energy states. For germanium the crossover wavelength is about 15,000 angstroms, for silicon about 12,000.

The most useful radiations in the other direction (*i.e.*, to shorter wavelengths) occur in the X-ray region (from one to 1,000 angstroms). These waves have energy sufficiently large to excite the ion-core electrons in all materials, whether metals, semiconductors, or insulators. Thus, discrete line absorption occurs at well-defined frequencies. Furthermore, at wavelengths in the range of one to five angstroms, diffraction effects occur, permitting crystal-structure determination to be made (see X-RAYS; CRYSTALLOGRAPHY).

Photochemical reactions, such as photosynthesis, photography, and the physics and chemistry of vision, constitute a fascinating field of study, the details of which are treated in the articles PHOTOCHEMICAL REACTIONS; PHOTOGRAPHY, TECHNOLOGY OF; and EYE AND VISION, HUMAN.

GENERATION OF ELECTROMAGNETIC RADIATION

The immediate re-emission of incident radiation associated with reflection or transmission of incident photons is not really generation of radiation. Solids (and liquids and gases), however, can be self-luminous; they may generate photons from energy supplied to the solid in some other form. The photons emitted may have a sharp, well-defined frequency, or they may cover a broad range of frequencies.

Conversion
of energy
into
photons

Energy can be converted into photons in a variety of ways. The most important is the conversion of heat into light—thermoluminescence. Another way, electron bombardment, is important in luminescence of both solids and gases. Fission and fusion reactions produce high-energy photons as well as ions and elementary particles of high kinetic energy. Some solids have the capability of converting photons of incoming radiation into photons of another frequency, photoluminescence. Others produce light by mechanical means, by rupture of materials, a phenomenon called triboluminescence; still others convert chemical energy into light, chemiluminescence; finally, some solids convert electrical energy into photons directly, electroluminescence.

The variety of ways in which these phenomena can occur is vast, almost beyond counting if one considers that they can occur in combination. Therefore, the discussion below is limited to a few examples that are important because of practical value or because of insight they give into basic features of the emission processes.

Monochromatic radiation. Photons of a single frequency—*i.e.*, monochromatic radiation—are produced when atoms or molecules in some excited state revert to a lower state. These photons may be of high energy, such as X-rays or gamma rays, if the states are of widely different energy; that is, different by more than 1,000 electron volts. Photons are in the visible spectrum if the energy difference is from 1.5 to three electron volts. The radiation is in the infrared or even radio wavelengths if the transitions involve energy differences of fractions of an electron volt.

Excitation of electrons to the higher states can be provided by several means. An electric discharge—a spark—can eject electrons from low levels into higher levels in the atom. A continuous electric arc, as in a neon tube or a sodium-vapour lamp, may produce excited states. Incident photons or high-energy electrons may provide energy for excitation.

Monochromatic light from isolated atoms (as in a gas) is of immense value. By its use the electronic structure of atoms has been deduced and many practical light sources have been developed: neon, sodium-vapour and mercury-vapour lamps, fluorescent lamps, and X-ray tubes. And an additional important feature, laser action, has recently been discovered and is now being exploited.

Laser
emission

Laser emission results from a special type of interaction of light with atoms. Not only can radiation be absorbed if

the photon energy matches an excitation energy of an atom, but an additional photon (of the same energy) can be emitted if the atom is already in the excited state. This emission process, called stimulated emission, results in amplification of light, in contrast to diminution caused by absorption. Amplification will predominate if more atoms are in the excited state than in the lower state and, in fact, sufficiently more to compensate for loss of photons that escape without participating in the process. Many materials are suitable for holding the excited atoms: gases (carbon dioxide is an example), liquids (such as organic molecules in alcohol), or solids (ruby or glass containing atoms of the rare-earth metal neodymium).

Band of radiation. Every photon has a certain frequency, but photons within a band of frequencies will be emitted if the allowed electron transitions form a continuous range. Much of the radiation of use is of this type; three examples are described in the following paragraphs.

1. Excitation of free electrons in metals by varying electric fields can be used to excite radio waves. By means of the electric field generated by an oscillator, the free electrons in an antenna are accelerated and decelerated. These electrons oscillating in phase in the antenna radiate photons whose frequency is that of the oscillator. The electrons themselves do not possess an inherent resonant frequency; rather, the frequency is set by the oscillator and the antenna. Enormous amounts of power, hundreds of thousands of watts (corresponding to myriads of individual photons), can be radiated in the radio and television frequencies.

2. Radiation from solids by thermally induced motion of atoms is by far the most important scheme of energy conversion. The allowed frequencies of vibration of atoms and groups of atoms in solids form a continuous band; hence, the radiation itself covers a wide range of frequencies. The greatest amount of light comes in the infrared and the visible parts of the electromagnetic spectrum; thus, hot objects can be used as sources of both heat and visible light.

Metals, semiconductors, and insulators, both solid and liquid, produce such radiation. The efficiency of production of light depends partly on the temperature of the material; the maximum energy in the spectrum comes at shorter wavelengths as the temperature of the solid is increased. Thus, a heat lamp may operate at 800° C (1,500° F), an incandescent lamp at 2,500° C (4,500° F). The energy radiated in the visible part of the spectrum from a lamp filament—*e.g.*, a 100-watt lamp—is only a few percent of the electrical energy supplied to the lamp. Even so, a 100-watt lamp filament radiates about 10^{19} photons per second in the visible range.

3. The abrupt deceleration of high-energy electrons when they strike solids also produces radiation in a broad band. This effect is most widely used to produce X-rays. With operating voltages of 10,000 to 50,000 volts, X-rays of wavelengths near one angstrom are generated when the incident electrons are slowed by collision with lattice ions of the target. Of course, the incident electrons may also cause generation of line spectra characteristic of the target ions, typically tungsten or molybdenum. The overall emission spectrum thus consists of sharp line spectra superimposed on broad-band (so-called white) radiation.

Production
of X-rays

Photoluminescence. Materials may emit radiation of one wavelength when they are irradiated with photons of another wavelength. This event, photoluminescence, is most widely used to produce visible light, but it also occurs in the X-ray region and in other regions of the electromagnetic spectrum. Radiation emitted immediately upon absorption of the incident light is called fluorescent radiation; such radiation in the visible spectrum is frequently produced when ultraviolet light, often the characteristic lines of mercury, is absorbed by an inorganic compound, often a metal oxide, a phosphide, or a sulfide, or by an organic material such as motor oil. The absorption of the incident photons is accompanied by excitation of valence electrons into some excited state. Recovery to the original state does not occur by a single-step process involving re-emission of a photon of the original wavelength; rather, the excited state decays in

two or more steps to the original state; hence, the re-emitted photons are of less energy (*i.e.*, of longer wavelength) than the original photons.

Practical use of fluorescence in lighting uses the mercury lines excited by electrons streaming through mercury vapour. These ultraviolet lines are absorbed by a mixture of compounds (called phosphors) coated on the inside of the glass envelope. These phosphors, blended to give the desired colour, produce visible light.

Visible light can also be produced by these same phosphors if the incident "radiation" is electrons. This process—**cathodoluminescence**—is widely used in cathode-ray tubes. Television display tubes and their predecessor—tubes for cathode-ray oscilloscopes—use this mode of light excitation.

Many other types of interactions of radiation with matter exist, some of which have practical application while others have only scientific interest; for details of these, see **LIGHT; SPECTROSCOPY, PRINCIPLES OF; MOSSBAUER EFFECT; LUMINESCENCE**.

BIBLIOGRAPHY. Among the most useful sources for the general reader are the magazine *Scientific American*, especially the September 1967 issue on "Materials" and the September 1968 issue on "Light"; issues of *Science* (weekly), the journal of the American Association for the Advancement of Science; and *Physics Today* (monthly), of the American Physical Society. General reference books include: HENRY HODGES, *Technology of the Ancient World* (1970), a readable history of man's development of materials usage; C.S. SMITH, *A History of Metallurgy* (1960); LAWRENCE VAN MACK, *Elements of Materials Science* (1964), an elementary modern textbook; CHARLES A. WERT and ROBB M. THOMSON, *The Physics of Solids*, 2nd ed. (1970), an intermediate level text; CHARLES KITTEL, *Introduction to Solid State Physics*, 4th ed. (1971), an advanced level text; and JOHN ZIMAN, *Electrons and Phonons* (1960), a treatise. See also the series FREDERICK SEITZ and DAVID TURNBULL, *Solid State Physics*, 22 vol. (1956–71), written for the expert.

The classic reference work on bonding is LINUS PAULING, *Nature of the Chemical Bond and the Structure of Molecules and Crystals*, 3rd ed. (1960). A readable treatment of crystal structure is C.S. BARRETT and T.B. MASSALSKI, *Structure of Metals*, 3rd ed. (1966).

References on mechanical properties are many; among the most useful at an intermediate level are A.H. COTTRELL, *The Mechanical Properties of Matter* (1964); and GEORGE E. DIETER, JR., *Mechanical Metallurgy* (1961). Interaction of radiation with matter may be found in many books, among them: EARLE B. BROWN, *Modern Optics* (1965); and GRANT R. FOWLES, *Introduction to Modern Optics* (1968); RALPH S. BECKER, *Theory and Interpretation of Fluorescence and Phosphorescence* (1969); and P.R. THORNTON, *The Physics of Electroluminescent Devices* (1967). General books on magnetism and magnetic materials are: JAN SMIT (ed.), *Magnetic Properties of Materials* (1971); JOHN E. THOMPSON, *The Magnetic Properties of Materials* (1968); and ROY CAREY and EVAN D. ISAAC, *Magnetic Domains and Techniques for Their Observation* (1966). The classic book on materials of ferromagnetism for many years has been RICHARD M. BOZORTH, *Ferromagnetism* (1956).

(C.A.W./H.K.B.)

Solomon

Solomon, the son and successor of David, has traditionally been remembered as the greatest king of Israel, although some modern historians have been less favourable in their judgment of him. The dates of his reign are not known with certainty, but it was a long reign of about 40 years that occurred in the middle of the 10th century BC. Nearly all that is factually known of him comes from the Bible (especially **I Kings** 1–11 and **II Chron.** 1–9). While the latter already contains some legendary material, it is, in the main, a wealth of historical facts of the most prosaic and reliable nature.

Background. Solomon's background is both well-known and colourful. His father, David, was a self-made king, who, against great odds, founded the Judean dynasty and carved out an empire from the border of Egypt to the Euphrates River. His first and greatest enemies were the Philistines, who controlled Palestine and kept the Tyrians and Sidonians from prospering on the sea. By training the Israelite infantry, especially the bowmen, he

proved more than a match for Philistine and other foes who employed horses and chariots. In addition, David made common cause with King Hiram of Tyre, forming a land and sea alliance that endured into Solomon's reign. Solomon, accordingly, inherited a considerable empire, along with a Phoenician ally of prime importance for naval and merchant marine operations.

Solomon's mother was Bathsheba, formerly the wife of David's Hittite general, Uriah. Bathsheba proved to be adept at court intrigue, and it is possible that she had exposed herself to David's susceptible eye with a view to rising from general's wife to queen.

David seems to have been senile toward the close of his reign, and one of his wives, Haggith, tried to execute a plot in which her son, Adonijah, would be appointed as David's successor. Adonijah enlisted the aid of powerful allies: David's senior general, Joab, Abiathar the priest, and several other court figures. It was only through the efforts of Bathsheba, in concert with the prophet Nathan, that Solomon, who was younger than several of his brothers, was anointed king while David was still alive.

Empire builder. As soon as he acceded to the throne, Solomon consolidated his position by liquidating his opponents ruthlessly, one by one. Once rid of his foes, he established his friends in the key posts of the military, governmental, and religious institutions. In an ancient Near Eastern empire, this was almost the only means of establishing stable government.

Solomon also strengthened his position through marital alliances. Although the astonishing harem of Solomon—700 wives and 300 concubines—recorded in **I Kings** is no doubt an exaggeration of popular tradition, the figures do indicate his position as a grand monarch. Such a **ménage** brought prestige as well as pleasure, and the marriages were a form of diplomacy. He wed the sisters and daughters of kings from far and wide, cementing alliances of arms and trade to facilitate his establishment of a huge commercial empire. One of his brides was the daughter of an Egyptian pharaoh; the pharaoh captured and burned down the Canaanite city of Gezer and gave it to his son-in-law Solomon.

Like all empire builders, Solomon maintained his dominions with military strength. In addition to infantry, he had at his disposal impressive chariotry and cavalry. **II Chron.** 8 recounts Solomon's successful military operations in Syria, where his targets included Tadmor-Palmyra, a caravan oasis city in the desert, midway between Syria and Mesopotamia. His aim was the control of a great overland trading route. To consolidate his interests in the province, he planted Israelite colonies to look after military, administrative, and commercial matters. Such colonies, often including cities in which chariots and provisions were kept, were in the long tradition of combining mercantile and military personnel to take care of their sovereign's trading interests far from home. Megiddo, a town located at the pass through the **Carmel** range connecting the coastal plain with the Plain of Esdraelon, is the best preserved example of one of Solomon's cities. The remains of stalls for 450 horses discovered in Megiddo show that the figures of 1,400 chariots and 12,000 horses given for Solomon's forces in **I Kings** are scarcely exaggerated. (Some scholars question whether these are horse stalls or shop stalls.) The network of Solomon's far-flung trading posts eventually formed the nucleus of the first great Jewish Diaspora.

Palestine was destined to be an important centre because of its strategic location for trade by land and sea. By land, it alone connects Asia and Africa; and, along with Egypt, it is the only area with ports on the Atlantic–Mediterranean and Red Sea–Indian Ocean waterways. It was Solomon who fulfilled the commercial destiny of Palestine and brought it to its greatest heights.

The nature of his empire was predominantly commercial—it served him and friendly rulers to increase trade by land and sea. Hiram of Tyre, for example, needed the port of Ezion-geber, near Elath on the Gulf of Aqaba, which leads into the Red Sea and thence into the Indian Ocean. The joint merchant marine expeditions of Hiram and Solomon sailed practically to the ends of the known

Marital
alliances

Relations
with the
Queen of
Sheba

world. Some of the scheduled voyages took three years for the round trip.

A celebrated episode in the reign of Solomon is the visit of the Queen of Sheba. Her south Arabian kingdom lay along the Red Sea route into the Indian Ocean, and her terrain was rich in gold, frankincense, and myrrh. Solomon needed her products and her trade routes for maintaining his commercial network; she needed Solomon's cooperation for marketing her goods in the Mediterranean via his Palestinian ports. Legend makes much of a romance between the Queen of Sheba and Solomon, for his granting her "all that she desired, whatever she asked" (1 Kings 10:13) has been interpreted to include an offspring.

Builder, administrator, and sage. The demand for fortresses and garrison cities throughout his homeland and empire made it necessary for Solomon to embark on a vast building program; the prosperity of the nation made such a program possible. He was especially lavish with his capital, Jerusalem, where he erected a city wall, a construction called the Millo, the royal palace, and the famous Temple. Around Jerusalem (but not in the Holy City itself), he built facilities, including shrines, for the main groups of foreigners on trading missions in Israel. Later generations, in less secure and less prosperous times, destroyed those shrines around Jerusalem in a parochial spirit that could not accommodate itself to Solomon's ecumenical outlook. Solomon's Temple was to assume an importance far beyond what its dimensions might suggest, for its site became the only central shrine for Judaism and early Christianity.

The prayer ascribed to Solomon in 1 Kings 8 when he dedicated the Temple is of far-reaching significance. In it the God of Jerusalem is the one and only God of the universe. In addition to invoking blessings on God's people Israel, Solomon begs God to heed also the prayers of aliens who come from the ends of the earth, having heard of the fame of Jerusalem and the great God who dwells there; and he reminds God that helping such aliens will further enhance the reputation of God and his Temple in every land. Solomon's involvement in international trade brought in its train intellectual and spiritual universalism, but it took a few centuries of maturation for the universality of the Solomonic age to find its classical expression in the words of Israel's prophets. Practical universality gave rise to universal religion, and not vice versa. Furthermore, international trade taught men the lesson that international peace is necessary for prosperity. The requirements of the Solomonic age led to the first known formulation of international peace; *i.e.*, "nation shall not lift up sword against nation, neither shall they learn war anymore" (Isaiah 2, Micah 4).

The vigour of Solomon's building program made it oppressive. For example, men had to put in one month out of every three in forced labour. In theory, such labour was to be performed by the Canaanites—not by the noble Hebrew tribesmen, who were supposed to be the administrators, priests, and fighters. But Solomon's demands were such that there were not enough Canaanites to go around, so that Israelites were forced to do menial labour for the crown.

Solomon was a vigorous administrator, and he realized that the old division of the nation into 12 tribes posed a threat to the unity of the realm because the tribal feeling that was retained was not for the good of the state. Accordingly, he redivided the realm into 12 administrative districts, deviating, for the most part, from the tribal boundaries. The figure of 12 was retained because each district was to "support the palace" (*i.e.*, shoulder federal obligations) for one of the 12 months in the year. Each district had its royally appointed governor, and a chief ruled over the 12 governors. Another important but unpopular appointee of the king was the chief of taxation; taxes were exacted most commonly in the form of forced labour and in kind.

Solomon also became famous as a sage. When two harlots each claimed to be the mother of the same baby, he determined the real mother by each woman's reaction to the prospect of dividing the child into two halves. Solo-

mon was deemed wiser than all the sages of Egypt and the Near East—even wiser than some ancient paragons of wisdom. The book of Proverbs contains collections of aphorisms and other wise teachings attributed to him. Solomon was also famed as a poet who composed 1,005 songs. The biblical Song of Solomon is attributed to him in the opening verse. His reputation as a great lover, reflected in the size of his harem, is appropriately a major theme in the Song of Solomon. Post-biblical tradition attributed later works to him: the apocryphal Wisdom of Solomon, on the one hand, and the *Odes of Solomon* and *Psalms of Solomon*, on the other, are tributes to his stature as a sage and poet.

Solomon's legend also stresses another dimension of his prowess: his power over all creatures, natural and supernatural. It was he, according to *The Arabian Nights*, who imprisoned jinn (supernatural beings below the level of angels and demons) in sealed jars and cast them into the sea. Magic texts, such as the Aramaic *Incantation Bowls*, invoke the potent seal of Solomon son of David. When Jesus is called "the Son of David," it does not mean simply that he was of the royal Davidic line but that the wonder-working Christ, against whom no demon could stand, was a veritable "Solomon son of David," that master over men and jinn.

Division of the nation. Solomon's personal prestige and genius were required to perpetuate the powerful nation he had acquired from his father and then further strengthened. It is suspected that the increase in Israel's wealth was matched by an increase in extravagance and that the wealth was not diffused to the people. It is also considered possible that Solomon's treatment of the northern tribes showed favouritism to his own tribe of Judah. When his son Rehoboam succeeded him, the northern tribes wanted to know his policy concerning the burdens borne by the people. Rehoboam ill-advisedly announced a harsher course, whereupon the northern tribes seceded and formed their own Kingdom of Israel, leaving the descendants of Solomon with the southern Kingdom of Judah. Thus Solomon's empire was lost beyond recall, and even the homeland was split into two, often hostile, kingdoms.

BIBLIOGRAPHY. EDOUARD MEYER *Geschichte des Altertums*, 2nd ed., vol. 2 (1931), provides a succinct but masterful account of Solomon in ancient Near Eastern context. A history of Solomon's reign with extensive bibliography is provided by O. EISSFELDT, "The Hebrew Kingdoms," in *Cambridge Ancient History*, rev. ed., vol. 2, ch. 34 (1965). CYRUS H. GORDON, *The Ancient Near East*, pp. 180–189 (1965), offers an account of Solomon, in keeping with the Bible sources but within the framework of extra-biblical materials. For a detailed analysis of the subject, see JAMES A. MONTGOMERY, *The Books of Kings* (1951). CYRUS H. GORDON, *Before Columbus*, pp. 113–135 (1971), outlines Solomon's maritime activities in a global setting. MARTIN NOTH, *Geschichte Israels* (1958; Eng. trans., *The History of Israel*, 2nd ed. rev., 1960), gives an account of Solomon within a recent standard history.

(C.H.G.)

Solon

Solon, Athenian statesman and poet, embodied the cardinal Greek virtue of moderation. He put an end to the worst evils of poverty in Attica (the territory of the city-state of Athens) and provided his fellow countrymen with a balanced constitution and a humane code of laws. Standing, in time, midway between the epic poets Homer and Hesiod (fl. c. 800) and the 5th-century classical tragedians Aeschylus, Sophocles, and Euripides, Solon was also Athens' first poet—and a poet who truly belonged to Athens. As the medium through which he warned, challenged, counselled the people, and urged them to action, his poetry was the instrument of his statesmanship.

In Solon's lifetime (c. 630–c. 560 BC), the Greeks had not yet begun to write history or biography. It was not until the 5th century that accounts of his life and works began to be put together, on the evidence of his poems (of which the 300 or so lines preserved by quotation probably represent only a small proportion), his law code, oral tradition, and inference from existing institutions. Al-

Effects of
Solomon's
trade policy

Reputation

though certain details have a legendary ring, the main features of the story seem to be reliable.

Solon was of noble descent but moderate means. As the tradition states and his travels and economic measures suggest, he may have been a merchant. He first became prominent about 600 BC, when the Athenians were disheartened by ill success in a war with their neighbours of Megara for possession of the island of Salamis. By publicly reciting a poem that made the issue a matter of national honour and that called on the Athenians to "arise and come to Salamis, to win that fair island and undo our shame," Solon induced them to resume the war, which they eventually won.

Social and political conditions of 6th-century Greece

The early 6th century was a troubled time for the Athenians in other ways as well. Society was dominated by an aristocracy of birth, the eupatridae, who owned the best land, monopolized the government, and were themselves split into rival factions. The poorer farmers were easily driven into debt by them and when unable to pay were reduced to the condition of serfs on their own land and, in extreme cases, sold into slavery. The intermediate classes of middling farmers, craftsmen, and merchants resented their exclusion from the government. As Solon described it, no Athenian could escape these social, economic, and political evils:

The public evil enters the house of each man, the gates of his courtyard cannot keep it out, it leaps over the high wall; let him flee to a corner of his bedchamber, it will certainly find him out.

The public evil might well have culminated in a revolution and subsequent tyranny (dictatorship), as it had in other Greek states, had it not been for Solon, to whom Athenians of all classes turned in the hope of a generally satisfactory solution of their problems. Because he believed in moderation and in an ordered society in which each class had its proper place and function, his solution was not revolution but reform.

Economic reforms. Solon had already held office as archon (annual chief ruler) c. 594 BC. It was probably about 20 years later that he was given full powers as reformer and legislator. His first concern was to relieve the immediate distress caused by debt. He redeemed all the forfeited land and freed all the enslaved citizens, probably by fiat. This measure, known popularly as the "shaking off of burdens," was described by Solon in one of his poems:

Relief for debtors

These things the black earth . . . could best witness for the judgement of posterity; from whose surface I plucked up the marking-stones [probably signs of the farmers' indebtedness] planted all about, so that she who was enslaved is now free. And I brought back to Athens . . . many who had been sold, justly or unjustly, or who had fled under the constraint of debt, wandering far afield and no longer speaking the Attic tongue; and I freed those who suffered shameful slavery here and trembled at their masters' whims.

He also prohibited for the future all loans secured on the borrower's person. But he refused to go to the length demanded by the poor, which was to redistribute the land. Instead, he passed measures designed to increase the general prosperity and to provide alternative occupations for those unable to live by farming: e.g., trades and professions were encouraged; the export of produce other than olive oil was forbidden (so much grain had been exported that not enough remained to feed the population of Attica); the circulation of coined money (invented in Solon's lifetime) was stimulated by the minting of a native Athenian coinage on a more suitable standard than that of the coins of neighbours, which had been used hitherto; and new weights and measures were introduced. The rapid spread of the new coinage and of Athenian products, particularly olive oil and pottery, throughout the commercial world of the times, attested by archaeology, shows that these measures were effective. Poverty, though not eliminated, was never again in Attica the crying evil that it had been before Solon's reforms.

Political reforms. Solon's new political constitution abolished the monopoly of the eupatridae and substituted for it government by the wealthy citizens. He instituted a census of annual income, reckoned primarily in measures

of grain, oil, and wine, the principal products of the soil, and divided the citizens into four income groups, accordingly. (Those whose income was in other forms, including money, must have been rated on a system of equivalents.) Henceforth, political privilege was allotted on the basis of these divisions, without regard to birth. All citizens were entitled to attend the general Assembly (Ecclesia), which became, at least potentially, the sovereign body, entitled to pass laws and decrees, elect officials, and hear appeals from the most important decisions of the courts. All but those in the poorest group might serve, a year at a time, on a new Council of Four Hundred, which was to prepare business for the Assembly. The higher governmental posts were reserved for citizens of the top two income groups. Thus, the foundations of the future democracy were laid. But a strong conservative element remained in the ancient Council of the Hill of Ares (Areopagus), and the people themselves for a long time preferred to entrust the most important positions to members of the old aristocratic families.

Code of laws. Solon's third great contribution to the future good of Athens was his new code of laws. The first written code at Athens, that of Draco (c. 624 BC), was still in force. Draco's laws were shockingly severe (hence the term draconian)—so severe that they were said to have been written not in ink but in blood. On the civil side they permitted enslavement for debt; and death seems to have been the penalty for almost all criminal offenses. Solon revised every statute except that on homicide and made Athenian law altogether more humane. His code, though supplemented and modified, remained the foundation of Athenian statute law until the end of the 5th century, and parts of it were embodied in the new codification made at that time.

Response to Solon's reforms. When Solon had completed his task, complaints came in from all sides. In attempting to satisfy all, he had satisfied none. The nobles had hoped that he would make only marginal changes; the poor, that he would distribute all the land in equal shares and, if necessary, make himself tyrant in order to enforce the redistribution. But Solon, although concerned for freedom, justice, and humanity, was no egalitarian, nor had he any ambition for autocratic power. His poems make this clear:

Solon and tyranny

I gave the people as much privilege as sufficed, . . . and I took care that the rich and powerful should suffer nothing amiss; I stood holding a strong shield over both parties, and let neither side prevail unjustly.

It does not please me to achieve anything by force as a tyrant, or to let the nobles and the meaner sort share equally in the rich land.

Though discontented, the Athenians stood by their promise to accept Solon's dispositions; they were given validity for 100 years and posted for all to see on revolving wooden tablets. To avoid having to defend and explain them further, he set off on a series of travels, undertaking not to return for ten years.

Later years. Among the places he visited were Egypt and Cyprus. These visits are attested by his poems. Less credible (because of chronological difficulties) is the famous encounter with the fabulously rich Croesus, king of Lydia, who, so the story goes, learned from Solon that wealth and power were not happiness and that, so long as he was alive, no man could be counted happy.

When Solon returned, he found the citizens divided into regional factions headed by prominent nobles. Of these, his friend Peisistratus, general in the final war for Salamis and leader of northeastern Attica, seemed to Solon to be planning to become tyrant. The old statesman's urgent warnings were disregarded, even dismissed as the ravings of a madman. His reply was that "A little time will show the citizens my madness, /Yes, will show, when truth comes in our midst." It was not long before he was proved right: Peisistratus did become tyrant (560 BC). Although on this occasion he was soon ejected, it seems that Solon did not live to see it.

Reputation. It was probably before the end of the 5th century that the Greeks first drew up a list of the Seven

Wise Men who had been prominent intellectually and politically in the 6th century. The earliest list, accepted by the Greek philosopher Plato, did not satisfy later writers, who expanded it to ten and even 17 to accommodate rival claimants. Every version, however, contained four names that were not challenged. One of them was that of Solon of Athens, a testimony to the abiding respect in which his memory was held.

BIBLIOGRAPHY. The principal ancient evidence for the life and work of Solon consists of the surviving fragments of his laws, edited, without translation, by E. RUSCHENBUSCH, *Σόλωνος νόμοι* (1966); poems (discussion, text, translation, and commentary) in I. M. LINFORTH, *Solon the Athenian*, pp. 103–245 (1919); the discussion of his reforms in the Aristotelian *Constitution of Athens*, trans. by K. VON FRITZ and E. KAPP, pp. 72–82 (1950); and the biography by PLUTARCH, written in the early 2nd century AD (translations in Everyman edition of the *Lives*, vol. 1, pp. 120–144; and by B. PERRIN in the Loeb edition, vol. 1, pp. 405–499). There are separate modern accounts of Solon in English by Linforth (cited above); by K. FREEMAN, *The Work and Life of Solon* (1926); and by W. J. WOODHOUSE, *Solon the Liberator* (1938), dealing mainly with the agrarian reforms. Although the main lines of Solon's life and work are clear, there are numerous unresolved controversies, and none of these three books, and little else on Solon, can be regarded as definitive. There is an excellent short account by A. ANDREWES in *The Greek Tyrants*, ch. 7 (1956). The constitutional problems raised by the ancient accounts of the reforms, and also their date, are fully discussed by C. HIGNETT in *History of the Athenian Constitution to the End of the Fifth Century B.C.* (1952); the economic background is given by A. FRENCH in *Growth of the Athenian Economy*, ch. 2 (1964). The most up-to-date treatment is by V. EHRENBURG in *From Solon to Socrates*, ch. 3 (1968).

(T.J.C.)

Solutions and Solubilities

The ability of liquids to dissolve solids, other liquids, or gases has long been recognized as one of the fundamental phenomena of nature encountered in daily life. The practical importance of solutions and the need to understand their properties have challenged numerous writers since the Ionian philosophers and Aristotle. From the Middle Ages to the Enlightenment, alchemists sought a universal solvent that would dissolve everything, seeing therein a physical counterpart to attainment of salvation. About a century ago, the beginnings of physical chemistry were motivated largely by fascination with liquid mixtures. Though many physicists and chemists have devoted themselves to a study of solutions, this is today still an incompletely understood subject under active investigation.

A solution is a mixture of two or more chemically distinct substances, a mixture that is said to be homogeneous on the molecular scale—the composition at any one point in the mixture is the same as that at any other point. This is in contrast to a suspension (or slurry), in which small discontinuous particles are surrounded by a continuous fluid. Although the word solution is commonly applied to the liquid state of matter, solutions of solids and gases are also possible; brass, for example, is a solution of copper and zinc, and air is a solution primarily of oxygen and nitrogen with a few other gases present in relatively small amounts.

The ability of one substance to dissolve another depends always on the chemical nature of the substances, frequently on the temperature, and occasionally on the pressure. Water, for example, readily dissolves methyl alcohol but does not dissolve mercury; it barely dissolves benzene at room temperature but does so increasingly as the temperature rises. While the solubility in water of the gases present in air is extremely small at atmospheric pressure, it becomes appreciable at high pressures where, in many cases, the solubility of a gas is (approximately) proportional to its pressure. Thus, a diver must breathe air (four-fifths nitrogen) at a pressure corresponding to the pressure around him, and, as he goes deeper, more air dissolves in his blood. When he ascends, the solubility of the gases decreases so that they leave his blood, forming bubbles in the blood vessels. This condition (known as

the bends) is extremely painful and may cause death; it can be alleviated by breathing, instead of air, a mixture of helium and oxygen because the solubility of helium in blood is much lower than that of nitrogen.

The solubility of one fluid in another may be complete or partial; thus, at room temperature, water and methyl alcohol mix in **all** proportions, but 100 grams of water dissolve only 0.07 gram of benzene. Though it is generally supposed that all gases are completely miscible—i.e., mutually soluble in all proportions—this is true only **at** normal pressures (pressure is usually expressed in atmospheres, one atmosphere being the pressure exerted by a column of mercury 760 millimetres high, or about 14.7 pounds per square inch). At high pressures, pairs of chemically unlike gases may exhibit only limited miscibility; for example, at 20° C (68° F) helium and xenon are completely miscible at pressures below 200 atmospheres but become increasingly immiscible as the pressure rises.

The ability of a liquid to dissolve selectively forms the basis of common separation operations in chemical and related industries. A mixture of two gases, carbon dioxide and nitrogen, can be separated by bringing it into contact with ethanolamine, a liquid solvent that readily dissolves carbon dioxide but hardly dissolves nitrogen. In this process, called absorption, the dissolved carbon dioxide is later recovered, and the solvent made usable again by heating the carbon dioxide-rich solvent, since the solubility of a gas in a liquid usually (but not always) decreases with rising temperature. A similar absorption operation can remove a pollutant such as sulfur dioxide from smokestack gases in a plant using sulfur-containing coal or petroleum as fuel.

The process wherein a dissolved substance is transferred from one liquid to another is called extraction. As an example, phenolic pollutants (organic compounds of the types known as phenol, cresol, and resorcinol) are frequently found in industrial aqueous waste streams, and, since these phenolics are damaging to marine life, it is important to remove them before dumping the waste stream into a lake or river. One way to do so is to bring the waste stream into contact with a water-insoluble solvent (e.g., an organic liquid such as a high-boiling hydrocarbon) that has a strong affinity for the phenolic pollutant. The solubility of the phenolic in the solvent divided by that in water is called the distribution coefficient, and it is clear that for an efficient extraction process it is desirable to have as large a distribution coefficient as possible.

For an understanding of solutions, it is desirable to have knowledge of the subjects treated in detail in the articles **MOLECULAR STRUCTURE**; **CHEMICAL REACTIONS**; **MECHANISMS OF**; **CHEMICAL BONDING**; **PHASE CHANGES AND EQUILIBRIA**; **LIQUID STATE**; **GASEOUS STATE**; **SOLID STATE OF MATTER**. Only the briefest reference to this information can be given here.

All matter is composed of elements consisting of atoms made up of a positively charged nucleus surrounded by negatively charged electrons. The nucleus, in **turn**, consists of tightly packed protons, each with a positive charge, and neutrons, which have no charge. The number of protons is the same for all atoms of an element and is called the atomic number, but the number of neutrons varies, thus producing atoms of the same element with different masses; these are called isotopes. The electrons around the nucleus determine the chemical and most of the physical properties of an atom. In a neutral atom, the positive charges of the protons are balanced by an equal number of electrons **arranged** according to a periodic system that makes the electron structure characteristic for each element. The main difference between the atoms of different elements is the affinity with which a nucleus holds its electrons. Some atoms have structures that are exceedingly stable, some tend to give up electrons easily, and others tend to add electrons to their normal complement. This potential for rearranging electron structures is the basis of chemical reaction and of bonding that takes place between atoms when they form the different molecules of the millions of known compounds. Compounds can be classified according to the type of bond holding

Effects of
tempera-
ture and
pressure

Bonds
between
atoms

the atoms together. In one class, called covalent, the bond consists of pairs of electrons shared mutually by the component nuclei. In another class, called ionic, one atom's affinity for electrons is so much greater than that of another that electrons are transferred, leaving the donor positively charged and the acceptor negatively charged. The charged atoms, called ions, then may associate (opposite charges attract) to form ionic, or electrovalent, bonds. In the third type of bonding, called metallic, the bonds between atoms free some electrons to move about and, thereby, form the basis for electrical conduction. Various other kinds of bonds are important to the phenomena of solutions. For example, an unsymmetrical distribution of charges on a molecule causes it to be attracted toward other unsymmetrically charged molecules, including its own kind, with the positive end of one toward the negative end of the other. Such polar molecules behave differently in solution from nonpolar molecules. When a hydrogen atom is bonded covalently to a molecule at a position at which the hydrogen nucleus (a single proton) is exposed, it will attach itself (and thus its molecule) to the dense electron structures surrounding atom? of certain elements in other molecules. The two molecules are thus linked by what is called a hydrogen bond, which, though not as strong as the usual chemical bonds, tends to be extremely influential in the behaviour of large, complex molecules, such as those found in the fluids of living organisms, as well as in the behaviour of such simple molecules as water. Groups of atoms, covalently bonded, may have a negative or positive charge, in which case they are also called ions or radicals, and their behaviour, too, is drastically different because of the attachments they make with other particles of opposite charge and because of the repulsion that they exert on particles with the same kind of charge.

An atom is represented by the symbol of the element, and molecules, or compounds, are represented by the symbols of their component atoms, with the number of atoms indicated in subscripts; thus, one molecule of water consists of two atoms of hydrogen (H) and one atom of oxygen (O), and the formula for water is written H_2O . Ions are represented by the symbols with the charge indicated in superscripts; thus, hydrogen ion, (H^+); hydroxide ion, (OH^-).

The properties of mixtures and solutions are, therefore, not merely the sum of the properties of their components; they usually have properties characteristic of themselves because molecules and atoms are not indifferent to one another's presence.

CLASSES OF SOLUTIONS

Electrolytes and nonelectrolytes. Broadly speaking, liquid mixtures can be classified as either solutions of electrolytes or solutions of nonelectrolytes. Electrolytes are substances that can dissociate into electrically charged particles called ions, while nonelectrolytes consist of molecules that bear no net electric charge. Thus when ordinary salt (sodium chloride, formula $NaCl$) is dissolved in water, it forms an electrolytic solution, dissociating into positive sodium ions (Na^+) and negative chloride ions (Cl^-), whereas sugar dissolved in water maintains its molecular integrity and does not dissociate. Because of its omnipresence, water is the most common solvent for electrolytes; the ocean is a solution of electrolytes. Electrolyte solutions, however, are also formed by other solvents (such as ammonia and sulfur dioxide) that have a large dielectric constant (a measure of the ability of a fluid to decrease the forces of attraction and repulsion between charged particles). The energy required to separate an ion pair (*i.e.*, one ion of positive charge and one ion of negative charge) varies inversely with the dielectric constant, and, therefore, appreciable dissociation into separate ions occurs only in solvents with large dielectric constants.

Most electrolytes (for example, salts) are nonvolatile, which means that they have essentially no tendency to enter the vapour phase. There are, however, some notable exceptions, such as hydrogen chloride (HCl), which is readily soluble in water, where it forms hydrogen ions

(H^+) and chloride ions (Cl^-). At normal temperature and pressure, pure hydrogen chloride is a gas, and, in the absence of water or some other ionizing solvent, hydrogen chloride exists in molecular, rather than ionic, form.

Solutions of electrolytes readily conduct electricity, whereas nonelectrolyte solutions do not. A dilute solution of hydrogen chloride in water is a good electrical conductor, but a dilute solution of hydrogen chloride in a hydrocarbon is a good insulator. Because of the large difference in dielectric constants, hydrogen chloride is ionized in water but not in hydrocarbons.

Weak electrolytes. While classification under electrolyte-solution or nonelectrolyte-solution headings is often useful, some solutions have properties near the boundary between these two broad classes. Although such substances as ordinary salt and hydrogen chloride are strong electrolytes—*i.e.*, they dissociate completely in an ionizing solvent—there are many substances, called weak electrolytes, that dissociate to only a small extent in ionizing solvents. For example, in aqueous solution, acetic acid can dissociate into a positive hydrogen ion (H^+) and a negative acetate ion (CH_3COO^-), but it does so to a very limited extent; in an aqueous solution containing 50 grams acetic acid and 1,000 grams water, less than 1 percent of the acetic acid molecules are dissociated into ions. Therefore, a solution of acetic acid in water exhibits some properties associated with electrolyte solutions (*e.g.*, it is a fair conductor of electricity), but in general terms it is more properly classified as a nonelectrolyte solution. By similar reasoning, an aqueous solution of carbon dioxide is also considered a nonelectrolyte solution even though carbon dioxide and water have a slight tendency to form carbonic acid, which, in turn, dissociates to a small extent to hydrogen ions and bicarbonate ions (HCO_3^-).

Endothermic and exothermic solutions. When two substances mix to form a solution, heat is either evolved (an exothermic process) or absorbed (an endothermic process); only in the special case of an ideal solution do substances mix without any heat effect. Most simple molecules mix with a small endothermic heat of solution, while exothermic heats of solution are observed when the components interact strongly with one another. An extreme example of an exothermic heat of mixing is provided by adding an aqueous solution of sodium hydroxide, a powerful base, to an aqueous solution of hydrogen chloride, a powerful acid; the hydroxide ions (OH^-) of the base combine with the hydrogen ions (H^+) of the acid to form water, a highly exothermic reaction that yields 75,300 calories per 100 grams of water formed. In nonelectrolyte solutions, heat effects are usually endothermic and much smaller, often about 100 calories, when roughly equal parts are mixed to form 100 grams of mixture.

Formation of a solution usually is accompanied by a small change in volume. If equal parts of benzene and stannic chloride are mixed, the temperature drops; if the mixture is then heated slightly to bring its temperature back to that of the unmixed liquids, the volume increases by about 2 percent. On the other hand, mixing roughly equal parts of acetone and chloroform produces a small decrease in volume, about 0.2 percent. It frequently happens that mixtures with endothermic heats of mixing expand—*i.e.*, show small increases in volume—while mixtures with exothermic heats of mixing tend to contract.

A large decrease in volume occurs when a gas is dissolved in a liquid. For example, at $0^\circ C$ ($32^\circ F$) and atmospheric pressure, the volume of 28 grams of nitrogen is 22,400 cubic centimetres. When these 28 grams of nitrogen are dissolved in an excess of water, the volume of the water increases only 40 cubic centimetres; the decrease in volume accompanying the dissolution of 28 grams of nitrogen in water is therefore 22,360 cubic centimetres. In this case, it is said that the nitrogen gas has been condensed into a liquid, the word *condense* meaning "to make dense"—*i.e.*, to decrease the volume.

PROPERTIES OF SOLUTIONS

Composition ratios. The composition of a liquid solution means the composition of that solution in the bulk

—that is, of that part that is not near the surface. The interface (the surface separating them) between the liquid solution and some other phase (for example, a gas such as air) has a composition that differs from that of the bulk, sometimes very much so. The environment at an interface is significantly different from that in the bulk of the liquid, and in a solution the molecules of a particular component may prefer one environment over the other. If the molecules of one component in the solution prefer to be at the interface as opposed to the bulk, it is said that this component is positively adsorbed at the interface. In aqueous solutions of organic liquids, the organic component is usually positively adsorbed at the solution-air interface; as a result, it is often possible to separate a mixture of an organic solute from water by a process called froth separation. Air is bubbled vigorously into the solution, and a froth is formed. The composition of the froth differs from that of the bulk because the organic solute concentrates at the interfacial region. The froth is mechanically removed and collapsed, and, if further separation is desired, a new froth is generated. The tendency of some dissolved molecules to congregate at the surface has been utilized in water conservation. A certain type of alcohol, when added to water, concentrates at the surface to form a barrier to evaporating water molecules. In warm climates, therefore, water loss by evaporation from lakes can be significantly reduced by introducing a solute that adsorbs positively at the lake-air interface.

The composition of a solution can be expressed in a variety of ways, the simplest of which is to use weight fraction, or weight percent; for example, the salt content of seawater is about 3.5 weight percent; *i.e.*, of 100 grams of seawater, 3.5 grams is salt. For a fundamental understanding of solution properties, however, it is often useful to express composition in terms of molecular units such as molecular concentration, molality, or mole fraction. To understand these terms, it is necessary to define atomic and molecular weights. The atomic weight of elements is a relative figure, with one atom of the carbon-12 isotope being assigned the atomic weight of 12; the atomic weight of hydrogen is then approximately 1, of oxygen approximately 16, and the molecular weight of water (H_2O) 18. The atomic and molecular theory of matter asserts that the atomic weight of any element in grams must contain the same number of atoms as the atomic weight in grams (the gram-atomic weight) of any other element. Thus, two grams of molecular hydrogen (H_2)—its gram-molecular weight—contain the same number of molecules as 18 grams of water or as 32 grams of oxygen molecules (O_2). Further, a specified volume of any gas (at low pressure) contains the same number of molecules as the same volume of any other gas, at the same temperature and pressure. At standard temperature and pressure (0°C and 1 atmosphere) the volume of one gram-molecular weight of any gas has been determined experimentally to be approximately 22.4 litres. The number of molecules in this volume of gas, or in the gram-molecular weight of any compound, is called Avogadro's number.

Molarity. By molecular concentration is meant the number of molecules of a particular component per unit volume. Since the number of molecules in a litre or even a cubic centimetre is enormous, it has become common practice to use what are called molar, rather than molecular, quantities. A mole is the gram-molecular weight of a substance and, therefore, also Avogadro's number of molecules (6.02×10^{23}). Thus, the number of moles in a sample is the weight of the sample divided by the molecular weight of the substance; and it is also the number of molecules in the sample divided by Avogadro's number. Instead of using molecular concentration, it is more convenient to use molar concentration; instead of saying, for example, that the concentration is 12.04×10^{23} molecules per litre, it is simpler to say that it is two moles per litre. Concentration in moles per litre (*i.e.*, molarity) is usually designated by the letter M.

Molality. In electrolyte solutions it is common to distinguish between the solvent (usually water) and the dissolved substance, or solute, which dissociates into

ions. For these solutions it is useful to express composition in terms of molality, designated as *m*, a unit proportional to the number of undissociated solute molecules (or, alternatively, to the number of ions) per 1,000 grams of solvent. The number of molecules or ions in 1,000 grams of solvent usually is very large, so molality is defined as the number of moles per 1,000 grams of solvent.

Formality. Many compounds do not exist in the form of molecules, either in the pure substances or in their solutions. The particles that make up sodium chloride (NaCl), for example, are sodium ions (Na^+) and chloride ions (Cl^-), and although equal numbers of these two ions are present in any sample of sodium chloride, no Na^+ ion is associated with a particular Cl^- ion to form a neutral molecule having the composition implied by the formula. Therefore, even though the compositions of such compounds are well defined, it would be erroneous to express concentrations of their solutions in terms of molecular weights. A useful concept in cases of this kind is that of the formula weight, defined as the sum of the weights of the atoms in the formula of the compound; thus, the formula weight of sodium chloride is the sum of the atomic weights of sodium and chlorine, 23 plus 35.5, or 58.5, and a solution containing 58.5 grams of sodium chloride per litre is said to have a concentration of one formal, or 1 f.

Mole fraction and mole percentage. It often is useful to express the composition of nonelectrolyte solutions in terms of mole fraction or mole percentage. In a binary mixture—*i.e.*, a mixture of two components, 1 and 2—there are two mole fractions, x_1 and x_2 , which must obey the relation $x_1 + x_2 = 1$. The mole fraction x_1 means the fraction of molecules of species 1 in the solution, and x_2 means the fraction of molecules of species 2 in the solution. (Mole percentage is the mole fraction multiplied by 100.)

Volume fraction. The composition of a nonelectrolyte solution containing very large molecules, known as polymers, is most conveniently expressed by the volume fraction (Φ)—*i.e.*, the volume of polymer used to prepare the solution divided by the sum of that volume of polymer and the volume of the solvent.

Equilibrium properties. A quantitative description of liquid-solution properties when the system is in equilibrium is provided by relating the vapour pressure of the solution to its composition. The vapour pressure of a liquid, pure or mixed, is the pressure exerted by those molecules that escape from the liquid to form a separate vapour phase above the liquid. If a quantity of liquid is placed in an evacuated, closed container the volume of which is slightly larger than that of the liquid, most of the container is filled with the liquid, but, immediately above the liquid surface, a vapour phase forms consisting of molecules that have passed through the liquid surface from liquid to gas; the pressure exerted by that vapour phase is called the vapour (or saturation) pressure. For a pure liquid, this pressure depends only on the temperature, the best known example being the normal boiling point, which is that temperature at which the vapour pressure is equal to the pressure of the atmosphere. (The standard atmosphere is equal to the pressure exerted by a column of mercury 760 millimetres high, or about 14.7 pounds per square inch.) Figure 1 shows vapour pressures for a few common liquids. The vapour pressure is one atmosphere at 100°C for water, at 78.5°C for ethyl alcohol, and at 125.7°C for octane. In a liquid solution the component with the higher vapour pressure is called the light component, and that with the lower vapour pressure is called the heavy component.

In a liquid mixture, the vapour pressure depends not only on the temperature but also on the composition, and the key problem in understanding the properties of solutions lies in determining this composition dependence. The simplest approximation is to assume that, at constant temperature, the vapour pressure of a solution is a linear function of its composition (*i.e.*, as one increases, so does the other in such proportion that, when the values are plotted, the resulting graph is a straight line). A mixture following this approximation is called an ideal solution.

Figure 1: Vapour pressures of several pure liquids.

Fugacity. In a pure liquid, the vapour generated by its escaping molecules necessarily has the same composition as that of the liquid. In a mixture, however, the composition of the vapour is not the same as that of the liquid; the vapour is richer in that component whose molecules have greater tendency to escape from the liquid phase. This tendency is measured by fugacity, a term derived from the Latin *fugere* ("to escape, to fly away"), which is also the root of the word fugitive. The fugacity of a component in a mixture is (essentially) the pressure that the component exerts in the vapour phase when the vapour is in equilibrium with the liquid mixture. (A state of equilibrium is attained when all the properties remain constant in time and there is no net transfer of energy or matter between the vapour and the liquid.) If the vapour phase can be considered to be an ideal gas (*i.e.*, the molecules in the gas phase are assumed to act independently and without any influence on each other), then the fugacity of a component, i , is equal to its partial pressure, which is defined as the product of the total vapour pressure, P , and the vapour-phase mole fraction, y_i . Assuming ideal gas behaviour for the vapour phase, the fugacity ($y_i P$) equals the product of the liquid-phase mole fraction, x_i , the vapour pressure of pure liquid at the same temperature as that of the mixture, P_i° , and the activity coefficient, γ_i . The real concentration of a substance may not be an accurate measure of its effectiveness because of physical and chemical interactions, in which case an effective concentration must be used, called the activity. The activity is given by the product of the mole fraction x_i and the activity coefficient γ_i . The equation is:

$$y_i P = \gamma_i x_i P_i^\circ.$$

Raoult's law. In a real solution, the activity coefficient, γ_i , depends on both temperature and composition, but, in an ideal solution, γ_i equals 1 for all components in the mixture. For an ideal binary mixture then, the above equation becomes, for components 1 and 2, $y_1 P = x_1 P_1^\circ$, and $y_2 P = x_2 P_2^\circ$, respectively. Upon adding these equations—remembering that $x_1 + x_2 = 1$, and $y_1 + y_2 = 1$ —total pressure, P , is shown to be expressed by the equation $P = x_1 P_1^\circ + x_2 P_2^\circ = x_1 [P_1^\circ - P_2^\circ] + P_2^\circ$, which is a linear function of x_i .

Assuming $\gamma_1 = \gamma_2 = 1$, equations for $y_1 P$ and $y_2 P$ express what is commonly known as Raoult's law, which states that at constant temperature the partial pressure of

a component in a liquid mixture is proportional to its mole fraction in that mixture (*i.e.*, each component exerts a pressure that depends directly on the number of its molecules present). It is unfortunate that the word law is associated with this relation, because only very few mixtures behave according to the equations for ideal binary mixtures. In most cases the activity coefficient, γ_i , is not equal to unity. When γ_i is greater than 1, there are positive deviations from Raoult's law; when γ_i is less than 1, there are negative deviations from Raoult's law.

An example of a binary system that exhibits positive deviations from Raoult's law is represented in Figure 2, the partial pressures and the total pressure being related to the liquid-phase composition; if Raoult's law were valid, all the lines would be straight, as indicated. As a practical result of these relationships, it is often possible by a series of repeated vaporizations and condensations to separate a liquid mixture into its components, a sequence of steps called fractional distillation.

When the vapour in equilibrium with a liquid mixture has a composition identical to that of the liquid, the mixture is called an azeotrope. It is not possible to separate an azeotropic mixture by fractional distillation because no change in composition is achieved by a series of vaporizations and condensations. Azeotropic mixtures are common. At the azeotropic composition, the total pressure (at constant temperature) is always either a maximum or a minimum, and the boiling temperature (at constant pressure) is always either a minimum or a maximum.

Azeotropic mixtures

Partial miscibility. Only pairs of liquids that are completely miscible have been considered so far. Many pairs of liquid mixtures, however, are only partially miscible in one another, the degree of miscibility often depending strongly on temperature. In most cases, rising temperature produces enhanced solubility, but this is not always so. For example, at 50° C (122° F) the solubility (weight percent) of n-butyl alcohol in water is 6.5 percent, whereas that of water in n-butyl alcohol is 22.4 percent. At 127° C (261° F), the upper consolute temperature, complete miscibility is attained: above 127° C the two liquids mix in all proportions, but below 127° C they show a

Figure 2: Total pressure and partial pressures for the system benzene-carbon disulfide at 25° C (see text).

The activity coefficient

miscibility gap. Thus, if *n*-butyl alcohol is added to water at 50° C, there is only one liquid phase until 6.5 weight percent of the mixture is alcohol; when more alcohol is added, a second liquid phase appears the composition of which is 22.4 weight percent water. When sufficient alcohol is present to make the overall composition 77.6 weight percent alcohol, the first phase disappears, and only one liquid phase remains. A qualitatively different example is the system water–triethylamine, which has a lower consolute temperature at 17° C (63° F). Below 17° C, the two liquids are completely miscible, but at higher temperatures they are only partially miscible. Finally, it is possible, although rare, for a binary system to exhibit both upper and lower consolute temperatures. Above 128° C (262° F) and below 49° C (120° F), butyl glycol and water are completely miscible, but between these temperatures they do not mix in all proportions.

Colligative properties. Colligative properties depend only on the concentration of the solute, not on the specific properties of the solute molecules. The concept of an ideal solution, as expressed by Raoult's law (at constant temperature the partial pressure of a component in a liquid mixture is proportional to its mole fraction in the mixture), was already well-known during the last quarter of the 19th century, and it provided the early physical chemists with a powerful technique for measuring molecular weights. (Reliable measurements of molecular weights, in turn, provided important evidence for the modern atomic and molecular theory of matter.)

Rise in boiling point. It was observed that, whenever one component in a binary solution is present in large excess, the partial pressure of that component is correctly predicted by Raoult's law, even though the solution may exhibit departures from ideal behaviour in other respects. When Raoult's law is applied to the solvent of a very dilute solution containing a nonvolatile solute, it is possible to calculate the mole fraction of the solute from an experimental determination of the rise in boiling point that results when the solute is dissolved in the solvent. Since the separate weights of solute and solvent are readily measured, the procedure provides a simple experimental method for the determination of molecular weight. If a weighed amount of a nonvolatile substance, w_2 , is dissolved in a weighed amount of a solvent, w_1 , at constant pressure, the increase in the boiling temperature, ΔT_{b1} , the gas constant, R (derived from the gas laws), the heat of vaporization of the pure solvent per unit weight, l_1^{vap} , the boiling temperature of pure solvent, T_{b1} , are related in a simple product of ratios to equal the molecular weight of the solute, M_2 . The equation is:

$$M_2 = \left(\frac{RT_{b1}^2}{l_1^{\text{vap}}} \right) \left(\frac{w_2}{w_1} \right) \left(\frac{1}{\Delta T_{b1}} \right).$$

The essence of this technique follows from the observation that, in a dilute solution of a nonvolatile solute, the rise in boiling point is proportional to the number of solute molecules, regardless of their size and mass.

Decrease in freezing point. Another colligative property of solutions is the decrease in the freezing temperature of a solvent that is observed when a small amount of solute is dissolved in that solvent. By reasoning similar to that leading to the equation above, the freezing-point depression, ΔT_f , the freezing temperature of pure solvent, T_{f1} , the heat of fusion (also called the heat of melting) of pure solvent per unit weight, l_1^{fusion} , and the weights of solute and solvent in the solution, w_2 and w_1 , respectively, are so related as to equal the molecular weight of solute, M_2 , in the equation

$$M_2 = \left(\frac{RT_{f1}^2}{l_1^{\text{fusion}}} \right) \left(\frac{w_2}{w_1} \right) \left(\frac{1}{\Delta T_f} \right).$$

A well-known practical application of freezing-point depression is provided by adding antifreeze to the cooling water in an automobile's radiator. Water alone freezes at 0° C (32° F), but the freezing temperature decreases appreciably when ethylene glycol is mixed with water.

Osmotic pressure. A third colligative property, osmotic pressure, helped to establish the fundamentals of mod-

ern physical chemistry and played a particularly important role in the early days of solution theory. Osmosis is especially important in medicine and biology, but in recent years it has also been applied industrially to problems such as the concentration of fruit juices, the desalting of seawater, and the purification of municipal sewage. Osmosis occurs whenever a liquid solution is in contact with a semipermeable membrane—*i.e.*, a thin, porous wall whose porosity is such that some, but not all, of the components in the liquid mixture can pass through the wall. A semipermeable membrane is a selective barrier, and many such barriers are found in plants and animals. Osmosis gives rise to what is known as osmotic pressure, as illustrated in Figure 3, which shows a container at

Figure 3: Osmotic pressure π caused by a membrane that allows A to pass, but not B.

uniform temperature divided into two parts by a semipermeable membrane that allows only molecules of component A to pass from the left to the right side; the selective membrane does not allow molecules of component B to pass. Molecules of component A are free to pass back and forth through the membrane, but, at equilibrium, when the fugacity (escaping tendency) of A in the right-hand side is the same as that in the left-hand side, there is no net transfer of A from one side to the other. On the left side, the presence of B molecules lowers the fugacity of A, and, therefore, to achieve equal fugacities for A on both sides, some compensating effect is needed on the left side. This compensating effect is an enhanced pressure, designated by π and called osmotic pressure. At equilibrium, the pressure in the left side of the container is larger than that in the right side; the difference in pressure is π . In the simplest case, when the concentration of B is small (*i.e.*, A is in excess), the osmotic pressure is the product of the gas constant (R), the absolute temperature (T), and the concentration of B (c_B) in the solution expressed in moles of B per unit volume: $\pi = RTc_B$. Since the osmotic pressure for a dilute solution is proportional to the number of solute molecules, it is a colligative property, and, as a result, osmotic-pressure measurements are often used to determine molecular weights, especially for large molecules such as polymers. When w_B grams of solute B are added to a large amount of solvent A at temperature T , and V is the volume of liquid solvent A in the left side of the container, then the molecular weight of B, M_B , is given by

$$M_B = \frac{w_B RT}{\pi V}.$$

Transport properties in solutions. Pure fluids have two transport properties that are of primary importance: viscosity and thermal conductivity. (Transport properties are not equilibrium properties because they reflect not what happens at equilibrium but the speed at which equilibrium is attained.) In solutions these two transport properties are also important. In addition, there is a third one, called diffusivity.

Viscosity. The viscosity of a fluid (pure or not) is a measure of its ability to resist deformation. If water is poured into a thin vertical tube with a funnel at the top, it flows easily through the tube, but salad oil is difficult

Osmotic
equilibrium

to force into the tube. If the oil is heated, however, its flow through the tube is much facilitated. The intrinsic property that is responsible for these phenomena is the viscosity (the "thickness") of the fluid, a property which is often strongly affected by temperature. All fluids (liquid or gas) exhibit viscous behaviour (*i.e.*, all fluids resist deformation), but the range of viscosity is enormous: the viscosity of air is extremely small, while that of glass is essentially infinite. The viscosity of a solution depends not only on temperature but also on its composition. By varying the composition of a petroleum mixture, it is possible to attain a desired viscosity at a particular temperature. This is precisely what the oil companies do when they sell oil to a motorist: in winter, they recommend an oil with lower viscosity than that used in summer, because otherwise, on a cold morning, the viscosity of the lubricating oil may be so high that the car's battery will not be powerful enough to move the lubricated piston.

Thermal conductivity. The thermal conductivity of a material reflects its ability to transfer heat by conduction. If one end of a rod of copper is held in a pot of boiling water, the other end soon burns the hand. If the same is done with a stick of wood, no discomfort is felt; the thermal conductivity of copper is much greater than that of wood. Gases and liquids also can transfer heat by conduction.

In practical situations both viscosity and thermal conductivity are important, as is illustrated by the contrast between an air mattress and a water bed. Because of its low viscosity, air yields rapidly to an imposed load, and thus the air mattress responds quickly when someone lying on it changes position. Water, because of its higher viscosity, noticeably resists deformation, and someone lying on a water bed experiences a caressing response whenever position is changed. At the same time, since the thermal conductivity as well as the viscosity of water are larger than those of air, the user of a water bed rapidly gets cold unless a heater keeps the water warm. No heater is required by the user of an air mattress because stagnant air is inefficient in removing heat from a warm body.

Composition and temperature affect the thermal conductivity of a solution but, in typical liquid mixtures, the effect on viscosity is much larger than that on thermal conductivity.

Diffusivity. While viscosity is concerned with the transfer of momentum and thermal conductivity with the transfer of heat, diffusivity is concerned with the transport of molecules in a mixture. If a lump of sugar is put into a cup of coffee, the sugar molecules travel from the surface of the lump into the coffee at a speed determined by the temperature and by the pertinent intermolecular forces. The characteristic property that determines this speed is called diffusivity—*i.e.*, the ability of a molecule to diffuse through a sea of other molecules. Diffusivities in solids are extremely small, and those in liquids are much smaller than those in gases. As a result, a spoon is used to stir the coffee to speed up the motion of the sugar molecules; but if a room smells foul from cigarette smoke, no effort is needed to obtain significant relief—opening the windows for a few minutes is sufficient.

In order to define diffusivity, it is necessary to consider a binary fluid mixture in which the concentration of solute molecules is c_1 at position 1 and c_2 at position 2, 1 centimetres from position 1; if c_1 is larger than c_2 , then the concentration gradient (change with respect to distance), or $(c_2 - c_1)/l$, is a negative number, indicating that molecules of solute spontaneously diffuse from position 1 to position 2; the number of solute molecules that pass through an area of one square centimetre perpendicular to l , per second, is called the flux J (expressed in molecules per second per square centimetre). The diffusivity D is given by the ratio of the flux to the gradient multiplied by minus one:

$$D = -\frac{J}{\left(\frac{c_2 - c_1}{l}\right)}$$

The minus sign is introduced because, when the gradient is positive, J is negative, and, by convention, D is a positive number. In binary gaseous mixtures, diffusivity depends only weakly on the composition, and, therefore, to a good approximation, the diffusivity of gas A in gas B is the same as that of gas B in gas A. In liquid systems, however, the diffusivity of solute A in solvent B may be significantly different from that of solute B in solvent A. In a very viscous fluid, molecules cannot rapidly move from one place to another. Therefore, in liquid systems, the diffusivity of solute A depends strongly on the viscosity of solvent B and vice versa. While the letter D is always used for diffusivity, viscosity is commonly given the symbol η (Greek eta); in many liquid solutions it is observed that, as the composition changes (as long as the temperature remains constant), the product $D\eta$ remains nearly the same.

THERMODYNAMICS AND INTERMOLECULAR FORCES IN SOLUTIONS

The properties of solutions depend, essentially, on two characteristics: first, the manner in which the molecules arrange themselves. (that is, the geometrical array in which the molecules occupy space) and, second, the nature and strength of the forces operating between the molecules.

Energy considerations. The first characteristic is reflected primarily in the thermodynamic quantity S , called entropy, which is a measure of disorder, and the second characteristic is reflected in the thermodynamic quantity H , called enthalpy, which is a measure of potential energy—*i.e.*, the energy that must be supplied to separate all the molecules from one another. Enthalpy minus the product of the absolute temperature T and entropy equals a thermodynamic quantity G , called Gibbs energy (also called free energy):

$$G = H - TS.$$

From the second law of thermodynamics, it can be shown that, at constant temperature and pressure, any spontaneous process is accompanied by a decrease in Gibbs energy. The change in G that results from mixing is designated by ΔG , which, in turn, is related to changes in H and S at constant temperature by the equation

$$\Delta G = \Delta H - T\Delta S.$$

At a fixed temperature and pressure, two substances mix spontaneously whenever ΔG is negative; that is, mixing (either partial or complete) occurs whenever the Gibbs energy of the substances after mixing is less than that before mixing.

The two characteristics that determine solution behaviour, structure and intermolecular forces, are, unfortunately, not independent, because the structure is influenced by the intermolecular forces and because the potential energy of the mixture depends on the structure. Only in limiting cases is it possible, on the one hand, to calculate ΔS (the entropy change upon mixing) from structural considerations alone and, on the other, to calculate ΔH (the enthalpy change of mixing) exclusively from relations describing intermolecular forces. Nevertheless, such calculations have proved to be useful for establishing models that approximate solution behaviour and that serve as guides in interpreting experimental measurements. Solutions for which structural considerations are dominant are called athermal solutions, and those for which the effects of intermolecular forces are more important than those of structure are called regular solutions (see below Regular solutions and Athermal solutions).

Effects of molecular structure. A variety of forces operate between molecules, and there is a qualitative relation between the properties of a solution and the types of intermolecular forces that operate within it. The volume occupied by a solution is determined primarily by repulsive forces. When two molecules are extremely close to one another, they must necessarily exert a repulsive force on each other since two molecules of finite dimensions cannot occupy the same space; two molecules in very

Raoult's
law

Hydrogen bonding: solvation. In a mixture of methanol and, say, pyridine (C_5H_5N), hydrogen bonds can also form between the electropositive hydrogen atom in methanol and the electronegative nitrogen atom in pyridine. Hydrogen bonding between dissimilar molecules is often called solvation. Since the extent of association or solvation or both depends on the concentrations of the solution's components, the partial pressure of a component is not even approximately proportional to its mole fraction as given by Raoult's law; therefore, large deviations from Raoult's law are commonly observed in solutions in which hydrogen bonding is extensive. Broadly speaking, association of one component, but not the other, tends to produce positive deviations from Raoult's law, because the associating component associates to a smaller extent when it is surrounded by other molecules than it does in the pure state. On the other hand, solvation between dissimilar molecules tends to produce negative deviations from Raoult's law.

THEORIES OF SOLUTIONS

Solutions of nonelectrolytes. Activity coefficients and excess functions. As has been explained previously, when actual concentrations do not give simple linear relations for the behaviour of a solution, activity coefficients, symbolized by γ , are used in expressing deviations from Raoult's law. Activity coefficients are directly related to excess functions, and, in attempting to understand solution behaviour, it is convenient to characterize nonelectrolyte solutions in terms of these functions. In particular, it is useful to distinguish between two types of limiting behaviour: one corresponds to that of a regular solution; the other, to that of an athermal solution (*i.e.*, when components are mixed, no heat is generated or absorbed).

In a binary mixture with mole fractions x_1 and x_2 and activity coefficients γ_1 and γ_2 , these quantities can be related to a thermodynamic function designated by G^E , called the excess Gibbs (or free) energy. The significance of the word excess lies in the fact that G^E is the Gibbs energy of a solution in excess of what it would be if it were ideal.

In a binary solution the two activity coefficients are not independent but are related by an exact differential equation called the Gibbs-Duhem relation. Thanks to this equation, if experimental data at constant temperature are available for γ_1 and γ_2 as a function of composition, it is possible to check the data for thermodynamic consistency: the data are said to be consistent only if they satisfy the Gibbs-Duhem relation. Experimental data that do not satisfy this relation are thermodynamically inconsistent and therefore must be erroneous.

To establish a theory of solutions, it is necessary to construct a theoretical (or semitheoretical) equation for the excess Gibbs energy as a function of absolute temperature (T) and the mole fractions x_1 and x_2 . After such an equation has been established, the individual activity coefficients can readily be calculated.

Gibbs energy, by definition, consists of two parts: one part is the enthalpy, which reflects the intermolecular forces between the molecules, which, in turn, are responsible for the heat effects that accompany the mixing process (enthalpy is, in a general sense, a measure of the heat content of a substance); and the other part is the entropy, which reflects the state of disorder (mixed-ness, or a measure of the random behaviour of particles) in the mixture. The excess Gibbs energy G^E is equal to the excess enthalpy H^E minus the excess entropy S^E times the absolute temperature T :

$$G^E = H^E - TS^E.$$

The word excess means in excess of that which would prevail if the solution were ideal. In the simplest case, both H^E and S^E are zero; in that case the solution is ideal and $\gamma_1 = \gamma_2 = 1$. In the general case, neither H^E nor S^E is zero, but two types of semi-ideal solutions can be designated: in the first, S^E is zero but H^E is not; this is called a regular solution. In the second, H^E is zero but S^E is not; this is called an athermal solution. An ideal solution is both regular and athermal.

Regular solutions. The word regular implies that the molecules mix in a completely random manner, which means that there is no segregation or preference; a given molecule chooses its neighbours with no regard for chemical identity (species 1 or 2). In a regular solution of composition x_1 and x_2 , the probability that the neighbour of a given molecule is of species 1 is given by x_1 , and the probability that it is of species 2 is given by x_2 .

Two liquids form a solution that is approximately regular when the molecules of the two liquids do not differ appreciably in size and there are no strong orienting forces caused by dipoles or hydrogen bonding. In that event, the mixing process can be represented by the lattice model shown in Figure 4; the left half of the diagram

Figure 4: Physical significance of interchange energy. The energy absorbed in the process above is $2w$ (see text).

shows pure liquids 1 and 2, and the right half shows the mixture obtained when the central molecule of liquid 1 is interchanged with the central molecule of liquid 2. Before interchange, the potential energy between central molecule 1 and one of its immediate neighbours is Γ_{11} , and that between central molecule 2 and one of its immediate neighbours is Γ_{22} . After interchange, the potential energy between molecule 1 and one of its immediate neighbours is Γ_{12} , and that between molecule 2 and one of its immediate neighbours is also Γ_{12} . The change in energy that accompanies this mixing process is equal to twice the interchange energy (w), which is equal to the potential energy after mixing less one-half the sum of the potential energies before mixing, the whole multiplied by the number of immediate neighbours, called the coordination number (z), surrounding the two shifted molecules:

$$w = z[\Gamma_{12} - \frac{1}{2}(\Gamma_{11} + \Gamma_{22})].$$

In the two-dimensional representation (Figure 4), z equals 4; but, in three dimensions, z varies between 6 and 12, depending on the lattice geometry. In this simple lattice model, the interchange process occurs without change of volume, and therefore, in this particular case, the excess enthalpy is the same as the energy change upon mixing. Assuming regular-solution behaviour (*i.e.*, $S^E = 0$), an equation may be derived relating Gibbs energy, Avogadro's number, interchange energy, and mole fractions. In principle, the interchange energy (w) may be positive or negative, but, for simple molecules, for which only London forces of attraction are important, w is positive. The equation obtained from the simple lattice model can be extended semi-empirically to apply to mixtures of molecules whose sizes are not nearly the same by using volume fractions, rather than mole fractions, to express the effect of composition and by introducing the concept of cohesive energy density, which is defined as the potential energy of a liquid divided by its volume. The adjective cohesive is well chosen because it correctly indi-

Types of
semi-ideal
solutions

cates that this energy is associated with the forces that keep the molecules close together in a condensed state. Again restricting attention to nonpolar molecules and again assuming a completely random mixture ($S^E = 0$), an equation may be derived that requires only pure-component properties to predict the excess Gibbs energy (and hence the activity coefficients) of binary mixtures. Because of many simplifying assumptions, this equation does not give consistently accurate results, but in many cases it provides good semiquantitative estimates. The form of the equation is such that the excess Gibbs energy is larger than zero; hence, the equation is not applicable to mixtures that have negative deviations from Raoult's law.

Athermal solutions. In a solution in which the molecules of one component are much larger than those of the other, the assumption that the solution is regular (*i.e.*, that $S^E = 0$) no longer provides a reasonable approximation even if the effect of intermolecular forces is neglected. A large flexible molecule (*e.g.*, a chain molecule such as polyethylene) can attain many more configurations when it is surrounded by small molecules than it can when surrounded by other large flexible molecules; the state of disorder in such a solution is therefore much larger than that of a regular solution in which $S^E = 0$. A solution of very large molecules (*i.e.*, polymers) in an ordinary liquid solvent is similar to a mixture of cooked spaghetti (the polymers) and tomato sauce. When there is a lot of sauce and little spaghetti, each piece of spaghetti is free to exist in many different shapes; this freedom, however, becomes restricted as the number of spaghetti pieces rises and the amount of sauce available for each strand declines. The excess entropy then is determined primarily by the freedom that the spaghetti has in the tomato sauce mixture relative to the freedom it has in the absence of sauce.

Regular solutions and athermal solutions represent limiting cases; real solutions are neither regular nor athermal. For real solutions it has been proposed to calculate G^E by combining the equations derived separately for regular solutions and for athermal solutions, but, in view of the restrictive and mutually inconsistent assumptions that were made in deriving these two equations, the proposal has met with only limited success.

Associated and solvated solutions. For those solutions in which there are strong intermolecular forces due to large dipole moments, hydrogen bonding, or complex formation, equations based on fundamental molecular theory cannot be applied, but it is frequently useful to apply a chemical treatment—*i.e.*, to describe the liquid mixture in terms of association and solvation, by assuming the existence of a variety of distinct chemical species in chemical equilibrium with one another. For example, there is much experimental evidence for association in acetic acid, in which most of the molecules dimerize; *i.e.*, two single acetic acid molecules, called monomers, combine to form a new molecule, called a dimer, through hydrogen bonding. When acetic acid is dissolved in a solvent such as benzene, the extent of dimerization of acetic acid depends on the temperature and on the total concentration of acetic acid in the solution. The escaping tendency (vapour pressure) of a monomer is much greater than that of a dimer, and it is thus possible to explain the variation of activity coefficient with composition for acetic acid in benzene; the activity coefficient of acetic acid in an excess of benzene is large because, under these conditions, acetic acid is primarily in the monomeric state, whereas pure acetic acid is almost completely dimerized. In the acetic acid–benzene system, association of acetic acid molecules produces positive deviations from Raoult's law.

When a solvent and a solute molecule link together with weak bonds, the process is called solvation. For example, in the system acetone–chloroform, a hydrogen bond is formed between the hydrogen atom in chloroform and the oxygen atom in acetone. In this case, hydrogen bonding depresses the escaping tendencies of both components, producing negative deviations from Raoult's law.

While hydrogen bonding is frequently encountered in solutions, there are many other examples of weak chemi-

cal bond-formation between dissimilar molecules. The formation of such weak bonds is called complex formation—that is, formation of a new chemical species, called a complex, which is held together by weak forces that are chemical in nature rather than physical. Such complexes usually exist only in solution; because of their low stability, they cannot, in general, be isolated. The ability of different molecules to form complexes has a strong effect on solution behaviour. For example, the solubility of a sparingly soluble solute can be very much increased by complex formation: the solubility of silver chloride in water is extremely small since silver chloride dissociates only slightly to silver ion and chloride ion; however, when a small quantity of ammonia is added, solubility rises dramatically because of the reaction of six molecules of ammonia with one silver ion to form the complex ion $\text{Ag}(\text{NH}_3)_6^+$. By tying up silver ions and thereby forcing extensive dissociation of molecular silver chloride, the ammonia pulls silver chloride into aqueous solution.

In recent years there has been much interest in the use of computers to generate theoretical expressions for the activity coefficients of solutions. In many cases the calculations have been restricted to model systems, in particular to mixtures of hard-sphere (envisioned as billiard balls) molecules—*i.e.*, idealized molecules that have finite size but no forces of attraction. These calculations have produced a better understanding of the structure of simple liquid solutions since the manner in which nonpolar and non-hydrogen-bonding molecules arrange themselves in space is determined primarily by their size and shape and only secondarily by their attractive intermolecular forces. The results obtained for hard-sphere molecules can be extended to real molecules by applying corrections required for attractive forces and for the "softness" of the molecules—*i.e.*, the ability of molecules to interpenetrate (overlap) at high temperatures. While practical results are still severely limited and while the amount of required computer calculation is large even for simple binary systems, there is good reason to believe that advances in the theory of solution will increasingly depend on computerized, as opposed to analytical, models.

Solutions of electrolytes. Near the end of the 19th century, the properties of electrolyte solutions were investigated extensively by the early workers in physical chemistry. A suggestion of Svante August Arrhenius, a Swedish chemist, that salts of strong acids and bases (for example, sodium chloride) are completely dissociated into ions when in aqueous solution received strong support from electrical-conductivity measurements and from molecular-weight studies (freezing-point depression, boiling-point elevation, and osmotic pressure). These studies showed that the number of solute particles was larger than it would be if no dissociation occurred. For example, a 0.001 molal solution of a uni-univalent electrolyte (each ion has a valence, or charge, of 1, and, when dissociated, two ions are produced) such as sodium chloride, Na^+Cl^- , exhibits colligative properties (dependent only on the concentration) corresponding to a nonelectrolyte solution whose molality is 0.002; the colligative properties of a 0.001 molal solution of a univalent–divalent electrolyte (yielding three ions) such as magnesium bromide, $\text{Mg}^{2+}\text{Br}_2^-$, correspond to those of a nonelectrolyte solution with a molality of 0.003. At somewhat higher concentrations the experimental data showed some inconsistencies with Arrhenius' dissociation theory, and initially these were ascribed to incomplete, or partial, dissociation. In the years 1920–30, however, it was shown that these inconsistencies could be explained by electrostatic interactions (called Coulomb forces) of the ions in solution. The current view of electrolyte solutions is that, in water at normal temperatures, the salts of strong acids and strong bases are completely dissociated into ions at all concentrations up to the solubility limit. At high concentrations Coulombic interactions may cause the formation of ion pairs, which implies that the ions are not dispersed uniformly in the solution but have a tendency to form two-ion aggregates in which a positive ion seeks the close proximity of a negative ion and vice

Arrhenius' theory of salts

Current theory of salts

Solution

versa. While the theory of dilute electrolyte solutions is well advanced, no adequate theory exists for concentrated electrolyte solutions primarily because of the long-range Coulomb forces that dominate in ionic solutions.

The equilibrium properties of electrolyte solutions can be studied experimentally by electrochemical measurements, freezing point depressions, solubility determinations, osmotic pressures, or measurements of vapour pressure. Most electrolytes, such as salts, are nonvolatile at ordinary temperature, and, in that event, the vapour pressure exerted by the solution is the same as the partial pressure of the solvent. The activity coefficient of the solvent can, therefore, be found from total-pressure measurements, and, using the Gibbs-Duhem equation, it is then possible to calculate the activity coefficient of the electrolyte solute. This activity coefficient is designated by γ_{\pm} to indicate that it is a mean activity coefficient for the positive and negative ions; since it is impossible to isolate positive ions and negative ions into separate containers, it is not possible to determine individual activity coefficients for the positive ions and for the negative ions. The mean activity coefficient γ_{\pm} is so defined that it approaches a value of unity at very low molality where the ions are so far apart that they exert negligible influence on one another. For small concentrations of electrolyte, the theory of Peter Debye, a Dutch-born U.S. physical chemist, and Erick Hückel, a German chemist, relates γ_{\pm} to the ionic strength, which is the sum of the products of the concentration of each ion (in moles per litre) and the square of its charge; the equation predicts that γ_{\pm} decreases with rising ionic strength in agreement with experiment at very low ionic strength; at higher ionic strength, however, γ_{\pm} rises, and in some cases γ_{\pm} is greater than 1. The derivation of the Debye-Hückel theory clearly shows that it is limited to low concentrations. Many attempts have been made to extend the Debye-Hückel equation to higher electrolyte concentrations. One of the more successful attempts is based on the idea that the ions are solvated, which means that every ion is surrounded by a tight-fitting shell of solvent molecules.

The concept of solvation is often used to explain properties of aqueous solutions; one well-known property is the salting-out effect, in which the solubility of a nonelectrolyte in water is decreased when electrolyte is added. For example, the solubility of ethyl ether in water at 25° C (77° F) is 0.91 mole percent, but, in an aqueous solution containing 15 weight percent sodium chloride, it is only 0.13 mole percent. This decrease in solubility can be explained by postulating that some of the water molecules cannot participate in the dissolution of the ether because they are tightly held (solvated) by sodium and chloride ions.

Electrolyte solutions have long been of interest in industry since many common inorganic chemicals are directly obtained, or else separated, by crystallization from aqueous solution. Further, many important chemical and metallurgical products (*e.g.*, aluminum) are obtained or refined by electrochemical processes that occur in liquid solution. In recent years there has been renewed interest in electrolyte solutions because of their relevance to fuel cells as a possible source of power for automobiles.

The properties of electrolyte solutions also have large importance in physiology. Many molecules that occur in biological systems bear electric charges; a large molecule that has a positive electric charge at one end and a negative charge at the other is called a zwitterion. Very large molecules, such as those of proteins, may have numerous positive and negative charges; such molecules are called polyelectrolytes. In solution, the conformation (that is, the three-dimensional structure) of a large, charged molecule is strongly dependent on the ionic strength of the dissolving medium; for example, depending on the nature and concentration of salts present in the solvent, a polyelectrolyte molecule may coagulate into a ball, it may stretch out like a rod, or it may form a coil or helix. The conformation, in turn, is closely related to the molecule's physiological function. As a result, improved understanding of the properties of electrolyte solutions has direct consequences in molecular biology and medicine.

SOLUBILITY OF SOLIDS AND GASES

Since the dissolution of one substance in another can occur only if there is a decrease in the Gibbs energy, it follows that, generally speaking, gases and solids do not dissolve in liquids as readily as do other liquids. To understand this, the dissolution of a solid can be visualized as occurring in two steps: in the first, the pure solid is melted at constant temperature to a pure liquid, and, in the second, that liquid is dissolved at constant temperature in the solvent. Similarly, the dissolution of a gas can be divided at some fixed pressure into two parts, the first corresponding to constant-temperature condensation of the pure gas to a liquid and the second to constant-temperature mixing of that liquid with solvent. In many cases, the pure liquids (obtained by melting or by condensation) may be hypothetical (*i.e.*, unstable and, therefore, physically unobtainable), but usually their properties can be estimated by reasonable extrapolations. It is found that the change in Gibbs energy corresponding to the first step is positive and, hence, in opposition to the change needed for dissolution. For example, at -10° C (14° F), ice is more stable than water, and, at 110° C (230° F) and one atmosphere, steam is more stable than water. Therefore, the Gibbs energy of melting ice at -10° C is positive, and the Gibbs energy of condensing steam at one atmosphere and 110° C is also positive. For the second step, however, the change in Gibbs energy is negative; its magnitude depends on the equilibrium composition of the mixture. Because of the positive Gibbs energy change that accompanies the first step, there is a barrier that makes it more difficult to dissolve solids and gases as compared with liquids.

For gases at normal pressures, the positive Gibbs energy of condensation increases with rising temperature, but, for solids, the positive Gibbs energy of melting decreases with rising temperature. For example, the change in energy, ΔG , of condensing steam at one atmosphere is larger at 120° C (248° F) than it is at 110° C (230° F), while the change in energy of melting ice at -5° C (23° F) is smaller than it is at -10° C (14° F). Thus, as temperature rises, the barrier becomes larger for gases but lower for solids, and therefore, with few exceptions, the solubility of a solid rises while the solubility of a gas falls as the temperature is raised.

For solids, the positive Gibbs energy "barrier" depends on the melting temperature. If the melting temperature is much higher than the temperature of the solution, the barrier is large, shrinking to zero when the melting temperature and solution temperature become identical.

Table 1 gives the solubilities of some common gases,

Table 1: Solubilities of Some Gases*
(mole percent)

	heptane	benzene	water
Hydrogen	0.069	0.026	0.0015
Nitrogen	0.12	0.45	0.0012
Methane	0.47	0.21	0.0024
Carbon dioxide	0.77	0.97	0.0608

*At one atmosphere partial pressure, 25° C.

and Table 2 the solubility of (solid) naphthalene in a few typical solvents. These solubilities illustrate the qualitative rule that "like dissolves like"; thus naphthalene, an aromatic hydrocarbon, dissolves more readily in another aromatic hydrocarbon such as benzene than it does in a chlorinated solvent such as carbon tetrachloride or in a hydrogen-bonded solvent such as methyl alcohol. By similar reasoning, the gas methane, a paraffinic hydrocarbon, dissolves more readily in another paraffin such as hexane than it does in water. In all three solvents, the gas hydrogen (which boils at -252.5° C, or -422.5° F) is less soluble than nitrogen (which boils at a higher temperature, -195.8° C, or -320.4° F).

While exceptions may occur at very high pressures, the solubility of a gas in a liquid generally rises as the pressure of that gas increases. When the pressure of the gas is much larger than the vapour pressure of the solvent, the

Table 2: Solubility of Naphthalene in Various Solvents*

solvent	mole percent naphthalene
Benzene	24.1
Carbon tetrachloride	20.5
Hexane	9.0
Methyl alcohol	1.8
Water	0.0004
*At 20° C.	

solubility is often proportional to the pressure; this proportionality is consistent with Henry's law, which states that, if the gas phase is ideal, the solubility x_2 of gas 2 in solvent 1 is equal to the partial pressure (the vapour-phase mole fraction y_2 times the total pressure P —i.e., y_2P) divided by a temperature-dependent constant, $H_{2,1}$ (called Henry's constant), which is determined to a large extent by the intermolecular forces between solute 2 and solvent 1; then

$$x_2 = \frac{y_2P}{H_{2,1}}$$

When the vapour pressure of solvent 1 is small compared with the total pressure, then the vapour-phase mole fraction of gas 2 is approximately one, and the solubility of the gas is proportional to the total pressure.

BIBLIOGRAPHY. An introductory but quantitative discussion of liquid solutions is given by A.G. WILLIAMSON in *An Introduction to Non-Electrolyte Solutions* (1967); and E.A. MOELWYN-HUGHES in *States of Matter* (1961). A comprehensive view is presented by J.H. HILDEBRAND and R.L. SCOTT in *Solubility of Non-Electrolytes*, 3rd ed. (1950); more recent work is reviewed in J.H. HILDEBRAND, J.M. PRAUSNITZ, and R.L. SCOTT, *Regular and Related Solutions* (1970). An advanced study of solutions of non-electrolytes is J.S. ROWLINSON, *Liquids and Liquid Mixtures*, 2nd ed. (1969); and I. PRIGOGINE, *Molecular Theory of Solutions* (1957). Hildebrand's books tend to stress phenomena while those of Rowlinson and Prigogine emphasize solution theory based on statistical mechanics. The more practical engineering aspects of solutions are presented by J.M. PRAUSNITZ in *Molecular Thermodynamics of Fluid-Phase Equilibria* (1969); and by M.B. KING in *Phase Equilibrium in Mixtures* (1969). A thorough discussion of solutions of electrolytes is R.A. ROBINSON and R.H. STOKES, *Electrolyte Solutions*, 2nd ed. (1959, reprinted 1965); the properties of solutions of large molecules (polymers) are discussed by H. TOMPA in *Polymer Solutions* (1956); and by H. MORAWETZ in *Macromolecules in Solution* (1965).

(J.M.P.)

Somalia

The Somali Democratic Republic, popularly known as Somalia, a state in northeast Africa stretching from the Equator to the Red Sea, occupies most of the Horn of Africa, the most easterly projection of the continent. With an area of about 246,000 square miles (637,500 square kilometres), it is bounded on the north by the Gulf of Aden and on the east by the Indian Ocean; from its southern point, its western border is bounded by Kenya and Ethiopia and, to the northwest, by the French-administered Territory of the Afars and Issas (formerly French Somaliland). The capital is Mogadiscio (Mogadishu). Somalia was known to the early Egyptians as the Land of Punt.

Living in a hot climate and on an unforgiving terrain, much of which is desert, the Somali inhabitants of the country, numbering almost 2,900,000, the majority of whom are nomadic, are Muslim by religion and fiercely independent by nature. Due to the existence of Somali communities in Kenya, Ethiopia, and the French Territory of the Afars and Issas (the Issas being Somalis) and the nomadic way of life that is virtually a national characteristic, most of the western boundary of the country is in dispute. When, on July 1, 1960, the former British Somaliland Protectorate joined with the former Italian-administered United Nations Trust Territory of Somalia to form the independent Somali Republic, efforts to reach international agreement on the bound-

aries of the new state were unsuccessful. The disputed frontier, particularly that shared with Ethiopia, and the need for economic development constitute the two most important problems facing Somalia today.

Somalia's geopolitical position is one of strategic significance, potentially affecting developments of the African hinterland, the Gulf of Aden, the Arabian Peninsula, and the Indian Ocean. Somalia receives budgetary assistance from Italy and has also received aid from the Soviet Union, which has modernized the port of Berbera on the Gulf of Aden, and from the United States, which has financed the building of a new port at Kismayu (Chisimaio) near the Equator. For coverage of historical aspects, see EAST AFRICA, HISTORY OF.

THE LANDSCAPE

In the north and northeast, some of the land is mountainous, but most of the remainder of the country is a flat, low plateau. In the south, there are two permanent rivers, the Giuba (Juba) and the Shebelle, both originating in the highlands of Ethiopia.

In the north, extending along the whole coastal area, is a barren coastal plain called the Guban ("burned"), characterized by hot, humid weather, low rainfall, and sparse vegetation. Inland, this gives way to maritime ranges forming the Ogo Highlands. To the west this begins with the Golis Range, which rises in the Eritrean Highland and continues intermittently up to the end of Migiurtinia (Mijurtein), which forms the tip of the Horn of Africa. Along this range occur the highest altitudes in the country, the Surud Ad, near Erigavo, reaching a height of 7,900 feet (2,408 metres). To the south the mountains give way to the Haud Plateau and to the Nogal (Nugal) Valley. The Haud Plateau is flat land with soil containing gypsum. It has slightly more rainfall than the Guban and is cooler and drier. In recent years, the lack of adequate rain has been overcome by the construction of *barkado*, or artificial water reservoirs, throughout the Haud area to supply the needs of the people and their livestock. The Nogal Valley, running from northwest to southeast, is a low depression that, despite the sparse rainfall, is relatively well watered. Its name means "the fertile land," as it was once noted for fertility. In recent years, however, erosion has wrought so much havoc that it is rapidly losing its rich soil and thick vegetation. The extreme south of the country consists mainly of flat plains; there are no mountains, and the highest altitudes are no more than 300 to 400 feet. Because of the two rivers and better rainfall, the southern plains are generally less arid.

Climate. Somalia extends from about latitude 2° S to 12° N, and so lies within the tropical and subtropical zones. The climate is monotonously uniform throughout the year, although slight changes occur at altitudes of 5,000 feet and above at certain times of year. Borama, Hargeisa, Sheikh, and Erigavo usually experience somewhat cooler and more pleasant temperatures from October to February. At Sheikh and Erigavo, temperatures sometimes drop to the freezing point, and frost appears on the ground. The coastal areas, on the other hand, experience weather that is hotter, more humid, and enervating; in such places as Berbera and Bosaso, temperatures rise as high as 108° F (42° C) from June to September. In the south, the weather is generally more uniform, being hot and humid in the coastal areas and hot and dry in the hinterland. Rainfall is usually higher in the south, varying from 13 inches to 20 inches a year. The Ogo Highlands in the north also receive as much as 20 inches a year, especially in the west.

The year is divided into several distinct seasons. There are two rainy seasons, each of which is followed by a dry season. The first rainy season, which generally lasts from March to June, is called *gu*; the second, which usually begins in September and ends in about December, is called *dayr*. Seasonal changes are not, however, entirely regular. Sometimes the rain fails to come when expected, and the much dreaded drought occurs, destroying plants and animals and impoverishing the land.

Vegetation and animal life. Vegetation consists primarily of shrub bush and grass. In some areas—for ex-

Importance of its geopolitical position

Climatic seasons

ample, in some parts of Migiurtinia—the land is practically denuded of trees. In most parts of the country, however, plants and grass are plentiful, and in the Haud and the extreme south vegetation is thick. The shrubs, which have adapted to the harsh environment, with its low rainfall and hot sun, are nutritious, sustaining the country's abundant livestock as well as its wild animals. Erosion and overgrazing in recent times, however, have damaged the fertility of the land, and conservation measures are now required. The most useful economic vegetation consists of dosok (a species of box tree); galol (a species of acacia, of which the roots are used as a framework for huts, the bark is used for making ropes and mats, the ripe fruit is eaten, and the leaves are fed to livestock); and the *Boswellia*, which produce frankincense, and other gum trees. In higher regions of the Ogo Highlands—for example, on Surud Ad Mountain, near Erigavo—small forests grow. At present the greatest single resource of the country consists of its livestock, chiefly cattle, camels, sheep, and goats. There are also many wild animals, such as lions, elephants, hyenas, foxes, leopards (the skin of the Somali leopard is the most valuable on the world market), and hippopotamuses, such game as giraffes, zebras, antelope, and many species of birds. The Basso Giuba (Lower Juba) Region is the most abundant in wild animals and game.

Traditional regions. Somalia is perhaps the most homogeneous of the nations of Africa. The country may, nevertheless, be divided into several traditional regions, although these cannot be sharply delineated. These are the following.

The Northern Region. This consists of the former British Somaliland Protectorate and the districts of Mudugh and Migiurtinia. Nomadic habits and customs predominate here, although seafarers and fishermen live in the coastal towns, while agriculture is also pursued in some parts of the west. The character of the nomadic people is martial, individualistic, egalitarian, and inimical to authority.

Benadir, including Hiran. The Benadir Region, extending for almost 400 miles (650 kilometres) along the coast, and the Hiran Region inland together comprise most of the Shebelle River Valley. These regions have a wide diversity in habits and customs. While agriculture remains the mainstay of the regional economy, the region is the most developed in the country, because Mogadiscio, the capital, is located in it.

Alto Giuba (Upper Juba). In this southern region, traversed by the Giuba River, the Somali dialect spoken differs from the standard Somali to such an extent that other Somalis rarely understand it at first. Dry farming (tilling the soil so as to conserve moisture and using

drought-resistant crops) is pursued, and the region is particularly rich in livestock. The people are generally placid, but tend to be suspicious of intrusions by Somalis from other regions.

Basso Giuba (Lower Juba). This region is potentially the richest region of the land. In the districts of Gelib and Giamama, the inhabitants are settled farmers. The potential, consisting of the fertile, arable land and the availability of the water of the Giuba River, still remains relatively untapped. Livestock raising is the most vital economic activity pursued in the districts of Kismayu and Afmedou. In Kismayu, the largest meat-packing factory in the country has been established. Kismayu is also the name of a coastal town possessing a recently built modern port, which facilitates the export of bananas, livestock, and canned meat.

Modes of life. In the country as a whole, as mentioned earlier, the nomadic mode of living predominates. The coastal towns once maintained contacts with ancient civilizations, but there were hardly any towns in the interior until the beginning of the 20th century. Nomadism consists essentially of a restless movement of people from place to place in search of water and grazing for their animals. This movement is governed by the incidence of the rainy seasons. A characteristic of the nomad is a tendency to engage in feuds that arise from competition for water and grazing lands. In the hinterland, tribal fighting and the theft of livestock, particularly of camels and cattle, frequently occurred. Feuding has been reduced by three factors. These are (1) the construction of *barkado*, which make water available for payment; (2) the more effective enforcement of law by the authorities; and (3) the growing spirit of nationalism, which acts as a unifying force among the nomadic peoples themselves. Villages are also springing up around the *barkado*, with the result that the nomads are now entering a money economy, selling livestock, hides, skins, and ghee in exchange for manufactured goods. In the Northern Region, for example, nomads now use transistor radios to listen to Somali-language broadcasts.

Cultivators, for their part, live in settled communities and practice agriculture, mostly of the subsistence type, using traditional implements and methods. These farmers are deeply attached to the land, but it does not provide them with an adequate standard of living.

Urban settlement has increased rapidly since World War II and is expected to continue. The cities of Somalia, however, are not large. Mogadiscio, the capital, had a population of nearly 173,000 inhabitants as of the 1967 estimate but is now estimated to have from 250,000 to 300,000 inhabitants. Other major towns include Hargeisa, with a population of about 50,000; Kismayu and Merca, with about 18,000 each; Burao and Berbera, each with about 12,000 inhabitants; Baidoa, with about 15,000; and Belet-Weine, with a population of over 11,000.

While the style of life in these towns is westernized on the surface, social behaviour does not differ much from that in Somali society elsewhere. Language, religion, and social customs are so similar that observable differences are viewed as slight modifications of the norm. The nomad comes to the town frequently, and many townsmen visit their nomadic relatives in the hinterland, particularly during the rainy seasons.

PEOPLE AND POPULATION

The Somali language, which is spoken throughout the country, forms one of the nation's strongest unifying factors. Rich, expressive, and poetic, Somali belongs to the Cushitic language family, which also includes the Afar and Galla. It has several dialects and is spoken with different accents in various parts of the country. Despite superficial differences, however, standard Somali dominates most of the country, except for parts of the south. This Somali is used by Somalia's two radio stations, in Mogadiscio and Hargeisa, and is also spoken and understood in the French Territory of the Afars and Issas, in the Somali-inhabited part of Ethiopia (referred to as Western Somalia by the Somalis), and in Wajir (Northern Frontier) District of Kenya, where there is also a

Somali community. Since, prior to 1973, the language was not written, the adoption of a script for Somali was a burning issue for nearly 20 years, and one of the declared objectives of the revolution proclaimed in 1969 was to find a speedy solution to the problem. Latin, Arabic, and Osmanian scripts were all suggested. Osmanian is a Somali script, named after its inventor, Osman Yusuf Kenadid, who, early in the 20th century, devised an alphabetic system for representing the peculiar sounds of the Somali language. In January 1973, a Latin script for the Somali language was adopted, and simultaneously made the sole official language. In the absence of a written Somali language, three foreign tongues, Arabic, English, and Italian, had been used as official languages. Arabic was the language of instruction in primary schools; English was used at higher levels.

Ethnically, the Somali are a Cushitic people, being closely related to the Gallas and the Afars. The typical Somali is tall and slender, with a long, oval face, a straight nose, and delicate features, and with a skin colour varying from jet black to light brown. The Somalis subdivide themselves into several major tribes, each of which traces its genealogical line to a single father. These tribes are the Ishaak, the Hawiya, the West Somali (Dir), the Geri (Darod), the Sab (Dighil), and the Mijurtein (Mirifle). Numerous subtribes branch off from these groups until, at its ultimate level, social organization is represented by the family unit. Because language, customs, and physical features remain so similar, tribalism does not have the connotation it often does elsewhere in Africa, nor does it represent a disintegrative force in the nation. Basically a homogeneous people, the Somalis had achieved nationhood long before the arrival of Europeans in Africa. Tribalism today is slowly being superseded by the growth of nationalism. Several small but distinct minorities nevertheless exist in Somalia, such as the riverine Bantus, who live along the banks of the Shebelle and Giuba rivers; the Bajun of Kismayu; the Brava town dwellers, who claim descent from Portuguese settlers; and some of the Rer Hamar and Merca people, who are of Arab if not of Persian origin.

Islām is the official religion of the Somali nation, and the vast majority of the people profess the Islāmic faith. There are extremely few Christian Somalis. Islām in Somalia is primarily of the strict Shāfi'ī rite of the Sunnī denomination. Šūfism also exists in the country in several forms. The two largest Šūfī orders are the Salihyah order, named after its founder, Shaykh Muhammad Šaliḥ of Mecca, which has a large following in the north, and the Qādiriyah order, also named after its founder, Shaykh 'Abd, al-Qādir al-Jilānī of Baghdad, which has many adherents in the south. The veil for women is a foreign importation, and those who wear it are largely of Arab or Indo-Pakistan origin. Animism is virtually nonexistent, although superstitious beliefs in demons and witchcraft sometimes still persist.

Due to the absence of an adequate census, reliable information about the demographic situation in Somalia is not available. The population is estimated to number between 2,500,000 and 3,000,000, and the annual rate of growth is

The nomadic way of life

The Somali language

said to be about 2 percent. Immigration and emigration are negligible. Because of growing urbanization, the settlement of some nomads, and the improved medical services in the towns, a higher rate of population growth is anticipated.

THE NATIONAL ECONOMY

Somalia is an underdeveloped country. Its economy is based upon livestock and agriculture, which are dominated by traditional modes of production. Industrialization is not yet even a dream, since trained manpower, easily available raw materials, and a cheap source of power are all lacking. Average per-capita income is among the lowest in the world, amounting to about \$50 or \$60 U.S. a year. Despite this situation, a potential for economic growth exists. While no complete evaluation of the country's mineral resources has been undertaken, mineral reserves of iron ore, gypsum and other minerals, and uranium ore, have been located.

Mineral resources. In the Alto Giuba region, iron ore deposits with an iron content of 40 percent are estimated at about 300,000,000 tons. Reserves at Dagareh are estimated at 40,000,000 tons, while those at el-Garas are in the vicinity of 30,000,000 tons. Altogether, iron ore deposits are estimated to total about 440,000,000 tons. Gypsum sepiolite (a clay mineral) and manganese also have been discovered. It is upon uranium, however, that the country has pinned its hopes for rapid economic growth. Prospecting has revealed that about 250,000 tons of exploitable ore are deposited in the Bur Hacaba area in the Upper Juba region. A United Nations Development Programme project operating in the Mudugh Region has also reported the existence of uranium there, but no estimates have yet been made. Exploration for oil has been proceeding for many years but so far without success.

Raising livestock is at present the principal economic activity of the country. Estimates of the animal wealth of Somalia range from 12,000,000 to 15,000,000 head, composed of sheep, goats, cattle, and camels. The economic importance of stock raising is evident from the fact that about 75 percent of the people make their living from it, while, at the same time, livestock is the chief export commodity and the principal earner of foreign exchange. Sheep, cattle, and camels are exported to Arab lands, especially to Egypt, Saudi Arabia, and Yemen (Aden). The livestock in Somalia are relatively free from serious diseases, so that the two perennial problems of animal husbandry remain the availability of water and of grazing. A serious program of *barkado* construction in all parts of the country is helping to remedy the water shortage, but grazing is being badly damaged by erosion, as well as by overgrazing in certain areas.

Agriculture, the second most important economic activity, suffers from an extremely low productivity, owing to the use of traditional methods. Arable land is nevertheless, plentiful. Of an estimated 20,000,000 acres (8,000,000 hectares) of arable land, only about 1,000,000 acres (400,000 hectares) are now under cultivation. Sugarcane and bananas are the two principal crops. Sugarcane is produced solely for domestic consumption, but bananas are the second most important export commodity. Other agricultural products are maize, sorghum, cotton, groundnuts (peanuts), and sesame oil.

Power supplies are scarce; electricity is generated by diesel engines for limited domestic and industrial use. Only the major towns have power stations, and rural settlements are practically without light or electricity.

Trade and finance. Livestock and agriculture represent the largest source of revenue. Animals, animal products, and agricultural crops constitute about 80 percent of the national income. Manufacturing is embryonic. Apart from the sugar factory at Giohar, the various small factories are no more than fledgling enterprises struggling to survive. The two principal banks, which were recently nationalized, are the Somali National Bank, which carries out central-banking and commercial-banking functions, and the Somali Development Bank, which provides loans for development projects. Foreign trade yields

much of the national income; exports earn foreign exchange, while import duties form the largest source of government revenue.

The budget suffers from chronic deficit that, although progressively decreasing, still presents financial problems. In 1963, the deficit was more than 50,000,000 Somali shillings (So. sh.), while by 1970 it had dropped to less than 14,000,000 So. sh. (The So. sh., which is the official unit of currency, is divided into 100 centesimis; 7.14 So. sh. = \$1 U.S., and 17.14 So. sh. = £1 sterling in 1971.) The deficit has hitherto always been met by the financial aid from the Italian government. Tax revenues are obtained from import duties (which amount to over half of the total), export duties, administrative taxes, production and consumption taxes, and taxes on income and property. The economic policy of the revolutionary government that came to power in 1969 is to reduce government expenditures and to increase revenue through investment in productive public enterprises.

TRANSPORT

There is no railroad in the country. Good asphalted roads are scarce, amounting to only about 600 miles (900 kilometres) out of 8,000 miles (14,000 kilometres) of roads. Large trucks are used for the transport of goods, materials, and people to distant areas. Minibuses operate where good roads are available, particularly in the Afgoi, Merca, Giohar, and Baidoa areas. Sea transport is used for overseas trade. Mogadiscio, Kismayu, Berbera, and Merca are the major ports. Kismayu is a modern port built recently with U.S. financing, while the port of Berbera has been vastly improved with Soviet assistance. The improvement of facilities at the port of Mogadiscio with a financial loan from the World Bank is also planned. From many smaller ports, dhows move people and goods from one part of the coast to another. Air transport is increasing; Somali Airlines has weekly flights to all major towns, particularly regional capitals such as Hargeisa (the second largest city), Kismayu, Burao, Galcaio, Bosaso, and Candala. Mogadiscio has an international airport, from which Alitalia flights leave for Rome and Egypt; East African Airways flies to East Africa; and Aeroflot flies to the Soviet Union. Somali Airlines has weekly flights to Aden, Djibouti, Nairobi, and Dar es Salaam.

ADMINISTRATION AND SOCIAL CONDITIONS

After nine years of parliamentary rule, a revolution occurred October 21, 1969, resulting in the accession to power of a military government. The administrative system has two organs. The first is the Supreme Revolutionary Council, presided over by Major General Mohammed Siad Barre, the former commander of the national army. It has 23 members, all of whom are military officers. The functions of this body are (1) to enact laws for the country; (2) to appoint secretaries of state; and (3) to approve the laws, decisions, and appointments made by the second organ, the Council of Secretaries. Some members of the Supreme Revolutionary Council also are secretaries of state and, therefore, have membership in both councils. The functions of the second organ, the Council of Secretaries, are (1) to prepare draft laws for the approval of the Supreme Revolutionary Council; (2) to make appointments to senior administrative posts, subject to the approval of the Supreme Revolutionary Council; and (3) to run the ministries. There are 8 regional revolutionary councils and over 40 district revolutionary councils, all charged with the responsibility of executing the laws, decisions, and policies of the Supreme Revolutionary Council. These administrative bodies also are entrusted with the task of generating development through self-help schemes. Each region has a governor, who is chairman of the regional revolutionary council and who is appointed by the Supreme Revolutionary Council.

Justice. The Supreme Revolutionary Council also is responsible for the administration of justice, having assumed the powers and functions of the former Higher Judicial Council, which regulated the appointments,

Port
improve-
ments

Livestock:
the
economic
mainstay

promotions, transfers, and disciplinary proceedings of the judiciary. The Supreme Revolutionary Council has created a new court, the National Security Court, which has jurisdiction over such crimes as treason, embezzlement of public funds, and antirevolutionary activities. Apart from these changes, the judiciary remains intact. At the lower level, there are district courts, above which there are regional courts, above which there are regional courts of appeal. At the apex of the judicial system is the Supreme Court. The legal system in use is a mixture of the Italian and British systems of law, modified by local factors. Islāmic law is also applied, particularly in civil cases.

Education. Education is little developed. Traditionally, Somali education consisted primarily of the teaching of the holy Qurʾān and of other aspects of the Islāmic religion. In the earlier colonial period, the Somalis vehemently resisted the introduction of Western education, fearing that it might be used to convert the Somali people to Christianity. Only after World War II did the Somalis permit the colonial powers to open modern schools. Since then, the educational system has been expanding slowly, while the demand for education has increased beyond the capacity of the state to satisfy it. The student population in all schools is about 60,000, out of which more than 40,000 are in government schools and the remainder in private schools. Schooling is divided into the elementary, intermediate, and secondary stages, each of which lasts for four years. University education does not yet exist in Somalia, although there is a National University (formerly the University Institute of Somalia) which is planning to expand its academic program in order to enable it, following the Italian pattern, to award a doctoral degree after the successful completion of four years of study. Most Somalis, however, still go abroad for higher education. In the academic year 1969–70, Somali students abroad numbered about 1,300, following courses in the Soviet Union, Italy, Egypt, West Germany, the United States, and elsewhere. The illiteracy rate in the country is probably about 85 percent. As, until 1973, Somali was unwritten, instruction in the schools has been in Arabic, English, and Italian. The educational system is beset by a lack of textbooks, qualified teachers, instructional materials, and classrooms.

Health. The health service in Somalia is insufficient. Hospitals exist only in major towns and, even when available, do not have the capacity to provide efficient medical service. Small towns and villages have only dispensaries. Doctors are few, specialists fewer, medical supplies scarce, instruments and techniques out of date, and nurses and laboratory technicians virtually unavailable.

Social conditions. Social conditions are poor. Wages and salaries are virtually at the subsistence level. There is an acute housing shortage in the towns, rents are high, and the cost of living has been rising faster than incomes. The Supreme Revolutionary Council has sought to combat these conditions by reducing salaries and wages as well as house rents.

CULTURAL LIFE AND INSTITUTIONS

Cultural activities consist primarily of poetry, folk dancing, the performance of plays, and singing. Somalis love poetry and accord recognition to poetic merit. The principal Somali poetic themes are war, peace, women, horses, and camels. Poetry recitals form a popular pastime. Folk

dancing is a popular art. The theatre, introduced only in 1950, is increasingly popular. Several theatre groups are in existence and tour the country regularly, performing plays with nationalistic or social themes or satires on contemporary politics, manners, and morals. The two principal cultural institutions in the country are the Garesa Museum and the National Theatre.

Because the Somali language was unwritten, the press in Somalia has been printed in Arabic, Italian, or English—a circumstance which restricts readership to a small, educated elite. The newspapers include the *October Star*, published daily in Arabic and Italian; the *Dawn*, which appears weekly in English; and the *New Era*, published periodically as occasion demands. All newspapers are government owned, and the publication of private newspapers is forbidden. Radio Mogadiscio and Radio Somali in Hargeisa broadcast daily in the Somali language. Broadcasts to the outside world are made in English, Arabic, Amharic, Swahili, and Italian. Daily Somali broadcasts also are made by several foreign stations, including the BBC, Moscow, Rome, Addis Ababa, and Cairo.

CONCLUSION

Stagnation, rather than development, is the present characteristic of the Somali economy. After a decade of independence, every major national enterprise—in finance, education, health, or development—presents serious problems. The attainment of a faster pace of economic development is a vital national objective. To achieve this, the first necessity is to build an administrative machinery capable of planning and implementing development programs. The second necessity is to utilize available resources to reach developmental goals, instead of squandering them on uneconomic but prestigious projects. The third necessity is to mobilize and harness the energies of the people themselves to forward development.
