The city was enlarged considerably in 1950 when seven satellite towns and 16 villages on its outskirts were merged in its territory. These were then divided into the present 22 administrative districts. One of the most momentous events in the city's postwar history was the revolution in October 1956. Once again the country followed the capital. For the first time a communist government was overthrown by the people. The "seven days that shook the Kremlin" ended in tragedy: the Soviet army retook Budapest, the town once more suffering damage, and the country was forced back into the communist mold. After bloody reprisals the city settled down to a role of providing a model for "goulash" (*i.e.,* market) socialism and for being a shop window to the West. Budapest again became the focus of national political drama in the late 1980s, when Hungary led the reform movement in eastern Europe that broke the communist monopoly on political power and ushered in the possibility of multiparty politics.

The Buddha and Buddhism

Buddhism is a Pan-Asian religion and philosophy that has played a central role in the spiritual, cultural, and social life of the Eastern world and during the 20th century has spread to the West. This article surveys Buddhism from its origins in the teachings of the Buddha Gautama to its elaboration in various schools, sects, and regional developments.

Ancient Buddhist scripture and doctrine developed primarily in two closely related literary languages of ancient India, Pāli and Sanskrit. In this article, Pāli and Sanskrit words that have gained some currency in English are treated as English words and are rendered in the form in which they appear in English-language dictionaries. Exceptions occur in special circumstances—as, for example, in the case of the Sanskrit term *dharma* (Pāli: *dhamma*), which has meanings that are not usually associated with the English "dharma." Pāli forms are given in the sections that deal with Buddhists whose primary sacred language was Pāli (including discussions of the life and teaching of the Buddha, which are reconstructed on the basis of Pāli texts). Sanskrit forms are given in the sections that deal with Buddhists whose primary focus was on Sanskritic traditions.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 823, and the *Index.*

The article is divided into the following sections:

The foundations of Buddhism

THE CULTURAL CONTEXT

Buddhism came into being in northeastern India during the period from the late 6th century to the early 4th century BC, a period of great social change and intense religious activity. There is disagreement among scholars about the dates of the Buddha's birth and death. Most scholars in Europe, the United States, and India believe that the historical Buddha lived from about 563 to about 483 BC. Many others, especially in Japan, believe that he lived about 100 years later (from about 448 to 368 BC).

At this time in India, many were no longer content with the external formalities of Brahmanic (Hindu high-caste) sacrifice and ritual. In northwestern India there were ascetics who tried to go beyond the Vedas (Hindu sacred scriptures). In the literature that grew out of this movement, the Upanishads, a new emphasis on renunciation and transcendental knowledge can be found. But northeastern India, which was less influenced by the Aryans who had developed the main tenets and practices of the Vedic Hindu faith, became the breeding ground of many heterodox sects. Society in this area was troubled by the breakdown of tribal unity and the expansion of several petty kingdoms. Religiously, this was a time of doubt, turmoil, and experimentation.

A proto-Sāṃkhya sect (a Hindu school founded by Kapila) was already well-established in the area. New sects abounded, including various kinds of skeptics (*e.g.,* Sañjaya Belaṭṭhiputta), atomists (*e.g.,* Pakudha Kaccāyana), materialists (*e.g.,* Ajita Kesakambalī), and antinomians (*i.e.,* those against rules or laws; *e.g.,* Pūraṇa Kassapa). Among the most important sects to arise at the time of the Buddha were the Ājīvikas (Ājīvakas), who emphasized the rule of fate (*niyati*), and the Jainas, an ascetic movement stressing the need to free the soul from matter. Though the Jainas, like the Buddhists, have often been regarded as atheists, their beliefs are actually more complicated. Unlike early Buddhists, both the Ājīvikas and Jainas believed in the permanence of the elements that constitute the universe, as well as the existence of the soul.

Despite the bewildering variety of religious communities, many shared the same vocabulary—nirvana (transcendent freedom), atman ("self," or "soul"), yoga ("union"), karma ("causality"), Tathāgata ("Thus-Gone," or "He Who Has Thus Attained"), buddha ("enlightened one"), samsara ("eternal recurrence," "becoming"), and *dhamma* ("rule," or "law")—and most were based on the practice of yoga. According to tradition, the Buddha himself was a yogi—that is, a miracle-working ascetic.

Buddhism, like many of the sects that developed in northeastern India at the time, was constituted by the presence of a charismatic teacher, by the teachings this leader promulgated, and by a community of adherents that was often made up of renunciant members and lay supporters. In the case of Buddhism this pattern became the basis for the Triratna—the "Three Jewels" of Buddha (the teacher), *dharma* (the teaching), and sangha (the community)—in which Buddhists have traditionally taken refuge.

In the centuries following the founder's death, Buddhism developed in two directions. One, usually called Theravāda by its present-day adherents, remained relatively faithful to what it considered to be the true tradition of the Buddha's teachings. The other is called Mahāyāna, "the means of salvation available to a larger number of people," by its followers, who call the first Hīnayāna, "the means of salvation restricted to a smaller number of people" (or simply the greater and lesser vehicles).

Theravāda and Mahāyāna

In its spread, Buddhism influenced the currents of thought and religion in other countries. In response to the diverse religious aspirations of the various Buddhist communities, the strict law of karma was modified to accommodate new emphases on the efficacy of ritual actions and various forms of devotional practice. Finally there developed in India a movement called Vajrayāna, or Esoteric Buddhism, the aim of which was to obtain liberation more speedily. This movement was influenced by gnostic and magical currents pervasive at that time.

For all the discussion on the two paths of salvation—the gradual and the instant—and the various ways of interpreting the key Mahāyāna concepts of the "void" and the mind-element, the ethics remain fundamentally the same. The monastic organizations suffered the influence of diverse historical situations, but the basic structure remains intact. The Buddha, the original teacher, is always recognized as the revealer of Buddhist truth. In the later doctrines, his preaching is not just that given to his first disciples: he multiplies himself in numberless epiphanies—all manifestations of a single immutable reality—and he emphasizes the certainty of the void and the relativity of all appearances.

In spite of these vicissitudes, Buddhism did not negate its basic principles. Instead they were reinterpreted, rethought, and reformulated, bringing to life an immense literature. This literature includes the Pāli *Tipiṭaka* ("Three Baskets"; three collections of the Buddha's teaching) and the commentaries on it; these were preserved by adherents of the Theravāda tradition. It also includes many sutras and tantras that have been recognized by the followers of the Mahāyāna and Tantric Buddhist traditions as *Buddhavacana,* "the word of the Buddha," along with commentaries on these texts. Consequently, from the first sermon of the Buddha at Sārnāth to the most recent derivations, there is an indisputable continuity—a development or metamorphosis around a central nucleus—by virtue of which Buddhism is differentiated from other religions.

(Gi.T./J.M.K./F.E.R.)

THE LIFE OF THE BUDDHA GOTAMA

The term buddha, literally meaning "awakened one" or "enlightened one," is not a proper name but rather a title, such as messiah (the Christ). Thus, the term should be accompanied by an article, such as "the Buddha" or "a buddha" (because of a belief that there will be innumerable buddhas in the future as there have been in the past). The Buddha who belongs to the present world era was born into the Gotama (in Pāli), or Gautama (in Sanskrit), clan and is often referred to as Gotama. When the term the Buddha is used, it is generally assumed that it refers to Gotama the Buddha.

According to virtually all Buddhist traditions, the Buddha lived many lives before his birth as Gotama; these previous lives are described in stories called Jātakas that play an important role in Buddhist art and education. Most Buddhists also affirm that the Buddha's life was continued in his teachings and his relics. The following account, however, focuses on the Buddha's "historical" life from his birth as Gotama to his death some 80 years later.

Sources

The version of the story presented here is based on the Pāli *Tipiṭaka,* which is recognized by scholars as the earliest extant record of the Buddha's discourses, and on the later Pāli commentaries. The style and technique of these ancient texts, followed in this biography, provide a record—sometimes symbolic, sometimes legendary, and always graphic—of the life of the revered Teacher. Just as there has been a vigorous search for the "historical Jesus" by Christian and other Western-oriented scholars, so also among some Western Orientalists there has been a scholarly search for the "historical Buddha," the history of whom the Buddhists themselves never questioned and which had never interested them as a historical problem. This section concentrates on Gotama the Enlightened One as depicted in the Buddhist scriptures and legends that developed about the man, his teachings, and his activities.

Birth and early life. The Buddha was born in the 6th or 5th century BC in the kingdom of the Sakyas, on the borders of present-day Nepal and India. As the son of Suddhodana, the king, and Mahāmāyā, the queen, the Buddha thus came from a Khattiya family (*i.e.,* the warrior caste or ruling class).

The story of the Buddha's life, however, begins with an account of a dream that his mother Mahāmāyā had one night before he was born: a beautiful elephant, white as silver, entered her womb through her side. Brahmans (Vedic priests) were asked to interpret the dream, and they foretold the birth of a son who would become either a universal monarch or a buddha. Ten lunar months after the conception, the queen and her retinue left Kapilavatthu, the capital of the Sakya kingdom, on a visit to her parents in Devadaha. She passed through Lumbinī, a park that was owned jointly by the people of both cities. There, she gave birth to the Buddha in a curtained enclosure in the park on the full-moon day of the month of Vesākha (May). The purported site of his birth, now called Rummindei, lies within the territory of Nepal. A pillar placed there in commemoration of the event by Aśoka, a 3rd-century-BC Buddhist emperor of India, still stands.

Immediately upon hearing of the birth of the Buddha, the sage Asita (also called Kāḷa Devala), who was King Suddhodana's teacher and religious adviser, went to see the child. From the auspicious signs on the child's body, Asita recognized that this child would one day become a buddha, and he was overjoyed and smiled. Because he was very old, however, he grew sad and wept, knowing that he would not remain alive to see the child's subsequent Enlightenment. Suddhodana, because of this strange display of alternate emotions, was concerned about possible dangers to the child, but Asita explained why he had first smiled and then wept and reassured the king about the child's future. Both the sage and the king then worshiped the child.

On the fifth day after birth, for the name-giving ceremony, 108 Brahmans were invited, among whom eight were specialists in interpreting bodily marks. Of these eight specialists, seven predicted two possibilities: if the child remained at home, he would become a universal monarch; if he left home, he would become a buddha. But Koṇḍañña, the youngest of the eight, predicted that he would definitely become a buddha. Later, this same Koṇḍañña became one of the Buddha's companions and was one of his first five disciples. The child was given the name Siddhattha (Sanskrit: Siddhārtha), which means "one whose aim is accomplished."

On the seventh day after his birth, his mother died, and the child was brought up by her sister Mahāpajāpatī Gotamī, Suddhodana's second consort.

Signs of the Buddha's eventual career

A significant incident in the Buddha's boyhood is recorded in ancient Pāli commentaries. One day, the little Siddhattha was taken to the state plowing festival, in which the king, with his ministers and the ordinary farmers, took part, according to the custom of the Sakyas. The boy was left with his nurses in a tent under a *jambu* tree. The nurses, attracted by the festivities, left the prince alone in the tent and went out to enjoy themselves. When they returned, they found the boy seated cross-legged, absorbed in a trance (Pāli: *jhāna*; Sanskrit: *dhyāna*). The king was immediately informed and saw his little son in the posture of a yogi (a practitioner of psychological, physiological meditation techniques). Upon seeing his son sitting in this fashion, he worshiped the child a second time. Many years later the Buddha himself, in one of his discourses (the *Mahā-Saccaka-sutta,* "The Great Discourse to Saccaka," of the Pāli *Majjhima Nikāya,* or the "Collection of the Middle Length Sayings of the Buddha"), briefly mentions his attaining to the first *jhāna* under the *jambu* tree.

The young prince was brought up in great luxury, and his father, always worried that his son might leave home to become a wandering ascetic as the Brahmans had predicted, took every care to influence him in favour of a worldly life. According to the *Aṅguttara Nikāya* ("Collection of the Gradual Sayings of the Buddha"), the Buddha himself is reported to have said later about his upbringing:

> Bhikkhus [monks], I was delicately nurtured, exceedingly delicately nurtured, delicately nurtured beyond measure. In my father's residence lotus-ponds were made: one of blue lotuses, one of red and another of white lotuses, just for my sake.... Of Kāsi cloth was my turban made; of Kāsi my jacket, my tunic, and my cloak.... I had three palaces: one for winter, one for summer and one for the rainy season.... in the rainy season palace, during the four months of the rains, entertained only by female musicians, I did not come down from the palace.

At the age of 16, Siddhattha married his cousin, a princess named Yasodharā, also 16 years old. Although Suddhodana tried his utmost to make Siddhattha content by providing him with luxury and comfort, the young prince's thoughts were generally elsewhere, occupied with other concerns.

The Four Signs. The turning point in the prince Siddhattha's life came when he was 29 years old. One day, while out driving with his charioteer, he saw "an aged man as bent as a roof gable, decrepit, leaning on a staff, tottering as he walked, afflicted and long past his prime." The charioteer, questioned by the prince as to what had happened to the man, explained that he was old and that all men were subject to old age. The prince, greatly perturbed by this sight, went back to the palace and became absorbed in thought. Another day, again driving with his charioteer, he saw "a sick man, suffering and very ill, fallen and weltering in his own excreta." Because Siddhattha was perturbed, the charioteer explained, as before, that this was a sick man and that all men are subject to sickness. On a third occasion the prince saw a dead body and again the charioteer provided the explanation. Finally, Siddhattha saw "a shaven-headed man, a wanderer who has gone forth, wearing the yellow robe." Impressed with the man's peaceful demeanour, the prince decided to leave home and go out into the world to discover the reason for such a display of serenity in the midst of misery.

On his way back to the palace after seeing the yellow-robed ascetic, Siddhattha received the news of the birth of his son, whom he named Rāhula, meaning "Fetter" or "Bond."

The Great Renunciation. Upon receiving this news, the prince decided to make what is known as the Great Renunciation: to give up the princely life and become a wandering ascetic. Waking up in the middle of the night, he ordered Channa, his charioteer and companion, to saddle his favourite horse, Kanthaka, and went to the bedchamber to have a last look at his sleeping wife and their son. He did not enter the chamber for fear of awakening his wife, which would be a sure obstacle to his plan. He thought he would one day come to see them again.

Beginning of the quest for the truth

That night Siddhattha left the city of Kapilavatthu, accompanied by Channa. By dawn he had crossed the Anomā River. He then gave all his ornaments to Channa, assumed the guise of an ascetic, and sent Channa and Kanthaka back to his father.

As an ascetic, Gotama went south, where centres of learning and spiritual discipline flourished, and arrived at Rājagaha (modern Rājgīr), the capital of the Magadha kingdom. Bimbisāra, the king of Magadha, was impressed by the handsome appearance and the serene personality of this strange ascetic and visited him when he was seated at the foot of a hill. The king, after he discovered that the ascetic was a former prince, offered him every comfort and suggested that he should stay with him to share his kingdom. Gotama, however, rejected the king's offer, saying that he had no need of those things that he had renounced and that he was in search of truth. Bimbisāra then requested that, when Gotama obtained the Enlightenment, he return to visit Rājagaha again, to which Gotama agreed.

The search for the truth. Leaving Rājagaha, Gotama went in search of teachers to instruct him in the way of truth. Two of them the Buddha himself mentioned by name in several discourses. He first went to Āḷāra Kālāma, a renowned sage, and expressed his wish to follow Āḷāra's system; Āḷāra gladly accepted Gotama as his pupil. Gotama studied and rapidly mastered Āḷāra's whole system and then asked his teacher how far the master himself had realized that teaching. Āḷāra told him that he had attained the "sphere of no-thing." Gotama soon attained the same mystical state himself. Āḷāra admitted that that state was the highest he could teach and declared that Gotama and himself were now equals in every respect—in knowledge, practice, and attainment—and invited the Sakyan ascetic to guide, along with him, the community of his disciples. The Buddha later spoke of this occasion in a *sutta:* "In this way did Āḷāra Kālāma, my teacher, set me, his pupil, on the same level as himself and honoured me with the highest honour." Gotama, however, was not satisfied with attaining the sphere of no-thing, though it was a very high mystical state. He was in quest of absolute truth, nirvana, and thus he left Āḷāra Kālāma.

He then went to Uddaka Rāmaputta, another great teacher, who taught him to attain the "sphere of neither-perception-nor-nonperception," a higher mystical state than the sphere of no-thing. Gotama, however, was not satisfied with this either, and he continued his search for the truth.

Traveling through the Magadha country, Gotama arrived at a village called Senānigama, near Uruvelā, and, according to his own words, found "a beautiful stretch of land, a lovely woodland grove, and a clear flowing river with a pleasant ford, and a village for support close by." He was joined there by a group of five ascetics, among whom was Koṇḍañña, the Brahman who had predicted at the name-giving ceremony that the child Siddhattha would definitely become a buddha one day.

The Buddha's practice of asceticism

Gotama's real struggle in his search for the truth began in the area around Uruvelā, near modern Gayā. Here, for nearly six years, he practiced various severe austerities and extreme self-mortifications. These austerities were vividly described in several discourses attributed to the Buddha himself (*e.g.,* in the *Majjhima Nikāya*). What he looked like and what happened to him is described in the following words from the ancient text:

> Because of so little nourishment, all my limbs became like some withered creepers with knotted joints; my buttocks like a buffalo's hoof; my back-bone protruding like a string of balls; my ribs like rafters of a dilapidated shed; the pupils of my eyes appeared sunk deep in their sockets as water appears shining at the bottom of a deep well; my scalp became shriveled and shrunk as a bitter gourd cut unripe becomes shriveled and shrunk by sun and wind; . . . the skin of my belly came to be cleaving to my back-bone; when I wanted to obey the calls of nature, I fell down on my face then and there; when I stroked my limbs with my hand, hairs rotted at the roots fell away from my body.

Many later representations of the Buddha portray him in this emaciated state.

As a consequence of these severe bodily austerities, Gotama became so weak that he once fainted and was believed by some to be dead. From these experiences, he realized that such mortifications could not lead him to what he sought; he therefore changed his way of life and again began to eat proper amounts of food.

His five companions, who had much faith in him, were disappointed at his rejection of extreme asceticism and left him in disgust. Gotama thus remained alone in Uruvelā, regained his health and strength, and then followed his own path to Enlightenment.

The Great Enlightenment. One morning, seated under a banyan tree, Gotama accepted an offering of a bowl of milk rice from Sujātā, the daughter of the landowner of the village of Senānigama. This was his last meal before his Enlightenment. He spent the day in a grove of sal trees and in the evening went to the base of a pipal tree (*Ficus religiosa*), now known as the bodhi, or bo, tree, and sat cross-legged, determined not to rise without attaining Enlightenment.

The struggle with Māra

At that point, the greatest of Gotama's struggles began: Māra, the evil one, the tempter who is the lord of the world of passion, determined to defeat him and prevent him from attaining Enlightenment; he approached Gotama with his hideous demonic hordes. Gotama, however, sat unmoved in meditation, supported only by the 10 paramitas ("great virtues") that he had perfected during innumerable past lives as a bodhisattva ("buddha-to-be") in order to attain Enlightenment. (In order to attain buddhahood, all bodhisattvas [*i.e.,* those who aspire to become buddhas] have to perfect, during innumerable lives, these 10 paramitas: charity, morality, renunciation, wisdom, effort, patience, truth, determination, universal love, and equanimity.) Māra was thus vanquished and fled headlong with his armies of evil spirits.

The battle with Māra is graphically described in ancient Buddhist texts and depicted in paintings on the walls of Buddhist temples. In the *Padhānasutta* ("Discourse on the Exertion") of the Pāli *Suttanipāta,* one of the earliest texts, the Buddha states that, when he was practicing austerities by the Nerañjarā River in Uruvelā, Māra approached him, speaking such words as: "You are emaciated, pale, you are near death. Live, Sir, life is better. Do meritorious deeds. What is the use of striving?" After some preliminary words, Gotama replied:

> Lust is your first army; the second is dislike for higher life; the third is hunger and thirst; the fourth is craving; the fifth is torpor and sloth; the sixth is fear (cowardice); the seventh is doubt; the eighth is hypocrisy and obduracy; the ninth is gains, praise, honour, false glory; the tenth is exalting self and despising others. Māra, these are your armies. No feeble man can conquer them, yet only by conquering them one wins bliss. I challenge you! Shame on my life if defeated! Better for me to die in battle than to live defeated.

Māra, overcome with grief, disappeared.

The realization of the Four Noble Truths

Having defeated Māra, Gotama spent the rest of the night in deep meditation under the tree. During the first part of the night he gained the knowledge of his former existences. During the second part of the night he attained the "superhuman divine eye," the power to see the passing away and rebirth of beings. In the last part of the night he directed his mind to the knowledge of the destruction of all cankers and defilements and realized the Four Noble Truths. In words attributed to the Buddha himself: "My mind was emancipated, . . . Ignorance was dispelled, science (knowledge) arose; darkness was dispelled, light arose."

Thus Gotama, at the age of 35, attained the Enlightenment, or Awakening, and became a supreme buddha during the night of the full-moon day of the month of Vesākha (May) at a place now called Bodh Gayā (Pāli and Sanskrit: Buddhagayā).

Milt and Joan Mann—CAMERAMANN INTERNATIONAL

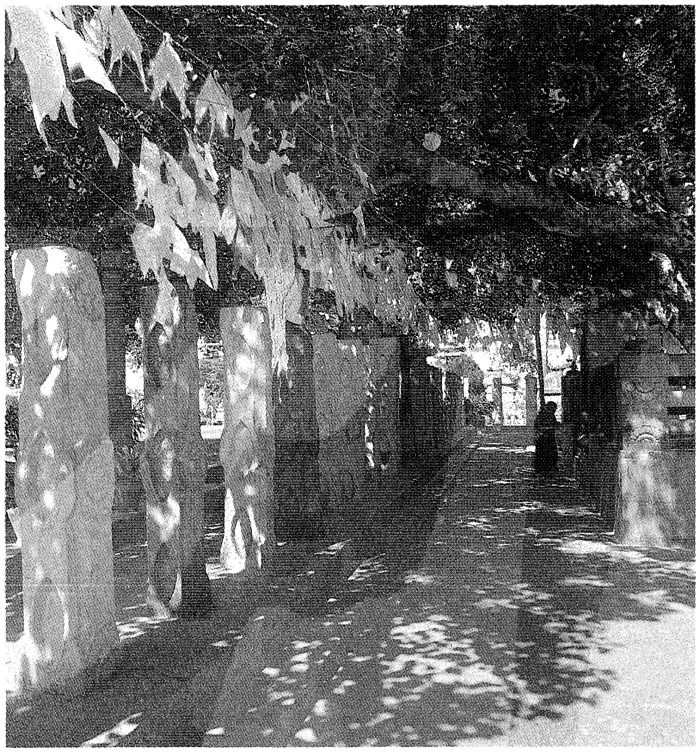

Figure 1: Prayer flags and pilgrim under the bodhi tree at Bodh Gayā, India, the site of the Buddha's Enlightenment.

Contemplation on the truth. After his Enlightenment the Buddha spent several weeks (five or seven weeks according to different accounts) in Uruvelā, meditating on the various aspects of the *dhamma* that he had realized, particularly on the most important and difficult doctrine of causal relations, known as the dependent origination or the conditioned genesis (*paṭicca-samuppāda*). This doctrine views everything as relative and interdependent and teaches that there is no eternal, everlasting, unchanging, permanent, or absolute substance, such as the soul, the self, or the ego, within or without man.

Four weeks after his Enlightenment, seated under a banyan tree, the Buddha is reported to have thought to himself: "I have realized this Truth which is deep, difficult to see, difficult to understand . . . comprehensible by the wise. Men who are overpowered by passion and surrounded by a mass of darkness cannot see this Truth which is against the current, which is lofty, deep, subtle and hard to comprehend."

With these thoughts in mind, the Buddha hesitated to try to explain to the world the truth that he had just realized. At this point, according to the tradition, the Brahman Sahampati intervened in order to convince the Buddha to accept his vocation as a teacher. This great Brahmanic deity set forth for him an image of a lotus pond: in a lotus pond there are some lotuses still under water; there are others that have risen only up to the water level; and there are still others that stand above water and are untouched by it. In a similar way, in this world there are people of different levels of development. Thus challenged, the Buddha determined to proclaim the insight he had gained.

At the outset he faced the problem of choosing those who would be the first to hear him preach the *dhamma.* He first thought of his two former teachers, Āḷāra Kālāma and Uddaka Rāmaputta, but they had died by this time. He then thought of the five companions who had left him and were now staying in Isipatana near Bārāṇasī (Benares; now Vārānasi) and decided to go there.

On meeting the five ascetics, the Buddha told them that now he was an arhat, a "perfected one" (Pāli: *arahant*), a "fully awakened one" (*sammāsambuddha*), that he had realized the "immortal" (*amata*), and that he wished to instruct and teach them the *dhamma.* They replied to him:

> But, Reverend Gotama, even by all that conduct, that practice, that austerity, you did not realize this supreme knowledge, this supreme state. So how can you now realize it when you live in abundance, when you have given up striving and have reverted to a life of abundance?

The Buddha denied that he had given up striving and that he had reverted to a life of abundance. He requested again that they listen to him. Again, however, they replied in a similar manner. A third time the Buddha repeated what he had said and asked them to listen to him, and they repeated their remark.

The Buddha then asked them a question: "Do you admit that I have never spoken anything like this before?" They were struck by such straightforwardness and knew how sincere and earnest he was. Convinced that he had attained what he claimed to have attained, they no longer addressed the Buddha as "Reverend Gotama" but changed their attitude toward him and answered him: "Lord, you have not." The Buddha then delivered to them his first sermon, known as the *Dhammacakkappavattana-sutta* ("Sermon on Setting in Motion the Wheel of Truth"), at Isipatana, now called Sārnāth. An ancient stupa (a building containing a religious relic) still marks the spot where this event supposedly occurred.

The teaching of moderation and the Eightfold Path

The substance of this *sutta* is as follows: a man who has left home and gone forth should not follow two extremes, namely self-indulgence and self-mortification. Avoiding these two extremes, the Tathāgata ("He Who Has Thus Attained"—*i.e.,* the Buddha) has discovered the middle path leading to vision, to knowledge, to calmness, to awakening, to nirvana. This middle path is known as the Noble Eightfold Path consisting of right view, right thought, right speech, right action, right mode of living, right endeavour, right mindfulness, and right concentration. The First Noble Truth is that man's existence is *dukkha,* full of conflict, dissatisfaction, sorrow, and suffering. The Second Noble Truth is that all this is caused by man's selfish desire—*i.e.,* craving or *taṇhā,* "thirst." The Third Noble Truth is that there is emancipation, liberation, and freedom for human beings from all this, which is nirvana. The Fourth Noble Truth, the Noble Eightfold Path, is the way to this liberation.

The founding of the sangha. At the end of the sermon, these five ascetics, the Buddha's first disciples, were admitted by him as bhikkhus (monks) and became the first members of the sangha ("community," or "order"). A few days later, this sermon was followed by the *Anattalakkhaṇa-sutta,* dealing with the doctrine of no-self, at the conclusion of which all five bhikkhus became arhats ("perfected ones").

The Buddha spent about three months in the Vārānasi/Benares region. During this period an important and influential wealthy young man named Yasa became his disciple and entered the order. His father and mother, along with his former wife, also were converted. They were the first lay disciples to take refuge in the "Triple Jewel": the Buddha, the *dhamma,* and the sangha. Later, four of Yasa's close friends followed his example and entered the order. Enthusiasm for this new movement became so impelling that 50 of their friends also joined them in the sangha. All these became arhats in due course, and the Buddha soon had 60 disciples who were perfected ones.

The Buddha addressed this group in the following words and sent them out into the world to spread his message of peace, compassion, and wisdom:

> Bhikkhus, I am freed from all fetters, both divine and human. You, too, are freed from all fetters, both divine and human. Wander forth, bhikkhus, for the good of the many, for the happiness of the many, out of compassion for the world.... Let not two of you go by one road [*i.e.,* go in different directions]. Teach the *Dhamma* which is good at the beginning, good in the middle, and good at the end.... There are people who will understand the *Dhamma.* I, too, will go to Uruvelā to teach the *Dhamma.*

The 60 disciples went in various directions to spread the teaching of the Buddha. The Buddha himself set out for Uruvelā. On the way he converted 30 young men, who then entered the order. In the region of Uruvelā he also converted three leading ascetics along with a large number of their disciples. To these ascetics, formerly known as "those with matted hair" (*jaṭilas*), the Buddha delivered the famous "Fire Sermon" (the *Adittapariyāya-sutta*), which states that all man's existence is burning with the fire of lust, the fire of hate, and the fire of delusion.

From Uruvelā the Buddha went on to Rājagaha, the capital of Magadha, fulfilling his promise to visit King Bimbisāra after his Enlightenment. Many people, including the king, became his lay disciples. The king offered his park, Veḷuvana, as a monastery site to the Buddha and his order. During this visit a very important event that had far-reaching effects took place: Sāriputta and Moggallāna, two Brahmanic ascetics who later became the Buddha's two chief disciples, joined the order. Sāriputta had first heard of the Buddha and his new teaching from Assaji, one of the original 60 disciples. At the request of his father, the Buddha visited Kapilavatthu with a large number of his disciples. In that city, where as prince he had lived in great splendour and luxury, he went about begging for his food from house to house. His father, King Suddhodana, was grieved and upset by this, but, upon learning that this was the custom of all buddhas, he conducted the Blessed One and his disciples to eat a meal at the palace.

Conversion of members of the Buddha's family

All the ladies of the court went to him to offer reverence, except his former wife, Yasodharā. She refused, saying that the Blessed One himself would come to her if he thought she had any virtue in her and that she would then worship him. The Buddha, with his two chief disciples and the king, went to see her in her apartment. She fell at his feet, clasped his ankles with her hands, and put her head on his feet.

The Buddha's father, his aunt Mahāpajāpatī, Yasodharā, and large numbers of Sakyans (who were fellow members of the Gotama clan) became his followers. On the following day he ordained his half-brother Nanda and a few days later his son, Rāhula. All this troubled the old king so much that he asked the Buddha to lay down a rule that no son should be ordained without the consent of his parents. Accordingly, the rule was formulated, and it continues to be followed by the sangha.

Anāthapiṇḍika, a banker of Sāvatthi (modern Śrāvasti), the capital of Kosala kingdom, had met the Buddha at Rājagaha and had become deeply devoted to him. He invited the Blessed One to his city, where he built for him the famous monastery at Jetavana. This monastery in Sāvatthi became the virtual headquarters of the Buddha's activities. There he spent most of his time and delivered most of his sermons. The Buddha and his new teaching became so popular that monasteries were built for him and his sangha in almost all the important cities in the valley of the Ganges, and the number of his followers among all classes of people increased rapidly.

The order of nuns, *bhikkhunī-saṅgha,* was instituted after some hesitation. Ānanda, the Buddha's cousin and later his chief attendant and constant companion, pleaded with the Master on behalf of women. The Buddha's own aunt Mahāpajāpatī Gotamī and her friends were the first women to enter the order.

Members of some hostile sects, who became jealous of the Buddha's success and popularity, made several attempts to vilify him.

Devadatta, one of the Buddha's cousins, an ambitious man of ability and guile, was his rival from early days. He too joined the order but was never sincerely devoted to the Master. He became popular and influential with some people, however, and, about eight years before the Buddha's death, Devadatta conceived the idea of becoming the Buddha's successor and suggested to him that the leadership of the sangha should be handed over to him in view of the Master's approaching old age. The suggestion, however, was rejected. The Buddha stated that he would not pass on the leadership of the order to anyone, not even to Sāriputta or Moggallāna. Rather, the sangha was to be run in accordance with democratic principles. Its constitution was to be the vinaya ("discipline"), rules that the Buddha himself had laid down to guide the spiritual and material life of the individual monks and nuns and to regulate the structure and dynamics of monastic life.

After being rebuffed in this way, Devadatta vowed vengeance. He made three cleverly designed attempts on the life of the Buddha, all of which failed. Devadatta next tried to bring about a schism in the sangha, taking with him a group of newly ordained monks to establish a separate community. All those who were misled by Devadatta, however, were later persuaded to go back to the Master by Sāriputta and Moggallāna. After this event Devadatta became seriously ill and died after about nine months of illness.

The death of the Buddha. After the Buddha had trained learned, well-disciplined followers and his mission was fulfilled, at the age of 80, with a group of monks, he set out on his last journey, from Rājagaha toward the north. As usual, he passed in leisurely fashion through cities, towns, and villages, teaching the people on his way and stopping wherever he wished.

The Buddha's attempt to recover his health

In due course he arrived at Vesālī, the capital city of the Licchavis. The Buddha spent that rainy season not in the park in Vesālī, which had just been donated to him by Ambapālī, the celebrated courtesan of that city, but in an adjoining village called Beluva. There the Buddha became seriously ill. He thought, however, that it was not right for him to die without preparing his disciples, who were dear to him. Thus, with courage, determination, and will, he bore all his pains, got the better of his illness, and recovered; but his health was still poor.

After the Buddha's recovery, Ānanda, his most devoted attendant, went to his beloved Master and said:

> Lord, I have looked after the health of the Blessed One. I have looked after him in his illness. But at the sight of his illness, the horizon became dim to me, and my faculties were no longer clear. Yet there was one little consolation: I thought the Blessed One would not pass away until he had left instructions concerning the Order of the Sangha.

The Buddha, full of compassion and feeling, replied:

> Ānanda, what does the Order of the Sangha expect from me? I have taught the *dhamma* without making any distinction as to exoteric and esoteric. With regard to the Truth, the Tathāgata has nothing like the 'closed fist of a teacher' (*ācariya-muṭṭhi*), who keeps something back. Surely, Ānanda, if there is anyone who thinks that he will lead the sangha and that the sangha should depend on him, let him set down his instructions. But the Tathāgata has no such idea. Why should he then leave instructions concerning the sangha? I am old now, Ānanda . . . eighty years old. As a worn-out cart has to be kept going by repairs, so, it seems to me, the body of the Tathāgata can only be kept going by repairs.... Therefore, Ānanda, dwell by making yourselves your island, making yourselves, not anyone else, your refuge; making the *dhamma* your island, the *dhamma* your refuge, nothing else your refuge.

Later the Buddha told Ānanda that he had decided to die after three months and asked him to assemble in the hall at Mahāvana all the monks who were at that time residing in the neighbourhood of Vesālī. At this meeting, the Buddha advised the monks to follow what he had taught them and to spread it abroad for the good of the many, out of compassion for the world. He then announced that he had decided to die after three months.

Leaving Vesālī, the Buddha gazed at the city in which he had stayed on many occasions and said: "This will be the last time, Ānanda, that the Tathāgata will behold Vesālī. Come, Ānanda, let us proceed."

Stopping at several villages and townships, the Buddha eventually arrived at Pāvā and stayed in the park of Cunda the goldsmith, who was already one of his devoted followers. At his invitation the Buddha and the monks went to his house for a meal. Cunda had prepared, besides various delicacies, a dish called *sūkara-maddava.* This is interpreted in the ancient Pāli commentaries in several ways: (1) as pork (this is generally accepted), (2) as bamboo sprouts trodden by pigs, (3) as a kind of mushroom growing in a spot trodden by pigs, (4) as a rice pudding rich with the essence of milk, or (5) as a special preparation (an elixir?) intended by Cunda to prolong the Buddha's life. Whatever it might have been, the Buddha asked Cunda to serve him with *sūkara-maddava* and to serve the bhikkhus with other dishes. At the end of the meal, the Buddha requested Cunda to bury in a hole whatever was left of the *sūkara-maddava,* saying that only a Tathāgata would be able to assimilate it. This was the Buddha's last meal.

After it the Buddha became sick and suffered violent pains but bore them without complaint. He set out for Kusinārā, accompanied by Ānanda and other monks. Explaining that he was tired, he stopped and rested in two places. On the way, the Buddha said to Ānanda:

> Now it may happen, Ānanda, that someone should stir up remorse in Cunda by saying that the Tathāgata died after eating his meal. Any such remorse in Cunda should be dispelled. Tell him, Ānanda, that you heard directly from my mouth that there are two offerings of food which are of equal fruit, of equal profit: the offering of food before the Enlightenment and the offering of food before the *Parinibbāna* (the passing away) of a Tathāgata. Tell him that he has done a good deed. In this way Ānanda, you should dispel any possible remorse in Cunda.

The Buddha arrived at Kusinārā (the modern Kasia, known in Sanskrit as Kuśinagara) toward evening, and, on a couch between two sal trees in the park Upavattana of the Mallas, he "laid himself down on his right side, with one leg resting on the other, mindful and self-possessed." This was the full-moon day of the month of Vesākha (May).

Final conversations with Ānanda and other monks

Ānanda asked the Buddha what they should do with his remains. He told Ānanda they should not occupy themselves with honouring the remains of the Tathāgata but should rather be zealous in their own spiritual development. The lay devotees, he said, would busy themselves with the remains.

Ānanda left the immediate area and cried out: "My Master is about to pass away from me—he who is so kind to me." The Buddha inquired where Ānanda was and, on being told that he was weeping, called to him and said: "No, Ānanda, don't weep. Haven't I already told you that separation is inevitable from all near and dear to us? Whatever is born, produced, conditioned, contains within itself the nature of its own dissolution. It cannot be otherwise." Then, the Master spoke to the monks in praise of Ānanda's wonderful qualities and abilities. The Mallas, in whose realm Kusinārā was located, came with their families to pay homage to the Blessed One. A wandering ascetic named Subhadda asked for permission to see the Buddha, but Ānanda refused, saying that the Blessed One was tired and that he should not be troubled. The Buddha, overhearing the conversation, called Ānanda and asked him to allow Subhadda to see him. After an interview with the Buddha, Subhadda joined the order the same night, thus becoming his last direct disciple.

The Buddha then addressed Ānanda:

> It may be, Ānanda, that to some of you the thought may come: 'Here we have the Word of the Master who is gone; our Master we have with us no more.' But, Ānanda, it should not be considered in this light. What I have taught and laid down, Ānanda, as *Dhamma* (Truth, Doctrine) and as *Vinaya* (Discipline), this will be your Master when I am gone. . . . If the sangha wish it, Ānanda, let them, when I am gone, abolish lesser and minor precepts (rules).

The Buddha next addressed the monks and requested them three times to ask him if they had any doubt or question that they wished clarified, but they all remained silent. The Buddha then addressed the monks: "Then, bhikkhus, I address you now: transient are all conditioned things. Try to accomplish your aim with diligence." These were the last words of the Tathāgata. A week later, his body was cremated by the Mallas in Kusinārā.

A dispute over the relics of the Buddha arose between the Mallas and the delegates of rulers of several kingdoms, such as Magadha, Vesālī, and Kapilavatthu. It was settled by a venerable old Brahman named Doṇa on the basis that they should not quarrel over the relics of one who preached peace. With common consent, the relics were then divided into eight portions to the satisfaction of all. Stupas were built over these relics, and feasts were held commemorating the Buddha.

Assessment of the personality and character of the Buddha. According to the Buddhist tradition, the Buddha was a very handsome man. Caṅkī, a highly respected Brahman leader, is reported to have said that "the recluse Gotama is lovely, good to look upon, charming, possessed of the greatest beauty of complexion, of a sublime colour, a perfect stature, noble of presence." Buddhists came to envision (and later represent) him as one endowed with the 32 bodily characteristics of a *mahāpuruṣa* ("great person").

He had a unique reputation as a superb teacher. His conversion and taming of Aṅgulimāla, a murderer and bandit who was a terror even to Pasenadi, the king of Kosala, is put forward as an example of his great powers and abilities. People who went to see and hear him were fascinated and were so quickly converted to his new teaching that his opponents described him as having some "enticing trick." King Pasenadi is reported to have said that those who went with the idea of confounding the Buddha in debate became his disciples at the end. Full of compassion and wisdom, he is recognized as knowing how and what to teach individual people for their own benefit according to the level of their capabilities.

The Buddha, affectionate and devoted to his disciples, was always inquiring after their well-being and progress. When he was staying in a monastery, he paid daily visits to the sick ward. Once, he himself attended a sick monk neglected by others and made the comment that "he who attends on the sick attends on me."

The Buddha as a social reformer

The Buddha refused to recognize the religious significance of the caste system that was a long-established and respected institution in India and recognized the religious potential of men and women of all social ranks. He also recognized the connection between economic welfare and moral development. Trying to suppress crime through punishment, he said, was futile. Poverty, according to the Buddha, was a cause of immorality and crime; therefore, the economic condition of people should be improved.

He appreciated both natural and physical beauty. On several occasions he was moved aesthetically, as he told Ānanda how delightful certain places were to him. At Vesālī he told the monks that, if they had not seen the devas (gods) of Tāvatiṃsa (Heaven), they should look at the handsome Licchavis, beautifully and elegantly dressed in different colours.

King Pasenadi could not understand how the Buddha maintained such order and discipline in the community of monks, when he, a king, with the power to inflict punishment, could not maintain it as well in his court. The Buddha, however, kept order and discipline on the basis of a mutual love, affection, and respect that exists between teacher and pupil.

Many miraculous powers were attributed to the Buddha, and he performed a number of miracles during his ministry. At the same time, however, he did not consider magical powers to be of primary importance. Once, when one of his disciples performed a miracle in public, the

Buddha reproached him and laid down a rule that his disciples should not perform miracles before the laity. In his view, the greatest miracle was to explain the truth and to make people recognize its importance.

Behind his philosophy and strict ethics, the Buddha had a quiet sense of humour. A conceited Brahman, who was in the habit of denigrating others, questioned him as to the qualities of a true Brahman. In a list of such high qualities as freedom from evil and purity of heart, the Buddha gently included "not denigrating others."

The portrait of the Buddha, as can be inferred from the lines of the ancient texts, is thus one of a man of great wisdom and great compassion, one who was moved by the spectacle of human suffering and was determined to teach his fellow human beings how that suffering could be confronted and overcome. (Wa.R./F.E.R.)

THE BUDDHA'S MESSAGE

The teaching attributed to the Buddha was transmitted orally by his disciples, prefaced by the phrase "evaṃ me sutaṃ" ("thus have I heard"); therefore, it is difficult to say whether his discourses were related as they were spoken. They usually allude, however, to the place, time, and community where he preached; and there is concordance between various versions. An attempt was made by Buddhist councils in the first centuries after the Buddha's death to establish his true and original teachings.

Suffering, impermanence, and no-self. It may be said that the Buddha based his entire teaching on the fact of human suffering. Existence is painful. The conditions that make an individual are precisely those that also give rise to suffering. Individuality implies limitation; limitation gives rise to desire; and, inevitably, desire causes suffering, since what is desired is transitory, changing, and perishing. It is the impermanence of the object of craving that causes disappointment and sorrow. By following the "path" taught by the Buddha, the individual can dispel the "ignorance" that perpetuates this suffering. The Buddha's doctrine was not one of despair. Living amid the impermanence of everything and being themselves impermanent, human beings search for the way of deliverance, for that which shines beyond the transitoriness of human existence—in short, for enlightenment.

The constituents of reality

According to the Buddha, reality, whether of external things or the psychophysical totality of human individuals, consists in a succession and concatenation of microseconds called *dhamma*s (these "components" of reality are not to be confused with *dhamma* meaning "law" or "teaching"). The Buddha departed from the main lines of traditional Indian thought in not asserting an essential or ultimate reality in things.

Moreover, contrary to the theories of the Upanishads, the Buddha did not want to assume the existence of the soul as a metaphysical substance, but he admitted the existence of the self as the subject of action in a practical and moral sense. Life is a stream of becoming, a series of manifestations and extinctions. The concept of the individual ego is a popular delusion; the objects with which people identify themselves—fortune, social position, family, body, and even mind—are not their true selves. There is nothing permanent, and, if only the permanent deserved to be called the self, or atman, then nothing is self. There can be no individuality without a putting together of components. This is becoming different, and there can be no way of becoming different without a dissolution, a passing away.

To make clear the concept of no-self (anatman), Buddhists set forth the theory of the five aggregates or constituents (*khandha*s) of human existence: (1) corporeality or physical forms (*rūpa*), (2) feelings or sensations (*vedanā*), (3) ideations (*saññā*), (4) mental formations or dispositions (*sankhāra*), and (5) consciousness (*viññāṇa*). Human existence is only a composite of the five aggregates, none of which is the self or soul. A person is in a process of continuous change, with no fixed underlying entity.

Karma. The belief in rebirth, or samsara, as a potentially endless series of worldly existences in which every being is caught up was already associated with the doctrine of karma (Sanskrit: *karman;* literally "act," or "deed") in pre-Buddhist India, and it was generally accepted by both the Theravāda and the Mahāyāna traditions. According to the doctrine of karma, good conduct brings a pleasant and happy result and creates a tendency toward similar good acts, while bad conduct brings an evil result and creates a tendency toward repeated evil actions. This furnishes the basic context for the moral life of the individual.

Some karmas bear fruit in the same life in which they are committed, others in the immediately succeeding one, and others in future lives that are more remote.

The acceptance by Buddhists of the belief in karma and rebirth while holding to the doctrine of no-self gave rise to a difficult problem: how can rebirth take place without a permanent subject to be reborn? Indian non-Buddhist philosophers attacked this vulnerable point in Buddhist thought, and many modern scholars have also considered it to be an insoluble question. The relation between existences in rebirth has been explained by the analogy of fire, which maintains itself unchanged in appearance and yet is different in every moment—what may be called the continuity of an ever-changing identity.

The Four Noble Truths. Awareness of these fundamental realities led the Buddha to formulate the Four Noble Truths: the truth of misery, the truth that misery originates within us from the craving for pleasure and for being or nonbeing, the truth that this craving can be eliminated, and the truth that this elimination is the result of a methodical way or path that must be followed. Thus, there must be an understanding of the mechanism by which a human being's psychophysical being evolves; otherwise, human beings would remain indefinitely in samsara, in the continual flow of transitory existence.

The law of dependent origination. Hence, the Buddha formulated the law of dependent origination (*paṭicca-samuppāda*), whereby one condition arises out of another, which in turn arises out of prior conditions. Every mode of being presupposes another immediately preceding mode from which the subsequent mode derives, in a chain of causes. According to the classical rendering, the 12 links in the chain are ignorance (*avijjā*), karmic predispositions (*sankhāras*), consciousness (*viññāṇa*), form and body (*nāma-rūpa*), the five sense organs and the mind (*saḷāyatana*), contact (*phassa*), feeling-response (*vedanā*), craving (*taṇhā*), grasping for an object (*upādāna*), action toward life (*bhava*), birth (*jāti*), and old age and death (*jarāmaraṇa*). Thus, the misery that is bound up with all sensate existence is accounted for by a methodical chain of causation.

The chain of causation

The law of dependent origination of the various aspects of becoming remains invariable and fundamental in all schools of Buddhism. There are, however, diverse interpretations.

The Eightfold Path. Given the awareness of this law, the question arises as to how one may escape the continually renewed cycle of birth, suffering, and death. Here ethical conduct enters in. It is not enough to know that misery pervades all existence and to know the way in which life evolves; there must also be a purification that leads to the overcoming of this process. Such a liberating purification is effected by following the Noble Eightfold Path constituted by right views, right aspirations, right speech, right conduct, right livelihood, right effort, right mindfulness, and right meditational attainment. The term right (true or correct) is used to distinguish sharply between the precepts of the Buddha and other teachings.

Nirvana. The aim of religious practice is to be rid of the delusion of ego, thus freeing oneself from the fetters of this mundane world. One who is successful in doing so is said to have overcome the round of rebirths and to have achieved enlightenment. This is the final goal—not a paradise or a heavenly world.

The living process is likened to a fire burning. Its remedy is the extinction of the fire of illusion, passions, and cravings. The Buddha, the Enlightened One, is one who is no longer kindled or enflamed. Many poetic terms are used to describe the state of the enlightened human being—the harbour of refuge, the cool cave, the place of bliss, the farther shore. The term that has become famous in the West is nirvana, translated as dying out—that is, the dying out

The dying out

in the heart of the fierce fires of lust, anger, and delusion. But nirvana is not extinction, and indeed the craving for annihilation or nonexistence was expressly repudiated by the Buddha. Buddhists search not for mere cessation but for salvation. Though nirvana is often presented negatively as "release from suffering," it is more accurate to describe it in a more positive fashion: as an ultimate goal to be sought and cherished.

The Buddha left indeterminate questions regarding the destiny of persons who have reached this ultimate goal. He even refused to speculate as to whether such purified saints, after death, continued to exist or ceased to exist. Such questions, he maintained, were not relevant to the practice of the path and could not in any event be answered from within the confines of ordinary human existence.

Though it is true that the Buddha avoided discussion of the ultimate condition that lay beyond the categories of the phenomenal world, he often affirmed the reality of the religious goal. For example, he is reported to have said: "There is an unborn, an unoriginated, an unmade, an uncompounded; were there not, there would be no escape from the world of the born, the originated, the made, and the compounded."

In his teaching, the Buddha strongly asserted that the ontological status and character of the unconditioned nirvana cannot be delineated in a way that does not distort or misrepresent it. But what is more important is that he asserted with even more insistence that nirvana can be experienced—and experienced in this present existence—by those who, knowing the Buddhist truth, practice the Buddhist path. (Gi.T./H.Na./F.E.R.)

Historical development

INDIA

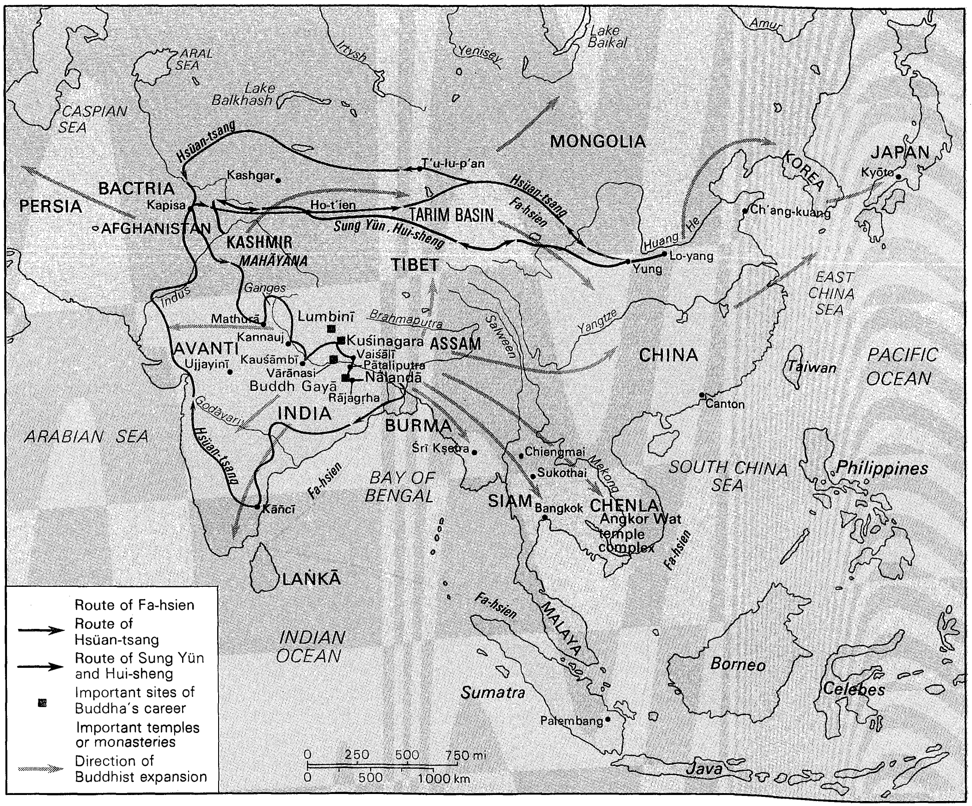
Expansion of Buddhism. The Buddha was a charismatic leader who discovered and proclaimed a religious message and founded a distinctive religious community. Some of the members of that community were, like the Buddha himself, wandering ascetics. Others were laypersons who venerated the Buddha, followed those aspects of his teachings that were relevant to them, and provided the wandering ascetics with the material support that they required.

During the first several centuries after the Buddha's death, the story of his life was remembered and embellished, his teachings were preserved and developed, and the community that he had established became a significant religious force. Many of the followers of the Buddha who were wandering ascetics began to settle in permanent monastic establishments and to develop the procedures needed to maintain large monastic institutions. At the same time, the Buddhist laity came to include important members of the economic and political elite.

During the first century of its existence Buddhism spread from its place of origin in Magadha and Kosala throughout much of northern India, including the areas of Mathurā (modern Madurai) and Ujjayanī in the west. According to the Buddhist tradition, invitations to the Council of Vesālī (Sanskrit: Vaiśālī), held just over a century after the Buddha's death, were sent to monks living in many distant places in northern and central India. By the middle of the 3rd century BC, Buddhism had gained the favour of a Mauryan king who had established an empire that extended from the Himalayas in the north almost as far south as Sri Lanka.

The Mauryan dynasty

To the rulers of the kingdoms and republics arising in northeastern India, the patronage of heteroprax sects (those with differing practices) was one way of counterbalancing the enormous political power enjoyed by Brahmans (high-caste Hindus) in the affairs of state. The first Mauryan emperor, Candra Gupta (*c.* 321–*c.* 297 BC), patronized Jainism and finally became a Jaina monk. His grandson, Aśoka, who ruled over the greater part of the subcontinent from about 270 to 230 BC, became the archetypal Buddhist king. Aśoka attempted to establish in his realm a "true *dhamma*" based on the virtues of self-control, impartiality, cheerfulness, truthfulness, and goodness. Though he did not found a state church, he did attempt to forge a Buddhist-oriented religiopolitical culture that would include Hindu, Jaina, Ājīvika (Ājīvaka), and Buddhist alike. His aim was to create a religious and social milieu that would enable all "children of the king" to live happily and attain heaven in the next life. Thus, he created a "welfare state" by setting up medical assistance for men and beasts, maintaining reservoirs and canals, and promoting trade. A system of *dhamma* officers (*dhamma-*



Important sites and routes of expansion of early Buddhism.

mahāmattas) was set up to provide for the empire magistrates, district attorneys, preachers, bureaucrats, social workers, and spies. The lay ethic preached by the king of the *dhamma* (*dhamma-rāja*) and his officers was focused on the layman's obligations in this world. Though Aśoka created a new ideal of kingship that would have powerful repercussions throughout the later Buddhist world, the various problems posed by a state of such vast dimensions in India proved greater than he could solve. Soon after Aśoka's death, the Mauryan empire began to crumble.

Although Buddhists seem to have suffered some persecutions during the subsequent Śuṅga–Kāṇva period (185–28 BC), Buddhism succeeded in maintaining and even expanding its influence. Buddhist monastic centres and magnificent Buddhist monuments such as the great stupas at Bhārhut and Sāñchi were established throughout the subcontinent, and these institutions often received royal patronage. In the early centuries of the Common era, Buddhism was especially flourishing in northwestern India, and from there it spread rapidly into Central Asia and China.

Buddhism under the Guptas and Pālas. By the time of the Gupta dynasty (*c.* AD 320–*c.* 600), Buddhism in India was being affected by the revival of Brahmanic religion and the rising tide of bhakti (a devotional movement that emphasized the intense love of a devotee for a personal god). During this period, for example, some Hindus were practicing devotion to the Buddha, whom they regarded as an avatar (incarnation) of the Hindu deity Vishnu.

During the Gupta period some monasteries joined together to form monastic centres (*mahāvihāras*) that functioned as universities. The most famous of these, located at Nālandā, had a curriculum that went far beyond the bounds of traditional Buddhism. Nālandā soon became the leading centre for the study of Mahāyāna, which was rapidly becoming the dominant Buddhist tradition in India.

Visits of Chinese pilgrims

Though Buddhist institutions seemed to be faring well under the Guptas, various Chinese pilgrims visiting India between AD 400 and 700 could discern an internal decline in the Buddhist community and the beginning of the reabsorption of Indian Buddhism by Hinduism. Among these pilgrims were Fa-hsien, Sung Yün, Hui-sheng, Hsüan-tsang, and I-ching.

The accounts of these Chinese travelers provide invaluable information about Asian cultures from the Sāsānian (Persian) empire in the west to Sumatra and Java in the east, and from Turfan in Central Asia to Kāñchi in the south of India. In 399 Fa-hsien left China, crossed the Gobi (Desert), and visited various holy places in India. He then returned to China via Sri Lanka and Java, taking with him numerous Buddhist scriptures and statues. The most famous of the Chinese travelers was the 7th-century monk Hsüan-tsang. When he arrived in northwestern India, he found "millions of monasteries" reduced to ruins by the Huns, a nomadic Central Asian people. Many of the remaining Buddhists were developing their own form of Tantrism, an esoteric psychic-physical system of belief and practice. In the northeast, Hsüan-tsang visited various holy places and studied Yogācāra, a Mahāyāna system, and Indian philosophy at Nālandā. After visiting Assam and southern India he returned to China with some 600 sutras.

After the destruction of numerous Buddhist monasteries in the 6th century AD by the Huns, Buddhism revived, especially in the northeast, where it flourished for a time under the Buddhist Pāla kings (8th–12th century AD). These kings continued to protect the great monastic establishments (*mahāvihāras*), building such new centres as Odantapurī, near Nālandā, and establishing a system of supervision for all such institutions. Under the Pālas, Tantric Buddhism (*i.e.,* Vajrayāna) became the dominant sect. Adepts of this sect, called siddhas, identified nirvana with the passions, maintaining that one could "touch the deathless element with his body." Though some of its practices seemed excessive, scholars of this school sought to revalorize some of the most archaic elements in Indian religion. During this period, the university of Nālandā became a centre for the study of Tantric Buddhism and the practice of Tantric magic and rituals. Under the Pāla kings, contacts with China decreased as Indians began to turn their attention to Tibet and Southeast Asia.

The decline of Buddhism in India. With the collapse of the Pāla dynasty in the 12th century, Buddhism suffered another defeat, and this time it did not recover. Though some pockets of Buddhist influence remained, the Buddhist presence in India became so negligible that it could hardly be noticed.

Scholars do not know all the factors that contributed to the demise of Buddhism in its original homeland. Some have maintained that Buddhism was so tolerant of other faiths that it was simply reabsorbed by a revitalized Hindu tradition. This did occur, although Indian Mahāyānists occasionally displayed a hostile attitude toward bhakti and toward Hinduism in general. However, there was another factor that was very important as well: Buddhism in India, having become mainly a monastic movement, probably paid little heed to the laity. Some monasteries became wealthy enough to have slaves and hired labourers to care for the monks and tend the lands they owned. Thus, after the Muslim invaders sacked the Indian monasteries in the 12th century AD, Buddhists had little basis for recovery. After the destruction of the monasteries, the Buddhist laity showed little interest in restoring the "Way."

Destruction of the monasteries

Contemporary revival. At the beginning of the 20th century Buddhism was virtually extinct in India. Since the early 1900s, however, a significant Buddhist presence has been reestablished. In the early decades of the 20th century a number of Buddhist societies were organized by Indian intellectuals who found in Buddhism an alternative to a Hindu tradition that they could no longer accept; an alternative that was, in addition, part of the cultural heritage of India. Following the Chinese conquest of Tibet in the late 1950s, there was an influx of Tibetan Buddhists who established a highly visible Buddhist community in northern India. In addition, the incorporation of Sikkim in 1975 into the Republic of India has brought into the modern Indian nation a small Himalayan society that has a strong Buddhist tradition related to the Vajrayāna Buddhism of Tibet.

The major component in the 20th-century resurgence of Buddhism in India has, however, been the mass conversion of large numbers of people from the so-called scheduled castes (formerly called Untouchables). This conversion movement, originally led by Bhimrao Ramji Ambedkar, began in the 1950s. In October 1956 Ambedkar and several hundred thousand of his followers converted to Buddhism, and—although accurate figures are difficult to determine—the group has continued to grow. Some estimates indicate that the number of converts is as high as four million. This group, which in the past has tended to favour the Theravāda version of Buddhism, is developing its own distinctive patterns of Buddhist teaching and practice.

SRI LANKA AND SOUTHEAST ASIA

The first clear evidence of the spread of Buddhism outside India dates from the reign of King Aśoka (3rd century BC). According to his inscriptions, Aśoka sent Buddhist emissaries not only to many different regions of the subcontinent but also into certain border areas as well. It is certain that Aśokan emissaries were sent to Sri Lanka and to an area called Suvarṇabhūmi that many modern scholars have identified with the Mon country in southern Myanmar (Burma) and central Thailand.

Transmission of Buddhism by Mauryan missionaries

Sri Lanka. According to the Sinhalese tradition, Buddhism took root in Sri Lanka with the arrival of Aśoka's son Mahinda and his six companions. Sent as missionaries by the Mauryan emperor, these travelers converted King Devānampiya Tissa and many of the nobility. Under King Tissa, the Mahāvihāra monastery was built, an institution that was to become the centre of Sinhalese orthodoxy. After Tissa's death (*c.* 207 BC) Sri Lanka fell into the hands of the South Indians until the time of Duṭṭhagāmaṇī (101–77 BC), a descendant of Tissa, who overthrew King Eḷāra. During this time, as a reaction to the threat posed by the South Indians, Buddhism and Sri Lankan political formations became closely intertwined. Again, it was probably because of this danger that the Pāli canon was first written down under King Vaṭṭagāmaṇī Abhaya in the 1st century BC. This king also built the Abhayagiri monastery, the main centre of the various Mahāyāna movements in Sri Lanka. These heterodox tendencies were openly supported by King Mahāsena (AD 276–303). Under Mahāsena's son, Śrī Meghavaṇṇa, the "Tooth of the Buddha" was brought to Abhayagiri and made the national palladium.

During the 1st millennium AD in Sri Lanka, the ancient Theravāda tradition coexisted with various forms of Hinduism, Mahāyāna Buddhism, and Buddhist Tantrism. Beginning in the 10th century—as Buddhism was declining in India—Sri Lanka became a major locus of a Theravāda Buddhist revival. As a result of this revival, Sri Lanka became a Theravāda kingdom, with a sangha that was unified under Theravāda auspices and a monarch who legitimated his rule in Theravāda terms. The new Theravāda tradition that was established spread from Sri Lanka into Southeast Asia, where it exerted a powerful influence.

In modern times Sri Lanka fell prey to the Western colonial powers (to the Portuguese in 1505–1658, the Dutch in 1658–1796, and finally the British in 1796–1947). Under King Kittisiri Rājasiha (1747–81) the ordination lineage was once again renewed, this time by monks recruited from Thailand.

The monastic community in Sri Lanka is now divided into three major bodies: (1) the Siam Nikaya, founded in the 18th century, a conservative and wealthy sect that admits only members of the Goyigama, the highest Sinhalese caste, (2) the Amarapura sect, founded in the 19th century, which has opened its ranks to members of lower castes, and (3) the reformed splinter group from the Siam Nikaya called the Ramanya sect. Among the laity several reform groups have been established. Among these the Sarvodaya community headed by A.T. Ariyaratne is especially important. This group has established religious, economic, and social development programs that have had a significant impact on Sinhalese village life.

Since Sri Lanka attained its independence from the British in 1947, the country has been increasingly drawn into a conflict between the Sinhalese Buddhist majority and the Tamil Hindu minority. Many Sinhalese Buddhists, including some monks, have closely associated their religion with the political agenda of the more militant Sinhalese nationalists. A few Buddhist leaders have, however, tried to adopt a more moderate position and to encourage a negotiated solution, the traditional basis for Sri Lankan political formation.

Southeast Asia. The peoples of Southeast Asia have not been mere satellites of the more powerful Indian and Chinese civilizations. On the contrary, the cultures that arose in these three vast areas might better be thought of as alternative developments that occurred within a greater Austroasiatic civilization, sometimes called "Asia of the monsoons." Therefore, the transmission of Buddhism and Hinduism to Southeast Asia can be regarded as the spread of the religious symbols of the more "advanced" elements within this Austroasiatic cluster to peoples sharing some of the basic religious presuppositions and traditions.

The main sources of Buddhist influence

In Southeast Asia the Buddhist impact has been made in very different ways in three different regions. In two of these (the region of Malaysia/Indonesia and the region on the mainland extending from Myanmar to southern Vietnam), the main connections have been via trade routes with India and Sri Lanka. In Vietnam the main connections have been with China.

Malaysia and Indonesia. Though some scholars locate the Suvarṇabhūmi ("Land of Gold"), to which Aśokan missionaries were supposedly sent, somewhere on the Malay Peninsula or in Indonesia, this is probably not accurate. It is, however, quite certain that Buddhism reached these areas by the beginning centuries of the 1st millennium AD.

With the help of Indian missionaries such as the monk Guṇavarman, Buddhism had gained a firm foothold on Java well before the 5th century AD. Buddhism was also introduced at about this time in Sumatra, and, by the 7th century, the king of Śrīvijaya on the island of Sumatra was a Buddhist. When the Chinese traveler I-ching visited this kingdom in the 7th century, he noted that Hīnayāna was dominant in the area but that there were also a few Mahāyānists. It was also in the 7th century that the great scholar Dharmapāla from Nālandā visited Indonesia.

The Śailendra dynasty, which ruled over the Malay Peninsula and a large section of Indonesia from the 7th to the 9th century, promoted the Mahāyāna and Tantric forms of Buddhism. During this period major Buddhist monuments were erected in Java, among them the marvelous Borobuḍur, which is perhaps the most magnificent of all Buddhist stupas. From the 7th century onward, Vajrayāna Buddhism spread rapidly throughout the area. King Kertanagara of Java (reigned 1268–92) was especially devoted to Tantric practice.

In the Malay Peninsula and Indonesia, as in India, Buddhism gradually lost its hold during the first half of the 2nd millennium AD. In many areas Buddhism was assimilated to Hinduism, forming a Hindu-oriented amalgam that in some places (for example in Bali) has persisted to the present. In most of Malaysia and Indonesia, however, both Hinduism and Buddhism were replaced by Islām, which remains the dominant religion in the area. (In modern Indonesia and Malaysia, Buddhism exists as a living religion only among the Chinese minority, but there is a growing community of converts, with its greatest strength in the vicinity of Borobuḍur.)

Suvarṇabhūmi

From Myanmar to the Mekong delta. A second pattern of Buddhist expansion in Southeast Asia developed in the mainland area that extends from Myanmar in the north and west to the Mekong delta in the south and east. According to the local Mon/Burman traditions, this is the area of Suvarṇabhūmi that was visited by missionaries from the Aśokan court. It is known that, by the early centuries of the 1st millennium AD, Buddhist kingdoms were beginning to appear in this region. In Myanmar and Thailand—despite the presence of Hindu, Mahāyāna, and Vajrayāna elements—the more conservative Hīnayāna forms of Buddhism were especially prominent throughout the 1st millennium AD. Farther to the east and south, in what is now Kampuchea (Cambodia) and southern Vietnam, various combinations of Hinduism, Mahāyāna Buddhism, and Vajrayāna Buddhism became dominant. Throughout much of the history of Angkor, the great imperial centre that dominated Kampuchea and much of the surrounding areas for many centuries, Hinduism seems to have been the preferred tradition, at least among the elite. In the late 12th and early 13th centuries, however, the Buddhist King Jayavarman VII built a new capital called Angkor Thom that was dominated by Mahāyāna/Vajrayāna monuments; these monuments represent one of the high points of Buddhist architectural achievement.

In mainland Southeast Asia, as in Sri Lanka, a Theravāda reform movement began to develop in the 11th century. Drawing heavily on the Theravāda heritage that had been preserved among the Mon in southern Myanmar, as well as on the new reform tradition that was developing in Sri Lanka, this revival soon established the Theravāda tradition as the most dynamic tradition in Myanmar, where the Burmans had conquered the Mon. By the late 13th century the reform movement had spread to Thailand, where the Thai were gradually displacing the Mon as the dominant population. Within another two centuries the Theravāda reformers had spread their tradition to Kampuchea and Laos.

The Theravāda preeminence that was thus established remained basically intact throughout the area during the remainder of the premodern period. The arrival of the Western powers in the 19th century, however, brought important changes. In Thailand, which retained its independence, a process of gradual reform and modernization took place. During the 19th century leadership in the reform and modernization process was taken by a new Buddhist sect, the Thammayut Nikāya, which was established and supported by the reigning Chakri dynasty. More recently, the reform and modernization process has become more diversified and has affected virtually all segments of the Thai Buddhist community.

Two Buddhist groups, Santi Asoke (founded 1975) and Dharmakaya, are especially interesting. Because of their hard-line demands for religious and moral reforms, both groups are at odds with the established ecclesiastical hierarchy. But, despite pressures from the government, they have acquired a large popular following.

In the other Theravāda countries in Southeast Asia, Buddhism has had a much more difficult time. In Myanmar, which endured an extended period of British rule, the sangha and the structures of Buddhist society have been seriously disrupted. Under the military regime of General Ne Win, established in 1962, reform and modernization were limited in all areas of national life, including religion. In Laos and Kampuchea, both of which suffered an extended period of French rule followed by the devastation of the Vietnam War and the violent imposition of communist rule, the Buddhist community has been severely crippled. During the late 20th century, however, many signs of a Buddhist revival began to appear.

Vietnam. There are some indications that Vietnam was involved in the early sea trade between India, Southeast Asia, and China and that Buddhism reached the country around the beginning of the 1st millennium AD, brought by missionaries traveling between India and the Chinese empire. The northern part of what is now Vietnam had been conquered by the Chinese empire in 111 BC; it remained under Chinese rule until AD 939. In the south there were two Indianized states, Funan (founded during the 1st century AD) and Champa (founded AD 192). In these areas both Hīnayāna and Mahāyāna traditions were represented. The traditions that most affected the long-term development of Buddhism in Vietnam, however, were Zen and Pure Land traditions introduced from China into the northern and central sections of the country beginning in the 6th century AD.

Funan and
Champa

The first *dhyāna* (Zen; Vietnamese: *thiên*), or "meditation," school was introduced by Vinītaruci, an Indian monk who had come to Vietnam from China in the 6th century. In the 9th century a school of "wall meditation" was introduced by the Chinese monk Vo Ngon Thong. A third major Zen school was established in the 11th century by the Chinese monk Thao Durong. From 1414 to 1428 Buddhism in Vietnam was persecuted by the Chinese, who had again conquered the country. Tantrism, Taoism, and Confucianism were also filtering into Vietnam at this time. Even after the Chinese had been driven back, a Chinese-like bureaucracy closely supervised the Vietnamese monasteries. The clergy was divided between the highborn and Sinicized (Chinese-influenced), on the one hand, and those in the lower ranks who often were active in peasant uprisings.

During the modern period these Mahāyāna traditions centred in northern and central Vietnam have coexisted with Theravāda traditions that have spilled over from Kampuchea in the south. Rather loosely joined together, the Vietnamese Buddhists managed to preserve their traditions through the period of French colonial rule in the 19th and 20th centuries. During the struggle between North and South Vietnam in the 1960s and early '70s, many Buddhists worked to achieve peace and reconciliation, but they met with little success. Under the communist regime that completed its victory in Vietnam in the early 1970s, conditions have been difficult, but Buddhism has persisted. Reports in the late 1980s and early '90s indicated that new signs of vitality were beginning to appear.

CENTRAL ASIA AND CHINA

Central Asia. The spread of Buddhism into Central Asia is still not completely understood by historians. But, however murky the details may be, it is clear that the trade routes that ran from northwestern India to northern China facilitated both the introduction of Buddhism and the maintenance, for many centuries, of a flourishing Buddhist culture.

By the beginning of the Common era, Buddhism had probably been introduced into eastern Turkistan. According to tradition, a son of Aśoka founded the kingdom of Khotan around 240 BC. The grandson of this king supposedly introduced Buddhism to Khotan, where it became the state religion. On more secure historical grounds, it is clear that the support given by the Indo-Scythian king Kaniṣka of the Kushān (Kuṣāṇa) dynasty, which ruled in northern India, Afghanistan, and parts of Central Asia in the 1st to 2nd century AD, encouraged the spread of Buddhism into Central Asia. Kaniṣka purportedly called an important Buddhist council; he patronized the Gandhāra school of Buddhist art, which introduced Greek and Persian elements into Buddhist iconography; and he supported Buddhist expansion within a vast region that extended far into the Central Asian heartland. In the northern part of Chinese Turkistan, Buddhism spread from Kucha (K'u-ch'e) to the kingdoms of Agnideśa (Karashahr), Kao-ch'ang (Turfan), and Bharuka (Aksu). According to Chinese travelers who visited Central Asia, the Hīnayānists (at least at the time of their visits) were strongest in Turfan, Shanshan, Kashgar, and Kucha, while Mahāyāna strongholds were located in Yarkand and Khotan.

Expansion
of
Buddhism

In Central Asia there was a confusing welter of languages, religions, and cultures, and, as Buddhism interacted with these various traditions, it changed and developed. Shamanism, Zoroastrianism, Nestorian Christianity, and Islām all penetrated these lands and coexisted with Buddhism. For example, some of the Mahāyāna bodhisattvas, such as Amitābha, may have been inspired, in part, by Zoroastrian influence. There is also evidence of some degree of syncretism between Buddhism and Manichaeism, an Iranian dualistic religion that was founded in the 3rd century AD.

Buddhism continued to flourish in parts of Central Asia until the 11th century, particularly under the patronage of the Uighur Turks. With the increasingly successful incursions of Islām (beginning in the 7th century AD) and the decline of the T'ang dynasty (618–907) in China, however, Central Asia ceased to be the important crossroads of Indian and Chinese culture that it once had been. Buddhism in the area gradually became a thing of the past.

China. Although there are reports of Buddhists in China as early as the 3rd century BC, Buddhism was not actively propagated in that country until the early centuries of the Common era. Tradition has it that Buddhism was introduced after the Han emperor Ming Ti (reigned AD 57/58–75/76) had a dream of a flying golden deity that was interpreted as a vision of the Buddha. Accordingly, the emperor dispatched emissaries to India who subsequently returned to China with the *Sutra in Forty-two Sections,* which was deposited in a temple outside the capital of Lo-yang. In actuality, Buddhism entered China gradually, first primarily through Central Asia and, later, by way of the trade routes around and through Southeast Asia.

The early centuries. The Buddhism that first became popular in China during the Han dynasty was deeply coloured with magical practices, making it compatible with popular Chinese Taoism (a combination of folk beliefs and practices and philosophy). Instead of the doctrine of no-self, early Chinese Buddhists taught the indestructibility of the soul. Nirvana became a kind of immortality. They also taught the theory of karma, the values of charity and compassion, and the need to suppress the passions. Until the end of the Han dynasty, there was a virtual symbiosis between Taoism and Buddhism and a common propagation of the means for attaining immortality through various ascetic practices. It was widely believed that Lao-tzu, the founder of Taoism, had been reborn in India as the Buddha. Many Chinese emperors worshiped Lao-tzu and the Buddha on the same altar. The first translations of Buddhist sutras into Chinese—namely those dealing with such topics as breath control and mystical concentration—utilized a Taoist vocabulary to make the Buddhist faith intelligible to the Chinese.

After the Han period, in the north of China, Buddhist monks were often used by non-Chinese emperors for their political-military counsel as well as for their skill in magic. At the same time, in the south, Buddhism began to penetrate the philosophical and literary circles of the gentry. One of the most important contributions to the growth of Buddhism in China during this period was the work of translation. The most important of the early translators was the learned monk Kumārajīva, who, before he was brought to the Chinese court in AD 401, had studied the Hindu Vedas, the occult sciences, and astronomy, as well as the Hinayāna and Mahāyāna sutras.

The translations of
Kumārajīva

During the 5th and 6th centuries AD Buddhist schools from India became established, and new, specifically Chinese schools began to form. Buddhism was becoming a powerful intellectual force in China, monastic establishments were proliferating, and Buddhism was becoming well-established among the peasantry. Thus, it is not surprising that, when the Sui dynasty (581–618) established its rule over a reunified China, Buddhism flourished as a state religion.

Developments during the T'ang dynasty (618–907). The golden age of Buddhism in China occurred during the T'ang dynasty. Though the T'ang emperors were usually Taoists themselves, they tended to favour Buddhism, which had become extremely popular. Under the T'ang the government extended its control over the monasteries and the ordination and legal status of monks. From this time forward, the Chinese monk styled himself simply *ch'en,* or "a subject."

During this period several Chinese schools developed their own distinctive approaches. Some of them produced comprehensive systematizations of the vast body of Buddhist texts and teachings. There was a great expansion in the number of Buddhist monasteries and the amount of land they owned. It was also during this period that many scholars made pilgrimages to India, heroic journeys that greatly enriched Buddhism in China, both by the texts that were acquired and by the intellectual and spiritual inspiration that was brought from India. Buddhism was never able to replace its Taoist and Confucian rivals, however, and in 845 the emperor Wu-tsung began a major persecution. According to records, 4,600 Buddhist temples and 40,000 shrines were destroyed, and 260,500 monks and nuns were forced to return to lay life.

Buddhism after the T'ang. Buddhism in China never recovered completely from the great persecution of 845. It did maintain much of its heritage, however, and it continued to play a significant role in the religious life of China. On the one hand, Buddhism retained its identity as Buddhism and generated new forms through which it was expressed. These included texts such as the *yü lu,* or "recorded sayings," of famous teachers that were oriented primarily toward monks, as well as more literary creations such as the *Journey to the West* (written in the 16th century) and *The Dream of the Red Chamber* (18th century). On the other hand, Buddhism coalesced with the Confucian–Neo-Confucian and Taoist traditions to form a complex multi-religious ethos within which all three traditions were more or less comfortably encompassed.

The Ch'an and Pure Land schools

Among the various schools the two that retained the greatest vitality were the Ch'an school (better known in the West by its Japanese name, Zen) which was noted for its emphasis on meditation, and the Pure Land tradition, which emphasized Buddhist devotion. The former school exerted the greatest influence among the cultured elite. It did so through various media, including the arts. For example, Ch'an artists during the Sung dynasty (960–1279) had a decisive impact on Chinese landscape painting. Artists used images of flowers, rivers, and trees, executed with sudden, deft strokes, to evoke an insight into the flux and emptiness of all reality. The Pure Land tradition exerted a greater influence on the population as a whole and was sometimes associated with secret societies and peasant uprisings. But the two seemingly disparate traditions were often very closely linked. In addition, they were mixed with other Buddhist elements such as the so-called "masses for the dead" that had originally been popularized by the practitioners of Esoteric Buddhism.

During the early decades of the 20th century, China experienced a Buddhist reform movement aimed at revitalizing the Chinese Buddhist tradition and adapting Buddhist teachings and institutions to modern conditions. However, the disruptions caused by the Sino-Japanese War and the subsequent establishment of a communist government have not been helpful to the Buddhist cause. The Buddhist community was the victim of severe repression during the Cultural Revolution (1966–69). Since 1976 the Chinese government has pursued a more tolerant policy, but the extent of continuing Buddhist vitality is difficult to determine.

KOREA AND JAPAN

Korea. Buddhism was first introduced into the Korean region when it was divided into the three kingdoms of Paekche, Koguryŏ, and Silla. After Buddhism was brought to the northern kingdom of Koguryŏ from China in the 4th century, it gradually spread throughout the other Korean kingdoms. As often happened, the new faith was first accepted by the court and then extended to the people. After the unification of the country by the kingdom of Silla in the 660s, Buddhism began to flourish throughout Korea. The monk Wŏnhyo (617–686) was one of the most impressive scholars and reformers of his day. He was married and taught an "ecumenical" version of Buddhism that included all branches and sects. He tried to use music, literature, and dance to express the meaning of Buddhism. Another scholar of the Silla era was Ŭi-sang (625–702), who went to China and returned to spread the Hwaŏm (Hua-yen in Chinese) sect in Korea. The Chinese Ch'an sect (Zen) was introduced in the 8th century and, by absorbing the Korean versions of Hua-yen, T'ien-t'ai, and Pure Land, gradually became the dominant school of Buddhism in Korea, as it did in Vietnam.

Early Korean Buddhism was characterized by a this-worldly attitude. It emphasized the pragmatic, nationalistic, and aristocratic aspects of the faith. Still, an indigenous tradition of shamanism influenced the development of popular Buddhism throughout the centuries. Buddhist monks danced, sang, and performed the rituals of shamans.

The Koryŏ period

During the Koryŏ period (935–1392), Korean Buddhism reached its zenith. During the first part of this period the Korean Buddhist community was active in the publication of the *Tripitaka Koreana,* one of the most inclusive editions of the Buddhist sutras up to that time. After 25 years of research, a monk by the name of Ŭich'ŏn (1055–1101) published an outstanding three-volume bibliography of Buddhist literature. Ŭich'ŏn also sponsored the growth of the T'ien-t'ai sect in Korea. He emphasized the need for cooperation between Ch'an and the other "Teaching" schools of Korean Buddhism.

Toward the end of the Koryŏ period, Buddhism began to suffer from internal corruption and external persecution, especially that promoted by the Neo-Confucians. The government began to put limits on the privileges of the monks, and Confucianism replaced Buddhism as the religion of the state. Though the Yi dynasty (1392–1910) continued these restrictions, Buddhist monks and laymen fought bravely against the invasion of the Japanese armies under Toyotomi Hideyoshi (1537–98) in 1592 and 1597. In the decade before the annexation of Korea by Japan (1910), some effort was made to unify Korean Buddhism. These efforts, as well as the subsequent efforts of Buddhist "missionaries" from Japan, were largely in vain.

Since the end of World War II, Buddhism in Korea has been hampered by communist rule in North Korea and by the great vitality of Christianity in South Korea. Despite these challenges, Buddhists, particularly in South Korea, have preserved the old traditions and initiated new movements.

Japan. *Introduction of Buddhism to Japan.* While Buddhism in China sent its roots down into the subsoil of the family system, in Japan it found anchorage in the nation itself. The Buddhism that was initially introduced into Japan in the 6th century from Korea was regarded as a talisman (charm) for the protection of the country. The new religion was accepted by the powerful Soga clan but was rejected by others, thus causing controversies that resembled the divisions caused by the introduction of Buddhism in Tibet. In both countries, some believed that the introduction of Buddhist statues had been an insult to the native deities, resulting in plagues and natural disasters. Only gradually were such feelings overcome. Though the Buddhism of the Soga clan was largely magical, under the influence of Prince Shōtoku, who became regent of the nation in 593, other aspects of Buddhism were emphasized. Shōtoku lectured on various scriptures that emphasized the ideals of the layman and monarch, and he composed a "Seventeen-Article Constitution" in which Buddhism was adroitly mixed with Confucianism as the spiritual foundation of the state. In later times he was widely regarded as an incarnation of the bodhisattva Avalokiteśvara.

Nara and Heian periods. During the Nara period (710–784), Buddhism became the state religion of Japan. Emperor Shōmu actively propagated the faith, making the imperial capital, Nara—with its "Great Buddha" statue (Daibutsu)—the national cult centre. Buddhist schools imported from China became established in Nara, and state-subsidized provincial temples (*kokubunji*) made the system effective at the local level.

The Tendai and Shingon schools

After the capital was moved to Heian-kyō (modern Kyōto) in 794, Buddhism continued to prosper. Chinese influence continued to play an important role, particularly through the introduction of new Chinese schools that became dominant at the royal court. Mount Hiei and Mount Kōya became the centres for the new T'ien-tai (Tendai) and Esoteric (Shingon) schools of Buddhism, which were characterized by highly sophisticated philosophies and complex and refined liturgies. Moreover, Buddhism interacted with the indigenous Shintō and local tradition, and various distinctively Japanese patterns of Buddhist-oriented folk religion became very popular.

New schools of the Kamakura period. The 12th and 13th centuries marked a turning point in Japanese history and in the history of Japanese Buddhism in particular. Late in the 12th century the imperial regime with its centre at Heian collapsed, and a new feudal government, or shogunate, established its headquarters at Kamakura. As a part of the same process, a number of new Buddhist leaders emerged and established schools of Japanese Buddhism. These reformers included proponents of the Zen traditions such as Eisai and Dōgen; Pure Land advocates such as Hōnen, Shinran, and Ippen; and Nichiren, the founder of a new school that gained considerable popularity. The distinctively Japanese traditions these creative reformers and founders established became—along with many very diverse synthetic expressions of Buddhist-Shintō piety—integral components of a Buddhist-oriented ethos that structured Japanese religious life into the 19th century. Also during this period many Buddhist groups allowed their clergy to marry, with the result that temples often fell under the control of particular families.

The premodern period to the present. Under the Tokugawa shogunate (1603–1867), Buddhism became an arm of the government. Temples were used for registering the populace; this was one way of preventing the spread of Christianity, which the feudal government regarded as a political menace. This association with the Tokugawa regime made Buddhism quite unpopular at the beginning of the Meiji period (1868–1912), at least among the elite. At that time, in order to set up Shintō as the new state religion, it was necessary for Japan's new ruling oligarchy to separate Shintō from Buddhism. This led to the confiscation of temple lands and the defrocking of many Buddhist priests.

During the period of ultranationalism (*c.* 1930–45), Buddhist thinkers called for uniting the East in one great "Buddhaland" under the tutelage of Japan. After the war, however, Buddhist groups, new and old alike, began to emphasize Buddhism as a religion of peace and brotherhood. During the postwar period the greatest visible activity among Buddhists has been among the "New Religions" such as Sōka-gakkai ("Value Creation Society") and Risshō-Kōsei-kai ("Society for Establishing Righteousness and Friendly Relations"). During this period, Sōka-gakkai entered politics with the same vigour it had traditionally shown in the conversion of individuals. Because of its highly ambiguous but conservative ideology, the Sōka-gakkai-based political party (the Kōmeitō) is regarded with suspicion and fear by many Japanese.

TIBET, MONGOLIA, AND THE HIMALAYAN KINGDOMS

Padmasambhava

Tibet. Buddhism, according to the Tibetan tradition, was first given recognition in Tibet during the reign of Srong-brtsan-sgam-po (*c.* 627–*c.* 650). This king had two queens who were early patrons of the religion and were later regarded in popular tradition as incarnations of the Buddhist savioruess Tārā. The religion received active encouragement from Khri-srong-lde-btsan, during whose reign (*c.* 755–797) the first Buddhist monastery in Tibet was built at Bsam-yas (Samye), the first seven monks were ordained, and the celebrated Indian Tantric master Padmasambhava was invited to Tibet. A great deal of legend surrounds Padmasambhava, who was a *mahāsiddha* ("master of miraculous powers"); he is credited with subduing the Bon spirits and demons (the spirits and demons associated with the indigenous religion of Tibet) and with subjugating them to the service of Buddhism. At the time, influences from Chinese Buddhism were strong, but it is recorded that at the Council of Bsam-yas (792–794) it was decided that the Indian tradition should prevail.

Following a period of suppression that lasted almost two centuries (from the early 800s to the early 1000s), Buddhism in Tibet enjoyed a revival. During the 11th and 12th centuries many Tibetans traveled to India to acquire and translate Buddhist texts and to receive training in Buddhist doctrine and practice. With the assistance of the renowned Indian master Atīśa, who arrived in Tibet in 1042, Buddhism became established as the dominant religion. From this point forward Buddhism was the primary culture of the elite, was a powerful force in the affairs of state, and penetrated deeply into all aspects of Tibetan life.

One of the great achievements of the Buddhist community in Tibet was the translation into Tibetan of a vast corpus of Buddhist literature, including the *Bka'-'gyur* ("Translation of the Buddha Word") and *Bstan-'gyur* ("Translation of Teachings") collections. The *Bka'-'gyur* contains six sections: (1) *Tantra,* (2) *Prajñāpāramitā,* (3) *Ratnakūṭa,* a collection of small Mahāyāna texts, (4) *Avataṃsaka,* (5) *Sūtra* (mostly Mahāyāna sutras, but some Hīnayāna texts are included), and (6) *Vinaya.* The *Bstan-'gyur* contains 224 volumes with 3,626 texts, divided into three major groups: (1) *stotra*s (hymns of praise) in one volume, including 64 texts, (2) commentaries on tantras in 86 volumes, including 3,055 texts, and (3) commentaries on sutras in 137 volumes, including 567 texts.

A major development in the history of Tibetan Buddhism occurred in the late 14th or early 15th century when a great Buddhist reformer named Tsong-kha-pa established the Dge-lugs-pa school, known more popularly as the Yellow Hats. In 1578, representatives of this school succeeded in converting the Mongol Altan Khan, and, under the Khan's sponsorship, their leader (the so-called third Dalai Lama) gained considerable monastic power. In the middle of the 17th century the Mongol overlords established the fifth Dalai Lama as the theocratic ruler of Tibet. The succeeding Dalai lamas, who were regarded as successive incarnations of the bodhisattva Avalokiteśvara, held this position during much of the remainder of the premodern period, ruling from the capital, Lhasa.

The fifth Dalai Lama instituted the high office of Panchen Lama for the abbot of the Tashilhunpo monastery, located to the west of Lhasa. The Panchen lamas were regarded as successive incarnations of the buddha Amitābha. Unlike the Dalai Lama, the Panchen Lama has usually been recognized only as a spiritual ruler.

Throughout much of Tibetan history many of the great monasteries were controlled by aristocratic abbots who were able to marry and pass along their monastic possessions to their sons. Monks were often warriors, and monasteries became armed fortresses. The Manchus in the 18th century and subsequently the British, the Nationalist Chinese, and the Chinese communists have all tried to exploit the division of power between the Panchen and the Dalai lamas for their own ends. In 1959, after the Dalai Lama fled to India, the Chinese communists took over his temporal powers.

Tibetan Buddhism under the Chinese

Under Chinese rule, Tibetan Buddhists have suffered periods of persecution, some of them severe. Not surprisingly, this has strengthened the bond between Buddhism and nationalist resistance.

Mongolia. The distinctive form of Buddhism that developed in Tibet has exerted a strong influence on neighbouring areas and peoples. Most important in this regard was the conversion of the Mongol tribes to the north and east of Tibet. There are some indications that Buddhism was present among the Mongols as early as the 4th century, but the sources are scarce. It is clear, however, that during the 13th century close relationships developed between the Mongol court in China and some of the leaders of Tibetan Buddhism. Kublai Khan himself became a supporter of the Tibetan form of Buddhism. Kublai Khan's Tibetan advisers helped to develop a block script for the Mongolian language, and many Buddhist texts were translated from Tibetan into Mongolian. In general, however, the religion failed to gain widespread popular support during this period.

In 1578 a new situation developed when the Altan Khan accepted the Dge-lugs-pa version of the Tibetan tradition and supported its spread among his followers at all levels of Mongol society. Over the centuries the Mongols developed their own very rich Buddhist traditions. Mongolian scholars translated a large corpus of texts from Tibetan, and they produced their own sophisticated original texts. The Mongols based their Buddhist doctrine, practice, and communal organization on Tibetan models, but they developed and adapted them in a distinctive way.

Between 1280 and 1368 China was part of the Mongol empire, and the Mongols established their variant of Tibetan Buddhism in China. When they no longer held power in China, they continued to maintain the traditions they had developed in their homeland in the Central Asian steppes. During the 20th century, however, Mongolian Buddhism has been undermined by the communist regimes that have ruled in the Mongol areas of the Soviet Union, Mongolia, and China.

The Himalayan kingdoms. Tibetan Buddhism has also exerted a considerable influence in the Himalayan kingdoms situated along Tibet's southern border. In Nepal Buddhism has been influenced by both India and Tibet. Though the Buddha was born in the southern part of the area that is now Nepal, at Lumbini, about 15 miles (24 kilometres) from Kapilavatthu (Kapilavastu), the Buddhist religion seems to have been actively propagated only later, probably under Aśoka. By the 8th century AD Nepal had fallen into the cultural orbit of Tibet. A few centuries later, as a result of the Muslim invasions of India, both Hindus (such as the Brahmanic Gurkha aristocracy) and Buddhists took refuge in the country. In modern times Buddhist prayer wheels and flags are reminders of the direct influence of Tibetan Buddhism. The Indian heritage is especially evident in the caste system that embraces Buddhists and non-Buddhists alike.

Bhutan

In Bhutan a Tibetan lama introduced Buddhism and a Tibetan style of hierarchical theocracy in the 17th century AD. The Buddhism practiced in Bhutan has been influenced by the Tibetan Bka'-brgyud-pa sect, which has stressed the magical benefits of living in caves and has not enforced on its clergy the discipline of celibacy. Buddhism in Bhutan, like Buddhism in Nepal, is coming into increasing contact with modernizing forces that are beginning to undermine many of its traditional practices.

BUDDHISM IN THE WEST

During the long course of Buddhist history, Buddhist influences have from time to time reached the Western world. Though the evidence is weak, some scholars have suggested that, about the beginning of the Christian era, Buddhist monks and teachings had reached as far as Egypt. There are occasional references to what seem to be Buddhist traditions in the writings of the Church Fathers. In addition, a version of the biography of the Buddha, known as the story of Barlaam and Josaphat, had a considerable dissemination in medieval Europe. In fact, the Buddha-figure in the story came to be recognized as a Christian saint.

Not until the modern period, however, is there evidence for a serious Buddhist presence in the Western world. The movement of Buddhism from Asia to the West that took place in the 19th and 20th centuries had two aspects. Beginning in the mid-19th century, Buddhism was introduced into the United States and other Western countries by large numbers of immigrants, first from China and Japan but more recently from other countries, especially countries of Southeast Asia. Buddhism gained a foothold among a significant number of Western intellectuals and—particularly during the 1960s and early '70s—among young people seeking new forms of religious experience and expression. The interest of Westerners in Buddhism has been increased by the work of Buddhist missionaries such as the Japanese scholar D.T. Suzuki (1870–1966) and a number of Tibetan Buddhist teachers who have come to the West since the Chinese conquest of their homeland in the late 1950s. (J.M.K./Gi.T./F.E.R.)

Sangha, society, and state

Buddhists of all times and places have recognized the importance of community life, and over the centuries there has developed a distinctive pattern involving a symbiotic relationship between monks (and in some cases nuns) and the lay community. The relationship between the monastics and the laity has differed from place to place and from time to time, but throughout most of Buddhist history both groups have played an essential role in the process of constituting and reconstituting the Buddhist world. Moreover, both the monastics and the laity have engaged in a variety of common and complementary religious practices that have expressed Buddhist orientations and values, structured Buddhist societies, and addressed the soteriological and practical concerns of Buddhist individuals.

The relationship between monastics and laypersons

MONASTIC INSTITUTIONS

The sangha is the assembly of Buddhist monks that has, from the origins of Buddhism, authoritatively studied, taught, and preserved the teachings of the Buddha. In their communities monks have served the laity through example and, as directed by the Buddha, through the teachings of morality (Pāli: *sīla;* Sanskrit: *śīla*). In exchange for their service the monks have received support from the laity, who thereby earn merit. Besides serving as the centre of Buddhist propaganda and learning, the monastery offers the monk an opportunity to live apart from worldly concerns, a situation that has usually been believed necessary or at least advisable in order to follow strictly the path that leads most directly to release.

The origin and development of the sangha. According to scholars of early Buddhism, at the time of the Buddha in northeastern India there existed numerous religious mendicants or almsmen who wandered and begged individually or in groups. These men had forsaken the life of a householder and the involvement with worldly affairs that this entails in order to seek a doctrine and form of practice which would meaningfully explain life and offer salvation. When such a seeker met someone who seemed to offer such a salvatory message, he would accept him as a teacher (guru) and wander with him. The situation of these mendicants is summed up in the greeting with which they met other religious wanderers. This greeting asked, "Under whose guidance have you accepted religious mendicancy? Who is your master (*sattha*)? Whose *dhamma* is agreeable to you?"

The groups of mendicants that had formed around a teacher broke their wanderings during the rainy season (*vassa*) from July through August. At this time they gathered at various rain retreats (*vassavāsa*), usually situated near villages. Here they would beg daily for their few needs and continue their spiritual quest. The Buddha and his followers may well have been the first group to found such a yearly rain retreat.

After the Buddha's death his followers did not separate but continued to wander and enjoy the rain retreat together. In their retreats the followers of the Buddha's teachings probably built their own huts and lived separately, but their sense of community with other Buddhists led them to gather fortnightly at the time of the full and new moons to recite the *Pātimokkha,* or declaration of their steadfastness in observing the monastic discipline. This ceremony, in which the laity also participated, was called the *uposatha.*

The *uposatha*

Within the first several centuries after the Buddha's death, the sangha came to include two different groups of monks. One retained the wandering mode of existence; this group has been a very creative force in Buddhist history and continues to play a role in contemporary

Buddhism, particularly in Sri Lanka and Southeast Asia. The other, much larger group gave up the life-in-the-forest and settled in permanent monastic settlements (viharas). There appear to be two major reasons for this change in the mode of living. First, the followers of the Buddha were able, through their confession of a common faith, to build up a certain coherent organization. Second, the laity gave meritorious gifts of land and raised buildings in which the followers of the Buddha might live permanently, assured of a supply of the staples of life and also fulfilling the Buddha's directive to minister to the laity. In this manner small viharas were raised in northeastern India and adjoining areas into which Buddhism spread. With the reign of King Aśoka in the 3rd century BC, further developments occurred. This king, who controlled much of India, took a protective interest in the unity and well-being of the Buddhist monastic community, and he promulgated a *dhamma* for his kingdom that shared a great deal with Buddhist teachings directed to the laity. As a result of his support and influence, Buddhism developed a more universal orientation.

In the post-Aśokan period, Buddhist monasteries grew in size and acquired a great deal of wealth. By about the 5th century AD there developed *mahāvihāra*s, or monastic centres, serving as universities, such as Nālandā. These universities were centres of Buddhist learning and propaganda, drawing monks from China and Tibet and sending forth missionaries to these lands. The institutions were open to the outside influence of a resurgent Hinduism, however, which is one of the factors that weakened Buddhism and led to its disappearance from India in the 13th century.

In all Buddhist countries, monasteries continued to serve as centres of missions and learning and as retreats. Different types of monastic establishments developed in particular areas and in particular contexts. In several regions there were at least two types of institutions. There were a few large public monasteries that usually functioned in greater or lesser accord with classical Buddhist norms. In addition, there were many smaller monasteries, often located in rural areas, that were much more loosely regulated. Often these were hereditary institutions in which the rights and privileges of the abbot were passed on to an adopted disciple. In areas where clerical marriage was practiced—for example, in medieval Sri Lanka and in post-Heian Japan—a tradition of blood inheritance developed.

Internal organization of the sangha. The development of the sangha from a group of wandering mendicants loosely bound together by their faith in the Buddha and his teachings, to monks living closely together in a permanent monastery necessitated the development of rules and a degree of hierarchical organization. It appears that the earliest organization within Indian monasteries was democratic in nature. This democratic nature arose from two important historical factors. First, the Buddha did not, as was the custom among the teachers of his time, designate a human successor. Instead, the Buddha taught that each monk should strive to follow the path that he had preached. This decision of the Buddha placed every monk on the same footing. There could be no absolute authority vested in one person, for the authority was the *dhamma* that the Buddha had taught. Second, the region in which Buddhism arose was noted for a system of tribal democracy, or republicanism. When a serious question demanded attention in the region, the male inhabitants would meet to decide upon a course of action, often electing a temporary ruler. This republican tradition, which supported the antiauthoritarian nature of the Buddha's teaching, was adopted by the early sangha.

The democratic nature of the early monasteries

When an issue arose, all the monks of the monastery assembled. The issue was put before the body of monks and discussed. If any solution was forthcoming, it had to be read three times, with silence signifying acceptance. If there was debate, a vote might be taken or the issue referred to committee or the arbitration of the elders of a neighbouring monastery. As the sangha developed, a certain division of labour and hierarchical administration was adopted. The abbot became the head of this administrative hierarchy and was vested with almost unlimited powers over monastic affairs. The antiauthoritarian character of Buddhism, however, continued to assert itself. In China, for instance, the abbot continued to refer all important questions to the assembled monks, who had elected him as their leader. Similarly, in Southeast Asian countries there has traditionally been a popular distaste for hierarchy, making rules difficult to enforce in the numerous almost independent monastic units.

As the Buddhist sangha developed, specific rules and rites were enacted that differ very little in all Buddhist monasteries even today. The rules by which the monks are judged and the punishments that should be assessed are found in the vinaya texts (vinaya literally means "that which leads"). The *Vinaya Piṭaka* of the Theravāda canon contains precepts that were supposedly given by the Buddha as he judged a particular situation. While in the majority of cases the Buddha's authorship can be doubted, the attempt is made to refer all authority to the Buddha and not to one of his disciples. The heart of the vinaya texts is the *Pātimokkha,* which, in the course of the sangha's development, became a list of monastic rules. The rules are recited by the assembled monks every fortnight, with a pause after each one so that any monk who has transgressed this rule may confess and receive his punishment. While the number of rules in the *Pātimokkha* differs in the various schools, with 227, 250, and 253, respectively in the Pāli, Chinese, and Tibetan canons, the rules are essentially the same. The first part of the *Pātimokkha* deals with the four gravest sins, which necessarily lead to expulsion from the monastery. They are sexual intercourse, theft, murder, and exaggeration of one's miraculous powers. The other rules, in seven sections, deal with transgressions of a lesser nature, such as drinking or lying.

The *Pātimokkha*

In the Theravāda countries—Sri Lanka, Myanmar, Thailand, Kampuchea, and Laos—the Buddhist monastic community is composed primarily of male monks and novices (the order of nuns died out in the Theravāda world more than a millennium ago, and contemporary efforts to reestablish it have met with only minimal success), white-robed ascetics (including various types of male and female practitioners who remain outside the sangha but follow a more or less renunciatory mode of life), and laymen and laywomen. In some Theravāda countries, notably in mainland Southeast Asia, boys or young men were traditionally expected to join the monastery for a period of instruction and meditation. Thus, the majority of men in these areas were (and to a lesser extent still are, at least in Myanmar and Thailand) directly involved with the monastic ethos. This practice has fostered a high degree of lay participation in monastic affairs.

In the Mahāyāna and Vajrayāna countries of China and Tibet there was traditionally a stage of one year before the aspirant could become a novice. This was a year of probation when the aspirant did not receive tonsure and remained subject to governmental taxation and service, while receiving instructions and performing menial tasks within the monastery. At the end of this one-year probationary period, the aspirant had to pass a test, including the recitation of part of a well-known sutra—the length depending upon whether the applicant was male or female—and a discussion on various doctrinal questions. In China, one usually did not progress beyond the novice stage unless he or she was of exceptional character or was affiliated with the government.

According to vinaya rules, entry into the sangha is an individual affair, dependent upon the wishes of the individual and his family. In some Buddhist countries, however, ordination was often under the control of the state, and the state conducted the examinations to determine entry or advancement in the sangha. In certain situations ordination could be obtained not only through such examinations but also by the favour of high officials or through the purchase of an ordination certificate from the government. This selling of ordination certificates was at times abused by the government in order to fill its treasury.

The life of a Buddhist monk was originally one of wandering, poverty, begging, and strict sexual abstinence. The monks were supposed to live only on alms, to wear clothes made from cloth taken from rubbish heaps, and to possess only three robes, one girdle, an alms bowl, a razor, a needle, and a water strainer used to filter insects from the drinking water (so as not to kill or imbibe them). Most Buddhist schools still stress celibacy, although some groups, particularly in Tibet and Japan, have relaxed the monastic discipline, and some Vajrayāna schools have allowed sexual intercourse as an esoteric ritual that contributes to the attainment of release. Begging, however, has tended in all schools to become merely a symbolic gesture used to teach humility or compassion or to raise funds for special purposes. Also, the growth of large monasteries has often led to compromises on the rule of poverty. While the monk might technically give up his property before entering the monastery—although even this rule is sometimes relaxed—the community of monks might inherit wealth and receive lavish gifts of land. This acquisition of wealth has led at times not only to a certain neglect of the Buddhist monastic ideal but also to the attainment of temporal power. This factor, in addition to the self-governing nature of Buddhist monasteries and the early Buddhist connection with Indian kingship, has influenced the interaction of the sangha and the state.

Relaxation of the poverty rule

SOCIETY AND STATE

Though Buddhism is sometimes described as a purely monastic, otherworldly religion, this is not accurate. In the earliest phases of the tradition the Buddha was pictured as a teacher who addressed not only renouncers but lay householders as well. Moreover, although he is not depicted in the early texts as a social reformer, he does address issues of social order and responsibility. (See, for example, the famous *Sigālovāda Sutta,* which has been called the "householder's vinaya.")

Throughout Buddhist history, Buddhists have put forth varying forms of social ethics based on notions of karmic justice (the "law" that good deeds will be rewarded with happy results while evil deeds will entail suffering for the one who does them); the cultivation of virtues such as self-giving, compassion, and evenhandedness; and the fulfillment of responsibilities to parents, teachers, rulers, and so on. Moreover, Buddhists have formulated various notions of cosmogony, cosmology, and soteriology that have provided legitimacy for the social hierarchies and political orders with which they have been associated. For the most part, Buddhism has played a conservative, moderating role in the social and political organization of various Asian societies, but the tradition has on occasion given rise to more radical and revolutionary movements as well.

Over the course of Buddhism's long history, the relationship between the Buddhist community and state authority has taken many forms. The early Buddhist sangha in India appears to have been treated by Indian rulers as a self-governing unit not subject to their power unless it proved subversive or was threatened by internal or external disruption. Aśoka, the Buddhist king whose personal faith and prestige helped Buddhism grow from a regional to a universal religion, appears to have been applying this policy of protection from disruption when he intervened in Buddhist monastic affairs to expel schismatics. He came to be remembered, however, as the Dharmarāja, the great king who protected and propagated the teachings of the Buddha.

In Theravāda countries Aśoka's image as a supporter and sponsor of the faith has traditionally been used to judge political authority. In general, Buddhism in Theravāda countries has been either heavily favoured or officially recognized by the government, so that the golden age in which there is a creative interaction between the government and the monks has been viewed as an obtainable goal. The sangha's role in this interaction has traditionally been to preserve the *dhamma* and to act as the spiritual guide and model, revealing to the secular power the need for furthering the welfare of the people. While the sangha and the government appear as two separate structures, there has been some intertwining; for monks (often of royal heritage) have commonly acted as temporal advisers, and the kings—at least in Thailand—occasionally have spent some time in the monastery. It should also be pointed out that Buddhist monastic institutions have served as a link between the rural peoples and the urban elites, helping to unify the various Theravāda countries.

Role of monastic institutions

In China the relationship between the sangha and the state has fluctuated. At times Buddhism has been seen as a foreign religion, as a potential competitor with the state, or as a drain on national resources of men and wealth. These perceptions have led to sharp purges of Buddhism and to rules curbing its influence. Some of the rules attempted to limit the number of monks and to guarantee governmental influence in ordination through state examinations and the granting of ordination certificates. At other times, such as during the early centuries of the T'ang dynasty (618–845), Buddhism was almost considered the state religion. The government created a commissioner of religion to earn merit for the state by erecting temples, monasteries, and images in honour of the Buddha.

In Japan, Buddhism has experienced similar fluctuations. During the period from the 10th to the 13th century, monasteries gained great landed wealth and temporal power. They formed large armies of monks and mercenaries that took part in wars with rival religious groups as well as in temporal struggles. By the 14th century, however, their power began to wane, and, under the Tokugawa regime that took control in the 17th century, Buddhist institutions became, to a considerable degree, instruments of state power and administration.

Only in Tibet did Buddhists establish a theocratic polity that lasted for an extended period of time. Beginning in the 12th century, Tibetan monastic groups developed relationships with the powerful Mongol khans that often gave them control of governmental affairs in Tibet. In the 17th century the Dge-lugs-pa school, working with the Mongols, established a monastic regime that was able to maintain more or less continual control until the Chinese occupation in the 1950s.

During the immediate premodern period, each of the various Buddhist communities in Asia developed some kind of working relationship with the sociopolitical system in its particular area. Within the sweep of Western colonialism and especially after the establishment of new political ideologies and political systems during the 19th and 20th centuries, these older patterns of accommodation between Buddhism and state authority were seriously challenged. In many cases bitter conflicts resulted—for example, between Buddhists and colonial regimes in Sri Lanka and Myanmar, between Buddhists and the Meiji reformers in Japan, and between Buddhists and many different communist regimes. In some cases, as in Japan, these conflicts have been resolved and new modes of accommodation have been established. In other cases, such as that of Tibet, there has been no resolution.

(Gi.T./F.E.R.)

Early Buddhist schools

THE EARLY COUNCILS

The early Buddhist councils (*sangītis*, or "recitals") were concerned largely with the purity of the faith and practice of the monastic community. Unfortunately, the councils pose an enormous problem to the historian because each major sect has its own account and opinion of them. Legend and even myth have so coloured these accounts that scholars cannot be sure when and where they took place or even who took part in them. Though many scholars deny its very existence, all Buddhist traditions maintain that a council was called at Rājagaha (modern Rājgīr) immediately after the Buddha's death. According to legend, this council (comprising 500 arhats, or accomplished monks) was responsible for the composition of the vinaya (monastic discipline), under the monk Upāli, and the *dhamma* (*i.e.,* the sutras), under the monk Ānanda, even though the latter was supposedly brought to trial at the same council. Though there were memorizers of sutras and the vinaya, as well as authorized commentators at work in the community during the period of the first three Buddhist councils, the scriptures as such existed only in an inchoate oral (yet normative) form.

Council of Rājagaha

More scholars are prone to accept the historicity of the second council that was held at Vesālī a little more than a century after the Buddha's death. According to the tradition, a controversy arose between a certain Yasa and the monks of Vajji. The 10 points of discipline observed by the Vajjian monks, and opposed by Yasa, permitted storing salt in a horn, eating in the afternoon, and drinking buttermilk after meals. These and other lax rules were condemned by the council. Many scholars believe this council to have been closely associated with the controversy that led to the open division between two segments of the early community—the Mahāsaṅghika school, which displayed more liberal attitudes, and the Sthaviravāda (Theravāda) school, which took a more conservative and elitist stance.

According to Theravāda accounts, a third council was called by King Aśoka at Pāṭaliputta (Patna) about 250 BC. Moggaliputta Tissa, president of the council, is said to have completed his *Abhidharma* treatise, the *Kathāvatthu* ("Points of Controversy"), during this council. It is also said that a controversy arose between the Sarvāstivādins and the Vibhajyavādins (usually identified with the early Theravādins) over the reality of past and future states of consciousness (*citta*s). After the Sarvāstivādin view that such states actually exist was condemned, the sect supposedly withdrew from the lower Ganges valley to Mathurā in the northwest. There it appears to have continued to develop as a transitional school between the older, more conservative schools and the nascent Mahāyāna movement.

A fourth council

According to northern Buddhist traditions, a fourth council was held under King Kaniṣka, probably in the 1st century AD, at Jalandhar or in Kashmir. This council seems to have been limited to the composition of commentaries. Because it appears that only the Sarvāstivādin viewpoint was represented, scholars generally conclude that this was a sectarian synod rather than an actual ecumenical Buddhist council. At any rate, the fourth council has never been recognized by southern Buddhists. (J.M.K./F.E.R.)

THE EIGHTEEN SCHOOLS AND THEIR SUCCESSORS

During the first several centuries of Buddhist history, at the time when the early councils were reportedly held, a number of different schools took form and developed particular traditions regarding the Buddha's teaching and its proper interpretation. In addition to the schools that scholars have connected with particular councils and the controversies associated with them, many other schools appeared. From the information available, it appears that many of these schools were loosely organized and fluid, that in some cases different names were used to designate the same group, and that in other cases the same name was applied to different groups.

According to later Buddhist tradition, 18 such schools emerged during the first few centuries of Buddhist history. (These are the schools that the practitioners of the Mahāyāna, or "Greater Vehicle," grouped together and dubbed the Hīnayāna, or "Lesser Vehicle.") Among these so-called Eighteen Schools there are a few about which some reasonably certain statements can be made. And in some cases it is possible to trace connections between the early schools and similarly oriented traditions that played a significant role in the later phases of Buddhist history.

Sthaviravāda/Theravāda. As noted above, many scholars trace the emergence of a specific "School of the Elders" (Sthaviravāda in Sanskrit, Theravāda in Pāli) to the second century following the Buddha's death. Whether or not this is true, it is clear that the Theravāda was one of the earliest of the early Buddhist schools, and it was certainly—from a historical point of view—the most successful. Because the Theravāda school ultimately became and has remained the predominant Buddhist school in Sri Lanka and much of mainland Southeast Asia, it is described in detail in the following section (see below *The major systems and their literature*).

Mahāsaṅghika/Lokottaravāda. According to traditional accounts, the Mahāsaṅghikas ("Adherents of the Great Order, or Assembly") split off from other Buddhists in the 4th or 3rd century BC, in what may have been the original schism. Their emphasis was on a more open community, a less strict version of the discipline, and a metaphysical view of the Buddha, all of which were later appropriated by the Mahāyāna (see below). In the developed form of their teaching they focused not on the historical Buddha and his teachings but on the transcendent Buddha. In their view, the Buddha is *lokottara* ("transcending the world"), indestructible, completely devoid of all worldly impurities, with stainless karma. When the Buddha utters a single word, its meaning can be understood by all creatures at a level determined by their degree of karmic purity. His body is perfect, for the body through which he reveals himself is not his true body; it is instead an apparitional body (*nirmāṇa-kāya*). Being above the world, he has boundless power and life; he neither sleeps nor dreams. Even in the state of a bodhisattva, prior to his final birth, the Buddha entered the maternal womb completely pure. All bodhisattvas can remain as long as they will among the inferior creatures for the purpose of leading creatures to salvation. The knowledge of things occurs in a single instant: all is void (*śūnya*) and without self; the ultimate end of the way of seeing is an instantaneous recognition that reveals the singular and proper character of all things.

Supramundane nature of the Buddha

The only surviving part of the Mahāsaṅghika canon, the *Mahāvastu* ("Great Subjects"), is derived from Lokottaravādins, who stem from the Mahāsaṅghikas. They assert that things of this world do not possess any reality at all. Only two principles are absolutely real, the two kinds of void (*śūnyatā*): of persons and of things. The (or a) Buddha is completely supramundane (*lokottara,* hence the name Lokottaravāda), and his historical life and actions are mere appearance, convention, or mental image.

Sarvāstivāda (P'i-t'an, Chü-she/Kusha). This group detached itself from the Sthaviravāda school, the predecessor of Theravāda, around the time of Aśoka and spread from Mathurā into Kashmir (northwestern India). Taking a different tack than the Sthaviravāda/Theravāda monks, the Sarvāstivādin scholastics developed their own set of "canonical" *Abhidharma* texts. (The *Abhidharma* [Pāli: *Abhidhamma*] texts are systematizations of the teaching in the early sutras that were composed by the monks of the various schools.) The name Sarvāstivāda refers to the doctrine that everything exists (*sarvam asti*). More specifically, this meant that all things, past and future as well as present, exist because the cognizing agent, at the moment of thinking of them, could not have contact with them if they did not exist. Karma exists, as do the component elements that constitute a human person (the five skandhas). Matter has aspects, hence characteristics, and therefore is definable. The other components have characteristics, and therefore they too are knowable. What does not exist is an atman, *pudgala,* or any other kind of underlying self or person.

A branch of this school, the Mūla-Sarvāstivāda, was widely diffused in India, Central Asia, Myanmar, Thailand, Kampuchea, and Indonesia.

The *Abhidharmakośa* of Vasubandhu

Vasubandhu's *Abhidharmakośa* ("Treasury of Abhidharma"; 4th or 5th century AD) was based on the Sarvāstivāda *Abhidharma* as interpreted in terms of its author's Sautrāntika propensities (see below *Sautrāntika/Satyasiddhi*). It became the basic text for the development of Sarvāstivāda in China and Japan, which is designated by the short form of the title: Chinese *Chü-she,* Japanese *Kusha,* for *kośa* ("treasure"). Before the Chinese translations of Vasubandhu's work in the 6th and 7th centuries, Sarvāstivāda *abhidharma* doctrine was represented in China by the P'i-t'an school, based on texts of the Gandhāra and Kashmir branch of Sarvāstivāda (*P'i-t'an* is the Chinese abbreviation for *Abhidharma*). Summarizing, interpreting, and confuting the theories of various masters in regard to external and psychosomatic *dharma*s, time, and categories, the *Abhidharmakośa* has, since its introduction, been regarded as a basic treatise on Buddhist dogma in China, as also in Tibet.

Vātsīputrīya/Sammatīya. The Vātsīputrīyas (or Pudgalavādins) probably split off sometime during the 3rd century BC. They affirmed the existence of an enduring person (*pudgala*) distinct from both the conditioned (*saṃskṛta*) and the unconditioned (*asaṃskṛta*); the sole *asaṃskṛta* for them is nirvana. The *pudgala* really exists and can transmigrate from life to life, unlike all other things, none of which possess this property. The Vātsīputrīyas refer to a text in which the Buddha speaks of a "bundle" (*i.e.,* the components of a human being, the skandhas) and of one "who carries the bundle." If consciousness exists, there must be a subject of consciousness, the *pudgala;* it is this alone that transmigrates. The Vātsīputrīyas recognized an intermediate life between death and rebirth.

The Sammatīya school, a derivation of the Vātsīputrīya school, had a wide diffusion. According to the reports of Chinese Buddhist pilgrims in the 7th century, its followers were numerous along the Ganges valley; the school flourished in Gujarāt and in eastern India, as well as in Champa, located in what is now central Vietnam; and a 16th-century Tibetan account states that it still flourished during the Pāla dynasty that ruled Bengal up to the end of the 11th century. The Sammatīyas maintained that an act vanishes but that it leaves a thrusting, a commitment to fructify, to have consequences. A person (*pudgala*) is an essence not wholly identical with its components. Thus, the Sammatīyas have tendencies toward an ontological concept of the *pudgala*—that it is real though undefinable. They also posit an intermediate existence between death and rebirth.

Sammatīya doctrines

Mahīśāsaka/Dharmaguptaka. The Mahīśāsaka school apparently took its name from its founder (but, according to others, from the name of a place). Its origins purportedly go back to a disagreement concerning disciplinary rules that occurred at the first Council of Rājagaha (483 BC); however, some of the school's theses seem to have developed later than the Sarvāstivāda.

A so-called Dharmaguptaka branch separated from the Mahīśāsaka school toward the end of the 2nd or the beginning of the 1st century BC. It recognized as its original master Maudgalyāyana (Pāli: Moggallāna), one of the first disciples of the Buddha, although its actual founder may have been Dharmagupta (3rd century BC?). It was still to be found in scattered places in the 7th century. The Dharmaguptakas added two new "baskets," or collections (*piṭakas*), a *Bodhisattvapiṭaka* and *Dhāraṇīpiṭaka,* to the regular *Tripiṭaka* of the Buddhist canon (see below). They held that the Buddha was not part of the sangha—consequently, a gift given to him is infinitely superior to one given the sangha. They emphasized the merit that derives from the cult of the stupa—a mound, often containing relics—which is a centre of devotion in lay Buddhism. They also contended that the paths of the buddha and the bodhisattva are distinct from that of the *śrāvaka* (disciple). Like the views of the closely related Mahāsaṅghika school (see above), the teachings of the Dharmaguptas contain many elements that were emphasized and developed by the Mahāyāna.

Sautrāntika/Satyasiddhi. The Sautrāntika school is so named (*sūtra* plus *anta,* "end") because it gave preeminence to the sutra portion of the canon. Its followers trace their school back to Ānanda, a close disciple of the Buddha. For them, the karmic factors (samskara) are insubstantial and momentary, disappearing as soon as they have been manifested only to reappear again to give rise to a new aggregate. There is continual motion by virtue of which a person passes from one condition to another. Every thought or act is pervaded by a very subtle impregnation that in turn is capable of impregnating the subconscious so as to generate new correlated psychic situations. The school is of great importance because its tenets were precursors of the Vijñānavāda (see below *Yogācāra/Vijñānavāda [Fa-hsiang/Hossō]*).

The Satyasiddhi school, probably derived from the earlier Sautrāntika school, is based on the *Satyasiddhi-śāstra,* a work attributed to Harivarman, a 3rd–4th century Indian writer, and known only in its Chinese version (4th–5th century). It gave birth to a school in China (Ch'eng-shih) and Japan (Jōjitsu) which maintained that all things are merely designations devoid of reality. Human beings are enveloped in the illusion that either the ego (*pudgala*) or the world (*dharmas*) is real, whereas in fact neither is. The past does not exist, the future has not yet come to be, and the present, as soon as it comes into being, disappears. Hence, the sense of continuity is illusory.

The Ch'eng-shih and Jōjitsu schools

Harivarman, like the Lokottaravādins, postulates a void, both of the *dharmas* and of the ego: no *dharmas* of any sort exist, though from the point of view of relative truth *dharmas* may appear to exist. In China this doctrine was sharply attacked by its opponents as destructive nihilism. It is perhaps improper to speak of Satyasiddhi as a school; it refers rather to certain centres that attached particular importance to the *Satyasiddhi-śāstra* without ignoring the rest of the Buddhist teachings. (In Japan, Jōjitsu is considered part of the Sanron school.)

Vinaya schools: Lü/Ritsu. The development of schools based on an emphasis on the *Abhidharma* and *Sūtra* "baskets" has been indicated above in the presentation of Sarvāstivāda and Sautrāntika. As for the *Vinaya,* however, although it constituted an integral part of the *Tripiṭaka* and regulated and consecrated the norms of monastic life, it gave rise to a school of its own only in China and Japan, apparently without any Indian precedent. The Lü-tsung (Vinaya school) originated in China in the 7th century during a period of highly intellectualist Buddhism and stressed observance of the ethical precepts and disciplinary rules. In the following century it was introduced into Japan by the famous Chinese priest Chien-chen (Japanese: Ganjin) at the invitation of the Japanese emperor and was known as Risshū or Ritsu (Japanese for Vinaya). The emphasis of Vinaya in Japan was on the correctness and validity of ordination (initiation) into the sangha, especially for monks and nuns; and controversy ensued between those who stressed the formal, external aspect and those who stressed the spiritual, internal aspect of vows and discipline. A reformed Ritsu school was established in the 13th century, based on a "self-vow discipline," marking a return to the validity of spontaneous vows, beyond any formalism, in accordance with Mahāyāna teachings. The Vinaya Lü-tsung, with its ethical, disciplinary emphasis, so congenial to the Chinese mind, continued to play a vital part in Chinese Buddhism down to modern times; Ritsu, whose teachings were in principle accepted by most Japanese Buddhists, still has its temples and following in contemporary Japan. (Gi.T./F.E.R.)

The major systems and their literature

THERAVĀDA (STHAVIRAVĀDA)

Adherents of Theravāda accept as authoritative the Pāli canon of ancient Indian Buddhism and trace their lineage back to the Sthaviras (Pāli: Theras; "Elders"), who followed in the tradition of the senior monks of the first Buddhist sangha. During the reign of the emperor Aśoka (3rd century BC), the Theravāda school traveled to Sri Lanka, where it divided into three subgroups, known after their monastic centres as the Mahāvihāravāsī, the Abhayagirivihāravāsī, and the Jetavanavihāravāsī. The Mahāvihāra form of the Theravāda tradition became dominant in Sri Lanka about the beginning of the 2nd millennium AD and gradually spread eastward, becoming established in Myanmar in the late 11th century, in Thailand in the 13th century, and in Kampuchea and Laos by the 14th century.

Beliefs, doctrines, and practices. *Cosmology.* In the Theravāda view there is a plurality of universes surrounded by water and mountain chains. Every universe has three planes: (1) the sphere of desire (*kāma-dhātu*), (2) the sphere of material form (*rūpa-dhātu*), which is associated with meditational states in which sensuous desire is reduced to a minimum, and (3) the sphere of immateriality or formlessness (*arūpa-dhātu*), which is associated with meditational states that are even more exalted and vacuous. On the plane of desire, creatures are divided into five or six species: hell beings; pretas, a species of wandering, famished ghosts; animals; human beings; gods; and a sixth group not universally acknowledged, the asuras (demigods). The matter of the world is made up of four elements: earth, water, fire, and air, held together in various combinations.

Plurality of universes, planes, and cycles

Time moves in cycles (kalpas), involving a period of involution (destruction by fire, water, air), a period of stability, a period of renewal, and a period of duration, at the end of which the destruction comes again and the cycle continues.

Human existence is a privileged state because only as a human being can a bodhisattva become a buddha. Moreover, human beings have the capability of choosing to do good works (which will result in a good birth) or bad works (which result in a bad birth); and, above all, they have the capacity to become perfected saints or even buddhas. All these capacities and activities are accounted for in terms of a series of *dhamma*s (Sanskrit: *dharmas*), instant points in continual motion or changing states, subject to appearing, aging, and disappearing.

Classification of dhammas. *Dhamma*s are divided and subdivided into many groups. The essential ones that concern the psychophysical person are the five components (skandhas; Pāli: *khandha*s), the 12 bases (*āyatana*), and the 18 sensory elements (*dhātu*). The lists converge and overlap because the teaching was codified in different ways.

The five components, or skandhas, are: (1) *rūpa,* materiality, or form, (2) *vedanā,* feelings of pleasure or pain or the absence of either one, (3) *saññā,* cognitive perception, (4) *sankhāra,* the forces that cooperate to condition the psychic activity of an individual, and (5) *viññāṇa* (Sanskrit: *vijñāna*), consciousness.

The 12 bases, or *āyatana*s, include the five sense organs and the mind (*manas*), as well as the five related sense fields and a cognizable object—that is, not an object as such but, rather, an object as it is reflected in mental perception.

The 18 elements, or *dhātu*s, comprise the five sense organs and the *mano-dhātu* (mind element), their six correlated objects, and the six consciousnesses (*viññāṇa*) of the eye, ear, nose, tongue, body, and *manas.*

Clearly in this Theravāda version, Buddhism is not concerned with metaphysical problems in the usual sense but with an analysis of the psychosomatic components of the human personality. This is because, from the Theravāda perspective, it is only through an awareness of the interrelation, combination, and operation of these components, and of the way to cultivate some and to suppress others, that a person can arrive at the state of an arhat (Pāli: *arahant;* "worthy one"). Its aim is not to promulgate a metaphysics but to liberate human beings by employing their psychic mechanism in such a way as to stop the operation of karma (Pāli: *kamma*).

The individual as a psychosomatic aggregate

Through the classification of *dhamma*s a person comes to be seen as an aggregate of many elements working together, ruled in his becoming by the law of karma, whether good or bad, and thus destined to suffer good or bad consequences. All this rests on the presupposition that there is no metaphysical entity such as an "I" or atman (Pāli: *attan*) outside of time but that there is a psychosomatic aggregate situated in time. This aggregate has the freedom of choice that allows it to perform this or that act, which can be with or without outflows, and thus capable or not capable of generating consequences.

Such classifications do not have a purely doctrinal goal; rather, they are preparatory distinctions that guide whoever accepts the teaching of the Buddha in passing from the temporal to the atemporal plane and overcoming the cycle of rebirths. Here enter the seven factors of enlightenment: clear memory, the exact investigation of the nature of things, energy and sympathy, tranquility, impartiality, and a disposition for concentration. These are assisted by subsidiaries, such as love for all living creatures, compassion, delight in that which is good or well done, and, again, impartiality. The last four are known as the "four sublime states," the necessary preconditions for liberation from karma and samsara.

The stages leading to arhatship. The Theravādins maintained that the ideal Buddhist is the arhat, the accomplished ascetic who attains nirvana through self-effort. Though the Theravādin arhat naturally "took refuge in the Buddha," his emphasis was not on the grace of the Saviour but on his *dhamma.*

In their "theology," the Theravādins tended to make distinctions. They insisted that nirvana was beyond the realm of empirical reality and that the Buddha who had founded the religion could be distiguished from the *dhamma* he taught. They maintained that monks and laymen have different roles to play both in society and in religion. The way that leads the disciple to the stages of arhatship traverses an immense number of lives, during which the aspirant gains true insight into the nature of things.

According to the Theravādins, one who gains true Buddhist insight passes through four stages. The first stage is that of the stream winner or stream enterer—*i.e.,* the one who has seen the truth, who has experienced the first real intimations of nirvana, and who will not undergo more than seven additional rebirths. The second stage is that of the once-returner—*i.e.,* the one who has moved further toward the goal so that no more than one additional rebirth will be required to attain it fully. The third stage is that of the non-returner, who will achieve complete release in the present life, or, at the very least, before another rebirth occurs. One who has reached this stage has broken free from the lower bonds: belief in a permanent self, doubt, faith in the results generated by rituals, sensual passion, and malice. The fourth and final stage is that of the arhat, who has attained complete freedom by completing all that has to be done. The arhat is free from all bonds including the desire for existence in the formed or formless worlds, as well as ignorance, excitability, and ambition.

The Buddha. The state of the Buddha, the perfectly Enlightened One, is nirvana (Pāli: *nibbāna*)—an attainment from which one does not return. It is beyond death, not caused, not born, not produced; it is beyond all becoming and devoid of all that makes up a human person. There are two kinds of nirvana. One is achieved by the Buddha while still alive, but he remains alive only until the last and most tenuous remains of karma have been expended. When these disappear, the Buddha dies and then enters the nirvana that is not burdened by any karmic residue at all.

The Buddha Metteyya

The Buddha has been given many other names, the most common of which are Arahant and Tathāgata ("He Who Has Thus Attained"). The Theravādin scriptures, in the later stages, express a belief in previous buddhas before Gotama (six in one list, more in others) and also in a future buddha, Metteyya (Sanskrit: Maitreya), who presently dwells in the Tuṣita Heaven and who will come into the world when the proper time arrives.

Meditation. In the Theravāda tradition two basic forms of meditation (Pāli: *jhāna;* Sanskrit: *dhyāna*) have been practiced in various forms and combinations. The first of these is closely related to a Hindu tradition of yoga practice involving a process of moral and intellectual purification associated with four stages of *jhānic* attainment. In the Theravāda context the meditator achieves detachment from sensual desires and impure states of mind through analysis and reflection and thereby attains an emotional state of satisfaction and joy. In the second stage, intellectual activities are abated to a complete inner serenity; the mind is in a state of "one-pointedness" or concentration, joy, and pleasantness. In the third stage, every emotion, including joy, has disappeared, leaving the meditator indifferent to everything while remaining completely conscious. The fourth stage is the abandoning of any sense of satisfaction, pain, or serenity because any inclination to a good or bad state of mind has disappeared. The meditator thus enters a state of supreme purity, indifference to everything, and pure consciousness.

At this point the meditator begins the *samāpatti*s (or the higher *jhānic* attainments). Beyond all perception of form, withdrawn from the influence of perception, immune to the perception of plurality, concentrating on infinite space, the meditator reposes in the condition of spacial infinity. Going beyond this stage, the meditator concentrates on the limitlessness of consciousness and attains it. Proceeding further and concentrating on the nonexistence of everything whatsoever, he achieves a state in which there is absolutely nothing. Even further on, the meditator attains the highest level of realization in which there is neither perception nor nonperception.

The second form of Theravāda meditation is called *vipassanā,* or insight meditation. This kind of meditation requires concentration (produced by exercises such as concentrating on one's breathing), which lead to one-pointedness of mind. This one-pointedness of mind is then used to attain—directly—Buddhist insight into the saving truth that all reality is without self and impermanent and is filled with suffering, even the exalted *jhānic* states of consciousness. This insight, from the Buddhist perspective, gives direct access to progress along the path and to the actual attainment of nirvana itself.

In the classical Theravāda texts the emphasis is placed on the *jhānic* forms of meditation, though the *vipassanā* forms are never completely ignored. In recent years, however, there has been an increasing emphasis on practices in which the *vipassanā* approach is predominant.

(Gi.T./F.E.R.)

The Three Baskets

The Pāli canon (*Tipiṭaka*). The earliest systematic and most complete collection of early Buddhist sacred literature is the Pāli *Tipiṭaka* ("The Three Baskets"; Sanskrit: *Tripiṭaka*). Its arrangement reflects the importance that the early followers attached to the regulations of the monastic life (*Vinaya*), to the discourses of the Buddha (*Sutta*), and subsequently to the interest in scholasticism (*Abhidhamma*).

By courtesy of the Newberry Library, Chicago

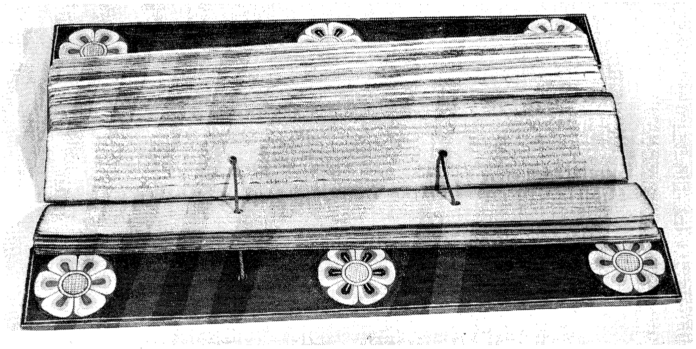


Figure 2: Buddhist Pāli manuscript from Kandy, Sri Lanka, about 45 centimetres (18 inches) long. The palm-leaf pages are threaded with twine, and the covers are wood with painted decoration. In the Newberry Library, Chicago.

The Pāli *Vinaya Piṭaka,* which is still in theory the rule in Theravāda monasteries, although large sections have fallen into disuse, is divided into five major parts grouped into three divisions—*Sutta-vibhaṅga* ("Division of Rules"), *Khandhaka*s ("Sections"), and *Parivāra* ("Accessory").

The *Sutta-vibhaṅga* is a commentary on the *Pātimokkha-sutta* ("Obligatory Rules"), which forms the nucleus of the *Vinaya Piṭaka.* It is one of the oldest parts of the Pāli canon and utilizes an archaic language. It consists of two parts, the *Bhikkhu-pātimokkha* ("Rules for Monks") and the *Bhikkhunī-pātimokkha* ("Rules for Nuns"). The offenses a monk or nun is likely to commit are listed according to their gravity, as, for instance, those warranting permanent expulsion from the order (*pārājika*), those entailing temporary suspension (*sanghādisesa*), and those of which a guilty person can be absolved by a formal confession before the monastic order (*pācittiya*). The commentary on the *Pātimokkha* is divided into the *Mahā-vibhaṅga* ("Great Division"; 227 rules for monks) and *Bhikkhunī-vibhaṅga* ("Division Concerning Nuns"). The latter lists additional specific rules and regulations.

The *Khandhaka* section of the *Vinaya* consists of two parts, the *Mahāvagga* ("Great Grouping") and the *Cullavagga* ("Small Grouping"). The topics dealt with in these two sections have not always been clearly distinguished and also lack logical sequence. They contain rules for ordination; rules for "observance days," when all monks resident within the district were required to assemble for recitation of the *Pātimokkha;* descriptions of rainy-season retreats, clothing, food, and medicines; judicial rules; rules for the instruction of nuns; and so forth. While the *Mahāvagga* is presented as a kind of history of the developing Buddhist community, the *Cullavagga* supplements the details of the former to make an authoritative compilation of the Buddha's sayings regarding the discipline.

The *Parivāra* contains summaries and classifications of the disciplinary rules. It is a later supplement intended not only to help monks and nuns to remember the rules but also to make them aware of the circumstances that would bring them within the orbit of these rules.

Sutta Piṭaka

By far the largest of the three "baskets" is the *Sutta Piṭaka* ("Basket of Discourse"), which consists of five collections (*nikāya*s) containing the discourses attributed to the Buddha. Although, from a literary viewpoint, many of the discourses seem to be drawn out and repetitive, they nevertheless make rewarding reading because of the sublimity of thought and the richness and beauty of the illustrative similes that they contain. The discourses, reported by the Buddha's disciples, begin with the affirmative statement "Thus I have heard" and then relate the place and occasion of the discourse. At the end they affirm that the listeners are delighted and that they rejoice in what the Buddha has said. It is obvious that these discourses do not represent the exact words of the Buddha, although some phrases may have been accurately remembered. Still, they reveal the personality, the didactic technique, and the spirit of the founder. The discourses are chiefly in prose, except for stanzas illustrating or summing up a particular point.

The grouping of the discourses into *nikāya*s does not rest on any kind of topical basis. Apparently there existed two groups of teachers (*bhāṇaka*s), who memorized certain *sutta*s ("discourses," or "sermons") and handed them down to their disciples orally. Reciters of lengthy verses were called Dīghabhāṇakas, and reciters of middle-length verses Majjhimabhāṇakas. The third and fourth *nikāya*s (*Saṃyutta* and *Aṅguttara*) seem to reflect a later development, their aim being to rearrange the topics dealt with in the *Dīgha* and *Majjhima Nikāya*s.

The *Dīgha Nikāya* ("Collection of Long Discourses") contains 34 *sutta*s, some of considerable length, presenting a vivid picture of the different aspects of life and thought at the Buddha's time. Divided into three books, it contrasts superstitious beliefs, various doctrinal and philosophical speculations, and ascetic practices with Buddhist ethical ideas, which are elucidated with the help of similes and examples taken from the everyday life of the people. One of the most interesting *suttanta*s ("discourses") is the *Mahāparinibbāna Sutta,* which gives an account of the last days of the Buddha and stresses the importance of striving for emancipation.

The *Majjhima Nikāya* ("Collection of the Middle Length Sayings") contains 152 *sutta*s in its present version, while the Chinese one, preserving the lost Sarvāstivāda collection, has 222, some of which are also found in other *nikāya*s of the Pāli canon. Like the *Dīgha,* the *sutta*s in the *Majjhima* present Buddhist ideas and ideals, illustrating them by similes of great literary beauty.

The *Saṃyutta Nikāya* ("Collection of Kindred Discourses") has altogether 2,941 *sutta*s, classed in 59 divisions (called *saṃyutta*) grouped in five parts (*vagga*). The first *vagga* has *sutta*s that contain stanzas. The *sutta*s begin with a description of the particular occasion when the stanzas were spoken; the stanzas themselves represent a kind of questioning and answering. The second *vagga* deals with the important principle of dependent origination—the chain of cause and effect affecting all things. The third *vagga* presents the anatman (no-self) doctrine, which is the rejection of an abiding principle that could be termed a self or a pure ego. The fourth *vagga* is very similar to the previous one, but here it is not the philosophical principle underlying the analysis that is stressed but the transitoriness of the elements constituting reality. The fifth *vagga* is devoted to a discussion of the basic principles of Buddhist philosophy, religion, and culture.

The *Aṅguttara Nikāya*

The *Aṅguttara Nikāya* ("Collection of the Gradual Sayings") contains as many as 2,308 small *sutta*s arranged according to the number of topics discussed, ranging from one to eleven. One *sutta* relates that loving kindness practiced for a fraction of a second only will yield great merit. Other *sutta*s state that there are three areas in which training is needed—in conduct, concentration, and insight—and that there are eight worldly concerns—gain, loss, fame, blame, rebuke, praise, pleasure, and pain. Here, too, similes enliven an otherwise dry presentation.

The *Khuddaka Nikāya* ("Collection of Small Texts") comprises 15 separate titles:

1. *Khuddaka-pāṭha* ("Small Reading"). This is the smallest book in the entire *Tipiṭaka.* Compiled for use by primary trainees, its contents are used on various occasions. Two *sutta*s have been borrowed from the *Suttanipāta* (see

below), and their recitation is regarded as very auspicious.

2. *Dhammapada* ("Verses on the *Dhamma*"). This work contains 423 verses in 26 chapters. Presenting the maxims of Buddhist ethics, it not only occupies an eminent place in the religious life of the peoples in Buddhist countries but is also of universal appeal, as it recommends a life of peace and nonviolence and declares that enmity can never be overcome by enmity, only by kindness.

3. *Udāna* ("Utterances"). This contains 80 utterances attributed to the Buddha or his chief disciples, when they had achieved the bliss of their emancipation or spoke in appreciation of a sublime state.

4. *Itivuttaka* ("Thus Said"). This contains 112 short pieces dealing with ethical principles, such as generosity, good and evil, greed, passion, and malice.

5. *Suttanipāta* ("Collection of *Sutta*s"). This is one of the oldest Buddhist texts in existence today. It is partly in verse, partly in a mixed style of prose and verse. The verse part is of high poetic quality.

6. *Vimānavatthu* ("Tales of Heavenly Mansions"). This book describes the different abodes of deities, male and female, who are born in the heavens as a result of their former meritorious deeds.

7. *Petavatthu* ("Tales of Ghosts"). This work gives an account of the various purgatories and the woes of the beings reborn there as a result of their wicked deeds.

8. *Theragāthā* ("Hymns of the Elders"). This collection contains songs attributed to 264 personal disciples of the Buddha. The songs are said to have been composed when their authors experienced the bliss of emancipation.

9. *Therīgāthā* ("Hymns of the Senior Nuns"). These are the songs attributed to about 100 female disciples of the Buddha. They provide rich material for the study of the position of women at the time of the Buddha. Their merit consists in their revealing the deep impression the Buddha's teaching made upon their life. A personal tone is unmistakable.

10. *Jātaka* ("Lives [of the Buddha]"). Only the verses are considered to be canonical, while the 547 tales of the Buddha's previous lives are considered a later addition. The prose stories contain legends, fables, humorous anecdotes, and short sayings, as well as lengthy romances.

11. *Niddesa* ("Exposition"). This work, consisting of two parts, *Mahāniddesa* and *Cullaniddesa,* actually belongs to the group of commentaries. The last two chapters comment on the *Suttanipāta.*

12. *Paṭisambhidā-magga* ("The Way of Analysis"). This is a kind of encyclopaedia of the philosophical ideas in the *Sutta Piṭaka.* It is primarily meant for reference and intensive study.

13. *Apadāna* ("Stories"). This is a collection of stories of the previous lives of the Buddha, the pratyeka buddhas (who attain enlightenment by themselves and are unconcerned about the enlightenment of others), and the arhats of the early Buddhist sangha, whose *Theragāthā* and *Therīgāthā* songs are incorporated and embellished with rich biographical detail. The concluding sentence of each *apadāna* in the collection is intended to show that even the smallest meritorious act has the potentiality of giving vast positive results even after a long time. All the stories are in verse.

14. *Buddhavaṃsa* ("Lineage of the Buddha"). This work relates the lives of 24 previous buddhas, of Gotama (the historical Buddha), and of Metteyya (Sanskrit: Maitreya; the future buddha). According to the text, the stories are told by the historical Buddha himself.

15. *Cariyā Piṭaka* ("Basket of Conduct"). This collection retells 35 Jātakas (stories of the Buddha's previous lives) in verse form, illustrating the bodhisattva's practice of the 10 perfections (paramitas) necessary for the attainment of Buddhahood.

Abhidhamma Piṭaka

The third of the three "baskets," the *Abhidhamma Piṭaka* ("Basket of Scholasticism"), comprises seven works that, although based on the contents of the Buddha's discourses, deal with selected and specific topics which form the basis for the later philosophical interpretations. The Pāli version is a strictly Theravāda collection and has little in common with the *Abhidhamma* works recognized by other schools of Buddhism. It consists of seven works: (1) *Dhammasaṅgaṇi* ("Summary of *Dhamma*"), an enumeration of the entities constituting reality, (2) *Vibhaṅga* ("Division"), a definition of these entities from various points of view, (3) *Dhātukathā* ("Discussion of Elements"), a classification of the elements of reality according to various levels of organization, (4) *Puggalapaññatti* ("Designation of Person"), an interesting psychological typology in which people are classified according to their intellectual acumen and spiritual attainments, (5) *Kathāvatthu* ("Points of Controversy"), a later work discussing the controversial doctrinal points among the various ancient schools, (6) *Yamaka* ("Pairs"), dealing with basic sets of categories arranged in pairs of questions, and (7) *Paṭṭhāna* ("Activations"), a voluminous work discussing 24 kinds of causal relations.

Early noncanonical texts in Pāli. The noncanonical literature of Theravāda Buddhism consists, to a large extent, of commentaries on the *Tipiṭaka* texts but also includes independent works. Among the Pāli writers and exponents of ancient Buddhism who attempted to harmonize the apparently conflicting teachings and to grasp the inner meaning of the doctrine, four names stand out—Nāgasena, Buddhadatta, Buddhaghosa, and Dhammapāla. Nothing is known of Nāgasena except that he was the learned monk who debated with the Greco-Bactrian ruler Menander, as described in the famous literary work *Milinda-pañha.* Buddhadatta and Buddhaghosa were 5th-century contemporaries, deeply versed in the Pāli tradition, while Dhammapāla was slightly later but followed the same tradition.

Nāgasena is supposed to have compiled the *Milinda-pañha* ("Questions of King Menander"). It is generally assumed that this work was written either at the time of Menander (*c.* 150 BC) or shortly afterward, but certainly before the time of Buddhaghosa (AD 400), who very often quotes this work as an authority.

The *Milinda-pañha* is one of the great literary achievements in the field of Indian prose writing. The author begins his work with an account of the past lives of himself and King Menander; it is because of events in these past lives that the two are to meet again in this life. Menander, a well-informed scholar and keen debater, was disheartened when he could find no one to solve his problems regarding Buddhist teachings. But one day he saw Nāgasena going on his begging round. The monk's serenity made a deep impression on the king, who visited him in his monastery. They had a conversation that was later resumed at the palace and that forms the subject matter of the *Milinda-pañha.* The *Milinda-pañha* presents a profound and comprehensive exposition of Buddhist doctrine, ethics, and psychology. This work, like several others, contains the famous statement that, just as the parts of a chariot put together in a specific way constitute the chariot and there is no chariot as such over and above its parts, similarly the different components of an individual make up the individual and there is no other additional entity to hold the components together.

Writings of Buddhaghosa

Buddhaghosa (fl. early 5th century AD) is undoubtedly the most prolific and important writer in the Pāli language. There are different views about his birthplace. Certainly, he stayed at Bodh Gayā, in eastern India, for a long time, and this brought him into contact with Sinhalese monks, because the vihara (monastery) there had been built with the permission of Emperor Samudra Gupta (*c.* AD 330–380) for Sinhalese pilgrims. Buddhaghosa moved from Bodh Gayā to Sri Lanka and stayed at the Mahāvihāra ("Great Monastery") in Anurādhapura,which possessed a rich collection of commentarial literature, probably in Old Sinhalese. The first work that Buddhaghosa wrote was the *Visuddhimagga* ("Way to Purity"), a compendium of Theravāda teaching that has been greatly revered by his successors. No chronological sequence can be established for his other works. Using the *Mahā-aṭṭhakathā* ("Great Commentary"), he wrote commentaries on the *Vinaya,* the first four *nikāya*s, and the seven books of the *Abhidhamma Piṭaka.*

A number of other works are traditionally attributed to Buddhaghosa, although modern scholarship indicates that he was not the author. These works include commentaries on the *Suttanipāta* and the *Khuddaka-pāṭha,* as well as the extremely important commentaries on the *Dhammapada* and the *Jātakas*. The commentary on the *Jātakas* has as its introduction what is perhaps the most famous "biography" of the Buddha in Pāli—a biography that begins with the hero's vow, made in a previous life, to become a buddha, and concludes with his coming to the Jetavana monastery where he purportedly was staying when he recounted the 547 stories that follow. These stories, which all recount events in one of the Buddha's previous lives, range from very brief narratives to full-scale romances (for example, the extremely famous *Mahāvessantara Jātaka,* which recounts the story of the Buddha's last life before his birth as Siddhattha, during which he perfected the virtue of sacrificial giving). In all Theravāda countries these narratives and romances have exerted a tremendous influence on everything from the fine arts to law.

Buddhadatta, a contemporary of Buddhaghosa, was a native of Uragapura, near modern Tiruchirāppalli, Tamil Nadu, southern India. Like Buddhaghosa, he went to Sri Lanka to study at the Mahāvihāra in Anurādhapura. On his return he wrote his works in a monastery on the banks of the Kaveri River. His *Abhidhammāvatāra* ("The Coming of the *Abhidhamma*"), although a summary of the older commentaries on the *Abhidhamma Piṭaka,* stands supreme. In no way did he follow Buddhaghosa blindly. He reduced Buddhaghosa's five metaphysical ultimates—*i.e.,* form, feeling, sensations, motivations, and perception—to four, namely, mind, mental events, forms, and nirvana. This creative classification, similar to that of the Sarvāstivādins, makes him a philosopher in his own right rather than a commentator who merely restates things in new terms.

Dhammapāla, who probably came from southern India, is credited with having written commentaries on all the works left untreated by Buddhaghosa, whom he mentions in his work the *Paramattha dīpanī* ("Elucidation of the True Meaning"), a commentary on several books of the *Khuddaka Nikāya.* In the *Paramattha Mañjūsā* ("Jewel Box of the True Meaning"), his commentary on Buddhaghosa's *Visuddhimagga,* he quotes a verse from the Hindu scripture *Bhagavadgītā* and frequently mentions the views of other schools and teachers. This work provides valuable information about intellectual activity in traditional circles.

Sinhalese chronicles

At the close of the 4th century AD there existed in Sri Lanka an older work, a kind of chronicle, of the history of the island from its legendary beginning onward. It probably formed part of the *Mahā-aṭṭhakathā,* the commentarial literature that formed the basis of the works by Buddhaghosa and others. The accounts contained therein are reflected in the *Dīpavaṃsa* ("History of the Island"), which appears to be a poor redaction in Pāli of an older Old Sinhalese version. The *Mahāvaṃsa* ("Great Chronicle") by Mahānāma, continued in the *Cūlavaṃsa* ("Little Chronicle"), shows much greater skill in the use of the Pāli language and makes liberal use of other material. It is an artistic composition containing rich mythic, legendary, and historical material. The *vaṃsa* tradition continued in Sri Lanka and other Theravāda countries and is still alive in Sri Lanka.

Later Theravāda literature. During and after the "revival" and spread of the Theravāda in the early centuries of the 2nd millennium AD, a new corpus of Theravāda literature came into being. This literature includes commentaries and independent works written in Pāli in Sri Lanka and the Theravāda countries of Southeast Asia (for example, the highly respected commentary on the *Maṅgala Sutta* written in northern Thailand in the 16th century). It also includes many important texts written in vernacular languages, including Sinhalese, Burmese, Thai, Laotian, and Khmer. One classic example is the 14th-century cosmology called the *Traiphūmikathā* (*Three Worlds According to King Ruang*), which is the oldest known full-length text written in Thai. (H.G./F.E.R.)

MAHĀYĀNA

Arising in India, the Mahāyāna version of Buddhism spread to Central Asia, China, Japan, mainland Southeast Asia, Java, Sumatra, and even Sri Lanka (Abhayagiri monastery). It became the Pan-Asiatic form of Buddhism and involved basic shifts in doctrine and approach for which, however, there were precedents in earlier schools. It taught that neither the self nor the *dharmas* exist. Moreover, for the elite arhat ideal, it substituted the bodhisattva—*i.e.,* the one who possesses the innate tendency to become a buddha, a disposition inherent in all persons. In Mahāyāna, love for creatures is exalted to the highest; a bodhisattva is encouraged to offer the merit he derives from good deeds for the good of others. The tension between morality and mysticism that agitated India also entered the Mahāyāna.

Nature and characteristics. Mahāyāna is not merely a metaphysics, dealing with the basic structure and principles of reality. It is also and primarily a theoretical propaedeutic to the achievement of a desired state or condition. Thus there is a coexistence of theoretical investigation and supreme experience: the former, the premise; the latter, the consequence. The convergence of meditative exercises leads to an emptying of thought to reach a point in which one proceeds from voidness to voidness and finally to the ultimate where even the most attenuated thought vanishes. Rational activity is exercised until it becomes quiescent: prajna itself, the supreme wisdom, by successive emptying becomes nullified, and only in doing so does it identify with the unutterable ultimate reality.

The doctrine of voidness

Basic teachings. *The Buddha: divinization and multiplicity.* In the Mahāyāna tradition, the Buddha is viewed not merely as a human master and model but also as a supramundane being. He multiplies himself and is reflected in a pentad of buddhas: Vairocana, Akṣobhya, Ratnasambhava, Amitābha, and Amoghasiddhi. Some of these, taking the place of Śākyamuni, are revealers of doctrines and elaborate, complicated liturgies.

As Mahāyāna developed, a great deal of literature called *Buddhavacana* (Revelation of the Buddha) was circulated, but it went far beyond the ancient canons; it was proposed as the highest revelation, superseding prior texts. In this literature the teaching is viewed not as merely of one kind but as on various levels, each adapted to the intellectual capacity and karmic propensities of those who hear it. The Buddha is no longer simply the historical sage of the Śākyas but is now supramundane (*lokottara*). Even the sangha is of two types: that of this world and that beyond it.

The bodhisattva ideal. The essential premise of the bodhisattva ideal is to generate in one's own self the thought of enlightenment and to fulfill the vow to become a buddha, foregoing entrance into nirvana in order to remain in the world as long as there are creatures to be saved from suffering. With that vow the aspirant begins the career of a bodhisattva, which traverses 10 stages or spiritual levels (*bhūmi*) and achieves purification through the practice of the 10 perfections (paramitas). These levels, which become progressively higher, elevate the bodhisattva to the condition of a buddha. The first six levels are preliminary, representing the true practice of the six perfections (generosity, morality, patience, vigour, concentration, and wisdom). Irreversibility occurs as soon as the seventh stage is reached. From this moment the bodhisattva assumes the true buddha nature, even though further purification and fortification must be achieved in the stages that follow. This is the moment when, having performed his duty, he engages in activity aimed at completely fulfilling the obligations of a bodhisattva. The difference between this and the preceding six stages is that now the activity is explained as an innate and spontaneous impulse manifested unconstrainedly and therefore not subjected to doubts. Everything is now uncreated, ungenerated; thus, the body of the bodhisattva becomes identified more and more completely with the essential body (*dharma-kāya*), with buddhahood, and with omniscience.

The three Buddha bodies. The three bodies (*tri-kāya; i.e.,* modes of being) of the Buddha, which became a subject of major discussion in the Mahāyāna, are rooted in the Theravāda teachings concerning the physical body (which consists of four elements), the mental body, and the body of the law. It is with the Mahāyāna, however, that the theory of the three bodies enters into the salvation

The phenomenal body

process and assumes central significance in the doctrine. The phenomenal body (*nirmāṇa-kāya*) is a manifestation of the Buddha among creatures to teach them the path to liberation—a body that for some schools is nothing but an illusory appearance of eternal reality. The enjoyment (or bliss) body (*sambhoga-kāya*) is the body to which contemplation can ascend. At the higher stages of supramundane contemplation that body manifests to the bodhisattva its splendour and reveals doctrines unintelligible to those who are unenlightened. The unmanifested body of the law (*dharma-kāya*) already appears in the *Saddharmapuṇḍarīka,* or *Lotus Sutra,* a transitional text that became central in many Mahāyāna devotional schools (see below *Saddharmapuṇḍarīka* and *Nichiren*). In many Mahāyāna texts buddhas are infinite, and all partake of an identical nature—the *dharma-kāya.*

As anticipated in ancient schools, the Buddha is the law (*dharma*). "He who sees the law sees me; he who sees me sees the law." There is identification of the Buddha with an eternal *dharma,* with enlightenment (bodhi), and hence with nirvana; later, real existence will be opposed to the mere appearance of existence, and voidness, the "thingness of things," an undefinable condition, present and immutable within the Buddhas, will be stressed. All is in the *dharma-kāya;* nothing is outside of it, just as nothing is outside of space; transcendence and immanence come together. Other schools posit a presence that is innate within all human beings, even if it is not perceived. It is like a gem hidden in dross, which shines in its purity as soon as the veil of ignorance is removed.

New revelations. New revelations are made not only to human beings on earth but also in the heavenly paradises by Śākyamuni and other buddhas. The teaching is expounded uninterruptedly in the universe because worlds and paradises are infinite and all buddhas are consubstantiated with the essential body. The assemblies to which they speak consist not only of *śrāvaka*s (disciples) but also of bodhisattvas, gods, and demons. The authors of the new doctrines were captivated by exaltations that often make their discourses logically implausible: phantasmagoria of celestial choruses, fabulous visions in which shine flashes of new speculations, and trains of thought under the influence, more or less conscious, of speculative and mystical Indian traditions. The texts, from which new trends spring, overflow with repetitions and modulate the same arguments with a variety of readings.

The task of Mahāyāna thinkers was very difficult because it was not easy to produce a completely logical arrangement from this prolix literature. The appearance of some of these books is surrounded with legend. The *Prajñāpāramitā* and the *Avataṃsaka-sūtra*s, for instance, are said to have been concealed by the nagas, demigods living at the bottom of lakes and rivers, in miraculous palaces. There are various *Prajñāpāramitā* ("Perfection of Wisdom") texts, ranging from 100,000 verses (the *Śatasāhasrikā*) to only a few lines (the *Prajñāpāramitāhṛdaya-sūtra,* famous in English as the *Heart Sutra*). The *Prajñāpāramitā-sūtra*s announce that the world as it appears to us does not exist, that reality is the indefinable "thingness of things" (tathata; *dharmāṇām dharmatā*), that voidness (*śūnyatā*) is an absolute "without signs or characteristics" (*animitta*).

Relative and absolute truth

The fundamental assumption of the *Prajñāpāramitā* is expounded in a famous verse: "like light, a mirage, a lamp, an illusion, a drop of water, a dream, a lightning flash; thus must all compounded things be considered." Not only is there no "self," but all things lack a real nature (*svabhāva*) of their own. There are two truths: relative truth, which "applies to things as they appear," and absolute truth, the intuition of voidness (it can be of 10, 14, 18, or 20 kinds).

The Mahāyāna schools and their texts. Mahāyāna comprises the following main schools: the Mādhyamika; the Yogācāra or Vijñānavāda (Vijñaptamātratā); the Avataṃsaka; the school of the identity of the paths to salvation (*ekāyana*) represented by the *Saddharmapuṇḍarīka* ("Lotus of the True Law"; the *Lotus Sutra*); the various devotional (Pure Land) schools; and the Dhyāna school (Ch'an in China, Zen in Japan).

Mādhyamika (San-lun/Sanron). The Mādhyamika ("Doctrine of the Middle Way"), also known as Śūnyavāda ("Theory of Negativity or Relativity"), system—which held both subject and object to be unreal—is the systematized form of the doctrine of *śūnyatā* (cosmic emptiness) contained in the *Prajñāpāramitā* literature. The most famous exponent of this system was the Indian philosopher Nāgārjuna (*c.* AD 150–*c.* 250), the presumed author of the voluminous *Mahāprajñāpāramitā-śāstra* ("The Great Treatise on the Perfection of Wisdom"), preserved in its Chinese translation (402–405) by Kumārajīva; of the *Mūlamadhyamakakārikā* (more commonly known as *Mādhyamika Kārikā;* "Fundamentals of the Middle Way"), which is the Mādhyamika work par excellence; of the *Śūnyatāsaptati,* expounding the unreality of all elements of reality; of the *Vigrahavyāvartanī,* a refutation of possible objections to the doctrine of *śūnyatā;* of the *Vyavahārasiddhi,* teaching that absoluteness and relativity can coexist in practice; and of the *Yukti-ṣaṣṭika,* dealing with relativity. It is possible that Nāgārjuna is also the author of the *Ratnāvalī,* of the *Pratītyasamutpādahṛdaya,* and of the *Sūtrasamuccaya,* besides many other works attributed to him. Nāgārjuna's chief pupil was Āryadeva. His main work, the *Catuḥśataka,* criticizes both other forms of Buddhism and the classical Sanskrit philosophical systems. Together with Nāgārjuna, Āryadeva is the real founder of the Mādhyamika system.

Nāgārjuna and his followers attempted to arrive at a middle position, devoid of name and character and beyond all thought and words. They began by employing a rigorous logic to demonstrate the absurdity of various philosophical positions, including those of the Hindus and those of other Buddhists. On the assumption that any contradiction is proof of error, Nāgārjuna took any point of view that would reveal the error of his opponents. Yet, he did not therefore accept the opposing point of view but only used it as a means to show the relativity of the system he was attacking. He was just as willing to refute his first position. In this way he claimed adherence to no doctrine.

The middle path

With this method of reduction to absurdity or to contradiction, Nāgārjuna attempted to prove that all worldly thought is empty (*śūnya*) or relative, and to point to his belief that the true path is that of the middle, the path that is between or, more correctly, above extremes. This belief has been called the doctrine of emptiness of all things; however, as has been pointed out, this too is relative and should be seen only as a means of argumentation, which must itself be transcended.

Nāgārjuna presented this middle path above extremes most clearly in the following statement of what he considered to be the Eightfold Truth of Buddhism:

> Nothing comes into being, nor does anything disappear. Nothing is eternal, nor has anything an end. Nothing is identical, nor is anything differentiated. Nothing moves here, nor does anything move there.

In presenting these pairs of opposites, Nāgārjuna taught that anything that can be conceptualized or put into words is relative. This led to the Mādhyamika identification of nirvana and samsara. Both are empty concepts with the truth lying somewhere beyond.

After the emptiness or relativity of the world has been proved, the question arises as to how one is to go beyond this position. Nāgārjuna answered that humans are not irreconcilably caught in this world, for this world can be used as a ladder leading to the absolute—beyond all duality. The transition that can be effected from this world to salvation has been called Nāgārjuna's doctrine of two truths. The relative truth is of this existence. By the logical method, all propositions can be destroyed. This leads to the realization that all is emptiness and from this to the intuition of an absolute truth beyond all conceptions. The link between these two truths—the relative and the absolute—is the Buddha. He experienced the absolute truth, which is *niṣprapañca—i.e.,* inexplicable in speech and unrealizable in ordinary thought—and yet he returned to point to this truth in the phenomenal world. By following this path, one can be saved.

Thus, Nāgārjuna taught that through the middle path of Mādhyamika, which is identified as the Buddha's true teachings, one is guided to an experience beyond affirmation and negation, being and nonbeing. Mādhyamika is a philosophy that can rightly be called a doctrine of salvation, for it claims to present humans with a system that leads to rescue from their situation.

A new phase in the development of the Mādhyamika system was initiated during the 5th and 6th centuries when two subtraditions became differentiated. The more conservative Prāsaṅgika school, which emphasized a more negative form of argumentation, was founded by Buddhapālita (*c.* 470–540), who wrote, among many other works, a commentary on Nāgārjuna's *Mādhyamika Kārikā.* The school was continued by Candrakīrti, a famous logician of the 7th century, who wrote another commentary on the same text; and by Śāntideva (7th–8th centuries), who wrote two of the most popular works in all Mahāyāna literature: the *Śikṣā-samuccaya* ("Summary of Training") and the *Bodhicaryāvatāra* ("The Coming of the Bodhisattva Way of Life"). The more liberal Svātantrika school, which utilized a more syllogistic mode of argument, was founded by Bhāvaviveka, a contemporary of Buddhapālita, who also wrote a commentary on Nāgārjuna's *Mādhyamika Kārikā.* The school was continued by Śāntirakṣita, a great scholar who wrote the *Tattvasaṃgraha* ("Summary of Essentials") and the *Mādhyamikālaṅkāra Kārikā* ("Verses on the Ornament of the Mādhyamika Teaching"), on which his disciple wrote a commentary. Both the Svātantrika tradition and the Prāsaṅgika tradition (reasserted by Atīśa) had a great influence on Buddhist philosophy in Tibet.

Introduction into China

The Mādhyamika school of thought was spread to China from India by Kumārajīva, a missionary translator of Indian-Kuchan parentage, in the 5th century. Three of the texts that he translated from Sanskrit into Chinese—the *Mādhyamika Kārikā* and the *Dvādaśamukha-śāstra* or *Dvādaśa-dvāra-śāstra* ("The Twelve Topics or Gates Treatise") of Nāgārjuna and the *Śata-śāstra* ("One Hundred Verses Treatise") of Āryadeva—became the basic texts of the Chinese San-lun (Japanese Sanron) or "Three Treatise" school of Mādhyamika. For a brief period this school was challenged by a more positivistic form of Mādhyamika called the Ssu-lun, or "Four Treatise," school, which also accepted the *Mahāprajñāpāramitā-śāstra* as a basic text. This school, however, was soon overwhelmed by San-lun as taught by Kumārajīva's disciple, Seng-chao, and later by Chi-tsang. Both of these Chinese Mādhyamika masters restated Nāgārjuna's thesis in numerous influential commentaries. A Korean disciple of Chi-tsang named Ekwan (Hui-kuan) then spread San-lun (Korean Samnŏn) to Japan in 625, thus completing the rapid spread of Mādhyamika thought from India to China and to Japan. This school, despite its profound and widespread influence, never gained popularity among the masses; it remained rather the basis for logical and philosophical thought among the learned few, rarely forming a separate or independent sect.

Yogācāra/Vijñānavāda (Fa-hsiang/Hossō). The Yogācāra (or Vijñānavāda) school is traditionally ascribed to the brothers Asaṅga and Vasubandhu (5th century AD), to whom may be added Sthiramati (6th century). These writers were systematizers of doctrines already being taught and contained in such literature as the *Laṅkāvatāra-sūtra* and the *Mahāyāna-śraddhotpada-śāstra* (attributed to Aśvaghoṣa but probably written in Central Asia or in China). Yogācāra explored and propounded basic doctrines that were to be fundamental in the future development of Mahāyāna and that influenced the rise of Tantric Buddhism (see below).

Its central doctrine is that only consciousness (*vijñāna-mātra;* hence the name Vijñānavāda) is real, that thought or mind is the ultimate reality. External things do not exist; nothing exists outside the mind. The common view that external things exist is due to an error or misconception that is removable through a meditative or yogic process that brings a complete withdrawal or "revulsion" from these fictitious externals and an inner concentration and tranquility.

Store consciousness (*ālaya-vijñāna*)

A store consciousness (*ālaya-vijñāna*) is postulated as the receptacle, or storehouse, of the imprint of thoughts and deeds, the *vāsanā* (literally, "dwelling") of various karmic seeds (*bīja*s). The "seeds" develop into touch, mental activity, feeling, perception, and will, corresponding to the five skandhas. Then ideation (*manas*) develops, which sets off a self or mind against an outer world. Finally comes the awareness of the objects of thought via sense perceptions and ideas. The store consciousness must be purified of its subject-object duality and notions of false existence and restored to its pure state. This pure state is equivalent to the absolute "suchness" (tathata), to buddhahood, to the undifferentiated.

Corresponding to these three elements of false imagination (*vikalpa*), right knowledge, and suchness are the three modes in which things are: (1) the mere fictions of false imagination, (2) the relative existence of things, under certain conditions or aspects, and (3) the perfect mode of being, corresponding to right knowledge. The latter state of consciousness and being is that ultimately attained by the bodhisattva in buddhahood. Corresponding to this threefold version of the modes of being and awareness is the *tri-kāya* doctrine of the Buddha noted above (the apparitional body, the enjoyment body, and the *dharma* body), a doctrine that was put into its systematic, developed form by Yogācāra thinkers.

The special characteristics of Yogācāra are its emphasis on meditation and a broadly psychological analysis. This contrasts with the other great Mahāyāna system, Mādhyamika, where the emphasis is on logical analysis and dialectic.

This consciousness-oriented school of thought was represented in China primarily by the Fa-hsiang (or Dharmalakṣaṇa; also Wei-shih) school, called Hossō in Japan. The basic teachings of Yogācāra became known in China primarily through the work of Paramārtha, a 6th-century Indian missionary-translator. His translation of the *Mahāyāna-saṃparigraha-śāstra* provided the foundation for the She-lun school, which preceded the Fa-hsiang school as the vehicle of Yogācāra thought in China. Fa-hsiang was founded by Hsüan-tsang, the 7th-century Chinese pilgrim-translator, and his main disciple, K'uei-chi. Hsüan-tsang went to India and studied the doctrines derived from Dharmapāla (d. 507) and taught at the Vijñānavāda centre at Valabhī. When he returned to China he translated Dharmapāla's *Vijñapti-mātratā-siddhi* and many other works. His teachings followed mainly the line of Dharmapāla but also included the ideas of other Indian teachers such as Dignāga and Sthiramati. They were expressed systematically in his works *Fa-yuan-i-lin-chang* and *Wei shih-shu chi,* the basic texts of the Fa-hsiang school.

Characteristics of *dharma*s (*dharmalakṣaṇa*)

Fa-hsiang is the Chinese translation of the Sanskrit *dharmalakṣaṇa* ("characteristic of *dharma*"), referring to the school's basic emphasis on the peculiar characteristics (*dharmalakṣaṇa*) of the *dharma*s that make up the world which appears in human ideation. The connection of this so-called idealist school with the "realist" Abhidharma-Kusha school (see above *Sarvāstivāda* [*P'i-t'an, Chü-she/Kusha*]) is evident, though many new elements are introduced. According to Fa-hsiang teaching, there are five categories of *dharmas*: (1) 8 mental *dharma*s (*cittadharma*), comprising the 5 sense consciousnesses, cognition, the cognitive faculty, and the store consciousness, (2) 51 mental functions or capacities, dispositions, and activities (*caitaśikadharma*), (3) 11 elements concerned with material forms or appearances (*rūpa-dharma*), (4) 24 things, situations, and processes not associated with the mind—*e.g.,* time, becoming (*cittaviprayuktasaṃskāra*), and (5) 6 noncreated or nonconditioned elements (*asaṃskṛtadharma*)—*e.g.,* space or "suchness" (tathata).

Hsüan-tsang's work *Ch'eng wei-shih lun* explained how there can be a common empirical world for different individuals who construct or ideate particular objects and who possess distinct bodies and sensory systems. According to Hsüan-tsang, the universal "seeds" in the store consciousness account for the common appearance of things and particular "seeds" for the differences.

Fa-hsiang was brought to Japan on various occasions, according to the traditional accounts: first by Dōshō, a Japanese priest who visited China, studied under Hsüan-tsang, and established the teaching (now called Hossō) at Gangō-ji monastery, and then by other priests, Japanese and Korean, who studied in China under Hsüan-tsang, K'uei-chi, or their disciples. Thus, the Japanese claim to have received the Hossō teaching in a direct line from its originators, and it continues to have a living and significant role in Japanese Buddhism.

Identity of proximate and ultimate

Avataṃsaka (Hua-yen/Kegon). In contrast with the Fa-hsiang (Hossō) concentration on the specific differentiating characteristics of things and its separation of facts and ultimate principles, the Avataṃsaka school (called Hua-yen in China, Kegon in Japan) stressed the sameness of things, the presence of absolute reality in them, and the identity of facts and ultimate principles. It took its name from the *Mahāvaipulya-Buddhāvataṃsaka-sūtra* ("The Great and Vast Buddha Garland Sutra"), often called simply the *Avataṃsaka-sūtra* ("Wreath Sutra" or "Garland Sutra").

According to legend, the *Avataṃsaka-sūtra* was first preached by the buddha Vairocana expressing the perfect truth revealed in his Enlightenment but then kept secret when it proved incomprehensible to his hearers and replaced with easier doctrines. The sutra tells of the pilgrimage of a young man in a quest to realize *dharma-dhātu* ("totality" or "universal principle"). Extant are three Chinese versions and one Sanskrit original (the *Gaṇḍavyūha*) that contains the last section only. There is no trace of an Indian sectarian development, and the school is known only in its Chinese and Japanese forms.

The school was preceded in China by the Ti-lun school, based on a translation (early 6th century) of Vasubandhu's *Daśabhūmika-sūtra,* concerning the 10 stages of a bodhisattva on the way to buddhahood; since this work was related to the *Avataṃsaka-sūtra,* the Ti-lun adherents readily joined the Hua-yen school established in the late 6th century (?) by Tu-shun (Fa-shun), the first patriarch (d. 640). Fa-tsang (or Hsien-shou), the third patriarch (d. 712), is considered the real founder because he systematized the teachings; hence, it is also called the Hsien-shou school. His student, Ch'eng-kuan (of Ch'ing-liang monastery; d. *c.* 820 or *c.* 838), wrote famous commentaries on the *Avataṃsaka-sūtra.* After the death of the fifth patriarch, Tsung-mi, in 841, Hua-yen declined during the general suppression of Buddhism that ensued in China. But it greatly influenced the development of Neo-Confucianism (a significant movement in Chinese thought beginning in the 11th century) and is regarded by many as the most highly developed form of Chinese Buddhist thought. It was brought into Japan by pupils of Fa-tsang and an Avataṃsaka missionary from central India during the period from about 725 to 740 and began a vital and important development there that has continued down to the present day.

Causation by "totality" (*dharma-dhātu*)

The most significant doctrine associated with this school is the theory of causation by *dharma-dhātu—i.e.,* that all of the elements arise simultaneously, that the whole of things creates itself, that ultimate principles and concrete manifestations are interfused, and that the manifestations are mutually identical. Thus, in Fa-tsang's example of the golden lion in the imperial palace, gold is the essential nature or principle (*li*) and lion is the particular manifestation or form (*shih*); moreover, as gold, each part or particle expresses the whole lion and is identical with every other part or particle. When this model is applied to the universe, it suggests that all phenomena are the expressions of the ultimate suchness or voidness, while at the same time they retain their phenomenal character; each phenomenon is both "all" and "one." All the constituents of the world (the *dharmas*) are interdependent, cannot exist independently, and each of them possesses a sixfold nature: universality, speciality, similarity, diversity, integration, and differentiation.

The ideal is a harmonious totality of things encountered in the perfectly enlightened buddha. The buddha-nature is present potentially in all things. There are an infinite number of buddhas and buddha realms. There are myriads of buddhas in every grain of sand and a buddha realm at the tip of a hair.

The universe is fourfold: a world of factual, practical reality; a world of principle or theory; a world of principle and facts harmonized; and a world of factual realities interwoven and mutually identified. The first three aspects are the particular emphases of other Buddhist schools. The fourth aspect—emphasizing the harmonious whole—is the distinctive doctrine that represents the perfect knowledge that was attained by the buddha Vairocana and is communicated in the *Avataṃsaka-sūtra.*

Figure 3: The Japanese priest Myōe (1173–1232), venerated as the restorer of the Kegon sect, depicted at his daily meditation seated in a tree near his monastery. Hanging scroll, light ink and colour on paper, 13th century. In the Kōzan Temple, Kyōto, Japan.

Kozan-ji, Kyoto, Japan

Saddharmapuṇḍarīka (T'ien-t'ai/Tendai). The T'ien-t'ai/Tendai school is one of the most important developments in Chinese and Japanese Buddhism; it is significant not only for its doctrines, which in many respects are similar to Hua-yen/Kegon, but also for its practical devotional influence. Its doctrines and practices are focused on the Indian or Central Asian *Saddharmapuṇḍarīka-sūtra* ("Lotus of the True Law Sutra"), or *Lotus Sutra.* Also central in the Nichiren school (see below) and recited in Zen temples, this sutra is one of the best known and most popular of Mahāyāna Buddhist texts. (The *Mahāparinirvāṇa* and *Mahāprajñāpāramitā-sūtras* were also important in the development of T'ien-t'ai/Tendai.) The school, which apparently had no separate development as such in India, is sometimes also called Lotus (Fa-hua in Chinese; Hokke in Japanese) but is usually known as T'ien-tai in China and Tendai in Japan, after the mountain in southeastern China where the basic interpretation of the *Lotus Sutra* was first propounded in the 6th century. Prior to this, the original Sanskrit text was studied extensively in China; it was translated into Chinese early in the 5th century by Kumārajīva, and it was taught in North China by the monks and first patriarchs, Hui-wen and Hui-ssū. The latter's student, Chih-i, who settled on Mount T'ien-t'ai and established a famous monastery there, is regarded as the true founder of the school because he propounded the systematic and definitive interpretation of Lotus doctrines. These later became known in Japan, where Saichō (later Dengyō Daishi), a Buddhist priest who studied them first in Japan and then on Mount T'ien-t'ai, founded a new Tendai Lotus Sect (early 9th century) and a monastery on Mount Hiei that became a great centre of Buddhist learning. With Shingon (see below), with which it was closely connected, Tendai became perhaps the most important religious and philosophical influence on the Japanese spirit. Tendai has been markedly syncretistic, striving to include various Buddhist tendencies, from Vinaya to Shingon and Zen, and also Shintō, the indigenous Japanese tradition.

The one way that includes all ways

The *Lotus Sutra*'s main purpose is to establish the one way (or "vehicle" or "career") for attaining salvation (buddhahood). It claims to be the definitive and complete teaching of the Buddha, here presented as a transcendent eternal being, preaching to myriad arhats, gods, bodhisattvas, and other figures using all sorts of sermons, lectures, imaginative parables, and miracles. Religious merit is attributed to preaching, reciting, and hearing the sutra, which is not merely a statement of the nature of things but also a central object of devotion. The three ways of salvation preached by the Buddha are adjusted to the level and situation of the hearers: *śrāvakayāna,* the way of the disciples (*śrāvaka*s), appropriate for becoming an arhat; *pratyeka-buddhayāna,* the way of those who aim at salvation for themselves alone; and *bodhisattvayāna,* the way of those (the bodhisattvas) who, on the point of attaining salvation, give it up to work for the salvation of all other beings. All are forms of the one way, the *buddhayāna.* Being a buddha is the one aim for all.

As systematized in the T'ien-t'ai/Tendai tradition, the Buddha's teachings are divided into five periods. The first is the period immediately following the Buddha's Enlightenment, when, without success, he preached the *Avataṃsaka-sūtra* (or *Hua-yen/Kegon Sutra*). The second is the so-called Deer Park period, when he preached the *Āgama*s (Hīnayāna scriptures) to those with ordinary human capacities. The third is the so-called Fang-teng (broad and equal) period, when he preached the Vaipulya or early Mahāyāna teachings, which were intended for all persons. During the fourth period he preached the Mahāprajñāpāramitā, or Ta-pan-jo-po-lo-mi-to, doctrines concerning absolute voidness and the falsity of all distinctions. Finally, in the fifth and culminating Saddharmapuṇḍarīka and Mahāparinirvāṇa (or Wisdom) period, he taught the identity of contrasts, the unity of the three "vehicles," and the supreme character of the *Lotus Sutra.*

Central to T'ien-t'ai/Tendai doctrine is the threefold truth principle (following Nāgārjuna's [?] commentary on the *Mahāprajñāpāramitā*): (1) that all things are void, without substantial reality, (2) that all things have temporary existence, and (3) that all things are in the mean or middle state, synthesizing voidness and temporary existence, being both at once. The three truths are a harmonious unity, mutually including one another, and the mean or middle truth is equivalent to the absolute suchness. The world of temporary appearances is thus the same as absolute reality.

T'ien-t'ai/Tendai cosmology

T'ien-t'ai/Tendai propounds an elaborate cosmology of 3,000 realms. First are the 10 basic realms, respectively, of buddhas, bodhisattvas, pratyeka buddhas, *śrāvaka*s, heavenly beings, fighting spirits (asuras), human beings, hungry spirits or ghosts (pretas), beasts, and depraved hellish beings. Since each includes the other nine and their characteristics, the 10 are squared to 100 realms. Each of these in turn is characterized by the 10 features of suchness manifested through phenomena: form, nature, substance, power, action, cause, condition, effect, compensation, and ultimacy. Thus the 100 realms in fact constitute 1,000 realms. Furthermore, each of the 1,000 realms comprises three divisions: living beings, space, and the aggregates (skandhas); hence, the whole of things consists of 3,000 realms.

These 3,000 realms interpenetrate one another, are mutually immanent, and are immanent in one moment of thought: "one thought is the three thousand worlds." The universe is not produced by thought or consciousness but is manifest in it, as is the absolute Suchness: hence, the central importance of concentration (*chih*) and insight (*kuan*) that leads to a realization of the unity of things and their manifestation of the ultimate.

Pure Land (Sukhāvatī/Ching-t'u/Jōdo, Shin, and Ji). The main text of the Pure Land schools is the *Sukhāvatīvyūha-sūtra* (*Pure Land Sutra*) written in northern India probably before the beginning of the 2nd century AD. (There are two original versions of the *Sukhāvatīvyūha.* The longer one includes an emphasis on good works; the shorter version emphasizes faith and devotion alone.) This sutra tells of a monk, Dharmākara, who heard the preaching of Lokeśvararāja Buddha many aeons ago and asked to become a buddha. After millions of years of study, Dharmākara promised to fulfill a number of vows if he finally attained buddhahood. He vowed to establish a Pure or Happy Land (Sanskrit: Sukhāvatī; Chinese: Ching-t'u; Japanese: Jōdo), also known as the Western Paradise. In this Pure Land no evil would exist, the people would be long-lived, they would receive whatever they desired, and from there they might attain nirvana. Dharmākara then revealed in a number of vows the means by which this Pure Land can be reached. Several of these vows emphasize meditation and good works on Earth as a prerequisite, but the 18th one (a famous vow in the later development of Pure Land schools) states that, if one merely calls the name of the Buddha at the moment of death, then that person will be reborn in the Pure Land.

Many years after these vows, Dharmākara attained buddahood and now sits in his Pure Land fulfilling his promises of helping humans achieve salvation. Here he is known as the Buddha of Unlimited Light (Sanskrit: Amitābha; Chinese: O-mi-t'o-fo; Japanese: Amida) or the Buddha of Unlimited Lifespan (Amitāyus). He is flanked by Avalokiteśvara (Chinese: Kuan-yin; Japanese: Kannon) on his left and Mahāsthāmaprāpta on his right, who assist Amitābha in bringing the faithful to his Pure Land.

Transmission to Japan

The Amitābhist doctrine spread from India to China by the 3rd century AD, where, through the work of five patriarchs, a sect based on it gradually became the most popular form of Buddhism. The sect was then transferred to Japan by the followers of the Tendai school, who attempted to weld the many sects of Buddhism into one system. By the 13th century AD the Pure Land sect had separated from the Tendai school and spread among the common people of Japan through the work of two outstanding figures, Hōnen and Shinran.

The basic doctrines of the Pure Land sects differ considerably from the doctrines of the early Buddhists. The Pure Land's leaders have generally taught that a person reaches salvation from this Earth not by individual effort or the accumulation of merit but through faith in the grace of the Buddha Amitābha. The main practice of those who follow the Pure Land teachings is not the learning of the texts nor meditation on the Buddha but rather the constant invocation of the name Amitābha. This practice, based on the 18th vow of Dharmākara, the future Amitābha, is called *nien-fo* in Chinese and *nembutsu* in Japanese. Furthermore, in Pure Land Buddhism, the attainment of nirvana is not the primary goal; it is rather to become reborn in the Pure Land of Amitābha.

These doctrines and the practice of invoking the name Amitābha gained great popularity in China and Japan, where it was believed that the world had reached a degenerate period in which the Buddhist doctrines were no longer clear and humans no longer possessed the purity of heart or determination to attain salvation by self-endeavour. Therefore, all people of every section of society could only hope to be saved by the grace of Amitābha. As the Pure Land sect spread from India to China and then to Japan, this doctrine of grace became more and more radical until individual actions were said to play no part in the attainment of salvation.

There is little available data on the practices of the Amitābhist believers in India, but scholars hold that while *nembutsu* was used, the main emphasis was upon meditation and worship of the Buddha. In China this stress on meditation and rites weakened, as indicated in the teachings of three important Pure Land patriarchs, T'an-luan, Tao-ch'o, and Shan-tao, who lived during the 6th–7th century.

T'an-luan was originally a follower of Taoism, who, while searching for the elixir of immortality, was converted to the Pure Land doctrine by an Indian monk. Dedicating his life to the spread of this doctrine, T'an-luan preached the invocation of the name Amitābha and declared that even evil persons were eligible for the Pure Land if they sincerely uttered the *nembutsu.* He warned, however, that the lowest hell awaited those who reviled the Buddhist *dharma.* T'an-luan was followed by Tao-ch'o, who argued that in this degenerate age people must take the "easy path" to salvation of complete trust in Amitābha, for they no longer possessed the capacity to follow the more difficult path of the saints. His disciple, Shan-tao, believed by the Japanese Pure Land sect to be the incarnation of Amida, was primarily responsible for shaping the doctrines of the later forms of Pure Land Buddhism. This evangelist distributed many copies of the *Pure Land Sutra* and wrote a famous commentary in which he taught that rebirth in the Western Paradise is effected primarily by *nembutsu.* This must be supplemented, however, by the chanting of sutras, meditation on the Buddha, worshiping of buddha images, and singing his praises.

Salvation
by Amida's
grace:
Hōnen and
Shinran

The work of Shan-tao inspired Hōnen, the founder of the Pure Land sect (Jōdo-shū) in Japan, to declare that in this evil period people must put complete faith in the saving grace of Amida and constantly invoke his name. Hōnen, who was well versed in Buddhist knowledge, wrote a treatise (*Senchaku hongan nembutsu-shū;* 1198) expressing his beliefs. While this treatise proved popular among the common people, as were his teachings generally, it was burned by the monks of Mount Hiei and his teachings were vigorously opposed by the established Buddhist priesthood.

One of Hōnen's disciples, Shinran, who was exiled at the same time, was the founder of a more radical sect named the True Pure Land sect (Jōdo Shinshū, or Shin). Shinran married, with Hōnen's consent, proving that one need not be a monk to attain the Pure Land; and he popularized his doctrines by preaching in Japanese villages. In his teachings he rejected all sutras except the *Pure Land Sutra* and rejected the vows of Dharmākara in the *Pure Land Sutra* that stress individual merit. Basing his doctrines on the 18th vow, Shinran discouraged any attempt to accumulate merit, for he felt that this stood in the way of absolute faith and dependence on Amida. Furthermore, he rejected Hōnen's practice of continual invocation of Amida, believing that the faithful need only say the *nembutsu* once in order to attain salvation. Any repetition after this *nembutsu* must be seen as praise of Amida and not as bringing merit or affecting one's salvation. Thus, with Shinran, the doctrine of grace gained total ascendancy. A third Pure Land sect grew up around the itinerant teacher Ippen. He traveled throughout Japan, advocating the chanting of Amida's name at set intervals throughout the day; hence, his school was called the Ji ("Times") sect, or Jishū.

Music, dance, and drama have been important forms of expression of Shin. Since the late 19th century it has engaged in extensive educational and social welfare programs and has played a significant role in Japanese life. It is the largest single Buddhist sect in Japan.

Nichiren. The indigenous Japanese Nichiren school is related both to the *Lotus Sutra* and Pure Land schools, for it, too, is centred on the "Lotus of the True Law" and also emphasizes fervent faith and the repetition of a key phrase. Hence it has been aptly called "Lotus-pietism" by a famous scholar in Japanese Buddhism. Its distinctiveness is rooted in the extraordinary personality and character of its founder; significantly, it is named after a man, a historical person, not after a book or a doctrine. Nichiren (1222–82), the son of a poor fisherman, became a monk at an early age and studied at Mount Hiei, the centre of the Tendai school. Nichiren was frustrated, however, by the many paths of Buddhism promising salvation and left Mount Hiei for 10 years to search for the true path. When he emerged from his independent studies he taught that the *Lotus Sutra* (*Saddharmapuṇḍarīka-sūtra*) contains the final and supreme teaching of the Buddha Śākyamuni and offers the only true way to salvation. According to Nichiren's interpretation of this sutra, the three forms of the Buddha—the universal or law body (*dharma-kāya*), the enjoyment body (*sambhoga-kāya*), and the phenomenal body (*nirmāṇa-kāya*)—should be granted equal respect, as they are important aspects of the Buddha Śākyamuni. Following the teachings of Chih'i, the Chinese founder of T'ien-t'ai/Tendai, that the *Lotus Sutra* is the essence of Buddhism, Nichiren held that this same buddha-nature was possessed by all people and could be realized only by proper worship of the *Lotus Sutra.* Furthermore, Nichiren felt that his time, which was marked by political upheaval and unrest, was the period of degeneration known in the *Lotus Sutra* as the time of the latter-day *dharma* (*Mappō*). During this time the purity of the Buddhist doctrines could be kept only by the bodhisattvas. Nichiren identified himself as an incarnation of several of these bodhisattvas, especially the bodhisattva of supreme conduct (Viśiṣṭacāritra; Japanese: Jōgyōbosatsu), and believed that his mission was to propagate the true teachings of the *Lotus Sutra* in Japan, which he felt would become the new repository of the Buddhist *dharma.*

Importance
of the
*Lotus
Sutra*

In attempting to guide Japan to the Buddhist *dharma* as he interpreted it, Nichiren drew great criticism for his strong-willed and uncompromising attitude. In one treatise Nichiren wrote that the unrest in Japan was caused by the chaotic state of religious beliefs, a condition that could be corrected only by adopting the teachings of the *Lotus Sutra.* He taught that if people turned to this sutra, they would realize their true buddha-nature, perceive that suffering is illusion, and see that this world is a paradise. If human beings—*i.e.,* the Japanese—did not follow the teachings of the *Lotus Sutra,* however, natural disasters and invasions would result. With firm confidence in the righteousness of his cause, Nichiren attacked the Shingon and Amida sects of Buddhism for neglecting Śākyamuni, the true Buddha of the *Lotus Sutra;* and he attacked Zen for placing stress only upon Śākyamuni's historical form. These sharp criticisms led Nichiren to be exiled twice and almost brought his execution, from which he was—according to his account and the belief of his adherents—miraculously saved.

Nichiren advocated two main religious practices based on his interpretation of the *Lotus Sutra.* The first is the worship of the *honzon* (or *gohonzon*), a mandala (symbolic diagram) designed by Nichiren, representing the buddha-nature that is in all humans, as well as the three forms of the Buddha Śākyamuni. The second is the repetition of the phrase *namu Myōhōrenge-kyō* (salutation to the *Lotus Sutra*), a practice called *daimoku* ("sacred title"), as the affirmation of the devotee's belief in the teaching and efficacy of the *Lotus Sutra.* This repetition was not only to be done orally but in every action of the true believer. Nichiren also taught that there should be a sacred place of ordination (*kaidan*) where the believer could receive training in the doctrines of the *Lotus Sutra* in order that he might keep the true spirit of this document. This sacred place might be seen as wherever the believer in the *Lotus Sutra* lives, for there is the Buddhist truth. The *honzon, daimoku,* and *kaidan* constitute "the three great secret laws" (or "mysteries") that are regarded as the essential teaching of Nichiren.

The great
secret laws

Nichiren's fervent faith brought him wide fame and many devotees, and at his death he chose six disciples to continue his work. This sect was known simply as Nichiren-shū (Sect of Nichiren). It still controls the main temple founded by Nichiren at Mount Minobu. One of his disciples, Nikkō, however, soon began another sect known as the Nichiren-shō-shū (True Sect of Nichiren), which taught that Nichiren, not Śākyamuni, was the saviour and that the mandala painted by Nichiren was alone efficacious in saving mankind. In the 20th century these sects have gained many devotees.

Within the Nichiren-shū the Reiyū-kai (Association of the Friend of the Spirit) arose in 1925. This sect, which preaches a combination of ancestor cult and the doctrines of Nichiren, places faith not in the Buddha or in bodhisattvas but in the mandala, in which all saving power is concentrated. The Risshō-Kosei-Kai (Society for Establishing Righteousness and Friendly Relations) split from Reiyū-kai in 1938. This sect teaches the recitation of the *daimoku* as an affirmation of faith in the teaching of the *Lotus Sutra,* and the worship of the Buddha Śākyamuni. Like Reiyū-kai, it also allows the veneration of ancestral spirits.

Risshō-Kosei-Kai gained many converts after World War II, but its success was soon eclipsed by Sōka-gakkai, the lay movement of Nichiren-shō-shū. Sōka-gakkai ("Value Creation Society") was founded by Makiguchi Tsunesaburo in 1930, dedicated to educational research and the extension of Nichiren-shō-shū. Its founder insisted on the practical values of worldly gain and satisfaction as well as the attainment of goodness and beauty; he taught that Nichiren was to be worshiped as the True Buddha predicted in the *Lotus Sutra.* The members also fervently practice *daimoku* and worship the *honzon* as the repository of magical power. After World War II, Sōka-gakkai, under the leadership of Toda Jōsei, grew rapidly through a technique of evangelism called *shakubuku* ("break and subdue"), in which the resistance of the other person is destroyed by forceful argument. A zealous missionary movement, it has spread to many countries, including the United States. Thus, Nichiren's teaching and personality are still strong influences today.

Dhyāna (Ch'an/Zen). The Dhyāna (Chinese: Ch'an; Japanese: Zen) school of Buddhism emphasizes meditation as the way to immediate awareness of ultimate reality, an important practice of Buddhism from its origin in India, and derives its name from the Sanskrit term for meditation, *dhyāna.* The meditative emphasis in other schools of Indian origin, such as Yogācāra, has been noted above. Ch'an, with its special training techniques and doctrines and its Taoist influence, however, is generally considered a specifically Chinese product.

The enlightenment experience: Satori

Scholars point out that 4th–5th-century Chinese Buddhist monks, such as Hui-yüan and Seng-chao, were teaching doctrines and practices similar to those of the Ch'an school before the traditional date of its arrival in China, but standard Chinese texts name a South Indian monk, Bodhidharma, who came to China about AD 520, as its founder. Bodhidharma is held by Ch'an devotees to be the 28th patriarch of the Indian meditational school, which began with the monk Kāśyapa, to whom the Buddha Śākyamuni revealed his supreme teaching. This teaching is found in the *Laṅkāvatāra-sūtra,* which relates that all beings possess a buddha-nature, often equated with *śūnya* (the void) in Ch'an, and that realization of this fact is enlightenment (Chinese: Wu; Japanese: Satori). The truly enlightened one cannot explain this ultimate truth or reality, for it is beyond the ordinary duality of subject and object. Books, words, concepts, and teachers cannot convey it directly. It must be realized in immediate personal experience.

Bodhidharma, who came to be known as the first patriarch of Ch'an in China, passed his mantle to Hui-k'o; and this line of transmission continued to the fifth patriarch, Heng-jen. After his death a schism occurred between the adherents of the Northern school founded by Shen-hsui, which held that enlightenment must be attained gradually, and the Southern school of Hui-neng, which taught that true wisdom, as undifferentiated, must be attained suddenly and spontaneously. Furthermore, Hui-neng's Southern school tended to neglect rituals and literature and to rely on teaching passed from master to pupil, adopting as well an iconoclastic attitude toward the Buddha. It was reasoned that, if all things contain the buddha-nature, then the Buddha could rightfully be equated with a dung heap. Eventually the Southern school won out, and its victory is attested in the standard Chinese Ch'an texts, which name Hui-neng as the true and only sixth patriarch, as opposed to the counterclaim of Shen-hsui and the Northern school. Hui-neng's *Platform Scripture* (Chinese: *T'an Ching*) became a key text of the Ch'an school.

Two branches of Ch'an Buddhism developed from the Southern school in the 9th century: Lin-chi (Japanese: Rinzai) and Ts'ao-tung (Japanese: Sōtō). The former relied heavily on the *kung-an* (Japanese: *kōan*), a paradoxical question or aphorism that aimed at inducing the student to realize that all conceptualization is wrong, thus leading him to enlightenment. The *kung-an* were often accompanied by shouts and slaps from the master to provoke anxiety and, from this, an instant realization of the truth. The Ts'ao-tung/Sōtō school emphasized the practice of "silent illumination" or "just sitting" (Chinese: *tso-ch'an;* Japanese: *zazen*). This consisted of sitting in silent meditation under the direction of a master and—in that context—of purging the mind of all notions and concepts.

Both schools followed the doctrine of Huai-hai, who taught that a monk who would not work should not eat and that the work (as well as everything else) should be done with spontaneity and naturalness. The emphasis on work made the Ch'an schools self-sufficient and helped to save them from the worst effects of the purge of supposedly parasitic Buddhist monks by the government in 845. The emphasis on spontaneity and naturalness stimulated the development of a Ch'an aesthetic that had a profound influence on later Chinese painting and writing. The relative success the Ch'an tradition was able to achieve in the subsequent religious history of China is demonstrated by the fact that virtually all Chinese monks eventually came to belong to one of the two Ch'an lineages.

Influence of Zen

Ch'an (Zen) Buddhism was introduced into Japan as early as the 7th century, but it did not flower until the 12th century, in the work of two monks, Eisai and Dōgen. Eisai, founder of the Rinzai school in the 12th century, was a Tendai monk who wished to restore pure Buddhism to Japan and with that aim visited China. When he returned, he taught a strict meditational system based on the use of the *kōan* phrases; however, this was taught as only one element in the Tendai system. Unlike the Ch'an schools, Eisai also taught that Zen should defend the state and could observe ceremonial rules and offer prayers and incantations. These teachings influenced the warrior class and led to a Zen influence over the martial arts of archery and swordsmanship. Zen influence can also be seen in the nō play, poetry, flower arrangement, and the tea ceremony, all of which stress grace and spontaneity.

Dōgen, who established the Sōtō school in Japan in the 13th century, joined the Tendai monastery of Mount Hiei at an early age, after the death of his mother and father had dramatically taught him the transitoriness of life. Searching for the true path of Buddhism, he, like Eisai, journeyed to China, where he fell under the influence of a Chinese Ch'an master. Upon his return to Japan, he taught a discipline of "sitting straight" (*zazen*) without any effort being directed toward achieving enlightenment. Unlike many of his Chinese counterparts, however, Dōgen studied scriptures and criticized those who did not.

The two Zen sects founded by Eisai and Dōgen have deeply influenced Japanese culture, and they continue to play a very significant role in contemporary Japan. By the mid-20th century Zen had become perhaps the best known of the Buddhist schools in the Western world.

(Gi.T./F.E.R.)

ESOTERIC BUDDHISM

Mystical practices and esoteric sects are to be found in all forms of Buddhism. In the course of history the mystical tendency that had suffused Buddhism as an aspect or element of Indian religion as a whole became increasingly pronounced. Following the codification of early Buddhism in the Theravāda canon and the subsequent emergence of Mahāyāna about the 1st century AD, this element began to precipitate into discrete schools of thought.

Buddhist mysticism (including the philosophical school of Ch'an, above), like other forms of mysticism, insists on the ineffability of the mystical experience, because it defies expression in terms that are intelligible to anyone who has not had analogous experience. The knowledge involved is never merely intellectual but is a kind of felt knowledge in which things are seen in a different perspective and take on a new significance. Related to its ineffability is the timeless quality of this experience, which means that the mystic seems to be outside time and space, oblivious to his surroundings and the passage of time.

The earliest Buddhist mysticism was concerned with the emptying of subjective being, considered to be the greatest obstacle to the individual's spiritual growth. This passing into a new dimension of reality was described in terms of a flame going out: it was merely extinguished; it could not be said that it had gone somewhere. In this emptying process the limits that constitute the individual's being, as defined by an analysis of both physical and mental components, were transcended, although all these components were said to be retained. The experience of this new dimension of reality was a vision in marked contrast to normal perception—a vision that went far beyond the reach of "mere logic."

While early Buddhism (as preserved in Theravāda) was analytical in its attempt to free reality from the imposition of subjectivity, Mahāyāna continued the analytical process by extending it to objective reality. In its rejection of subjectivism and objectivism, it emphasized the nature of reality-as-such, which was experienced in enlightenment (bodhi). While the various philosophical trends associated with the emergence and development of Mahāyāna dealt with the intellectual problem of reality, shorn of all its positive and negative qualifications, the tantras ("treatises"), which form the distinctive literature of Esoteric Buddhism, dealt with the existential problem of how it is or feels to attain the highest goal.

Vajrayāna Buddhism in India. *Origins.* Vajrayāna ("Diamond Vehicle") or Mantrayāna ("Path of the Sacred Formulas"), also known as Tantric Buddhism, first gained prominence in various parts of India and Sri Lanka. Scholars infer that, because of the esoteric nature of Tantric practice and doctrine, this school might have been developing quietly from the 2nd or 4th century AD, when Buddhist tradition associates Nāgārjuna or Asaṅga with its origins. Although a modified version of Vajrayāna Buddhism, apparently without sexoyogic practices, spread to China and then to Japan, where it became known as Shingon, most scholars associate the Vajrayāna tradition primarily with India and Tibet.

Identity and unity of opposites

Although Vajrayāna texts describe numerous yogic or contemplative stages that an aspirant must experience before achieving enlightenment, rather than elaborating doctrines, they hold the Mahāyāna identification of nirvana and samsara as a basic truth. Moreover, Vajrayāna maintains that nirvana as *śūnyatā* (voidness) is one side of a polarity that must be complemented by karuna (compassion of the bodhisattva). *Śūnyatā* is seen as passive wisdom (prajna) that possesses an absolutely indestructible or diamondlike (*vajra*) nature beyond all duality, whereas karuna is the means (*upāya*) or dynamic aspect of the world. Enlightenment arises when these seeming opposites are realized to be in truth one. This realization, which is known experientially and not through a purely cognitive process, is portrayed in some types of Vajrayāna imagery and practice as the union of the passive female deity, which signifies wisdom or voidness, with the dynamic male, signifying compassion without attachment. Such a union, called *yab-yum* ("father-mother") in Tibetan, is not a satisfaction of physical impulses but a symbol of the unity of opposites that brings the "great bliss," or enlightenment.

Adherents of the Vajrayāna tradition believe that as all things are in truth of one nature—the void—the physical-mental processes can be used as a vehicle for enlightenment. In the *Kālacakra Tantra* it is written that the Buddha taught that in this age of degeneration enlightenment must be achieved through one's own body, which contains the whole cosmos. This doctrine is taught in all the tantras. Vajrayāna specialists warn, however, that in order to use correctly the body's processes to achieve an identification of the void with compassion, the aspirant must follow absolutely the instructions of a master or teacher who has been initiated into the mysteries. Such a master alone can direct every step so that the pupil learns to control mental and physical processes instead of being dominated by them. Therefore, the first step toward enlightenment in Vajrayāna practice is the undergoing of initiation by a master.

Figure 4: Tibetan Buddhist monk reading with handbell in Lamayuru Monastery, Ladakh, India.

The master first endeavours to direct the student to compassion through meditation on the transitoriness of life, the relation of cause and effect of one's actions, and the general suffering of humanity. After this sympathy for the suffering of humanity is aroused, the master guides his pupil in yogic, or contemplative, exercises that help to produce inner experiences corresponding to the various stages of spiritual growth. This process of advancement toward enlightenment involves the identification of the initiate with gods or goddesses that represent various cosmic forces. These gods are first visualized with the help of mudras (meditative gestures and postures), mantras (sacred syllables and phrases), and icons, all of which are believed to possess the essence of the divinities to be invoked. The icons are portrayed in a mandala, a sacred design that represents the universe as an aid to meditation. After this visualization, the initiate identifies with the divinities and finds that each in turn is *śūnyatā,* or voidness.

The four stages

The culmination of this process, called *vajrasattva yoga,* gives the initiate a diamondlike body beyond all duality. Four stages in the process are described in four different groups of tantras, the *Kriyā-tantra, Caryā-tantra, Yoga-tantra,* and *Anuttarayoga-tantra.* These four stages are likened to the fourfold phases of courtship: the exchange of glances, a pleasing or encouraging smile, the holding of hands, and consummation in the sexual act. The first stage involves external ritual acts, whereas the second combines these outward acts with contemplation. The third stage involves only contemplation, and the fourth is the unification of all dualities in the sexual act, symbolically or effectively. This last stage, however, is divided into two phases. The first involves the use by the initiate of controlled imagination, which allows him to experience the union on an ideational level. The second phase is the *maithuna,* or sexual coupling. This act, however, cannot be construed as an ordinary physical mating, because the initiate has already realized the voidness of all things, allowing him to act with perfect control over his emotions and without attachment. Whereas the ordinary sexual act gives rise to only momentary pleasure, this *maithuna* is considered to be an appropriate technique for attaining enlightenment and eternal bliss.

These Vajrayāna practices have been unjustly condemned as a degeneration of Buddhism by those who do not look beyond the surface. It is quite easy to misinterpret the *Guhyasamāja-tantra* when it states that adultery and eating of human flesh are actions of the bodhisattva if one does not realize that this imagery points to the belief that voidness alone exists, beyond good or evil, or that the initiate must act only with compassion for the benefit of the salvation of the world. Once the true depths of Vajrayāna doctrines and practices are perceived, this school can be designated as a development of Buddhist thought that emphasizes the attainment of enlightenment through a graduated process of meditation under the direction of an initiated teacher.

Vajrayāna literature. While the sutras can be said to represent the theoretical and speculative aspect of Buddhism, the tantras, written in a highly figurative language, express Buddhism as individually lived. The tantras are essentially individually oriented works that apply to larger groups of persons because of the similarity of the experiences described in them. The individual spiritual development occurs through symbols that must not be reduced to signs; a symbol always points beyond itself. Because of this symbolic character, the tantras have usually been kept secret, and a literalist interpretation of such texts has usually failed to make any sense out of them.

The *Guhyasamāja-tantra* ("Treatise on the Sum Total of Mysteries"), also known as the *Tathāgataguhyaka* ("The Mystery of Tathāgatahood [Buddhahood]"), is the earliest known written tantra. It is by tradition ascribed to the renowned Indian scholar Asaṅga (*c.* 4th century AD), the propounder of the Yogācāra philosophy. Usually the tantras do not give an explanation of the technical or symbolic terms, as this explanation is left to the teacher, but the *Guhyasamāja-tantra* devotes a very long chapter to the elucidation of these terms.

Polarity symbolism

An important feature of all tantras is a polarity symbolism, which on the physical level appears as the union of male and female; on the ethical level it appears as the union of beneficial activity and an appreciation of what there is as it is; and on the philosophical level it appears as the synthesis of absolute reality and absolute compassion. The richness of this symbolism is already indicated in the opening of the *Guhyasamāja,* where the absolute, which is depicted as a polarity, manifests itself in various mandalas (circular diagrams that have both a psychological and cosmic reference), each related to one of the celestial, meditational buddhas—Akṣobhya, Vairocana, Ratnasambhava and Amitābha, and Amoghasiddhi—each of whom again represents a polarity, portrayed in iconographic works through their union with their female consorts.

The ideas and symbols presented in the *Guhyasamāja-tantra* became in the course of time more and more clearly elaborated. Because the tantras reflect an individual process of growth, the centre toward which this process gravitates, and from which it is also fed, appears in various symbols given various designations. Thus, there is the *Hevajra-tantra,* in which the sustaining life force is called *Hevajra,* and the *Mahāvairocana-tantra,* in which it is called Mahāvairocana ("The Great Resplendent One").

In view of the fact that the tantras may emphasize either "beneficial activity" or "appreciative awareness" or their "unity," the Tantric literature has been divided into the so-called *Father Tantra* (emphasizing activity), the *Mother Tantra* (emphasizing appreciation), and the *Nondual Tantra* (dealing with both aspects unitively). Almost all these works have been lost in their original Sanskrit versions, but their influence is noticeable in such works as *Jñānasiddhi* ("Attainment of Knowledge") by the great Vajrayāna teacher Indrabhūti (*c.* 687–717), *Prajñopāyaviniścayasiddhi* ("The Realization of the Certitude of Appreciative Awareness and Ethical Action") by the 8th-century writer Anaṅgavajra, and the songs of the 84 *mahāsiddhas* ("masters of miraculous powers," who were considered to have attained the Vajrāyana goal). One of the last Sanskrit works to have been written in Central Asia was the *Kālacakra-tantra.* Its penetration into India may be dated AD 966. The central theme is the Ādi-Buddha—primeval buddhahood—manifesting itself as a continuum of time (*kāla*) and space (*cakra*).

Vajrayāna schools in Tibet. During the period when Tibet was being converted to Buddhism (7th to 11th centuries), the most dynamic form of Buddhism in India was Vajrayāna. Thus, it was this Buddhist tradition that became established in Tibet. Though it is probable that some form of Vajrayāna played an important role in the original conversion of Tibet (7th to 9th centuries), little is known about the details. Beginning in the 11th century, however, it is possible to identify several different schools.

Like most Buddhist schools, those that developed within the Tibetan tradition were highly permeable associations that encompassed a number of different and often competing lineages. This having been said, it is still possible to single out several groupings.

Rnying-ma-pa. Among the various Vajrayāna schools of Tibet and neighbouring regions, the Rnying-ma-pa claims to preserve most purely the spirit of the teachings of the 8th-century Indian miracle worker Padmasambhava. It makes fuller use than any other school of a group of "discovered" texts, said to have been hidden since the period of persecution that began in Tibet in the first half of the 9th century. (In the Rnying-ma-pa tradition the notion of "hidden treasure" has strong spiritual as well as historical overtones.) The discoveries of hidden texts associated with Padmasambhava began to occur in the 11th century and have continued until very recently.

Discovered texts

The Rnying-ma-pa order divides Buddhist revelation into nine progressively superior groups; it also subdivides the tantras in a manner somewhat different from the way they are divided in other Vajrayāna schools. Six groups of tantras are enumerated: (1) *Kriyā,* or ritual, (2) *Upayoga,* which involves the convergence of the two truths and meditation on the pentad of buddhas, (3) *Yoga,* which involves the evocation of the god, the identification of the self with the god, and meditation on the mandala (ritual drawing), (4) *Mahāyoga,* which involves meditation on the factors of human consciousness (skandhas) as divine forms, (5) *Anuyoga,* which involves secret initiation into the presence of the god and his consort and meditation on "voidness" in order to destroy the illusory nature of things, and (6) *Atiyoga,* which involves meditation on the union of the god and his consort, leading to the experience of bliss. Those initiated into the *Kriyātantra* can attain buddhahood after seven lives, the *Upayoga* after five lives, the *Yoga* after three lives, the *Mahāyoga* in the next existence, the *Anuyoga* at death, and the *Atiyoga* in the present existence.

Among the exponents of the Rnying-ma-pa tradition, Klong-chen rab-'byams-pa (1308–63), who wrote the *Klong-chen-mdzod-bdun* ("Seven Treasures of Klong-chen"), is one of the most profound Vajrayāna thinkers. More recently, Mi-'pham of Khams (1846–1914) wrote important Vajrayāna commentaries on the canonical texts.

Sa-skya-pa, Bka'-brgyud-pa, and related schools. Several Tibetan schools that came into being during the 11th and 12th centuries traced their lineage back to particular Vajrayāna saints who had lived in India some centuries earlier. Among these the Sa-skya-pa and the Bka'-brgyud-pa orders were especially prominent, and during the course of Tibetan history they gave rise to many other orders.

The Sa-skya-pa order traces its lineage back to an Indian *mahāsiddha* named Virupa. The order's founder was a Tibetan named 'Brog-mi (992–1072) who went to India, received training in the Vajrayāna, and translated the *Hevajra-tantra* into Tibetan; the order places a strong emphasis on this tantra. The Sa-skya-pa system is also called *lam-'bras* ("the path and its fruit").

The Sa-skya-pa order produced many great translators, and its scholars also contributed original works on Vajrayāna philosophy and linguistics. On the ecclesiastical and political level the order sometimes exerted considerable power. During the 13th century, for example, the Sa-

Initiation of Kublai Khan

skya-pa abbot ’Phags-pa (1235–80?) conferred initiation according to the *Hevajra-tantra* on Kublai Khan (founder of the Yüan, or Mongol, dynasty in China) and in turn was appointed *ti-shih* (Chinese: “Imperial Preceptor”) and invested with the authority to govern Tibet, though under the control of the Mongol court.

The Bka’-brgyud-pa school traces its spiritual lineage from the Indian master Tilopa, who transmitted the teachings to the Indian yogi Naropa, the master of Mar-pa, the 11th-century householder-teacher, who was in turn the master of Mi-la-ras-pa (1040–1123). The school has preserved an important collection of songs attributed to Mi-la-ras-pa and a fascinating hagiographic account of his life. Sgam-po-pa (1079–1153), who was his greatest disciple, did much to systematize the teaching and to establish the basis for further development. His most famous work, *Thar-rgyan* (“The Jewel Ornament of Liberation”), is one of the earliest examples of a genre that became extremely important in the later development of the Vajrayāna tradition in Tibet and Mongolia. Known as *Lam Rim* (“Stages on the Path”), this genre presents the whole of Buddhist teachings in terms of gradations in a soteriological process leading to the attainment of buddhahood.

The Bka’-brgyud-pa teachers stressed, among other techniques, the exercises of Haṭha Yoga (a yoga emphasizing breathing and special postures) and posited as the supreme goal the *mahāmudrā* (“the Great Seal”), or the overcoming of dichotomous thought in the emptiness of buddhahood. Frequent reference is made by the Bka’-brgyud-pa to the “Six Teachings of Naropa.” These teachings set forth techniques for attaining enlightenment, either in this life or at the moment of death, that are associated with: (1) self-produced heat (the voluntary raising of the body temperature), (2) the illusory body, (3) dreams, (4) the experience of light, (5) the state of existence intermediate between death and rebirth (Bardo), and (6) the passing over from one existence to another.

Among the many lineages that have developed within the Bka’-brgyud-pa order, the one that is best known today is the Karma-pa (Black Hat) lineage, which has its major centre at the monastery of Mtshur-phu.

The Bka’-gdams-pa and Dge-lugs-pa. The Bka’-gdams-pa school was based on the teachings of Atīśa (an Indian monk who came to Tibet in the 11th century). It was founded by his chief disciple, ’Brom-ston (*c.* 1008–*c.* 1064), who emphasized austere discipline. The school produced the *Bka’-gdams gces-bsdus* (“Collection of the Sayings of the Bka’-gdams-pa Saints”), which preserves the often highly poetic utterances of those close to the founder. The central practice of the school was the purification of the mind, which required the elimination of intellectual and moral blemishes in order to obtain a clear vision of emptiness (*śūnyatā*). The school relied on the *Prajñāpāramitā* and related texts and also made use of mantras. The Bka’-gdams-pa order was absorbed in the 15th century by the Dge-lugs-pa school.

Reforms of Tsong-kha-pa

The Dge-lugs-pa (Gelugpa; the “Virtuous”) represents the reformed sect in Tibet; its members are commonly known as Yellow Hats from the colour of their head cover. Their founder, Tsong-kha-pa, attended the most important schools in 14th-century Tibet, the Sa-skya-pa, Bka’-brgyud-pa, and Bka’-gdams-pa. His own school is considered the continuation of the Bka’-gdams-pa. Tsong-kha-pa was prompted to initiate a reform of monastic discipline by what he considered to be a general laxity of morals, an increasingly less rigorous observance of monastic rules, and the prevalence of deviations in the interpretation of the tantras. He imposed respect for the traditional rules of the *Vinaya* and placed renewed emphasis on dogmatics and on logic as aids to salvation. His treatise, the *Lam-rim chen-mo* (“The Great Gradual Path”), is based on the *Bodhipathapradīpa* by Atīśa. In it Tsong-kha-pa presents a process of mental purification ascending through 10 spiritual levels (*bhūmi*) that lead to buddhahood. The essential points of such a process are the state of quiescence and the state of enhanced vision.

Tsong-kha-pa attributed great importance to the study of logic and instituted regular debates at monasteries. Competing monks sought to reach, by means of formal logic and in the presence of an abbot of great learning, an unassailable conclusion on a chosen topic. Various ranks of monks were established on the basis of examinations, the highest being that of *dge-bshes* (the philosophers).

This insistence on the importance of doctrinal and logical problems did not exclude interest in the tantras, and Tsong-kha-pa’s *Sngags-rim chen-mo* (“The Great Gradual Tantric Path”) deals with Tantric ritual. Tantric initiation, however, was open only to those students who had previously mastered theoretical learning. The literature of the Dge-lugs-pa is enormous, including also the gigantic collections of the Dalai and Panchen lamas, both of whom are members of this school.

The Dge-lugs-pa assert that the nature of the mind element (*sems*) is light, which constitutes the cognitive capacity. The continuum of each person, therefore, is a thinking and luminous energy, which is in either a coarse or subtle state, the latter state being achieved only after purification through meditation and contemplation.

(Gi.T./H.G./F.E.R.)

Esoteric traditions in China and Japan. During the 7th, 8th, and 9th centuries the Vajrayāna forms of Esoteric Buddhism that were developing in India spread to Southeast Asia (for example, to Indonesia, where Esoteric teachings were an important component in the symbolism of the great Buddhist stupa at Borobuḍur) and to East Asia. In East Asia Esoteric Buddhism became established in the Chen-yen (“True Word”) school in China and in the Tendai and Shingon schools in Japan.

The basic Chen-yen texts

Chen-yen. According to the Chen-yen tradition, developed and systematized forms of the Esoteric tradition were first brought from India to China by three missionary monks: Śubhākarasiṃha, Vajrabodhi, and Amoghavajra. Śubhākarasiṃha arrived in China from the famous Indian centre of learning at Nālandā in 716, and he translated into Chinese the *Mahāvairocana-sūtra* and a closely related ritual compendium known as the *Susiddhikāra*. Vajrabodhi and his disciple Amoghavajra arrived in 720 and produced two abridged translations of the *Sarvātathāgatatattvasaṃgraha* (“Symposium of Truth of All the Buddhas”), also known as the *Tattvasaṃgraha*. The *Tattvasaṃgraha* and the *Mahāvairocana-sūtra* became the two basic Chen-yen texts.

In the period of approximately 130 years between the arrival of Śubhākarasiṃha and the great persecution of 845, the Chen-yen school enjoyed amazing success. The tradition represented by Śubhākarasiṃha and the *Mahāvairocana-sūtra* and the tradition represented by Vajrabodhi and the *Tattvasaṃgraha* were melded. Chinese disciples such as Hui-kuo were initiated into a common lineage and contributed to an emerging Chen-yen synthesis. Through a combination of sophisticated doctrinal instruction and the exercise of the miracle-working powers supposedly conferred by the Esoteric rituals, the Chen-yen leaders won the confidence of the court, especially of Emperor Tai-tsung (762–779/780), who rejected Taoism in favour of Buddhism in its Chen-yen form. Chen-yen became a dominant force among the Chinese elite.

After the great persecution of 845, Chen-yen lost its position of prominence in China, but it maintained a certain degree of spiritual vitality and communal visibility on through the Sung dynasty (960–1279). Moreover, the Chen-yen school contributed a variety of elements—particularly ritual elements—that have become persisting threads within the larger fabric of Chinese religion.

Shingon. Though Esoteric Buddhism played a much greater role in China than is usually recognized, it was in Japan that it became most firmly established and exerted its most extensive influence. Esoteric elements, called Taimitsu in Japanese, became and have remained an important element in the Japanese Tendai school (see above). The Tendai school was founded by the monk Saichō (764–822), who studied with Chen-yen and T’ien-tai masters in China. The most systematized and elaborated expressions of the Esoteric tradition, however, were developed in the Shingon school, the Japanese version of Chen-yen.

The founder of the Shingon school in Japan was Kūkai, better known by his posthumous name, Kōbō Daishi (“Great Master Who Understood the *Dharma*”). He was an exceptional scholar, poet, painter, and calligrapher who early in life wrote a treatise comparing Confucian, Taoist, and Buddhist thought, naming the latter as superior. Although he had trained for government service, he experienced a change of heart and became a Buddhist monk. In pursuit of the pure Buddhist doctrine, he, like many great monks of his time, journeyed to China, where he met the Chen-yen master Hui-kuo, who recognized Kūkai's potential and bestowed upon him the teachings of his school. After the death of Hui-kuo, Kūkai returned to Japan, where he received many governmental honours and established a monastery on Mount Kōya as the centre of Shingon Buddhism.

In propagating the teachings of his sect, Kūkai wrote many important texts, including the *Jūjū shinron* ("The Ten Stages of Consciousness") and the *Sokushin-jōbutsugi* ("The Doctrine of Becoming a Buddha with One's Body During One's Earthly Existence"). In the first of these treatises, Kūkai presented a theory of the development of the spiritual life of human beings by placing the teachings of Buddhist schools and several other religions into a hierarchical system. He taught that the first stage of human spiritual development was one in which human beings are completely controlled by their instincts. In the second stage, which Kūkai identifies with Confucian teachings, human beings attempt to live a proper moral existence. The third stage is that of Brahmanism and Taoism, where the individual strives for supernatural powers and heavenly rewards. The fourth and fifth stages of spiritual development are taught by the Hīnayāna schools and are characterized by the striving for self-enlightenment. The next stages, from six to nine, are Mahāyānist paths identified with the teachings of Hossō, Sanron, Tendai, and Kegon, which lead the individual to compassion for others. The zenith of spiritual development is identified by Kūkai with the esoteric teachings of Shingon.

The stages of spiritual development

The Shingon school preached that it possessed the highest and purest doctrine, for its beliefs were not based on the teachings of the historical Buddha, Śākyamuni, who expounded the doctrine with limitations of his audience in mind, but on the timeless and immutable teachings of the Buddha in his *dharma-kāya,* or cosmic body. This Buddha, named Mahāvairocana, was felt to be beyond all earthly dualism and impurity but at the same instant to be within all things as their buddha-nature.

In Shingon the realization that one's own buddha-nature is identical with Mahāvairocana is enlightenment. This enlightenment, as depicted in the title of Kūkai's treatise mentioned above, can be achieved in this world while possessing a human body. In order to achieve this enlightened state, however, one must be given the secret doctrine of Shingon. The gift of this doctrine is handed down to the aspirant only orally by the Shingon master. The truth that the master reveals is founded on the three ritual mysteries of the body, speech, and mind. These mysteries invoke the cosmic forces embodied in the form of buddhas and bodhisattvas with which the aspirant identifies until he can become one with Mahāvairocana. The experience of the mystery of the body involves the use of mudras: various devotional gestures of the hands and fingers in accordance with the buddha to be invoked, postures of meditation, and the handling of such sacred instruments as the *vajra* (diamond) and the lotus. Experiencing the mystery of speech involves the recitation of dharanis or mantras, which are mystical verses and sounds believed to be the essence of the cosmic forces with which one wishes to commune. Attaining the mystery of the mind involves yogic contemplation of and absorption in the Buddha Mahāvairocana and his attendants.

The aspirant was further helped in his quest to identify his buddha-nature with the Cosmic Buddha by means of two sacred drawings, or mandalas, often placed on the Shingon altar. These mandalas, believed to contain all the power of the cosmos, were drawn in accordance with the teaching of Hui-kuo that the doctrines of the Buddha Mahāvairocana were so deep and abstruse that their meanings could be conveyed only in art. One mandala, called the "Diamond Mandala" (based on the *Tattvasaṃgraha* and known in Japanese as *kongō-kai*), portrayed the Buddha Mahāvairocana sitting upon a white lotus in deep contemplation, surrounded by the buddhas of the four regions. This symbolized Mahāvairocana's indestructible, immutable, or potential aspect. The second mandala, called the "Womb Mandala of Great Compassion" (based on the *Mahāvairocana-sūtra* and known in Japanese as *taizō-kai*), revealed Mahāvairocana sitting on a red lotus surrounded by innumerable buddhas, bodhisattvas, and Indian gods, with consorts. This represents the Cosmic Buddha's dynamic manifestation in which he is immanent in everything. Through the correct meditation on these two mandalas it was believed that the aspirant would realize the unity beyond the diversity of the world.

The emphasis of Shingon upon ritual, symbolism, and iconography, coupled with the government's praise of Kūkai and the bestowal upon him of the shrine for the protection of the country, led to a great popularity of Shingon among the Japanese. Many people came to use Shingon rites, believed to control the forces of the cosmos, to ward off evil and bring supernatural help in everyday life. The popularity of Shingon was one of the causes for the growth of Ryōbu Shintō ("Two Aspects Shintō"), which identified Shintō gods with bodhisattvas. While this combination of Esoteric Buddhism with more this-worldly concerns led to some schisms in Shingon, it has continued as one of Japan's strongest Buddhist sects. (Gi.T./F.E.R.)

Popularity of Shingon

Mythology

Myth in Buddhism is used at various intellectual levels in order to give symbolic and sometimes quasi-historical expression to apprehended or presumed religious truths. Accepted on its own terms, Buddhism is a supernatural religion in the sense that, without a buddha to reveal them, the truths remain unknown. Only after human beings have received the Buddha revelation can they proceed apparently by their own efforts. This teaching was explicit in the early schools, in which the revelation was still thought of as historically related to Śākyamuni's mission in the world. Gradually the idea formed, in some schools, of the Buddha's continuous revelation and gracious assistance, deriving from his glorified state of time-transcending Enlightenment. Thus the comparatively simple mythology of the great Buddha myth developed into the far more elaborate mythology of the Mahāyāna.

The acceptance of the mythology, whether early or fully developed, depends upon faith. Without faith the whole religion crumbles to nothing, and nothing is left but a demythologized supposedly historical figure who has no special revelation to give. He becomes a wandering ascetic of ancient India, like the many others known to scholars, and his religion has no explanation. One must, thus, emphasize that it was the extraordinary combination of the historical Śākyamuni and the relevant myth that he was seen to fulfill that set the whole great religious tradition known as Buddhism on its varied historical course.

It has been observed also how myth is continually used at second or even third remove to bolster the primary myth and to give it a more convincing expression. These subsidiary forms of myth include, for example, stories about the recitation of the Buddhist canon soon after Śākyamuni's decease, details of his previous lives, and descriptions of the six spheres of rebirth. Some Buddhist traditions take these subsidiary forms of myth more seriously than others. Within each tradition there are variations among individual adherents. But, even for those Buddhists who are most skeptical, the various myths associated with the Buddha and his saving activity remain central and useful. They rest on premises always provisional but, insofar as they serve the gaining of the chief objective, never really false.

ŚĀKYAMUNI IN LITERATURE AND ART

Traditional literary accounts. The traditional biographies of Śākyamuni, in whatever language they are written, all derive ultimately from early Indian extracanonical rearrangements of the still earlier, scattered canonical accounts of his great acts. The best-known of the Indian "biographies" are the Sanskrit works, the

Mahāvastu, the *Buddhacarita,* and the *Lalitavistara;* the Chinese *Abhiniṣkramaṇa-sūtra,* translated from an Indian original; and the Pāli *Nidānakathā,* as well as the commentary on the *Buddhavaṃsa.* These early works themselves are the result of a continual traditional growth, and to ascertain the dates of their final versions helps in no way to estimate the actual age or reliability of much of the material they contain. All that can be said is that this material agrees substantially with the earliest known fragmentary canonical accounts and that, once presented in coherent biographical form, there are only minor variations in the later "national" versions of the story. The later Sinhalese, Thai, Myanmar (Burmese), and Kampuchean stories are all firmly based on the earlier Pāli versions. The Koreans and Japanese have derived their accounts direct from the Chinese, who in turn derive their traditions, via Central Asia, from Indian sources. The Tibetans, who represent the extreme limits of Indian Buddhist developments, draw their versions from the same earlier Indian versions. The biography of Śākyamuni included by the Tibetan historian Bu-ston (1290–1364) in his *Chos 'byung* (*History of Buddhism*) differs from other traditional accounts only by its listing of the later Mahāyāna doctrines as part of Śākyamuni's teaching program on Earth. All in all, the unity of the mythological and quasi-historical interpretations of the life and death of the "historical" Buddha, in whatever Buddhist country they have been retold, remains impressive.

Myths and biographies of the Buddha

The kernel of truth in the claim of the Theravādin Buddhists of Sri Lanka and mainland Southeast Asia to represent unadulterated "original Buddhism" derives from the fact that they have remained faithful to the early enthusiastic acclamation of Śākyamuni as the one and only Buddha of the present dispensation. Though other buddhas were recognized from a very early date, the attention of the early community was focused almost exclusively on the person and activities of Śākyamuni.

All of the early canonical accounts agree in describing Śākyamuni's experience of Enlightenment as a definitive victory over Māra, the Evil One, and as resulting in a threefold knowledge: that of his own previous births, that of the births and deaths of all other sentient beings, and that of the saving insight that brings final release from the whole unhappy process. However symbolically one may treat the descriptions of the various possible spheres of rebirth among gods, humans, animals, ghosts (pretas), and the denizens of hell, belief in the cosmological myth of continual rebirth is an integral component in the fundamental myth.

Śākyamuni was acclaimed "Great Sage" (Mahāmuni) and Lord (Bhagavat) not because he achieved a state of spiritual equilibrium in the context of ordinary existence but because he attained the supramundane state of nirvana. There are no textual indications that he was ever regarded by his followers as a kind of Socratic sage but rather as a typical perfected yogi (ascetic with magical powers) of his day, possessed—as was then expected—of miraculous powers and divine insight, combined with an altogether extraordinary concern for the spiritual advancement of others. Thus, from the first, his state of Enlightenment, or buddhahood, was recognized as "transcendent" (*lokottara*) and as the transient embodiment of such supramundane knowledge. Śākyamuni was identified with the pre-Buddhist Indian myth of the "Great Man" (Mahāpuruṣa), conceived of as the universal religious teacher who appears on Earth when the circumstances are ripe.

The myth of the Mahāpuruṣa

He was thus accepted as the seventh in an imagined series of previous buddhas. Why the seventh is not known, unless the number was derived from astronomical association, and the question may be pointless from the mythical viewpoint. His contemporary Mahāvīra, leader of the Jains, was linked to a similar series of 24. The essential mythical idea consists not in the numbers but in the notion of a necessary soteriological process. The title Tathāgata, probably meaning "He Who Has Thus Attained," is regularly used by Śākyamuni of himself, and it would seem likely (whatever 19th-century demythologizing scholars might say to the contrary) that he did indeed use this title. Apart from such utter confidence in his achievement, his religious movement would doubtless have died with him.

Not only do buddhas appear at more or less regular intervals, but the final appearance of any buddha is the culmination of a whole series of previous lives, during which he gradually advances toward enlightenment. Such a belief accords with the whole worldview in which Buddhism had its origin, and it may be supposed fairly that Śākyamuni believed this of himself. In any case, the earliest known Buddhist tradition most certainly presented him as so believing. Popular mythology soon set to work to give some tangible substance to the fundamental myth, and no scholar would doubt that the stories of Śākyamuni's previous lives (Jātaka), included in such profusion in the early canonical texts, are accretions, culled from Indian folk literature in order to exploit an opportunity provided by an aspect of the fundamental myth.

Another example of an aspect of the fundamental myth supplemented by later additions concerns Māra, the Evil One, who represented the force of spiritual evil that Śākyamuni was conscious of having confronted and overcome. Māra is explicitly identified as Concupiscence and as Death, the twin foes of all those who strive toward the tranquil and immortal state of nirvana. At the same time, he is identified with various demons and evil spirits, and the texts usually describe him in these terms. It should be noted that the definitive victory over Māra, on whatever spiritual or popular level this may be understood, remains an inalienable element of the myth. It is just as important as the belief, universally attested in the earliest traditions of all Buddhists, in the omniscience and the miraculous powers of Śākyamuni.

Since Śākyamuni's followers were interested in him as a marvelous being and a transcendent Buddha, such historical reminiscences as may have been preserved in the story are incidental to the recounting of such things as the great acts of his previous lives, his miraculous birth in his last life, the drama of his final Enlightenment while sitting under the pipal tree, his stupendous decision to convert and save others (as symbolized by his first sermon in the Deer Park near Vārānasi [Benares]), and his final decease at Kusinārā.

Śākyamuni in art and archaeology. The primary Buddhist monument, both in early Buddhism and in Buddhist usage to the present day, is the stupa, originally a reliquary mound or tumulus. The cult of the stupa may be attested archaeologically from the 3rd century BC onward, but the canonical literary tradition of all Buddhist lands links this all-important cult to the great events associated with Śākyamuni's decease. Mythologically the stupa becomes

The cult of the stupa

Pramod Chandra

Figure 5: Devotees worshiping at a stupa, the monument that symbolizes the Buddha's Parinirvāṇa, or final transcendence. Detail of a Bhārhut stupa railing, mid-2nd century BC. In the Indian Museum, Calcutta.

the supreme symbol of the Buddha in his fully realized state beyond the bonds of mortality. Carved stonework preserved from the 2nd century BC onward, especially from the ancient stupas of Bhārhut and Sāñchi in India, reveals the total identity of the great Buddha myth, as it has been revealed in the texts and the monuments. The scenes portrayed are those not only of the great events of Śākyamuni's last life but also of the great events of his previous births (Jātaka).

It is noteworthy that in the earliest period (viz, the centuries BC) the supramundane lord is represented by symbols—a tree indicating his Enlightenment, a wheel his first preaching, and a miniature stupa his final nirvana. Such was felt to be the sanctity of his being, that, after his birth as Śākyamuni, even before his Enlightenment, he was not physically portrayed. The tree cult itself involved ancient pre-Buddhist traditions that coalesced with the act of the Enlightenment as performed beneath the pipal or bodhi tree. The wheel was both the symbol of the universal monarch (*cakravartin*) and of the Buddha as universal guide and teacher. The stupa cult, with its extraordinary preoccupation with human relics, may have been a special Buddhist development, related to the clearly expressed faith in nirvana as a supramundane state. It is in marked contrast with the usual Hindu (Brahmanic) horror of mortal remains as unclean.

Śākyamuni began to be figured in sculpture in northwestern India from about the 1st century BC onward, and stereotyped presentations of him soon became the model for future use throughout Asia. Common types of Buddha image are those that represent his calling the earth to witness against Māra by touching it with the fingertips of the right hand, the meditating Buddha protected by a cobra's hood, and the Buddha lying on his right side as he enters final nirvana. The Buddha protected by a cobra's hood represents a coalescing of the Buddha myth with the pre-Buddhist cult of snakes as protecting divinities (the naga cult). This coalescence was justified canonically by a legend that recounts an occasion on which the Buddha was protected from a rainstorm by a great naga king named Mucilinda.

Iconographically, the Buddha image was adapted to all of the main scenes of Śākyamuni's life, and while the later stupas in India and Southeast Asia achieve ever greater artistic splendour, they remain fundamentally the symbols of Śākyamuni's transcendence and continue to be decorated by scenes from his previous lives as well as from his last life. Famous examples are Amarāvatī in South India, dating from about the 3rd century AD (some of its stone carvings are preserved in the British Museum), and Borobuḍur in Java, 9th century AD. Borobuḍur is "Mahāyānist" or even "Vajrayānist" in its symbolic structure, but it reveals the close association between later developments and the great Buddha myth of Śākyamuni.

Cave monasteries

Temples and indeed whole monasteries hewn out of the rock were used by Buddhists at least from the 2nd century BC until the 8th century AD and probably later. Early cave monasteries, famous for their temples with internal stupas set in a kind of sanctuary, are Bhājā, Bhedsa, and Kārli, all within reach of Bombay; others famous for the development of the iconography of the Buddha figure are Kanheri (near Bombay), Nāsik, Ellora, and, especially, Ajanta. At Ajanta are also preserved fine murals dating from the 1st century BC to the 9th century AD. These mainly represent Śākyamuni in his last life and in his previous lives as a compassionate bodhisattva.

The traditions of imagery relating to Śākyamuni thrive to this day chiefly in Sri Lanka and the Southeast Asian countries where Theravāda Buddhism prevails, but even in the Mahāyāna countries of Nepal, Tibet, China, Japan, Mongolia, and Korea the same iconographic traditions are preserved whenever an image or painting of Śākyamuni is required. Nowhere, thus, are they really lost so long as Buddhism remains.

CELESTIAL BUDDHAS AND BODHISATTVAS

Literary references. The starting point of all of the later developed Buddhology was the great Buddha myth under one aspect or another. The early idea of a series of buddhas in time, first 7 and later 24, soon allowed for the idea of a future Buddha, the bodhisattva Maitreya. Next was mooted the possibility of buddhas in other buddha lands elsewhere through endless space. Vague popular knowledge in northwestern India of the great Iranian divinity Ahura Mazdā seems to have led to the general belief in a Great Buddha of the West, known as "Infinite Light" (Amitābha) or "Infinite Life" (Amitāyus). From its beginnings in northwestern India this cult spread across Central Asia to China, Korea, and Japan, where it still has an enormous influence.

Five Celestial Buddhas

In Indian beliefs this Western Buddha was balanced with the Buddha of the East, the "Imperturbable" (Akṣobhya), who iconographically is identical with Śākyamuni in the "earth-witness" posture. The cult of the "Imperturbable" Buddha probably derives from the actual Buddha cult at Bodh Gayā, the historical place of enlightenment. In addition to Amitābha of the West and Akṣobhya of the East, there are three others—Vairocana, Ratnasambhava, and Amoghasiddhi—that make up the Five Celestial Buddhas (one for the centre of the universe and one for the other two cardinal directions). Vairocana, the "Illuminator" (centre), is the universal sage or *cakravartin* buddha, indicated by his gesture of preaching and by the symbol of the wheel. Ratnasambhava, the "Jewel Born" (south), represents the Buddha's selfless giving, indicated by the gesture of giving gifts—right hand open, pointing outward and downward. Amoghasiddhi, "Infallible Success" (north), represents the miraculous power to save, indicated by the hand gesture of giving protection—right hand raised, palm outward and pointing upward. These Five Celestial Buddhas, also sometimes called Dhyāni Buddhas, seem—in the early stages of their development—to have been hypostases (concrete manifestations) of various aspects of Śākyamuni.

Celestial bodhisattvas

The cult of Śākyamuni in his previous lives when he was a future buddha (bodhisattva) likewise developed manifold forms. Maitreya, the buddha-yet-to-come, was already known in the earlier period, but from the 1st century onward there was a great cult of celestial bodhisattvas. Bodhisattvas who became especially popular included Mañjughoṣa ("Gentle Voice") or Mañjuśrī ("Glorious Gentle One"), the representative of divine wisdom; Avalokiteśvara, the "Lord of Compassion"; and Vajrapāṇi, "the one who wields the ritual thunderbolt (*vajra*)" and who, as lord of *yakṣas* (a class of local Indian divinities), entered

the pantheon as a great protector. In accord with later developments, these three bodhisattvas were associated with particular buddhas. With the development of the set of Five Buddhas, attendant bodhisattvas were allocated symmetrically to each. Such a balanced systematization was, however, a gradual process and can be traced in the main Mahāyāna sutras.

The *Saddharmapuṇḍarīka* ("Lotus of the Good Law"), a text existing before the 2nd century AD, reveals a great theophany (divine manifestation) of Śākyamuni as glorified lord of the universe. The text of the *Sukhāvatīvyūha* recounts the wonders of Amitābha's Western "Land of Bliss" (Sukhāvatī). The *Karunāpuṇḍarīka* ("The White Lotus of Compassion") is a text concerned with a Buddha Padmottara of the southeast direction but treats also of other buddhas, especially Amitābha and Śākyamuni, as well as of their previous manifestations as bodhisattvas. An important distinction is made between pure Buddha Lands, like that of Amitābha, and impure Buddha Lands, such as the present world in which Śākyamuni appeared. In some texts Śākyamuni is praised as the more noble because out of his great compassion he chose an impure Land.

A new mythology of great importance in East Asian Buddhism developed in association with the pure Buddha Lands. In popular aspiration these replaced for Buddhists the paradises of the ordinary Indian gods, which already formed part of the fivefold or sixfold "wheel of life"—a metaphor for and diagrammatic schematization of the cycle of rebirths. In the case of the pure Buddha Lands, there was the great added advantage of never falling back into unhappy states of existence.

Faith alone suffices to ensure one's rebirth in Amitābha's Western paradise. This particular Buddhist devotion may have begun in northwestern India, whence it passed to Central Asia and on to China and Japan. It had some following in India and Nepal, whence it passed to Tibet, but Amitābha usually remains in later Indian tradition as merely one important member of the Five Buddha group.

The fully developed "Five Buddha" complex found its primary expression in the *Tattvasaṃgraha* ("Symposium of Truth of All the Buddhas"), in which Śākyamuni, as Vairocana, appears as the central buddha. Another related text is the *Mahāvairocana-sūtra,* important for Japanese Esoteric Buddhism (Shingon). The set of Five Buddhas represents the limits of Mahāyāna Buddhological developments, preparing the way for the psychophysical theories of the tantras. The set of five was correlated not only with the centre and four compass points, namely, the macrocosm, conceived as a unity of the Five Great Elements, but also with the microcosm of the human personality understood in terms of the Five Components (skandhas)—*rūpa* (material qualities), *vedanā* (feeling or sensation), *saṃjñā* (perception), samskara (components of consciousness), and *vijñāna* (consciousness)—and with the Five Great Evils (ignorance, wrath, desire, malignity, and envy), typifying normal phenomenal existence. At this stage mythology and psychological symbolization are inextricably bound together.

Correlations of the Five Buddhas

With the tantras, Buddhist mythology began at last to part company with the original Buddha myth and clearly linked up with the Hindu mythology in a scarcely disguised form. Akṣobhya thus has as his fierce Tantric form what is in effect the fierce form of the Hindu god Śiva; in this form he is known under Buddhist names such as Heruka, Hevajra, or Saṃvara. He is known in Japan in this fierce form as Fudō ("Imperturbable"). The Indian god Bhairava, a fierce bull-headed divinity, was adopted by Tantric Buddhists as Vajrabhairava. Also known as Yamāntaka ("Slayer of Death") and identified as the fierce form of the gentle Mañjuśrī, he was accorded quasi-buddha rank.

Some bodhisattvas have become the object of very special devotion. Chief of these is Avalokiteśvara, the Lord of Compassion, who as patron saint of Tibet is believed to reincarnate in the Dalai lamas. As Kuan-yin in China, Kannon in Japan, and Kwanseium in Korea, this bodhisattva coalesces with his feminine counterpart, Tārā, and becomes a kindly madonna. The bodhisattva Kṣitigarbha ("Womb of the Earth"), who was of no great significance in India and hence of none in Nepal and Tibet, attracted a cult as lord of the underworld in Central Asia, whence it spread to China and East Asia generally. Known as Ti-ts'ang in Chinese and Jizō in Japanese, he is Lord of hell and therefore the centre of afterdeath liturgies.

Celestial buddhas and bodhisattvas in art and archaeology. It is mainly from archaeological and artistic remains that scholars have been able to trace the remarkable spread of Mahāyāna Buddhist mythology throughout the whole of Asia from the 1st century AD onward. The main points of departure were northwestern India for Central Asia and East Asia, and the Bay of Bengal, especially the port of Tāmraliptī. Early Mahāyāna developments also affected South India, and thence Sri Lanka and Southeast Asia.

In India itself, Bihar and Bengal remained Buddhist, largely late Mahāyāna and Tantric, until the 13th century, and in Java and Sumatra there is ample iconographic evidence of the popularity of the buddhas, bodhisattvas, and fierce quasi-buddha figures mentioned above. There are even traces in Myanmar, Thailand, and Kampuchea of images and paintings of late Mahāyāna and Tantric divinities. Alone in Southeast Asia, the island of Bali still retains a living but mixed Hindu-Tantric Buddhist culture.

Paintings and figures unearthed during the 20th century in Central Asia (Chinese Turkistan) have revealed the manner in which Buddhist architecture, iconography, and painting passed from northwestern India to China and East Asia. Especially important are the paintings of buddhas and bodhisattvas in the caves of Tun-huang (4th to 10th century AD). Especially popular in China, and hence in Japan and Korea, are Amitābha-Amitāyus, Vairocana, Maitreya, Mañjuśrī, Kṣitigarbha, and Avalokiteśvara (as the goddess Kuan-yin).

The main repository of Indian Mahāyāna and Vajrayāna iconographic traditions is Tibet, where Buddhism was introduced, mainly via Nepal, from the 8th to the 13th centuries. Until the communist takeover of 1959 the Tibetans preserved Indian (Pāla) styles of iconography. They also preserved ancient techniques and styles of Indian Buddhist painting that were modified and enriched in some schools by much later influence from China.

Tibetan art

RECURRENT MYTHIC THEMES

Myths of buddhas and bodhisattvas. The buddhas, the celestial bodhisattvas, and the fierce quasi-buddha manifestations recognized by the followers of the tantras all transcend phenomenal existence in their absolute state while readily involving themselves in it for the sake of suffering living creatures. Although this idea was fully developed only by the Mahāyāna and Esoteric traditions, it has been noted above that the same fundamental conception of a buddha as supramundane, but at the same time operative as world saviour in an immanent sense, belonged to the great Buddha myth constructed around Śākyamuni by the first Buddhist believers. Thus, while a small contemplative elite may always regard any buddha as the impersonal symbol of the ineffable state of enlightenment, most of the faithful have been equally justified in approaching him as a divine saviour. Buddhism has always been a religion of faith, whether of faith in the realizability of final enlightenment or of faith in the buddhas and bodhisattvas as helpers along the way. The Mahāyāna and certainly the Esoteric schools vastly increased the available means of progress to suit all local tastes and propensities, but the fundamental psychology of an accepted dual approach remains scarcely changed. The direct, immediate approach aims at comparatively rapid results and risks wholesale denials, both bodily and mental. The slow approach, through devotion to buddhas and bodhisattvas as divine beings and through the practice of morality in the everyday world, posits religious realities that some members of the spiritual elite in theory deny. But in practice they readily accept them, for they know that a denial would be just as relative to the desired end as the actual acceptance.

Mythic figures in the Three Worlds cosmology. In the early Buddhist tradition Gotama is represented as denying all importance to the questions of whether or not the universe is infinite and whether or not it is eternal. It was enough to realize that normal existence consists of a process of continual birth, death, and rebirth, a process from which, by following the path the Buddha had discovered, one might procure release. If the early texts are correct, however, such an ordinance did not prevent the Buddha, and certainly did not prevent his followers, from accepting the general cosmological beliefs of the time, modified by conclusions drawn from the Buddha's own moral and religious insights.

The three realms

The cosmology, as it was systematized by later Buddhists, included three different realms, all of which were within the confines of samsara (the ongoing cycle of birth, death, and rebirth) and were regulated more or less strictly by the law of karma, according to which good and pious deeds are rewarded while evil and impious deeds are punished. At the top of this universe is the *arūpa-dhātu* ("realm of formlessness"), which has no material qualities. This realm is inhabited by extremely long-lived brahma deities who are absorbed in the deepest levels of yogic trance. Although the existence of the *arūpa* realm is theoretically important for the cosmological system as a whole, the inhabitant deities (when they are distinguished from other brahma deities) play no active role in Buddhist mythology.

Situated just below the *arūpa-dhātu* is the *rūpa-dhātu,* "the realm of form," which has only a remnant of material qualities. This realm is inhabited by brahma deities who are associated with somewhat less exalted levels of yogic attainment than the deities of the *arūpa-dhātu.* Unlike the deities that inhabit the *arūpa* realm, the brahma deities of the *rūpa-dhātu* have a role in Buddhist mythology, particularly in the Buddhist cosmogony through which the lower strata of the cosmological structure are brought back into being after each of the eschatological cataclysms that periodically destroy them. According to one influential version of the primary creation myth, certain brahma deities whose abode is above the destruction begin—as the waters that are left from the old cataclysm start to coagulate below them—to savour the taste of the matter that constitutes these lower strata. As the strata take form, these brahma deities gradually descend into the lower realms and eventually become the first inhabitants of the new earth from whom all the other human inhabitants then descend.

Below the two realms inhabited by brahma deities is the *kāma-dhātu,* "the realm of desire." This realm includes a set of six *gati*s, or destinies, that have played an important role in virtually all Buddhist traditions in Asia. The highest of these six destinies is that of the *devatā* (though both gods and goddesses are included among the *devatā,* the goddesses generally have a secondary role). Within this destiny there are many heavens, each inhabited by many deities. Mythologically the most important are the Tuṣita Heaven where the future Buddha, Metteyya (Sanskrit: Maitreya), awaits the time for his coming to Earth; the Heaven of the Thirty-Three Gods, which is presided over by Inda (Sanskrit: Indra; a deity sometimes called Sakka [Sanskrit: Śakra], who plays a significant mythological role, especially but not exclusively in the Theravāda tradition); and the Heaven of the Four Guardian Kings, who are important protective deities in many Buddhist contexts.

The second of the six *gati*s is the destiny that is enjoyed and suffered by human beings. It is the locus for a myriad of mythic stories about pious monks, nuns, kings, and other laypersons. The third *gati* is the destiny of the asuras; it is relatively uninteresting from a mythic point of view, and it is often omitted. The fourth *gati* is the destiny of the animals. It provides the setting for the description of many fabulous creatures, including nagas, Garuḍa, lions, and elephants.

Pretas and hell beings

The two remaining *gati*s, those of the pretas (hungry ghosts) and the hell beings, are mythically important in two respects. The descriptions provided of the punishments that are inflicted and suffered in these realms are very vivid indeed. In addition, there are widely distributed and well-known mythic stories of compassionate bodhisattvas and Buddhist saints who make journeys to these *gati*s to assuage the torment of those who suffer and to secure their release.

In different areas of Asia new gods, goddesses, and demonic figures were incorporated into the cosmology (for example, in Southeast Asia the great Hindu gods Vishnu [Viṣṇu] and Śiva were often depicted as devas). Despite the new mythic contents that were added, however, the structure itself remained remarkably intact.

Local gods and demons. While the contemplative elite may deny the real existence of gods and demons together with the rest of phenomenal existence, the majority of Buddhists from the earliest times in India, and in other countries where Buddhism has spread, have never neglected indigenous religious beliefs. It has already been noted how Māra, the manifestation of spiritual evil, was presented in the earliest literature in the terms of local demonological beliefs. It is also to be noted that the early stupas and entrances to cave temples were decorated with local male and female deities (usually referred to as *yakṣa* and *yakṣinī*) who were presumably already conceived as converted defenders of the new faith. This proved the easier way of justifying the continuance of the cult of local deities, and it has been employed in varying degrees in every Buddhist land. There thus began to develop a pantheon of minor deities, which from a common original stock has continued to take in new members wherever Buddhism has become an established religion.

The Mahāyāna and Vajrayāna traditions have given these local deities a more ready welcome, even admitting some of their cults as a subsidiary part of the liturgies in honour of buddhas and bodhisattvas. Such favoured deities include Mahākāla, the great black divinity; the mother goddess Hārītī; Kuvera, the god of wealth; and especially Hayagrīva, a fierce horse-faced god who is powerful in driving off unconverted demonic forces.

Throughout the Mahāyāna and Vajrayāna world local deities have become manifestations of various buddhas and bodhisattvas. Perhaps the locus classicus for this process is Japan, where the identification of buddhas and bodhisattvas with indigenous kami has extended from the elite level (for example, in the identification of the buddha Mahāvairocana with the great ancestral Sun goddess, Amaterasu) to temples throughout the country, where a particular buddha or bodhisattva is identified with the kami of the local territory.

Subjugation of Bon deities

In other cases that are equally widespread, local gods and demons have been conquered, converted and brought into the pantheon, or relegated to the periphery (where they may still require propitiation). Perhaps the most interesting example is found in Tibet, where it is commonly believed that Buddhism became established in the 8th century only as the result of the wholesale subjugation of opposing local deities—a subjugation that must, from time to time, be repeated through the performance of rituals marked by their dynamism and ferocity.

Quite as much in Theravāda as in Mahāyāna countries, Buddhism has had to come to terms with local beliefs. In some cases well-organized pantheons have been constructed. For example, in Sri Lanka various local, Hindu, and Buddhist deities hold places within a hierarchy headed by the Buddha himself. In Myanmar the traditional hierarchy of local nats is headed by Thagya Min nat, who is identified with Inda (also known as Sakka). As Inda, he becomes a divine protector of Buddhism, who—in the classical Buddhist cosmology—reigns in the Heaven of the Thirty-Three Gods.

These neatly organized systems, even where they exist, are, however, only a small part of the story. Throughout the various Theravāda countries a wide variety of deities and spirits have been incorporated into the Buddhist world as the inhabitants of particular realms within the Buddhist cosmos or as the guardians of various images, stupas, and temples. At the same time, there are others who, like the demons of Tibet, remain only partially encompassed within the Buddhist domain.

Female deities. In many Buddhist traditions female deities and spirits have been relegated to minor and secondary positions in the pantheon. Among the Theravādins, for example, it is rare for female deities to play a major role. In Sri Lanka, however, the goddess Pattinī is a major deity.

In the Mahāyāna tradition several female deities became major figures. For example, Supreme Wisdom (*Prajñāpāramitā*) is often personified as the Mother of All Buddhas who is manifest especially in Mahāmāyā, the virgin mother of Śākyamuni. Tārā, the saviouress, is a closely related and much more popular figure who has often been taken to be the female counterpart of the bodhisattva Avalokiteśvara. In China and Japan Avalokiteśvara himself gradually assumed a female form. As Kuan-yin (Japanese: Kannon) he/she became probably the most popular figure in the entire panoply of buddhas and bodhisattvas.

Sexual symbolism

It was, however, in the Vajrayāna and Esoteric traditions that female deities became ubiquitous at the highest levels of the pantheon. From the 7th century onward a riot of female divinities began to find their way into certain circles of Buddhist yogis, where they were actually represented by women partners in a special kind of sexual yoga (physical and mental discipline). The process was gradually interpreted as an internal form of celibate yoga, for, in accordance with Vajrayāna and Esoteric theory, enlightenment was achieved by the union of Wisdom and Method, now conceived of symbolically as female and male. Thus it became possible to present supreme buddhahood as the union of a male and female pair and then to represent every celestial buddha or quasi-buddha by a pair of male and female forms. The actual sexual ritual was certainly performed at one time in India and Nepal, seemingly to a very limited extent in Tibet, and perhaps not at all in China and Japan. Nonetheless this form of Tantric symbolism, with its plethora of female buddhas and quasi-buddhas, became a powerful symbolism that virtually all Vajrayāna and Esoteric Buddhists have simply taken for granted as part of their received tradition.

Kings and yogis. The great Buddha myth is a combination of the ideals of universal kingship and universal religious preeminence. This is clearly expressed in the myth of the prophetic utterance of future greatness by the sage Asita—an astrologer who examined auspicious signs on the infant Gotama—over the child bodhisattva. Also in his previous life as Vessantara (Sanskrit: Viśvāntara), Gotama had already realized the perfection of the extraordinary combination of kingship and all-abandoning asceticism. As crown prince, Vessantara was famous for his vast generosity, and, to the despair of his more practical-minded father, he accepted banishment to the forest, where he attained the ultimate of self-abnegation by giving away his children and his wife and in some accounts even his own eyes. These and all the rest were restored to him miraculously, and, responding to the demands of his countrymen, he returned home to become the best of kings. Similarly, the last life of Gotama, up to the time of his great renunciation, is told entirely as a royal story.

Although the practice of Buddhist religion strictly required withdrawal from the world, or at least renunciation of its pleasures, Buddhist monks were, understandably enough, anxious to win royal support. They always needed benefactors, and what better benefactor than a king. Any suggestion of royal benefaction thus resulted in the revival of the "myth" of the vastly generous monarch. Whenever Mahāyāna tendencies have been at work, the notion of the beneficent king as a bodhisattva has been prominent. The most famous example of the mythologized kings is the Indian emperor Aśoka, who facilitated the spread of Buddhism and concerning whom vast legends have grown up. Among other things, he is credited with having built 84,000 stupas. Surrounding countries all claim to have received Buddhism through his mediacy. On a smaller scale legends embellish the life of King Tissa of Sri Lanka (3rd century BC), who presided over the arrival of Buddhism. In the same context one may mention Prince Shōtoku of Japan (d. AD 621) and Srong-brtsan-sgam-po of Tibet (d. AD 650), noting, however, that the enthusiasm of the first for Buddhism is genuinely historical. This is also true of Tibet's two other great "kings of religion": Khri-srong-lde-btsan (reigned 755–797) and Ral-pa-can, assassinated by enemies of the faith in AD 838.

The great stupa of Borobudur, mentioned above, deliberately represents the self-identification of the ruling monarch of Java with the aspiration toward buddhahood. The king presents himself as the bodhisattva par excellence. At the other side of the Buddhist world, the Tibetans developed the same idea when they identified their reincarnating Dalai Lama as a manifestation of their patron "saint," the bodhisattva Avalokiteśvara. By polite mythical fiction the Manchu emperors of China were regarded as manifestations of the bodhisattva Mañjuśrī. As a result of the more restrained nature of their doctrines, Theravādin countries have provided less support for these interesting developments. There such kings as Dhammaceti of Pegu (d. 1491) or Mindon of Myanmar (d. 1878), and even great religious ascetics, remain transient mortal beings of flesh and blood.

The king as bodhisattva

Under the aspect of the pre-Buddhist Indian myth of the ideal perfected yogi, possessed of miraculous powers, however, the greatness of the Buddhist ascetic is a theme well suited to Buddhism everywhere. The early disciples of Śākyamuni, known as arhats when they achieved perfection, were conceived of as miracle-working yogis, and the early canonical literature presents them in this way. This same ideal was acknowledged in Theravādin Sri Lanka, and the Sinhalese claim their share of arhats. But it was in Tibet, which drew on the more developed Indian myth of the "great yogi" (*mahāsiddha*) of the Tantric period (8th to 12th century AD) that this theme showed its most luxurious development. Especially famous are Padmasambhava (also called Guru Rimpoche), an 8th-century Indian yogi credited with having quelled the evil spirits of Tibet, and the strange figure of Pha-dam-pa Sangs-rgyas (d. 1117), a Brahman of South India who became a Buddhist and visited Tibet and possibly China in the 11th century. Doubtless historical, Pha-dam-pa Sangs-rgyas passed out of history into myth with his fantastic powers and equally fantastic longevity. Better known in Europe is the story of the Tibetan yogi Mi-la-ras-pa (1040–1123).

Early in the history of Chinese Buddhism the same mythical tendencies appeared. Bodhidharma (6th century), the founder of Ch'an (Zen) Buddhism, was also an Indian yogi, appearing in quasi-historical, quasi-mythical guise. Subsequently the ideal of the Buddhist sage, as typified by the arhats, coalesced in Chinese thought with the Taoist immortals. In Japan new mythicized stories developed, some associated with the founders of Japanese sects, such as Kūkai and Shinran, others with popular holy men who were the Buddhist counterparts of indigenous shamans and ascetics. Through the continued generation of such new myths and stories, Buddhism was able to move from culture to culture, taking root in each one along the way.

(D.L.S./F.E.R.)

Popular religious practices

Like other great religious traditions, Buddhism has generated a wide range of popular practices. Among these, there are two simple practices that are deeply rooted in the experience of the earliest Buddhist community and that have remained basic to all Buddhist traditions.

Veneration of the Buddha

The first of these is the practice of venerating the Buddha or other buddhas, bodhisattvas, or saints who manifest the same reality. This sometimes takes the form of showing respect, meditating on the qualities of the Buddha, or giving gifts. These gifts are often given to the relics of the Buddha, to images made to represent him, and to other traces of his presence (such as, for example, places where his footprint can supposedly be seen). After the Buddha's death the first foci for this sort of veneration seem to have been his relics and the stupas that were built to hold them. About the beginning of the Common era, anthropomorphic images of the Buddha were produced, and they took their place alongside relics and stupas as focal points for venerating the Buddha. Still later, in the context of the Mahāyāna and Vajrayāna traditions, the veneration of other buddhas and bodhisattvas came to supplement or replace the veneration of the Buddha Gautama. In the course of Buddhist history, the forms have become diverse, but the practice of honouring and even worshiping the Buddha or Buddha-figure has remained a central component in all Buddhist traditions.

The second basic practice is the reciprocal exchange that

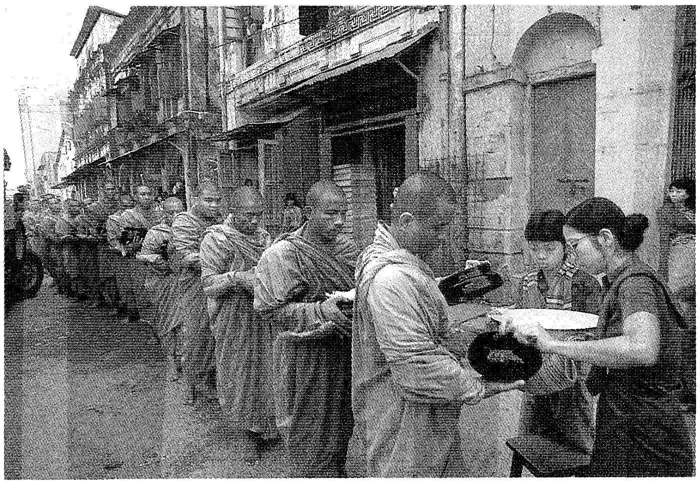

Figure 7: Monks receiving alms from a laywoman in Yangôn, Myanmar.

Photobank BKK/Robert Harding Picture Library

takes place between Buddhist monks and Buddhist laypersons. Like the Buddha himself, the monks embody or represent the higher levels of spiritual achievement, which they make available in various ways to the laity. The laity make merit and improve their soteriological condition by giving the monks material gifts that function as sacrificial offerings. Though the exchange is structured differently in different Buddhist traditions, it has remained until recently a component in virtually all forms of Buddhist community life.

Both of these fundamental forms of Buddhist practice appear independently within the tradition. The veneration of the Buddha or Buddha figure is a common ritual often practiced independently of other rituals. So, too, the practice of exchange between monks and laypersons often structures rituals such as the *dāna* (gift-giving) in the Theravāda tradition, which are performed independently of other rituals. Both of these forms of practice, however, are embedded in one way or another in virtually all other Buddhist rituals, including calendric rituals, pilgrimage rituals, rites of passage, and protective rites.

CALENDRIC RITES AND PILGRIMAGE

Uposatha. The four monthly holy days of ancient Buddhism continue to be observed in the Theravāda countries of Southeast Asia. These *uposatha* days—the new moon and full moon days of each lunar month and the eighth day following the new and full moons—have their origin, according to some scholars, in the fast days that preceded the Vedic soma sacrifices. In the Buddhist context laypersons and monks are expected to perform religious duties during the *uposatha* days.

The *uposatha* service typically includes the repetition of the precepts, the offering of flowers to the Buddha image, the recitation of Pāli sutras, meditation practices, and a sermon by one of the monks for the benefit of the visitors. The more pious laymen may vow to observe the eight precepts for the duration of the *uposatha.* These are the five precepts normally observed by all Buddhists—not to kill, steal, lie, take intoxicants, or commit sexual offenses—upgraded to include complete sexual continence, plus injunctions against eating food after noon, attending entertainments or wearing bodily adornments, and sleeping on a luxurious bed. The monks observe the *uposatha* days by listening to the recitation by one of their members of the *Pātimokkha,* or rules of conduct, contained in the *Vinaya Piṭaka* and by confessing any infractions of the rules they have committed.

Commemorations of the Buddha's birth, Enlightenment, and final nirvana

Anniversaries. The three major events of the Buddha's life—his birth, Enlightenment, and entrance into final nirvana—are commemorated in all Buddhist countries but not everywhere on the same day. In the Theravāda countries the three events are all observed together on Vesak, the full moon day of the sixth lunar month (Vesākha), which usually occurs in May. (The Māgha Pūjā takes place three months earlier—on the full moon of February—and celebrates the Buddha's first exposition of the *Pātimokkha.*)

In Japan and other Mahāyāna countries, the three anniversaries of the Buddha are observed on separate days (in some countries the birth date is April 8, the Enlightenment date is December 8, and the death date is February 15). Festival days honouring other buddhas and bodhisattvas of the Mahāyāna and Vajrayāna traditions are also observed, and considerable emphasis is placed on anniversaries connected with the patriarchs of certain sects. Padmasambhava's anniversary, for example, is especially observed by the Rnying-ma-pa sect in Tibet, and the birthday of Nichiren is celebrated by his followers in Japan.

Vassa. The beginning of *vassa,* the three-month rainy-season retreat from July to October, and its conclusion are two of the major festivals of the year among Theravāda Buddhists, particularly in Myanmar, Kampuchea, Thailand, and Laos. The retreat has largely been given up by Mahāyāna Buddhists. It is an accepted practice in countries such as Thailand for a layman to take monastic vows for the *vassa* period and then to return to lay life. Commonly, the number of years a monk has spent in monastic life is expressed by counting up the number of *vassas* he has observed.

The end of *vassa* is marked by joyous celebration. The following month is a major occasion for presenting gifts to monks and acquiring the consequent merit. The *kaṭhina,* or robe-offering ceremony, is a public event during this period and usually involves a collective effort by a village, a group of villages, or a company to bestow gifts on an entire monastery. A public feast and display of

the robes and other presents on a "wishing-tree" are the usual components of the ceremony. The *kaṭhina* season is climaxed by the making and presentation of the *mahākaṭhina* ("great robe"), a particularly meritorious gift that requires the cooperation of a number of people who, theoretically at least, must produce it—from spinning the thread to stitching the cloth—in a single day and night. The robe commemorates the act of the Buddha's mother, who on hearing that he was about to renounce worldly life, wove his first mendicant robes in one night.

All Souls festival. The importance of the virtues of filial piety and the reverence of ancestors in China and Japan have established Ullambana, or All Souls Day, as one of the major Buddhist festivals in those countries. In China, worshipers in Buddhist temples make "boats of the law" (*fa-ch'uan*) out of paper, some very large, which are then burned in the evening. The purpose of the celebration is twofold: to remember the dead and to free and let ascend to heaven the pretas. The pretas are the spirits of those who died as a result of an accident or a drowning and as a consequence were never buried; their presence among men is thought to be dangerous. Under the guidance of Buddhist temples, societies (*hui, Yu-lan-hui*) are formed to carry out ceremonies for the pretas—lanterns are lit, monks are invited to recite sacred verses, and offerings of fruit are presented. An 8th-century Indian monk, Amoghavajra, is said to have introduced the ceremony into China, from where it was transmitted to Japan. During the Japanese festival of Bon, two altars are constructed, one to make offerings to the spirits of dead ancestors and the other to the souls of those dead who have no peace. Odorinembutsu (the chanting of invocations accompanied by dancing and singing) and invocations to Amida are features of the Bon celebrations.

The Japanese Bon festival

New Year's and harvest festivals. New Year's festivals and harvest festivals are examples of Buddhism's involvement in preexisting local traditions. On the occasion of the New Year, images of the Buddha are in some countries taken in procession through the streets. Worshipers visit Buddhist sanctuaries and circumambulate the stupa, or sacred image, and monks are fed and presented with gifts. One of the most remarkable examples of the absorption of local custom was the Smonlam festival in Tibet, celebrated on a large scale in Lhasa until the beginning of Chinese communist rule in the 1950s. The festival was instituted in 1408 by Tsong-kha-pa, the founder of the predominant Dge-lugs-pa sect, who transformed an old custom into a Buddhist festivity. Smonlam took place at the beginning of the winter thaw, when caravans began to set out once again and the hunting season was resumed. The observances included exorcistic ceremonies, performed privately within each family to remove evil forces lying in wait for individuals as well as for the community as a whole, and propitiatory rites, performed to ward off evil such as droughts, epidemics, or hail, during the coming year. During the more public propitiatory rites, the sangha cooperated with the laity by invoking the merciful forces that watch over good order, and processions, fireworks, and various amusements created an atmosphere of hopefulness. Through the collaboration of the monastic community and the laity, a general reserve of good karma was accumulated to see everyone through the dangerous moment of passage from the old year to the new.

The harvest festival celebrated in the Tibetan villages during the eighth lunar month was quite different in nature from the New Year ceremonies. Most commonly, offerings of thanks were made to local deities in rites that were only externally Buddhist. The same interplay between Buddhism and folk tradition is observable elsewhere. In Sri Lanka at harvest time, for example, there is a "first fruits" ceremony that entails offering the Buddha a large bowl of milk and rice.

An integral part of the harvest celebrations in many Buddhist countries is the sacred performance of an episode in the life of a buddha or a bodhisattva. In Tibet, troupes of actors specialize in performances of Buddhist legends. In Thailand, the recitation of the story of Phra Wes (Pāli: Vessantara) constitutes one of the most important festival events of the agricultural calendar.

Buddhist pilgrimage. Within the first two centuries following the Buddha's death, pilgrimage had already become an important component in the life of the Buddhist community. During these early centuries of Buddhist history there were at least four major pilgrimage centres—the place of the Buddha's birth at Lumbinī, the place of his Enlightenment at Bodh Gayā, the Deer Park in Vārānasi (Benares) where he supposedly preached his first sermon, and the village of Kusinārā, which was recognized as the place of his Parinirvāna. During this period, the place of the Buddha's Enlightenment at Bodh Gayā was the most important pilgrimage centre; it continued to hold a preeminent position through much of Buddhist history, and it is the major pilgrimage site of world Buddhism today.

Bodh Gayā

In addition to these four primary sites, major pilgrimage centres have emerged in every region or country where Buddhism has been established. Many local temples have their own festivals associated with a relic enshrined there or an event in the life of a sacred figure. Some of these, such as the display of the tooth relic at Kandy, Sri Lanka, are occasions for great celebrations attracting many pilgrims. In many Buddhist countries famous mountains have become sacred sites that draw pilgrims from both near and far. In China, for example, four such mountain sites are especially important: O-mei, Wu t'ai, P'u-t'o, and Chiu-hua. Each is devoted to a different bodhisattva whose temples and monasteries are located on the mountainside. In many Buddhist regions there are pilgrimages that include stops at a whole series of sacred places. One of the most interesting of these is the Shikoku pilgrimage in Japan, which involves visits to 88 temples located along a route that extends for more than 700 miles.

Buddhist pilgrimages, like pilgrimages in other religions, are undertaken for a wide range of reasons. For some Buddhists, pilgrimage is a discipline that fosters spiritual development; for others it is the fulfillment of a vow—as, for example, after recovery from an illness; and for others it is simply an occasion for travel and enjoyment. Whatever the motivations that support it may be, pilgrimage is one of the most important Buddhist practices.

RITES OF PASSAGE AND PROTECTIVE RITES

Initiation. *Ordination.* Admission to the sangha involves two distinct acts: *pabbajjā,* which consists of renunciation of secular life and acceptance of monasticism as a novice, and *upasampadā,* the official consecration as a monk. The evolution of the procedure is not entirely clear; in early times, the two acts probably occurred at the same time. Subsequently, the *Vinaya* established that *upasampadā,* or full acceptance into the monastic community, should not occur before the age of 20, which, if the *pabbajjā* ceremony took place as early as the age of 8, would mean after 12 years of training. Ordination could not occur without the permission of the aspirant's parents. The initial Pāli formula was "Ehi bhikkhu," "Come, O monk!"

The rite established in ancient Buddhism remains essentially the same in the Theravāda tradition. To be accepted, the postulant shaves his hair and beard and dons the yellow robes of the monk. He bows to the abbot or senior monk, to whom he makes his petition for admittance, and then seats himself with legs crossed and hands folded, pronouncing three times the formula of the Triple Refuge ("I take refuge in the Buddha, I take refuge in the *dhamma,* I take refuge in the sangha.") He repeats after the officiating monk the Ten Precepts and vows to observe them. Thereafter, in the presence of at least 10 monks (fewer in some cases) the postulant is questioned in detail by the abbot—as to the name of the master under whom he studied, whether he is free of faults and defects that would prevent his admission, and whether he has committed any infamous sins, is diseased, mutilated, or in debt. The abbot, when satisfied, thrice proposes acceptance of the petition; the chapter's silence signifies consent. Nuns were once ordained in basically the same way.

The *upasampadā* rite

Bodhisattva vows. In Mahāyāna Buddhism, new rituals were added onto the ceremony of ordination prescribed by the Pāli *Vinaya.* The declaration of the Triple Refuge is as central an assertion as ever, but special emphasis is placed on the candidate's intention to achieve enlightenment and his undertaking of the vow to become a bodhisattva. Five monks are required for the ordination: the head monk, one who guards the ceremony, a master of secrets (the esoteric teachings, such as mantras), and two assisting officiants.

Abhiṣeka. The esoteric content of Vajrayāna tradition requires a more complex ceremony of consecration. In addition to the other ordination rites, preparatory study, and training in yoga, the Tantric neophyte receives *abhiṣeka* (literally, "sprinkling," of water). This initiation takes several forms, each of which has its own corresponding "wisdom" (*vidyā*), rituals, and esoteric formulas; each form of initiation is associated with one of the Five Buddhas of the supreme pentad. The initiate meditates on the *vajra* ("thunderbolt") as a symbol of Vajrasattva Buddha (the Adamantine Being), on the bell as a symbol of the void, and on the mudra (ritual gesture) as "seal." The intent of the initiation ceremony is to produce an experience that anticipates the moment of death. The candidate emerges reborn as a new being, a state marked by his receipt of a new name.

Funeral rites. The origin of the Buddhist funeral observances can be traced back to Indian customs. The cremation of the body of the Buddha and the subsequent distribution of his ashes are told in the *Mahāparinibbāna Sutta* ("Sutra on the Great Final Deliverance"). Early Chinese travelers such as Fa-hsien described cremations of venerable monks. After cremation, the ashes and bones of the monk were collected and a stupa built over them. That this custom was widely observed is evident from the large number of stupas found near monasteries.

With less pomp, cremation is also used for ordinary monks and laymen, though not universally. In Sri Lanka, for example, burial is also common. In Tibet also, because of the scarcity of wood, cremation is rare. The bodies of great lamas, such as the Dalai and Panchen lamas, are placed in rich stupas in attitudes of meditation, while lay corpses are exposed in remote places to be devoured by vultures and wild animals.

Beliefs about the state and journey of the dead

Buddhists generally agree that the thoughts held by a person at the moment of death are of essential significance. For this reason, sacred texts are sometimes read to the dying person to prepare the mind for the moment of death; similarly, sacred texts may be read to the newly dead, since the conscious principle is thought to remain in the body for about three days following death. In Tibetan, Mongolian, and Chinese lamaseries, a lama sometimes recites the famous *Bardo Thödrol* (commonly referred to in English as *The Tibetan Book of the Dead*).

Protective rites. From a very early period in its development, Buddhism has included within its repertoire of religious practices specific rituals that are intended to protect against various kinds of danger and to exorcise evil influences. In the Theravāda tradition protective, exorcistic rituals are closely associated with texts called *paritta*s, many of which are attributed directly to the Buddha. In Sri Lanka and the Theravāda countries of Southeast Asia, *paritta*s are traditionally chanted during large public rituals designed to avert collective, public danger. They are also very widely used in private rituals intended to protect the sponsor against illness and various other misfortunes.

In the Mahāyāna and Esoteric traditions, the role taken by protective and exorcistic rituals was even greater. For example, dharanis (short statements of doctrine that supposedly encapsulate its power) and mantras (a further reduction of the dharani, often to a single word) were widely used for this purpose. Protective and exorcistic rituals that used such dharanis and mantras were extremely important in the process through which the populations of Tibet and East Asia were converted to Buddhism. They have remained an integral part of the Buddhist traditions in these areas, reaching what was perhaps their fullest development in Tibet. (Gi.T./F.E.R.)

Buddhism in the contemporary world

MODERN TRENDS

During the 19th and 20th centuries Buddhism has been forced to respond to new challenges and opportunities that cut across the regional religious and cultural patterns that characterized the Buddhist world in the premodern period. A number of Buddhist countries were subjected to Western rule, and even those that were not felt the heavy pressure of Western religious, political, economic, and cultural influence. Modern rationalistic and scientific modes of thinking, modern notions of liberal democracy and socialism, and modern patterns of economic organization were introduced and became important elements in the thought and life of Buddhists and non-Buddhists in these countries. In this situation the Buddhists' response was twofold. They came to associate Buddhism with the religious and cultural identity that they sought to preserve and reassert in the face of Western domination. In addition, they sought to initiate reforms that would make Buddhism a more appealing and effective force in the modern world.

The Buddhist concern to challenge Western domination manifested itself both in the specifically religious and in the religiopolitical sphere. In the former, Buddhists used a variety of measures to meet the challenge posed by the presence of Western Christian missionaries, often adopting modern Christian practices such as the establishment of Sunday schools, the distribution of tracts, and the like. They also attempted to strengthen the Buddhist cause through the initiation of Buddhist missions, including missions to the West, and through ecumenical cooperation among various Buddhist groups. Organizations such as the World Fellowship of Buddhists (founded 1950) and the World Buddhist Sangha Council (1966) were established to promote cooperation among Buddhists from all countries and denominations.

International Buddhist organizations

In the religiopolitical sphere, many Buddhist leaders—including many politically active monks—sought to associate Buddhism with various nationalist movements that were struggling to achieve political, economic, and cultural independence. Where these leaders and the nationalist causes with which they associated themselves have been successful (as, for example, in Thailand), Buddhism has retained a central role in political life. Where they were superseded by other forces (as in China), Buddhism has been relegated to the periphery.

Three emphases have been especially important in the various reform movements. First, many Buddhist leaders have put forward a highly rationalized, Protestant-type interpretation of Buddhism that deemphasizes the supernormal and ritualized aspects of the tradition and focuses on the supposed continuity between Buddhism and modern science and on the centrality of ethics and morality. This interpretation, according to its proponents, represents a recovery of the true Buddhism of the Buddha.

A second, closely related emphasis that has been prominent among modern Buddhist reformers represents Buddhism as a form of religious teaching and practice that provides a basis for social, political, and economic life in the modern world. In some cases the focus has been on Buddhist ideas that supposedly provide a religious grounding for an international order supporting world peace. Other reformers have presented Buddhism as a basis for a modern democratic order or have advocated a Buddhist form of socialism.

Finally, Buddhist reformers have initiated and supported movements that give the Buddhist laity (and in some cases Buddhist women) a much stronger role than they have had in the past. In the Theravāda world, lay societies have been formed and lay-oriented meditation movements have enjoyed great success. In East Asia an anticlerical, lay-oriented trend that was evident even before the modern period has culminated in the formation and rapid expansion of new, thoroughly laicized Buddhist movements, particularly in Japan.

CHALLENGES AND OPPORTUNITIES

The status of contemporary Buddhist communities and the kinds of challenges those communities face differ radically from area to area. Five different kinds of situations can be identified.

First, there are a number of countries where previously well-established Buddhist communities have suffered se-

Buddhism under communist governments

vere setbacks that have curtailed their influence and seriously sapped their vitality. This kind of situation prevails primarily in countries ruled by communist governments where Buddhism has, for many decades, been subjected to intense pressures that have undercut its institutional power and weakened its influence on large segments of the population. This has happened in the Mongol areas of Central Asia, in China (outside of Tibet), in North Korea, and, to a lesser extent, in Vietnam.

Second, there are places where well-established Buddhist communities have suffered similar setbacks but have retained the loyalty of large segments of the population. Perhaps the most vivid example is Tibet, where the Chinese communists have implemented anti-Buddhist policies that, despite their brutality, have failed to break the bond between Buddhism and the Tibetan sense of identity. In Kampuchea and Laos, similarly, communist rule (including even the reign of terror imposed by the Pol Pot regime that controlled Kampuchea from 1975 to 1979) does not seem to have broken the people's loyalty to Buddhism.

Third, there are situations in which the Buddhist community has retained a more or less accepted position as the leading religious force and has continued to exert a strong influence on political, economic, and social life. This is the case in Sri Lanka and Myanmar, where Buddhism is the dominant religion among the Sinhalese and Burman majorities, and in Thailand, where more than 90 percent of the population is counted as Buddhist. In Sri Lanka and Myanmar, ethnic conflict and (especially in Myanmar) authoritarian rule and economic stagnation have resulted in political instability that has had a disruptive effect on the local Buddhist communities. In Thailand, however, Buddhism has a firm position within a relatively stable and rapidly modernizing society.

The fourth type of situation is one in which well-developed Buddhist traditions are operating with a considerable degree of freedom and effectiveness in societies where Buddhism plays a more circumscribed role. This situation prevails in several of the Pacific Rim countries, including South Korea, Taiwan, Hong Kong and Singapore, and to a lesser extent in Southeast Asian countries such as Malaysia and Indonesia, where Buddhism is practiced by significant numbers of overseas Chinese. The primary example, however, is Japan, where Buddhism has continued to play an important role. In the highly modernized society that has developed in Japan, many deeply rooted Buddhist traditions, such as Shingon, Tendai, the Pure Land schools, and Zen, have persisted and have been adapted to changing conditions. At the same time, new Buddhist sects such as Rissho-Kosei-Kai and Soka-gakkai have gained millions of converts in Japan and throughout the world.

Finally, new Buddhist communities have developed in areas where Buddhism disappeared long ago or never existed at all. Thus in India, where Buddhism had been virtually extinct since at least the 15th century, new Buddhist societies have been formed by Indian intellectuals, new Buddhist settlements have been established by Tibetan refugees, and a significant Buddhist community has been founded by converts from the so-called scheduled castes. In the West (particularly but not exclusively in the United States), important Buddhist communities have been established by immigrants from East and Southeast Asia. Buddhist influences have penetrated into many aspects of Western culture, and communities of Buddhist converts are active.

For more than two millennia Buddhism has been a powerful religious, political, and social force, first in India, its original homeland, and then in many other lands. It remains a powerful religious, political, and cultural force in many parts of the world today. (F.E.R.)

BIBLIOGRAPHY

General treatments: Among the more popular introductions to Buddhism, WILLIAM R. LAFLEUR, *Buddhism: A Cultural Perspective* (1988), is outstanding. A more advanced overview of the whole Buddhist tradition is provided by JOSEPH M. KITAGAWA and MARK D. CUMMINGS (eds.), *Buddhism and Asian History* (1989), a collection of some of the articles on Buddhism originally published in MIRCEA ELIADE (ed.), *The Encyclopedia of Religion,* 16 vol. (1987); these articles, and the others on Buddhism in *The Encyclopedia of Religion,* contain excellent bibliographies. Another basic introductory work with an extensive bibliography is HEINZ BECHERT and RICHARD GOMBRICH (eds.), *The World of Buddhism: Buddhist Monks and Nuns in Society and Culture* (1984). Important reference works include TREVOR LING, *A Dictionary of Buddhism: Indian and South-East Asian* (1981); GEORGE P. MALALASEKERA (ed.), *Encyclopaedia of Buddhism* (1961–), appearing in fascicles; and SYLVAIN LÉVI, J. TAKAKUSU, and PAUL DEMIÉVILLE (eds.), *Hôbôgirin: dictionnaire encyclopédique du bouddhisme d'après sources chinoises et japonaises* (1929–), also issued in fascicles. An extensive, fully annotated bibliography of Western-language materials is provided in FRANK E. REYNOLDS *et al., Guide to Buddhist Religion* (1981). More recent references can be located in the sections on Buddhism under each country in the ongoing *Bibliography of Asian Studies* (annual).

Historical development in Asian countries: Introductions to Buddhist history include E. ZÜRCHER, *Buddhism: Its Origin and Spread in Words, Maps, and Pictures* (1962); and PETER A. PARDUE, *Buddhism: A Historical Introduction to Buddhist Values and the Social and Political Forms They Have Assumed in Asia* (1971). More extensive introductory works with essays by a wide range of authors include P.V. BAPAT (ed.), *2500 Years of Buddhism* (1956, reprinted 1976); and RENÉ DE BERVAL (ed.), *Présence du bouddhisme* (1959). Among the major works by individual authors is CHARLES ELIOT, *Hinduism and Buddhism: An Historical Sketch,* 3 vol. (1921, reprinted 1971), seriously dated but still valuable; sections dealing with Buddhism are included in each of the three volumes and cover all the Buddhist traditions of Asia except that of Japan. The most original and creative of the individually authored works is PAUL MUS, *Barabudur,* 2 vol. (1935, reprinted in 1 vol., 1978); perhaps the greatest Buddhological work ever written in the West, it has been largely neglected because of its length and difficulty; fortunately, however, the main themes are consolidated in a "Preface" of 305 pages. HAJIME NAKAMURA, *Ways of Thinking of Eastern Peoples: India, China, Tibet, Japan,* rev. trans. ed. by PHILIP P. WIENER (1964, reissued 1981), is a wide-ranging work that identifies four different Asian ways of thinking by contrasting the distinctive forms in which Buddhism was expressed in the four countries.

One of the best introductions to the historical development of early Buddhism is still SUKUMAR DUTT, *The Buddha and Five After-Centuries* (1957, reprinted 1978). The classic treatment of the period, which all serious students will want to consult, is ÉTIENNE LAMOTTE, *History of Indian Buddhism: From the Origins to the Saka Era* (1988; originally published in French, 1958). Two studies that go beyond the early period are A.K. WARDER, *Indian Buddhism,* 2nd rev. ed. (1980), which emphasizes doctrine; and SUKUMAR DUTT, *Buddhist Monks and Monasteries of India* (1962), which is based on archaeological as well as textual sources. One of the few good books on Buddhism in India during the 7th and 8th centuries AD is LAL MANI JOSHI, *Studies in the Buddhistic Culture of India,* 2nd rev. ed. (1977).

The Sri Lankan tradition has been surveyed by RICHARD F. GOMBRICH, *Theravada Buddhism: A Social History from Ancient Benares to Modern Colombo* (1988). It can be supplemented by GANANATH OBEYESEKERE, FRANK REYNOLDS, and BARDWELL L. SMITH, *Two Wheels of Dhamma: Essays on the Theravada Tradition in India and Ceylon* (1972); and BARDWELL L. SMITH (ed.), *Religion and Legitimation of Power in Sri Lanka* (1978). For the premodern period, WALPOLA RĀHULA, *History of Buddhism in Ceylon: The Anuradhapura Period, 3d Century BC–10th Century AD* (1956, reissued 1966), is still useful. For the early modern period, KITSIRI MALALGODA, *Buddhism in Sinhalese Society, 1750–1900: A Study of Religious Revival and Change* (1976), makes a major contribution. The contemporary situation is presented in RICHARD F. GOMBRICH, *Precept and Practice: Traditional Buddhism in the Rural Highlands of Ceylon* (1971); and GEORGE D. BOND, *The Buddhist Revival in Sri Lanka: Religious Tradition, Reinterpretation, and Response* (1988).

On Southeast Asia, book-length treatments of Buddhism are limited to the countries of the mainland. The best introductory survey that covers most of these countries is ROBERT C. LESTER, *Theravada Buddhism in Southeast Asia* (1973); it should be supplemented by BARDWELL L. SMITH (ed.), *Religion and Legitimation of Power in Thailand, Laos, and Burma* (1978). More detailed studies of Buddhism in Myanmar include three historical works: NIHARRANJAN RAY, *Sanskrit Buddhism in Burma* (1936), and *An Introduction to the Study of Theravāda Buddhism in Burma: A Study in Indo-Burmese Historical and Cultural Relations from the Earliest Times to the British Conquest* (1946); and MICHAEL AUNG-THWIN, *Pagan: The Origins of Modern Burma* (1985). Books on more contemporary topics include E. SARKISYANZ, *Buddhist Backgrounds of the Burmese*

Revolution (1965); WINSTON L. KING, *A Thousand Lives Away: Buddhism in Contemporary Burma* (1964, reissued 1990); and MELFORD E. SPIRO, *Buddhism and Society: A Great Tradition and Its Burmese Vicissitudes,* 2nd expanded ed. (1982).

Various historical and contemporary aspects of Thai Buddhism are explored in STANLEY J. TAMBIAH, *World Conqueror and World Renouncer: A Study of Buddhism and Polity in Thailand Against a Historical Background* (1976), and *The Buddhist Saints of the Forest and the Cult of Amulets: A Study in Charisma, Hagiography, Sectarianism, and Millenial Buddhism* (1984); and DONALD K. SWEARER, *Wat Haripuñjaya: A Study of the Royal Temple of the Buddha's Relic, Lamphun, Thailand* (1976). For the Indochinese traditions, the reader can consult the dated classic by ADHÉMARD LECLÈRE, *Le Buddhisme au Cambodge* (1899, reprinted 1975); see also THICH THIEN-AN, *Buddhism and Zen in Vietnam in Relation to the Development of Buddhism in Asia* (1975).

By far the best introduction to Chinese Buddhism is PAUL DEMIEVILLE, "Le Bouddhisme chinois," which is published in two collections: HENRI-CHARLES PUECH (ed.), *Histoire des religions,* vol. 1 (1970), pp. 1249–1319; and PAUL DEMIEVILLE, *Choix d'études bouddhiques, 1929–1970* (1973), pp. 365–435. A readable but dated work is ARTHUR F. WRIGHT, *Buddhism in Chinese History* (1959, reprinted 1971). KENNETH K.S. CH'EN, *Buddhism in China: A Historical Survey* (1964, reprinted 1972), provides a survey of the entire tradition. E. ZÜRCHER, *The Buddhist Conquest of China: The Spread and Adaptation of Buddhism in Early Medieval China,* 2 vol. (1959, reprinted 1972), covers the period up to the early 5th century AD. A detailed study of religion and politics at the high point of Chinese Buddhism is STANLEY WEINSTEIN, *Buddhism Under the T'ang* (1987). A significant though often overlooked topic is covered by DANIEL L. OVERMYER, *Folk Buddhist Religion: Dissenting Sects in Late Traditional China* (1976). The modern period is treated by HOLMES WELCH, *The Buddhist Revival in China* (1968), and *Buddhism Under Mao* (1972).

JOSEPH M. KITAGAWA, *Religion in Japanese History* (1966), sets Japanese Buddhist traditions in their cultural context. Broad-ranging historical studies that focus more exclusively on Buddhism are CHARLES ELIOT, *Japanese Buddhism* (1935, reissued 1969); SHINSHŌ HANAYAMA, *A History of Japanese Buddhism* (1960); DAIGAN MATSUNAGA and ALICIA MATSUNAGA, *Foundation of Japanese Buddhism,* 2 vol. (1974–76); and WILLIAM R. LAFLEUR, *The Karma of Words: Buddhism and the Literary Arts in Medieval Japan* (1983). HELEN HARDACRE, *Kurozumikyō and the New Religions of Japan* (1986), discusses one of the Buddhist-oriented "new religions."

For Tibet and neighbouring countries, the best introduction is GUISEPPE TUCCI, *The Religions of Tibet* (1980; originally published in German, 1970); it can be supplemented by R.A. STEIN, *Tibetan Civilization* (1972; originally published in French, 1962), which emphasizes the integration of religion and culture in Tibet and Mongolia. The formation of the tradition is treated in depth by DAVID SNELLGROVE, *Indo-Tibetan Buddhism: Indian Buddhists and Their Tibetan Successors,* 2 vol. (1987), particularly in vol. 2.

The Buddha: A short but helpful introduction for those new to Buddhism is MICHAEL CARRITHERS, *The Buddha* (1983). A more extensive treatment that is based on artistic as well as textual evidence is provided in ALFRED FOUCHER, *La Vie du Bouddha* (1949), available also in an abridged English translation, *The Life of the Buddha* (1963, reissued 1972); it may be supplemented by his *Les Vies antérieures du Bouddha* (1955), a survey of the Buddha's previous lives. An excellent though technical study of the earliest sources is ANDRÉ BAREAU, *Recherches sur la biographie du Buddha dans les Sūtrapiṭaka et les Vinayapiṭaka anciens,* 2 vol. in 3 (1963–70).

In addition to works on the Buddha Gotama, readers may wish to consult three important books on related topics: HAR DAYAL, *The Bodhisattva Doctrine in Buddhist Sanskrit Literature* (1932, reissued 1978), a classic; MARIE-THÉRÈSE DE MALLMANN, *Introduction à l'étude d'Avalokiteçvara* (1948, reissued 1967); and ALAN SPONBERG and HELEN HARDACRE (eds.), *Maitreya, the Future Buddha* (1988).

Dharma: A lucid introduction to basic Buddhist teachings presented in a modernist Theravāda mode is WALPOLA RĀHULA, *What the Buddha Taught,* 2nd ed. (1967, reissued 1978). For a similar presentation of Buddhist ethics, see H. SADDHATISSA, *Buddhist Ethics: Essence of Buddhism* (1970); and GUNAPALA DHARMASIRI, *Fundamentals of Buddhist Ethics* (1989). A more nuanced presentation of basic Buddhist teaching by a more diverse group of scholars can be found in KENNETH W. MORGAN (ed.), *The Path of the Buddha: Buddhism Interpreted by Buddhists* (1956, reissued 1986). A high-quality collection of essays covering a variety of traditions may be found in DONALD S. LOPEZ, JR. (ed.), *Buddhist Hermeneutics* (1988). An advanced treatment of a broad range of Buddhist positions is provided in J. TAKAKUSU, *The Essentials of Buddhist Philosophy,* 3rd ed. (1956, reissued 1978). Those interested in the history of Western scholarship will want to consult GUY RICHARD WELBON, *The Buddhist Nirvāna and Its Western Interpreters* (1968, reprinted 1975).

The classic study of the early Buddhist schools is ANDRÉ BAREAU, *Les Sectes bouddhiques du petit véhicule* (1955). The doctrine of the Sarvastivādins, which is especially important for later Buddhist philosophy, is presented by TH. STCHERBATSKY, *The Central Conception of Buddhism and the Meaning of the Word "Dharma"* (1923, reissued 1974). The early Theravāda teaching is discussed in JOHN ROSS CARTER, *Dhamma: Western Academic and Sinhalese Buddhist Interpretation* (1978); and in the excellent work by STEVEN COLLINS, *Selfless Persons: Imagery and Thought in Theravāda Buddhism* (1982). Theravāda ethics are discussed in WINSTON L. KING, *In the Hope of Nibbana* (1964). King has also published *Theravāda Meditation: The Buddhist Transformation of Yoga* (1980), a significant work. The teachings of an important contemporary reformer are comprehensively presented by LOUIS GABAUDE, *Une Herméneutique Bouddhique contemporaine de Thaïlande: Buddhadasa Bhikku* (1988).

EDWARD CONZE, *Buddhist Thought in India: Three Phases of Buddhist Philosophy* (1962, reprinted 1983), is a good introduction to the development of Buddhist philosophy in India. More detailed studies include the classic L. DE LA VALLÉE POUSSIN, *Le Dogme et la philosophie du bouddhisme* (1930); and D. SEYFORT RUEGG, *The Study of Indian and Tibetan Thought* (1967), a difficult but important work. The rise of Mahāyāna is considered by PAUL WILLIAMS, *Mahāyāna Buddhism: The Doctrinal Foundation* (1989). Among the several excellent books on the Buddhist philosopher Nāgārjuna, two deserve special mention: T.R.V. MURTI, *The Central Philosophy of Buddhism* (1955, reissued 1980); and FREDERICK I. STRENG, *Emptiness: A Study in Religious Meaning* (1967). A central topic is treated in WILLIAM MONTGOMERY MCGOVERN, *A Manual of Buddhist Philosophy,* vol. 1, *Cosmology* (1923, reprinted 1977); and RANDY KLOETZLI, *Buddhist Cosmology: From Single World System to Pure Land: Science and Theology in the Images of Motion and Light* (1983). For studies of the Indo-Tibetan Tantric tradition, see SHASHI BHUSHAN DASGUPTA, *An Introduction to Tantric Buddhism,* 2nd ed. (1958, reprinted 1974); and ALEX WAYMAN, *The Buddhist Tantras: Light on Indo-Tibetan Esoterism* (1973), a collection of more specialized essays.

Among the East Asian traditions, Ch'an (Zen) has been the most adequately studied. See, for example, HEINRICH DUMOULIN, *Zen Buddhism: A History,* 2 vol. (1988–89; originally published in German, 1959); T.P. KASULIS, *Zen Action/Zen Person* (1981), a lucid presentation; and WINSTON KING, *Death Was His Kōan: The Samurai-Zen of Suzuki Shōsan* (1986). Significant books that introduce the teachings of other East Asian schools include FRANCIS H. COOK, *Hua-yen Buddhism: The Jewel Net of Indra* (1977); MINORU KIYOTA, *Shingon Buddhism: Theory and Practice* (1978); and ALFRED BLOOM, *Shinran's Gospel of Pure Grace* (1965).

In recent years Buddhists have begun to address Western philosophy and Christian thought in a serious way. KEIJI NISHITANI, *Religion and Nothingness* (1982), is an expression of the Kyōto school of Japanese Buddhist thinkers who have taken Western philosophy very seriously. GUNAPALA DHARMASIRI, *A Buddhist Critique of the Christian Concept of God* (1974, reissued 1988), is a Sri Lankan Buddhist's more polemical engagement with Christian theology.

Sangha: The basic "constitution" of the Buddhist sangha is discussed in JOHN CLIFFORD HOLT, *Discipline, the Canonical Buddhism of the Vinayapiṭaka* (1981). SUKUMAR DUTT, *Early Buddhist Monachism, 600 B.C.–100 B.C.* (1924, reissued 1984), traces the early history of the sangha in India. H.D. SANKALIA, *The University of Nalanda,* 2nd rev. and enlarged ed. (1972), recounts the history of one of the most important of all Buddhist monastic establishments.

The best study of premodern monasticism in the Theravāda world is R.A.L.H. GUNAWARDANA, *Robe and Plough: Monasticism and Economic Interest in Early Medieval Sri Lanka* (1979). Discussions of more recent monastic situations include E. MICHAEL MENDELSON, *Sangha and State in Burma: A Study of Monastic Sectarianism and Leadership* (1975); and JANE BUNNAG, *Buddhist Monk, Buddhist Layman: A Study of Urban Monastic Organization in Central Thailand* (1973). A more idyllic picture of Theravāda monastic life is depicted by MICHAEL CARRITHERS, *The Forest Monks of Sri Lanka: An Anthropological and Historical Study* (1983). The relationship between the monastic community and society is definitively treated in HEINZ BECHERT, *Buddhismus, Staat und Gesellschaft in den Ländern des Theravāda-Buddhismus,* 3 vol. (1966–73).

Good book-length discussions of Buddhist monasteries and monastic life in Central and East Asia are fewer, but the following can be recommended: ROBERT J. MILLER, *Monasteries and Culture Change in Inner Mongolia* (1959); J. PRIP-MØLLER, *Chinese Buddhist Monasteries* (1937, reissued 1967); J.J.M. de GROOT, *La Code du mahâyâna en Chine: son influence sur la vie monacale et sur le monde laïque* (1893, reprinted 1980); and HOLMES WELCH, *The Practice of Chinese Buddhism: 1900–1950* (1967), a detailed discussion of monastic institutions. One aspect of monastic life in Japan has been presented by DAISETZ TEITARO SUZUKI, *The Training of the Zen Buddhist Monk* (1934, reprinted 1974). NEIL MCMULLIN, *Buddhism and the State in Sixteenth-Century Japan* (1984), is a historical study.

Myths and legends: Except for the myth of Śākyamuni, Buddhist myths and legends have not, for the most part, received extended scholarly discussion. One of the few studies of Theravāda materials is TREVOR LING, *Buddhism and the Mythology of Evil: A Study of Theravāda Buddhism* (1962). JOHN S. STRONG, *The Legend of King Aśoka: A Study and Translation of Aśokāvadāna* (1983), though it has a pan-Buddhist relevance, focuses on a Sanskrit Hīnayāna tradition in superb fashion. For Mahāyāna and Vajrayāna/Esoteric mythology, two major sources are available: the *Mythologie asiatique illustrée* (1928), which provides extensive coverage of the relevant material; and ALICE GETTY, *The Gods of Northern Buddhism: Their History, Iconography, and Progressive Evolution Through the Northern Buddhist Countries,* 2nd ed. (1928, reprinted 1988). ALICIA MATSUNAGA, *The Buddhist Philosophy of Assimilation: The Historical Development of the Honji-Suijaku Theory* (1969), discusses the way in which Buddhism assimilated local deities and cults in China and particularly in Japan.

Images and symbols: Two books that provide excellent Pan-Asian introductions are DIETRICH SECKEL, *The Art of Buddhism* (1964; originally published in German, 1962); and DAVID L. SNELLGROVE (ed.), *The Image of the Buddha* (1978). A less readable collection, though on a very important topic, is ANNA LIBERA DALLAPICCOLA and STEPHANIE ZINGEL-AVE LALLEMANT (eds.), *The Stupa: Its Religious, Historical, and Architectural Significance* (1979).

Although there are many studies of Buddhist images and symbols, few of them focus on the distinctively Buddhist significance of such images. Among the exceptions are ANANDA K. COOMARASWAMY, *Elements of Buddhist Iconography,* 3rd ed. (1979); an important book-length article by PAUL MUS, "Le Buddha Paré: son origine indienne: Çākyamuni dans le mahāyānisme moyen," *Bulletin de l'École Française d'Extrême-Orient,* 28:(1–2)153–280 (January–June 1928); MARIE-THÉRÈSE MALLMANN, *Introduction à l'iconographie du tântrisme bouddhique* (1975); a number of the articles contained in LUIS O. GÓMEZ and HIRAM W. WOODWARD, JR. (eds.), *Barabudur: History and Significance of a Buddhist Monument* (1981); FERDINAND DIEDERICH LESSING, *Yung-Ho-Kung: An Iconography of the Lamaist Cathedral in Peking, with Notes on Lamaist Mythology and Cult* (1942), a very complex work; RYUJUN TAJIMA, *Les Deux Grand Mandalas et la doctrine de l'ésotérisme shingon* (1959); and SHIN'ICHI HISAMATSU, *Zen and the Fine Arts* (1971, reissued 1982).

Popular religious practices: Though many books on various topics mention popular religious practices, few full-length studies are available. STEPHEN F. TEISER, *The Ghost Festival in Medieval China* (1988), a reconstruction and analysis, is the best work available on premodern rites and ceremonies. Among the full-length studies based to a considerable extent on personal observation, three of the most interesting focus on Thailand and Laos: KENNETH E. WELLS, *Thai Buddhism: Its Rites and Activities* (1960, reprinted 1982); STANLEY J. TAMBIAH, *Buddhism and the Spirit Cults in North-East Thailand* (1970); and MARCEL ZAGO, *Rites et cérémonies en milieu bouddhiste lao* (1972). There are four quite different but equally interesting works that focus on practices in Tibet and neighbouring regions: ROBERT B. EKVALL, *Religious Observances in Tibet: Patterns and Function* (1964); STEPHEN BEYER, *The Cult of Tārā: Magic and Ritual in Tibet* (1973), an important descriptive and interpretive work; and two anthropological studies by SHERRY B. ORTNER, *Sherpas Through Their Rituals* (1978) and *High Religion: A Cultural and Political History of Sherpa Buddhism* (1989).

Contemporary trends: Since the mid-1960s, two broad surveys of Buddhism in the modern world have been published. ERNST BENZ, *Buddhism or Communism: Which Holds the Future of Asia?* (1965; originally published in German, 1963), though rather superficial and seriously dated, contains interesting material on Buddhist reform movements that have crossed national boundaries. HEINRICH DUMOULIN and JOHN C. MARALDO (eds.), *Buddhism in the Modern World* (1976; originally published in German, 1970), includes essays on Buddhism in various regions and countries in Asia, Europe, and America.

Several books have been published that deal with the new Buddhist communities that have been established in India and in the West: TREVOR LING, *Buddhist Revival in India: Aspects of the Sociology of Buddhism* (1980); KŌSHŌ YAMAMOTO, *Buddhism in Europe: Report of a Journey to the West, in 1966, of an Eastern Buddhist* (1967); EMMA MCCLOY LAYMAN, *Buddhism in America* (1976); CHARLES S. PREBISH, *American Buddhism* (1979); and LOUISE H. HUNTER, *Buddhism in Hawaii: Its Impact on a Yankee Community* (1971).

(F.E.R.)

Buenos Aires

Buenos Aires, the federal capital of Argentina, is one of the most populous cities in the world. The city proper, which is also the Federal District, is located on the western shore of the Río de la Plata and covers an area of 77 square miles (200 square kilometres). The total metropolitan area, however, occupies some 1,500 square miles. According to tradition, 16th-century Spanish sailors named the port for their patron saint, Santa María del Buen Aire (St. Mary of the Good Air).

The city is the national centre of commerce, industry, politics, and culture. Its wealth and influence overshadow the life of the rest of the nation, and it also presents Argentina with its severest economic and social problems. In addition, because of its location, Buenos Aires often has been a centre for political and social unrest. The Argentine poet and philosopher Ezequiel Martínez Estrada has called the city "The Head of Goliath," a metaphor that illustrates its imbalance in relation to the rest of the country, much like a large-headed giant with a feeble body.

Buenos Aires, which celebrated its 400th anniversary in 1980, is beset with many of the same problems encountered by other large cities. Growing industry is causing increased pollution; limited land area in the city proper has led to the construction of high-rise buildings, adding to urban congestion; rapid expansion is hampered by inadequate public services; increased migration from the countryside is creating a growing urban population composed of the poor and unskilled. Adding to the complexity of daily living is a high rate of inflation, which hampers efforts to improve conditions. There are, in spite of all this, signs of progress and burgeoning strength in the city.

This article is divided into the following sections:

Physical and human geography

CHARACTER OF THE CITY

Even the most casual visitor to the city of Buenos Aires is impressed with its energy and bustle. Tourists who stay only a day or two may walk along the Calle Florida, a pedestrian mall lined with elegant shops, and admire the wealth of goods for sale and the number of elegant, well-dressed people. They can enjoy bargain shopping—mainly of world-class leather goods and woolen clothing—and the steak dinners available in numerous restaurants for considerably less than what the same meal might cost in the United States or in Europe. At night the visitor to the city may be taken to a *boite* ("nightclub") for an evening of tango, the emotional dance that originated in the lower-class areas of the city and is said to reflect the essence of the soul of the *porteño,* the name given to a resident of Buenos Aires.

Origin of the tango

A brief tour usually includes La Boca, a picturesque section at the mouth (Spanish *boca*) of the Riachuelo River, where the city's first settlers landed. The section is filled with Italian restaurants, and some streets, such as the Caminito, are lined with wooden houses painted in bright, gay colours. La Boca, now an artists' colony, was the site of the city's first meat salting plants, which brought great wealth to Buenos Aires in the 19th century.

The visitor will also notice the broad avenues that define the limits between districts in the central city and that are lined by seemingly endless rows of apartment houses. During rush hours these avenues are clogged with traffic, a portion of which is created by a peculiar microbus, called the colectivo, an Argentine invention that is one of the city's distinctive features. Half the size of a typical city bus, it is usually seen crammed with people and often barely pauses as passengers jump on and off. The drivers, usually one of the *socios,* or owners, of the cooperative that operates the line, are often colourful characters, noted for their frequent lively commentary on everything from weather to politics and football (soccer). Their aggressiveness on the road is legendary. Depicted as high-strung but competent, the colectivo driver has become a symbol of the frenetic pace of life in the city.

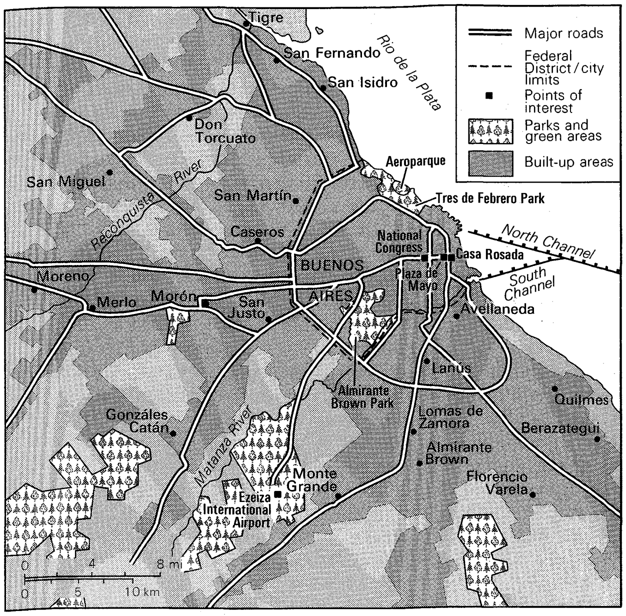
The colectivo

Having observed some elements of the city's essence, the visitor may miss others. Few tourists, for instance, ever get out of the *centro,* the old city centre, which occupies only a fraction of the metropolitan area. Almost everything attractive to the tourist lies there. In addition to the fancy shops, the *centro* is the site of virtually all of the major financial institutions and corporate headquarters. Most of the first-run motion-picture and live theatres are clustered within a four- or five-block stretch on the Avenida Corrientes and the Calle Lavalle, which forms the centre of a crowded entertainment district that is ablaze with light at night.

Buenos Aires cannot be fully known and understood, however, without a visit to the suburban hinterland and the many, varied neighbourhoods that give the city its flavour and explain its relationship to the rest of the country. This helps bring into focus the lives of the people who live in a sprawling city that by the late 20th century was growing nearly five times faster than the country as a whole. Buenos Aires is a city of distinctive neighbourhoods that have their own meeting places, generally coffeehouses or bars. This is a tradition rooted in the colonial period, when the centre of each neighbourhood was a general store and bar known as the pulperia.

THE LANDSCAPE

The city site. The city of Buenos Aires is located at the northeastern edge of the flat plain known as the Pampa, which occupies the heartland of Argentina. It is situated at the point where the Paraná River delta widens to meet the Río de la Plata. The eastern and northern limits of the metropolitan area are defined by the Río de la Plata, and the city's most prominent physical characteristics are the numerous small rivers that flow through its periphery. The



Buenos Aires and surrounding area.

centre of the city lies on a bluff overlooking the Río de la Plata, and to the south flows another river, the Riachuelo, the banks of which mark the other high land in the city. The rest of the city is laid out on the floodplains of the rivers, virtually without significant elevations.

Seasonal temperatures

Climate. The temperate climate of the city is characteristic of the Río de la Plata's coastal plain. The city is hot and humid during the summer months of December to February, with a mean high temperature of 83°F (28°C). The autumn and spring are characterized by fluctuating temperatures and quickly changing weather. The winter months of June to August are mild but humid, with a mean temperature of 52°F (11°C). The average annual temperature is slightly higher than 60° F (16° C). Frosts occur from May to September, but snowfall is extremely rare. Winds are generally of low velocity and are more frequent during the season of electrical storms, between September and March. Rainfall is heaviest in March.

The city layout. The metropolitan area is divided into the Federal District, established in 1880, and the surrounding suburbs, or *partidos.* The Federal District contains less than one-third of the population of the metropolitan area, a proportion that shrinks as the suburbs continue to attract industry and residential communities. The city is divided into districts that coincide mostly with the old neighbourhoods, or barrios. The *centro* is built on the original colonial foundation. It has narrow streets laid out at 90-degree angles to form a grid pattern. This rectilinear pattern holds for more than 20 square blocks, an area that defined the limits of the city until the late 19th century. Since that time, expansion has been less planned, and the pattern of streets is less regular. The limits of the Federal District are marked by the Riachuelo River and the Avenida General Paz, which was opened in 1941 after nearly a decade of construction.

The modern city developed outward from the Plaza de Mayo, a historic square flanked by the Town Hall (Cabildo), which dates from the 18th century, and the Government House, commonly called the Casa Rosada. The Casa Rosada faces west, up the broad Avenida de Mayo, which leads directly to the Plaza del Congreso and the National Congress building, built in the early 20th century. All distances on national highways are measured from the zero-kilometre point in the small square across from the building. The Plaza de Mayo is also the site of the Metropolitan Cathedral, another monumental building from the colonial period. The rest of what remains of colonial Buenos Aires lies mostly south of the plaza, in San Telmo, or Barrio Sur, which, after nearly a century of neglect and decay, has been restored and gentrified.

Architectural styles

Architecturally, the city can be divided into four residential styles. The most common is a structure that began as a single-family dwelling along the street, with an interior patio or garden and rows of small rooms down either side that lead to a kitchen. These houses are attached one to another to form an unbroken facade at the sidewalk. As population density increased in the early 20th century, this basic house was broken up into smaller units and gave rise to a second style, a two- and three-story version known as the *petit hotel,* which was neither as wide nor as deep as its predecessor. The lots on which these houses were constructed defined the size of the first generation of high-rise apartment houses that now dominate the middle-class sections of the city, including Palermo, Recoleta, and Retiro, which, together with other neighbourhoods, are collectively called Barrio Norte. These high rises, representing a third style, were built one next to the other, stretching for block after block in the northern sector of the city. In Belgrano, just north of Barrio Norte, these apartment houses are freestanding; many are as large as city blocks, with their own gardens, because they were built on the lots of single-family detached houses that were common in outer districts of the capital and in the suburban *partidos.*

The *villas miserias*

The fourth residential style is the corrugated metal shack, typical of the shantytowns that have come to constitute about one-fourth of the homes in the metropolitan area and house about 30 percent of the population. These settlements are characterized by their precarious tenure and the absence of basic public services. While such settlements are common to large cities, they have become a significant aspect of the urban landscape in Buenos Aires only since the 1960s. These *villas miserias,* or "popular settlements" as they are called officially, are largely inhabited by rural migrants who felt that they could improve their condition by moving to the city. Because these migrants were utterly without resources, they had little choice but to move onto unoccupied land that was otherwise undesirable.

THE PEOPLE

Buenos Aires is often described as Latin America's most European city. The population is made up largely of the descendants of immigrants from Spain and Italy who came to Argentina in the late 19th or early 20th century. There are also significant minorities of Germans, British, Jews from central and eastern Europe, and Middle East-

The Casa Rosada on the Plaza de Mayo, Buenos Aires.

ern peoples, who are known collectively as *turcos*. Roman Catholicism is the predominant religion.

Since the 1930s, most of the immigrants to the city have come from the north of Argentina, where the population is predominantly mestizo (mixed Indian and European). Today, the mestizos make up between one-fourth and one-third of the population in the metropolitan area. It is mostly the mestizos who live in the poorest sections of the city, in the *villas miserias* and the distant suburbs. The area's black and mulatto population is negligible in size.

Cultural and linguistic influences

While there are no ethnic neighbourhoods, strictly speaking, many of the smaller minorities tend to settle close to one another in tightly knit communities. Villa Crespo, for example, is known as a Jewish neighbourhood; the Avenida de Mayo is a centre for Spaniards; and Flores is the home of many *turcos*. The assimilation of these groups has been less than complete, but the Argentine identity has been flexible enough to allow ethnocentric mutual-aid societies and social clubs to emerge. Even the dominant Spanish language has been affected by other European cultures and has undergone changes; in the slums and waterfront districts an Italianized dialect has emerged, and Italian cuisine is popular in the city.

THE ECONOMY

The importance of Buenos Aires, the nation's chief port, to the Argentine economy is related to the country's overwhelming dependence on the production and export of agricultural commodities. Buenos Aires is the country's chief point of consumption, processing, and shipping. Unlike much of the rest of the country, the city has a varied economy, which helps it maintain a degree of stability despite the rampant inflation that affects the entire nation.

The port

The port of Buenos Aires is the largest in South America. Ships from all parts of the world stream in to deliver machine goods and consumer durables and to take away grains or agricultural by-products, such as food oils. And yet, as with so much of the city, the port facilities are old and inefficient. At harvest time it is common to see long lines of trucks at the port entrance, waiting to transfer their loads to one of the ships lying offshore, which in turn are waiting to use the narrow channel into the port. Serious proposals to move the port to another, better harbour have met with little response.

Industry. Heavy industry has grown much faster in metropolitan Buenos Aires than elsewhere in Argentina. More than one-third of the industrial capacity of the country is in the Buenos Aires metropolitan area, and about one-half of all manufacturing jobs are located there. During the 1950s there was great emphasis on the production of consumer goods aimed toward making the city self-sufficient in this area. The main industries include food processing (meat, fish, and grain), metalworking, automobile assembly, oil refining, printing and publishing, and the manufacture of textiles, beverages, paper, and chemicals. Service industries account for more than 20 percent of the jobs in the metropolitan area. The area consumes more than half of all the electric and natural gas energy produced in the country. Inside the city proper larger industrial and manufacturing establishments are mostly located in the barrio of Barracas, but they are becoming increasingly more concentrated in the southern suburbs.

Finance and commerce. The city virtually monopolizes the banking activity of the country. Banks in Buenos Aires hold the largest share of the nation's bank deposits, a large portion of which are held by foreign investors. The Banco Central de la República Argentina controls the federal banking system. The Buenos Aires stock exchange, along with specialized markets for meat, cattle, fruit, and grain, makes the city the dominant stock and commodities trading centre in the country. The financial district is concentrated just north of the Plaza de Mayo.

Transportation. Buenos Aires has developed one of the world's better urban transportation systems, although it evolved serendipitously around the unique colectivo. Travelers are seldom more than one block from a bus, and often they have a choice of buses to take. On the other hand, the subway system was designed for the Buenos Aires of the 1940s. Its adequacy in the modern city has been diminishing, given the two socially distinct, yet similar patterns of commuting. Most professionals, businessmen, and other white-collar workers commute to the centre of town by car or train from the northern zones. Blue-collar workers commute across town, from residential to industrial sections, generally by colectivo. Though most city traffic is regulated by automatic traffic lights, the city's residents are notorious for ignoring them. For many years, two major streets, Calle Florida and Calle Lavalle, were traditionally closed to motor traffic during part of the day to allow for a free flow of pedestrians. Calle Florida, however, has been reserved for pedestrians at all times.

Inner-city traffic

The highway system includes several expressways that radiate out from the *centro* to connect it with the Avenida General Paz, which circles most of the city, thus forming a spokelike pattern. Other main avenues connect the Plaza de Mayo, in the heart of the city, with outlying neighbourhoods. The city is the terminus of every major railway in the country. There are also electric suburban lines connecting the city with the towns of Tigre and Moreno.

The international airport of Ezeiza, Don Torcuato airport, and El Palomar, the military airport, are respectively located outside the city limits in the *partidos* of Esteban Echeverria, Tigre, and Morón. They are connected to the city by expressways. Jorge Newbery, the Buenos Aires City Airport, lies within the Federal District and serves domestic airlines, as well as those that operate to and from neighbouring countries.

ADMINISTRATION AND SOCIAL CONDITIONS

Federal power over the city

Government. The municipal government is headed by an appointed intendant, or mayor, and the elected City Council. The legislative and executive powers of the council and mayor are limited, however, by the centralizing tendency of the federal government, which, of course, has its seat in the Federal District.

By law, the president of the republic actually controls the municipality, and the National Congress is ultimately responsible for legislation pertaining to it. The president appoints the mayor. Over the years the elected city council has functioned only intermittently, and in times of military rule the actual governing of the city often has been assumed directly by the junta in power.

The city territory is divided into administrative districts, some of which coincide approximately with the traditional barrios. Each district has a neighbourhood junta, or council, which deals with neighbourhood problems.

Services. Almost all public-service facilities are controlled by national governmental organizations, functioning independently of the city administration. The municipal government is in charge only of the construction and maintenance of pavements and sidewalks and of parks. Because of population growth and uncontrolled building, public services have been severely strained.

Sanitary facilities—water supply, drainage, sewers—are the responsibility of the General Administration of Sanitary Works of the Nation, which services a major part of Greater Buenos Aires. The large water purification plant in Palermo Park treats water from the Río de la Plata and sends it underground through tunnels to reservoirs in different parts of the city. Electricity is provided by the Company of Electrical Services of Greater Buenos Aires, a government stock company. The National Telecommunications Enterprise operates many centres and provides telephone service for the capital and its surrounding areas. Natural gas is provided for all of Greater Buenos Aires by the State Gas Corporation from oil fields to the north, south, and west.

Health. The city has municipal and private hospitals, as well as numerous dispensaries, pharmacies, and social hygiene centres in the various barrios. A relatively high number of hospital beds are maintained in order to accommodate the many patients from other parts of Argentina who travel to Buenos Aires for specialized treatment.

The waste disposal system includes garbage-burning centres, but most wastes are used to fill lowlands along the Río de la Plata. Reclaimed areas are converted into parks, sports areas, and construction sites.

Education. Argentines are among the most literate peo-

The University of Buenos Aires

ple in the world, and the *porteño* has access to the country's finest educational facilities. The primary and secondary schools are based on the neighbourhood system, and the government runs special national high schools as college preparatory schools. Students in those high schools and others, including numerous schools administered by the Roman Catholic Church or by other religious orders, aim for entrance into the University of Buenos Aires (1821). Despite the repressive years of military dictatorship, this institution has continued to produce outstanding students and teachers. Faculty members have earned Nobel prizes in the medical and scientific fields. The political difficulties suffered by the University of Buenos Aires has encouraged the foundation of several private universities, the most prominent being the University of Belgrano. In addition, the city is the site of the University of Morón, and there are two major universities run by the Roman Catholic Church, the Catholic University of Argentina and Salvador University.

CULTURAL LIFE

Military curtailment of free expression

Buenos Aires' monopoly over the nation's activities is, perhaps, most evident in the capital's cultural life. The plastic arts are always active, with dozens of galleries along and near Calle Florida, just off Avenida Santa Fe, or in elegant, remodeled colonial houses in the San Telmo district. Every modernist movement of note has had its adherents in Buenos Aires, and it is easy to see the world movements in art, letters, theatre, and music reflected in the city. The magnificent opera house, for instance, the Colón Theatre, is one of the major stops for opera stars from all parts of the world. Cultural life in the capital has been peculiarly vulnerable to political change. Military governments, wary of artistic expression, tended to be more restrictive than democratic governments. Newspapers particularly have struggled for free expression during periods of military dominance. Buenos Aires, one of the major publishing centres of Latin America, has a wide variety of newspapers, including several in foreign languages. At least two dailies, *La Prensa* and *La Nación,* are internationally known.

The performing arts. The most important of the city's theatres is the Colón Theatre, which is the opera house as well as the headquarters of the national ballet and the national symphony. The San Martín Municipal Theatre houses three simultaneously available stages as well as an art gallery; the Presidente Alvear Theatre offers performances almost daily. Another theatre of note is the Cervantes National Theatre. Amateur theatre groups are active, and there is an open-air stage in La Boca. Performances of folk songs and dances, known as *peñas,* are extremely popular.

Museums and libraries. The city's museums—several of which are run by the municipal government—house varied collections. The Bernardino Rivadavia Argentine Museum of Natural Sciences has an exceptionally rich fossil collection and operates a scientific institute. The National Museum of Fine Arts contains collections of world masters and of Argentine painters and sculptors, while the National Museum of Decorative Arts houses tapestries and antiques. The Isaac Fernández Blanco Municipal Museum of Hispanic-American Art contains antique silver objects in a replica of a colonial home. Other art collections include Spanish, Italian, and modern works, and there are several historical museums and documentary centres.

The public municipal libraries, distributed throughout the city, are complemented by larger university and institutionally sponsored libraries. The National Library, the city's largest, is now housed in a modern building in Barrio Norte.

Recreation. The city is ringed with *espacios verdes* ("green areas"), which include plazas, parks, and tree-lined boulevards. Two extensive parks that were built on reclaimed floodlands are the Almirante Brown Park, in the Riachuelo Valley, and the Tres de Febrero Park, on the Río de la Plata. Palermo is the oldest park.

Favourite sports

Equestrian sports are enormously popular, especially polo, which has become the national sport. *Pato,* another popular game played on horseback, traces its origin to nomadic pampean Indians. The most popular team sport is football (soccer), which can be seen being played in parks and on fields throughout the urban area. Sports facilities include the Municipal Auto Race Track, the zoological and botanical gardens, the university campuses, the public baths, and various nautical and sports clubs.

(J.M.F.P./Jo.B./J.S.T.)

History

THE EARLY PERIOD

Founding

The city of Buenos Aires was founded twice. It was first founded in 1536 by an expedition led by the Spaniard Pedro de Mendoza, who had been made the first governor general of the Río de la Plata region. That settlement soon fell victim to local Indians and to deficient supplies, and the survivors had to retreat up the river to the fortified settlement of Asunción. Nearly 50 years later Juan de Garay led a more substantial expedition back to the site, and there, at the mouth of the Río Riachuelo, he refounded Nuestra Señora Santa María del Buen Aire in 1580. Huge tracts of land in the environs of the city were granted to members of the expedition, and they began immediately to harvest the pastoral animals that had multiplied since having been left by the original party.

For nearly two centuries Buenos Aires grew at a modest pace. It was a reasonably good port, but it suffered from the rigid organization of the Spanish Empire in America, by which only selected ports could be used for trade. The entire Río de la Plata region was made part of the Viceroyalty of Peru and governed from Lima. Within the Viceroyalty, only Callao, the port near Lima, was granted permission to trade with Spanish merchants. This effectively reduced Buenos Aires to a backwater. Goods from Callao took nearly six months to reach Buenos Aires by oxcart. Any goods the settlers wanted to sell to Spain took that long to reach Callao and another four or six months before they might be shipped from the port to Cádiz. A complete exchange took at least 24 months.

The vast distance separating Buenos Aires from other centres of population in the viceroyalty left the city with only sporadic contact with the administrative authority of the crown. Gradually, the city evolved its own way of life, based on extensive ranching and contraband trade, while the rest of the viceroyalty was focused to one degree or another on the mining enterprises of the Andean region, called Upper Peru (modern Bolivia). A string of settlements was established along the foothills of the Andes to serve the mining region. Their links with the port on the Río de la Plata were of little consequence.

Contraband trade

Instead of suffering from neglect, the *porteños* thrived. In the last quarter of the 17th century and the first half of the 18th, settlements spread rapidly to the northwest along the banks of the Paraná River, a fertile area well irrigated by many streams and small rivers; these were easily navigated by small boats operated by smugglers who reached the many farms and ranches that lined the river. By the beginning of the 18th century, Argentines were exporting thousands of tons of cereals, tens of thousands of cattle hides, and tons of dried beef destined for the plantations of northern Brazil and the Caribbean islands. The British were the principal source of capital and of transportation for this contraband trade.

By the middle of the 18th century, Buenos Aires was a thriving, if still modest commercial entrepôt of nearly 20,000 inhabitants. The houses were built along the narrow earthen streets stretching north from the Riachuelo. The original harbour had become silted up, and the larger boats that now called at the port had to anchor offshore. But the economic success of the region was undeniable, and in 1776, as part of the Bourbon monarchy's broad reform effort, Buenos Aires was named the capital of the new Viceroyalty of the Río de la Plata. The Bourbon monarchs hoped that by expanding their administrative setup in the Americas they would increase tax revenue from the colonies and, at the same time, increase control over the colonies to protect them from the covetous attentions of Spain's rivals, especially the British. Trade out of Buenos Aires was by this time legal, although the crown still attempted to control its flow and pattern. Because the major mining towns of Upper Peru were now within the confines of the viceroyalty, silver was the most valuable export. The city flourished, and, over the last quarter of the 18th and in the early 19th century, the population of the city nearly doubled, from 24,000 in 1778 to 42,500 in 1810. Official trade reflected Buenos Aires' position as the administrative centre of the viceroyalty. Spain became the region's principal trading partner.

The divided elite

Perhaps the most significant result of the administrative reforms of 1776 was that they split the elite into two groups whose economic interests were divergent. One continued to concentrate its energies on the pastoral activities of the city's hinterland and the related trade with Cuba, Brazil, and Great Britain; its interests were more international. The other group was tied economically and administratively to the official activities of the viceroyalty. It was linked to the official bodies, such as the *consulado* (the trade board), that were recognized by the crown and through which the crown attempted to channel all economic activity. This group's interests were more regional.

THE INDEPENDENT CAPITAL

The independent spirit of the city was given a tremendous boost in 1806 and 1807 when local militia forces fought off two attempted invasions by British troops. Neither invasion was a major effort, but the fact that local forces had defeated a British army marked the initial episode in the history of Argentine nationalism. In 1808 when Napoleon invaded Spain and placed his brother Joseph Bonaparte on the throne in Madrid, many *porteños,* like people throughout the empire, reconsidered their ties to the crown. In May 1810 the town council severed ties with Spain and the viceregal government, and on May 25 it declared allegiance to a new ruling junta.

The events of the next decade emphasized the split between the city and the rest of the region. Few residents of the interior were disposed to follow the lead of Buenos Aires, and it was not until 1816, at a congress in Tucumán, that the other provinces declared their independence. A provisional government was created, and Buenos Aires was named capital of the United Provinces of the Río de la Plata. The more distant provinces of the former viceroyalty, Bolivia, Uruguay, and Paraguay, refused to become part of a new nation dominated by the port city, however. For nearly 30 years, the provinces were held together in an uneasy truce, called federalism, in which the city of Buenos Aires and its hinterland exercised whatever central authority existed in the new nation; the interior provinces were allowed to go their own way.

The United Provinces of the Río de la Plata

Ironically, it was the interior provinces that suffered most from this arrangement, and in 1851 they mounted a coalition that attempted to change the balance of power by force. They succeeded in ousting the *porteño* leader, Juan Manuel de Rosas, but were unable to reorganize the nation in an effective manner. A decade later, the *porteños,* led by the military leader Bartolomé Mitre, imposed their will on the interior through a strong government centred in Buenos Aires. This development was recognized officially when the city was made the federal capital in 1880.

The political struggles between the *porteños* and the interior became more intense after 1850 because the stakes became greater. Dramatic changes in the European market as a result of industrialization and the transformation of capitalism, together with significant advances in technology, made exploitation of the fertile plains of Argentina economically viable. All that was required was the labour to work the land and the capital to pay for the transportation of products to the ports. For the most part, the capital came from Britain. The bulk of the labour came from Spain and Italy. In little more than a generation the land was transformed. By the beginning of World War I, Argentina had become one of the world's principal exporters of agricultural products.

The economic change in the countryside led to three fundamental changes in the character of the city. First, the population changed. Immigrants who had been attracted to the country with the hope of settling on the land found it impossible to buy land and they migrated back to the city. At the same time, the need for new port facilities and service activities related to increasing exports created a demand for labour. Those newcomers, mainly from Spain and Italy, but also from eastern Europe and Germany, jammed into the older houses on the south side of the city, pushing the middle-class residents north across the Avenida de Mayo. Because many jobs were in the port and in the slaughterhouses on the outskirts of the city, the newcomers also pushed south across the Riachuelo into adjoining counties.

The European immigrants

The second significant change in the city was the massive amount of wealth that came into the hands of individuals and to the state. The former built great mansions, modeled after French châteaus. These mansions today house government ministries or the embassies of foreign governments. At the time, they were the international symbol of vast wealth. In Paris, at the turn of the century, a common phrase was "to be as rich as an Argentine." These mansions were constructed in the Barrio Norte, many around the Plaza San Martín, at the northern end of the Calle Florida, or close to the Avenida Santa Fe.

The Paris of South America

The third major transformation was in the physical layout of the city. The owners of the mansions, members of the ruling elite, decided that they would transform Buenos Aires into the Paris of South America. As part of the preparations for the May 1910 celebration of the centennial of the first declaration of independence, the City Council decided to build a subway system and a network of broad avenues radiating out from the city centre, in frank imitation of the urban reforms imposed on Paris by Napoleon III. The plan called for the construction of broad avenues every four blocks, running east and west, and every 10 blocks, running north and south, and for construction of what would be claimed as the broadest avenue in the world, patterned on the Champs-Élysées. Named 9 de Julio after the official national day of independence, that block-wide swath was cut through the city in the 1930s and opened officially in October 1937.

The infrastructure put into place in the years before World War I endures to the present. The broad avenues in the core of the city, most of them carved out during the 1920s and '30s, continue to carry the burden of vehicular traffic, and only one of the five subway lines was built after World War II. Although the infrastructure of the city is severely strained, the urban structure still adheres to the form conceived by the generation of leaders born in the 19th century.

THE MODERN CITY

Since the mid-20th century, three important developments have affected the character of the city. The first was the virtual halting of international immigration after 1930. The demand for labour in the metropolitan area was met thereafter, in large measure, by migrants from the interior—Argentines of mestizo ancestry, whose presence created conflicts with the *porteños.* These people came from northwestern Argentina or from the neighbouring countries of Uruguay, Paraguay, and Bolivia.

Migration of the mestizos

The second development stemmed from the movement of the mestizos, who, finding the inner city slums too crowded, settled on unoccupied land in the suburbs near the manufacturing establishments that provided many jobs. The mestizos founded the first shantytowns, the *villas miserias.* The racial difference of these newer migrants to the city added a nuance of bitterness to the social conflicts that characterized the development of industrial capitalism in the metropolitan area in the 1930s, '40s, and '50s. Many of the newcomers would become staunch followers of the populist leader Juan D. Perón, who came to power in a military coup in 1943 and served as president from 1946 to 1955 and again from 1973 until his death in 1974.

The third important development in the second half of the century was the replacement of the tramway and train by the automobile and the colectivo as the dominant modes of transportation in the city. Unlike many other large Western cities, Buenos Aires is not yet ringed by a network of superhighways. A complete network was planned after World War II, but economic and political difficulties have prevented their construction. By the late

20th century the existing network of streets was saturated with vehicular traffic, and the need to improve other modes of transportation seemed imperative as traffic jams and gridlock added to the more frustrating characteristics of contemporary Buenos Aires. Some progress was made in 1979 when the Metropolitan Railroad was established to cope with the capital's traffic problems. City and suburban authorities were coordinated, and in succeeding years plans to expand rail lines and, employing Japanese companies, to electrify them, were implemented. New Japanese-built railroad cars began replacing older cars on the line.

Urban problems in the late 20th century

The new underclass in the city, the recent migrants, have complicated the city's problems. These peoples are undereducated and lack employment skills, and it has been difficult for the service-oriented economy to absorb and employ them. The government, no matter how willing, has had little success in finding the resources to help the newcomers raise their standard of living. Dealing with massive urban poverty and its accompanying social and financial problems was a major concern of the national and local governments in the final decades of the 20th century.

BIBLIOGRAPHY. JAMES R. SCOBIE, *Buenos Aires: Plaza to Suburb, 1870–1910* (1974), is the best single volume on the city in English, chronicling the city's transformation from a relatively small town to one of the world's largest metropolitan areas. Dealing with much the same period, CHARLES S. SARGENT, *The Spatial Evolution of Greater Buenos Aires, Argentina, 1870–1930* (1974), focuses on the effects of innovations in transportation on urban growth. HORACIO A. DIFRIERI, *Buenos Aires: geohistoria de una metrópóli* (1981), chronicles the city's geographical evolution. The entire history of the city is covered in a collection of conference papers, STANLEY R. ROSS and THOMAS F. MCGANN (eds.), *Buenos Aires: 400 Years* (1982); and in JOSÉ LUIS ROMERO and LUIS ALBERTO ROMERO (eds.), *Buenos Aires, historia de cuatro siglos*, 2 vol. (1983). Various periods of the city's history are examined in R. DE LAFUENTE MACHAIN, *Buenos Aires en el siglo XVII* (1980), and *Buenos Aires en el siglo XVIII* (1980); RICARDO LUIS MOLINARI, *Buenos Aires, 4 siglos*, rev. ed. (1983); MANUEL MUJICA LÁINEZ, *Los porteños* (1979), essential for cultural history; JOSÉ MARÍA PEÑA, *Buenos Aires anteayer: testimonios gráficos de una ciudad, 1854–1910* (1981), and *Buenos Aires ayer: testimonios gráficos de una ciudad, 1910–1930* (1984), mostly photographs; and RÓMULO ZABALA and ENRIQUE DE GANDÍA, *Historia de la ciudad de Buenos Aires*, 2 vol. (1936, reissued 1980), spanning the years 1536–1800.

Demographic data on the city is readily available in *Censo nacional de población y vivienda, 1980, Serie B, Características generales*, in the volume titled *Capital federal* (1981); and in "Buenos Aires," *International Demographics*, 4(10):1–11 (October 1985). More statistical data can be found in Argentina's other national censuses. An outstanding work on Buenos Aires' urban poverty and its shantytowns is *La pobreza en la Argentina: indicadores de necesidades básicas insatisfechas a partir de los datos del censo nacional de población y vivienda, 1980* (1984), an official report by the Argentine census bureau.

Building Construction

Building construction is an ancient human activity. It began with the purely functional need for a controlled environment to moderate the effects of climate. Constructed shelters were one means by which human beings were able to adapt themselves to a wide variety of climates and become a global species.

Human shelters were at first very simple and perhaps lasted only a few days or months. Over time, however, even temporary structures evolved into such highly refined forms as the igloo. Gradually more durable structures began to appear, particularly after the advent of agriculture, when people began to stay in one place for long periods. The first shelters were dwellings, but later other functions, such as food storage and ceremony, were housed in separate buildings. Some structures began to have symbolic as well as functional value, marking the beginning of the distinction between architecture and building.

The history of building is marked by a number of trends. One is the increasing durability of the materials used. Early building materials were perishable, such as leaves, branches, and animal hides. Later, more durable natural materials—such as clay, stone, and timber—and, finally, synthetic materials—such as brick, concrete, metals, and plastics—were used. Another is a quest for buildings of ever greater height and span; this was made possible by the development of stronger materials and by knowledge of how materials behave and how to exploit them to greater advantage. A third major trend involves the degree of control exercised over the interior environment of buildings: increasingly precise regulation of air temperature, light and sound levels, humidity, odours, air speed, and other factors that affect human comfort has been possible. Yet another trend is the change in energy available to the construction process, starting with human muscle power and developing toward the powerful machinery used today.

The present state of building construction is complex. There is a wide range of building products and systems which are aimed primarily at groups of building types or markets. The design process for buildings is highly organized and draws upon research establishments that study material properties and performance, code officials who adopt and enforce safety standards, and design professionals who determine user needs and design a building to meet those needs. The construction process is also highly organized; it includes the manufacturers of building products and systems, the craftsmen who assemble them on the building site, the contractors who employ and coordinate the work of the craftsmen, and consultants who specialize in such aspects as construction management, quality control, and insurance.

Building construction today is a significant part of industrial culture, a manifestation of its diversity and complexity and a measure of its mastery of natural forces, which can produce a widely varied built environment to serve the diverse needs of society. This article first traces the history of building construction, then surveys its development at the present time. For treatment of the aesthetic considerations of building design, see ARCHITECTURE, THE ART OF. For further treatment of historical development, see AFRICAN ARTS; ARCHITECTURE, THE HISTORY OF WESTERN; CENTRAL ASIAN ARTS; EAST ASIAN ARTS; EGYPTIAN ARTS AND ARCHITECTURE; ISLĀMIC ARTS; SOUTH ASIAN ARTS; and SOUTHEAST ASIAN ARTS.

The article is divided into the following sections:

The history of building construction

PRIMITIVE BUILDING: THE STONE AGE

The hunter-gatherers of the late Stone Age, who moved about a wide area in search of food, built the earliest temporary shelters that appear in the archaeological record. Excavations at a number of sites in Europe dated to before 12,000 BC show circular rings of stones that are believed to have formed part of such shelters. They may have braced crude huts made of wooden poles or have weighted down the walls of tents made of animal skins, presumably supported by central poles.

Elements of shelter

A tent illustrates the basic elements of environmental control that are the concern of building construction. The tent creates a membrane to shed rain and snow; cold water on the human skin absorbs body heat. The membrane reduces wind speed as well; air over the human skin also promotes heat loss. It controls heat transfer by keeping out the hot rays of the sun and confining heated air in cold weather. It also blocks out light and provides visual privacy. The membrane must be supported against the forces of gravity and wind; a structure is necessary. Membranes of hides are strong in tension (stresses imposed by stretching forces), but poles must be added to take compression (stresses imposed by compacting forces). Indeed, much of the history of building construction is the search for more sophisticated solutions to the same basic problems that the tent was set out to solve. The tent has continued in use to the present. The Saudi Arabian goats' hair tent, the Mongolian yurt with its collapsible wooden frame and felt coverings, and the American Indian tepee with its multiple pole supports and double membrane are more refined and elegant descendants of the crude shelters of the early hunter-gatherers.

The agricultural revolution, dated to about 10,000 BC, gave a major impetus to building construction. People no longer traveled in search of game or followed their herds but stayed in one place to tend their fields. Dwellings began to be more permanent. Archaeological records are scanty, but in the Middle East are found the remains of whole villages of round dwellings called tholoi, whose walls are made of packed clay; all traces of roofs have disappeared. In Europe, tholoi were built of dry-laid stone with domed roofs; there are still surviving examples (of more recent construction) of these beehive structures in the Alps (Figure 1). In later Middle Eastern tholoi a rectangular antechamber or entrance hall appeared, attached to the main circular chamber—the first examples of the rectangular plan form in building. Still later the circular form was dropped in favour of the rectangle as dwellings were divided into more rooms and more dwellings were placed together in settlements. The tholoi marked an important step in the search for durability; they were the beginning of masonry construction.

Evidence of composite building construction of clay and wood, the so-called wattle-and-daub method, is also found in Europe and the Middle East. The walls were made of small saplings or reeds, which were easy to cut with stone tools. They were driven into the ground, tied together laterally with vegetable fibres, and then plastered over with wet clay to give added rigidity and weatherproofing. The roofs have not survived, but the structures were probably covered with crude thatch or bundled reeds. Both round and rectangular forms are found, usually with central hearths.

Early frame construction

Heavier timber buildings also appeared in Neolithic cultures, although the difficulties of cutting large trees with stone tools limited the use of sizable timbers to frames. These frames were usually rectangular in plan, with a central row of columns to support a ridgepole and matching rows of columns along the long walls; rafters were run from the ridgepole to the wall beams. The lateral stability of the frame was achieved by burying the columns deep in the ground; the ridgepole and rafters were then tied to the columns with vegetable fibres. The usual roofing material was thatch: dried grasses or reeds tied together in small bundles, which in turn were tied in an overlapping pattern to the light wooden poles that spanned between the rafters. Horizontal thatched roofs leak rain badly, but, if they are placed at the proper angle, the rainwater runs off before it has time to soak through. Primitive builders soon determined the roof pitch that would shed the water but not the thatch. Many types of infill were used in the walls of these frame houses, including clay, wattle and daub, tree bark (favoured by American Woodland Indians), and thatch. In Polynesia and Indonesia, where such houses are still built, they are raised above the ground on stilts for security and dryness; the roofing is often made of leaves and the walls are largely open to allow air movement for natural cooling. Another variation of the frame was found in Egypt and the Middle East, where timbers were substituted for bundles of reeds.

BRONZE AGE AND EARLY URBAN CULTURES

It was the cultures of the great river valleys—including the Nile, the Tigris and Euphrates, the Indus, and the Huang Ho—with their intensive agriculture based on irrigation, that developed the first communities large enough to be called cities. These cities were built with a new building technology, based on the clay available on the riverbanks. The packed clay walls of earlier times were replaced by those constructed of prefabricated units: mud bricks. This represented a major conceptual change from the free forms of packed clay to the geometric modulation imposed by the rectangular brick, and the building plans too became strictly rectangular.

Bricks were made from mud and straw formed in a four-sided wooden frame, which was removed after evaporation had sufficiently hardened the contents. The bricks were then thoroughly dried in the sun. The straw acted as reinforcing to hold the brick together when the inevitable shrinkage cracks appeared during the drying process. The bricks were laid in walls with wet mud mortar or sometimes bitumen to join them together; openings were apparently supported by wooden lintels. In the warm, dry climates of the river valleys, weathering action was not a major problem, and the mud bricks were left exposed or covered with a layer of mud plaster. The roofs of these early urban buildings have disappeared, but it seems likely that they were supported by timber beams and were mostly flat, since there is little rainfall in these areas. Such mud brick or adobe construction is still widely used in the Middle East, Africa, Asia, and Latin America.

Appearance of fired brick

Later, about 3000 BC in Mesopotamia, the first fired bricks appeared. Ceramic pottery had been developing in these cultures for some time, and the techniques of kiln-firing were applied to bricks, which were made of the same clay. Because of their cost in labour and fuel, fired bricks were used at first only in areas of greater wear, such as pavements or the tops of walls subject to weathering. They were used not only in buildings but also to build sewers to drain wastewater from cities. It is in the roofs of these underground drains that the first surviving true arches in brick are found, a humble beginning for what would become a major structural form. Corbel vaults and domes made of limestone rubble appeared at about the same time in Mesopotamian tombs (Figure 2). Corbel vaults are constructed of rows of masonry placed so that each row projects slightly beyond the one below, the two opposite walls thus meeting at the top. The arch and the vault may have been used in the roofs and floors of other buildings, but no examples have survived from this period. The well-developed masonry technology of Mesopotamia was used to build large structures of great masses of brick, such as the temple at Tepe Gawra and the ziggurats at Ur and Borsippa (Birs Nimrud), which were up to 26 metres (87 feet) high. These symbolic buildings marked the beginnings of architecture in this culture.

The development of bronze, and later iron, technology

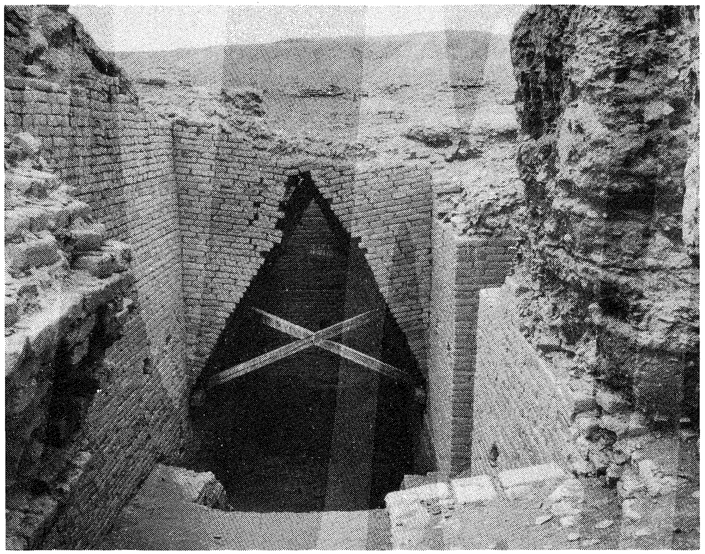

Figure 2: Brick walls and corbel vault at the entrance to the tomb chamber of Ur-nammu in the royal mausoleum at Ur, late 3rd millennium BC.

Hirmer Verlag, Munich

in this period led to the making of metal tools for working wood, such as axes and saws. Less effort was thus required to fell and work large trees. This led in turn to new developments in building technics; timbers were cut and shaped extensively, hewed into square posts, sawed into planks, and split into shingles. Log cabin construction appeared in the forested areas of Europe, and timber framing became more sophisticated. Although the excavated remains are fragmentary, undoubtedly major advances were made in timber technology in this period; some of the products, such as the sawed plank and the shingle, are still used today.

STONE CONSTRUCTION IN EGYPT

Like the other great river valley cultures, Egypt built its cities with mud brick; fired brick did not appear there until Roman times. Timber was used sparingly, for it was never abundant. It was used mainly in roofs, where it was heavily supplemented by reeds. Only a few royal buildings were built with full timber frames.

It was against this drab background of endless mud brick houses that a new technology of cut-stone construction emerged in the temples and pyramids of the 4th dynasty (*c.* 2575–*c.* 2465 BC). Egypt, unlike Mesopotamia or the Indus valley, had excellent deposits of stone exposed above ground; limestone, sandstone, and granite were all available. But the extracting, moving, and working of stone was a costly process, and the quarrying of stone was a state monopoly. Stone emerged as an elite construction material used only for important state buildings.

The Egyptians developed cut stone for use in royal mortuary buildings not only for its strength but also for its durability. It seemed the best material to offer eternal protection to the pharaoh's *ka,* the vital force he derived from the sun-god and through which he ruled. Thus stone had both a functional and symbolic significance.

Djoser's complex at Ṣaqqārah

Within the long tradition of brick masonry, stone construction appeared abruptly, with little transition. The brick mastaba tombs of the early kings and nobles suddenly gave way to the stone technics of King Djoser's ceremonial complex at Ṣaqqārah, the construction of which is associated with his adviser and builder Imhotep. It is a structure of somewhat curious and uncertain forms but of great elegance in execution and detail. It consists mostly of massive limestone walls that enclose a series of interior courtyards. The walls have convoluted surfaces, which recall the mastaba tombs, with dummy doors, and there are even whole dummy buildings of solid stone. The complex has a large entrance hall with a roof supported by massive stone lintels that rest on rows of short wing walls projecting from the enclosing walls. There are no free-standing columns, but incipient fluted columns appear at the ends of the wing walls and engaged $^3/_4$-columns project from the walls of the courtyards. The complex also contains the first pyramid, created from successively smaller mastabas. All these elements are built of small stones, which could be handled by one or two men. It represents a technology that was already highly developed, involving elaborate methods of quarrying, transporting, and working stone.

Quarrying methods

The construction process began at the quarries. Most of them were open-faced, although in some cases tunnels were extended several hundred metres into cliffs to reach the best quality stone. For extracting sedimentary rock, the chief tool was the mason's pick with a 2.5-kilogram metal head and a 45-centimetre haft. With these picks vertical channels as wide as a man were cut around rectangular blocks, exposing five faces. The final separation of the sixth face was accomplished by drilling rows of holes into the rock with metal bow drills. Wooden wedges were driven into the holes to fill them completely. The wedges were doused with water, which they absorbed and which caused them to expand, breaking the stone free from its bed. In the extraction of igneous rock such as granite, which is much harder and stronger than limestone, the mason's pick was supplemented by balls of dolerite weighing up to 5 kilograms, which were used to break the rock by beating and pounding. Granite was also drilled and sawed with the help of abrasives, and expanding wooden wedges were used in splitting.

The Egyptians were able to move blocks weighing up to 1,000,000 kilograms from quarries to distant building sites. This was an amazing accomplishment, as their only machinery was levers and crude wooden sledges worked by masses of men and draft animals. There were no wheeled vehicles before 1500 BC, and they were never widely used in building. Most quarries were near the Nile, however, and boats were also extensively used in transporting stone.

At the building site the rough stones were precisely finished to their final forms, with particular attention to their exposed faces. This was done with metal chisels and mallets; squares, plumb bobs, and straightedges were used to check the accuracy of the work. These tools remained standard until the 19th century. After the first appearance of small stones at Ṣaqqārah, their size began to increase until they attained the cyclopean scale usually associated with Egyptian masonry at about the time of the building of the pyramids. In spite of the heavy loads that stone structures created, foundations were of a surprisingly shoddy and improvised character, made of small blocks of poor quality stone. Not until the 25th dynasty (*c.* 750–656 BC) were important buildings placed on a below-grade (underground) platform of masonry several metres thick.

The Egyptians possessed no lifting machinery to raise stones vertically. It is generally thought that the laying of successive courses of masonry was accomplished with earth or mud brick ramps, over which the stones were dragged to their places in the walls by animal and human muscle power. Later, as the ramps were removed, they served as platforms for the masons to apply the final finishes to the stone surfaces. The remains of such ramps can still be seen at unfinished temples that were begun in the Ptolemaic period. The stones were usually laid with a bed of mortar made of gypsum, sand, and water, which perhaps acted more as a lubricant to push the stone into place than as a bonding agent. There was also limited use of metal dovetail anchors between blocks.

Stone frame construction

The great Pyramids of Giza, the tallest of which rose to a height of 147 metres (481 feet), are a marvelous technological achievement, and their visual impact is stunning even today; it was not until the 19th century that taller structures would be built. But they also represent a dead end in massive stone construction, which soon moved in the direction of lighter and more flexible stone frames and the creation of larger interior spaces. The free-standing stone column supporting stone beams appeared for the first time in the royal temples associated with the pyramids of about 2600 BC (Figure 3). Square granite columns carrying heavy granite lintels spanned three to four metres (10 to 13 feet); the spaces between the lintels were roofed by massive granite slabs. In these structures the abstract

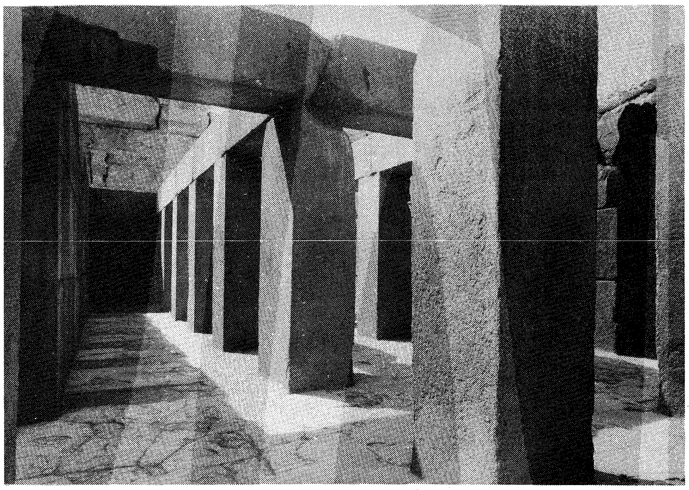

Figure 3: Stone frame showing post-and-lintel construction, Khafre's Valley Temple, Giza, *c.* 2600 BC.
Hirmer Verlag, Munich

notion of the timber frames of the early royal buildings was translated into stone.

Although stone is more durable than timber, it is quite different in structural strength. Stone is much stronger in compression than timber but is weaker in tension. For this reason, stone works well for columns, which could be made very high—for example, 24 metres (80 feet) in the great temple of Amon-Re at Karnak. But stone lintels spanning between columns are limited by the tension they develop on their bottom surfaces; their maximum span is perhaps five metres (16 feet). Thus, for longer spans, another structural form was needed to exploit the higher compressive strength of stone. But the arch, which could span a longer distance in compression, remained confined to the sewers and to the underground roofs of the tombs of minor officials. So, perhaps with the image of the timber building frame still strong in their minds, the Egyptian masons were content to explore the limitations of the analogous stone frame in a series of great temples built during the New Kingdom (1539–1075 BC) at Karnak and Luxor, culminating in the elegant loggias of Queen Hatshepsut's temple at Dayr al-Baḥrī. The paradigm of the stone-frame temple that they established would endure to the end of the classical world.

GREEK AND HELLENISTIC CULTURES

Use of the Egyptian stone frame diffused throughout the eastern Mediterranean after 1800 BC, and the cultures of mainland Greece were particularly attracted to it. In the Greek world of the Aegean and southern Italy, many stone-frame temples were built; some have survived to the present day in various states of preservation. They were built largely of local marble or limestone; there was no granite for huge monoliths. The basic technology was little changed from that of Egypt; the major difference was in the labour force. There were no state-mobilized masses of unskilled workers to move huge stones; there were instead small groups of skilled masons who worked independently. The building accounts of the Parthenon show that each column was built under a separate contract with a master mason. There was certainly lifting machinery for handling the blocks, although its precise description is unknown; the concealed faces of stones still have grooves and holes that engaged the ropes used to lift them into place. Metal cramps and dowels were introduced for joining stones together; mortar was almost never used. There was some experimentation with iron beams to reinforce longer spans in stone, but the maximum remained about five to six metres (16 to 20 feet). Longer spans were achieved with timber beams supported by the stone frame; the solid stone roof slabs of the great Egyptian temples could not be duplicated.

Much of the mason's effort was concentrated on the refinements of detail and optical corrections for which Greek architecture is justly famous. This same sense is also seen in the first surviving construction drawings, which were made on the unfinished surfaces of the stone walls of the Temple of Didyma. Such drawings would normally have been erased during the final finishing of the wall surfaces, and those at Didyma survived because the temple was never completed. The drawings show how the masons developed the final profiles of columns and moldings—a rare glimpse of the design processes of builders before the days of pencil and paper.

First use of construction drawings

In contrast to stone technology, which remained largely unchanged from Egyptian methods, clay masonry underwent considerable development. Although mud brick remained standard for dwellings, fired brick was more widely used and began to be laid with lime mortar, a technique borrowed from stone construction. Glazed brick also appeared in this period, particularly outside the Greek world among the Babylonians and Persians, who made considerable use of it in royal palaces. A fine surviving example is the Ishtar Gate of the Palace of Nebuchadrezzar at Babylon, with a true arch spanning 7.5 metres (25 feet) and dated to 575 BC. Another major innovation was the fired clay roof tile. This was much more waterproof than thatch, and tile roofs could have the lower pitch characteristic of Greek temples. Hollow terra-cotta blocks for wall ornaments also appeared about this time, probably derived from the highly advanced pottery industry, which routinely made fired clay vessels more than one metre long.

Although stone technology remained confined to the trabeated (column-and-beam, or post-and-lintel) frame, there were a few structures that hinted at future developments. Perhaps the most spectacular building achievement of the age was the Pharos of Alexandria, the great lighthouse built for Ptolemy II in the 3rd century BC. It was a huge stone tower nearly as high as the Great Pyramid but much smaller at the base—perhaps 30 metres (100 feet) square. Within this mass of masonry was a complex system of ramps over which pack animals carried fuel for the beacon at the top. The Pharos was the first high-rise building, but the limitations of masonry structures and the lack of a rapid way of moving people vertically precluded any further development of tall buildings until the 19th century. The Pharos remained the only example of this type long after it was demolished by the Arabs beginning in the 7th century AD.

Another example of a new stone technology that was tried but not pursued further by the Greeks was the underground tombs of Mycenae, built about 1300 BC. These tombs have main chambers enclosed by pointed domes of corbeled stone construction, about 14 metres (47 feet) in diameter and 13 metres (43 feet) high. Crude versions of the corbel dome had appeared earlier in Mesopotamian tombs and the tholoi of Neolithic Europe, but in Mycenae the technics were refined and enlarged in scale. A corbel dome or arch does not develop the high compressive forces that characterize true arches and domes, which are built of radial segments of stone or brick. Thus it does not take full advantage of the great compressive strength of stone and cannot span long distances; 14 metres is near the upper limit. Greek masons did not choose to explore this type of structure; their buildings remained largely concerned with exterior forms. The Roman builders who followed them, however, exploited masonry to its full potential and created the first great interior spaces.

ROMAN ACHIEVEMENTS

It was from the Etruscans, who lived in the northern part of Italy, that the Romans derived much of their early building technology. The Etruscans, probably influenced by a few rare Greek examples in southern Italy, developed the true arch in stone. A late specimen of the 3rd century BC is the Porta Marzia, an arched city gateway with a span of about six metres (20 feet), in Perugia. The Etruscans also had a highly developed terra-cotta technology and made excellent fired bricks.

Masonry construction. The Romans adopted Etruscan stone construction based on the arch and built many spectacular examples of what they called *opus quadratum,* or structures of cut stone blocks laid in regular courses. Most of these were public works in conquered provinces, such

Opus quadratum

as the late 1st-century-BC Pont du Gard, a many-arched bridge and aqueduct spanning 22 metres (72 feet) near Nîmes, in France, or the fine bridge over the Tagus River at Alcântara in Spain, with a span of almost 30 metres (100 feet), built about AD 110. Oddly enough, such long spans in stone were never applied to buildings. The surviving Roman buildings with stone arches or vaults have typical spans of only four to seven metres (15 to 25 feet); small stone domes with diameters of four to nine metres were built in Roman Syria. Such arches and domes imply the existence of sophisticated timber formwork to support them during construction, as well as advanced lifting machinery, but there are no extant records of either. Many of these structures survived the fall of the empire, and they became models for the revival of stone construction in medieval Europe, when masons again sought to build "in the Roman manner." The Romans also inherited the trabeated stone frame from the Greeks of southern Italy and continued to build temples and other public buildings with this type of construction into the 3rd century AD.

Brickmaking, particularly in the region of Rome itself, became a major industry and finally, under the empire, a state monopoly. Brick construction was cheaper than stone due to the economies of scale in mass production and the lower level of skill needed to put it in place. The brick arch was adopted to span openings in walls, precluding the need for lintels. Mortar was at first the traditional mixture of sand, lime, and water, but, beginning in the 2nd century BC, a new ingredient was introduced. The Romans called it *pulvis puteoli* after the town of Puteoli (modern Pozzuoli), near Naples, where it was first found; the material, formed in Mount Vesuvius and mined on its slopes, is now called pozzolana. When mixed with lime, pozzolana forms a natural cement that is much stronger and more weather-resistant than lime mortar alone and that will harden even under water. Pozzolanic mortars were so strong and cheap, and could be placed by labourers of such low skill, that the Romans began to substitute them for bricks in the interiors of walls; the outer wythes of bricks were used mainly as forms to lay the pozzolana into place. Finally, the mortar of lime, sand, water, and pozzolana was mixed with stones and broken brick to form a true concrete, called *opus caementicium.* This concrete was still used with brick forms in walls, but soon it began to be placed into wooden forms, which were removed after the concrete had hardened.

Concrete as a building material

One of the earliest surviving examples of this concrete construction is the Temple of the Sybil (or Temple of Vesta) at Tivoli, built during the 1st century BC. This temple has a circular plan with a peristyle of stone columns and lintels around the outside, but the wall of the circular cella, or sanctuary room, inside is built of concrete—an uneasy confrontation of new and traditional forms of construction. An early large-scale example in Rome itself of brick-faced concrete is the plain rectangular walls of the Camp of the Praetorian Guard, built by Sejanus in AD 21–23. But the possibilities of plastic form suggested by this initially liquid material, which could easily assume curved shapes in plan and section, soon led to the creation of a series of remarkable interior spaces, spanned by domes or vaults and uncluttered by the columns required by trabeated stone construction, that showed the power of the imperial state. The first of these is the octagonal domed fountain hall of Nero's Golden House (AD 64–68), which is about 15 metres (50 feet) in diameter with a large circular opening, or oculus, in the top of the dome. The domed form was rapidly developed in a series of imperial buildings that culminated in the emperor Hadrian's Pantheon of about AD 118–128 (Figure 4). This huge circular structure was entered from a portico of stone columns and was surmounted by a dome 43.2 metres (142 feet) in diameter, lighted by an oculus at the top. The walls supporting the dome are of brick-faced concrete six metres (20 feet) thick lightened at intervals by internal recesses; the dome is of solid concrete 1.5 metres (five feet) in average thickness and rising 43.2 metres above the floor. This magnificent structure has survived in good condition to modern times; the diameter of its circular dome remained unsurpassed until the 19th century.

Two large fragments of great concrete cross-vault buildings still survive from the late empire. The first of these is a portion of the Baths of Diocletian (*c.* 298–306) with a span of 26 metres (85 feet); it was converted into the church of Santa Maria degli Angeli by Michelangelo in the 16th century. The other is the Basilica of Maxentius (AD 307–312), also with a span of 26 metres. All of these buildings contained stone columns, but they were purely ornamental and could have been removed at will. The brick-faced concrete walls were left exposed on the exteriors, but the interiors were lavishly decorated with a veneer of thin slabs of coloured stone held in place by metal fasteners that engaged slots cut in the edges of the slabs, a technique still used in the 20th century. These and other great Roman public spaces spanned by concrete domes and vaults made a major advance in scale over the short spans of the stone frame.

In the late empire, concrete technology gradually disappeared, and even brickmaking ceased in western Europe. But significant developments in brick technology continued in the eastern Roman world, where the achievements of earlier periods in concrete were now duplicated in brickwork. The tomb of the emperor Galerius (now the Church of St. George) of about AD 300 at Salonika in Greece has a brick dome 24 metres (80 feet) in diameter. It probably was the model for the climactic example of late Roman building, the great church of Hagia Sophia (532–537) in Constantinople, which features a central dome spanning 32.6 metres (107 feet). Even Rome's great enemies, the Sāsānian Persians, built a large brick-vaulted hall in the palace at Ctesiphon (usually identified with Khosrow I [mid-6th century] but probably a 4th-century structure) with a span of 25 metres (82 feet) by borrowing Roman methods. These late brick structures were the last triumphs of Roman building technology and would not be equaled for the next 900 years.

Timber and metal construction. The Romans also made major advances in timber technology. Reliefs on Trajan's Column show the timber lattice truss bridges used by Roman armies to cross the Danube. The truss, a hollowed-out beam with the forces concentrated in a triangulated network of linear members, was apparently a Roman in-

Invention of the truss

vention. No evidence of their theoretical understanding of it exists, but nevertheless they were able to master the design of trusses in a practical way. A fine example is the Basilica of Constantine at Trier (AD 297–299), where timber king-post roof trusses (triangular frames with a vertical central strut) span a hall 23 metres (75 feet) wide; the present roof is a restoration, but the original must have been similar.

The notion of the truss was extended from timber to metal. Bronze trusses, running over three spans of about nine metres (30 feet) each, supported the roof of the portico of the Pantheon. The choice of bronze was probably made more for durability than strength, because Pope Urban VIII was able to remove this bronze work in 1625 (to melt it down for cannon) and replace it with timber trusses. The truss remained an isolated achievement of Roman building that would not be equaled until the Renaissance.

Metals were used extensively in Roman buildings. In addition to bronze trusses, the Pantheon had bronze doors and gilded bronze roof tiles. Lead was another material introduced by the Romans for roofing; it was waterproof and could be used with very low pitches.

Building support systems. Perhaps the most important use of lead was for pipes to supply fresh water to buildings and to remove wastewater from them (the word plumbing comes from the Latin *plumbum,* which means lead). The Romans provided generous water supplies for their cities; all of the supply systems worked by gravity and many of them used aqueducts and syphons. Although most people had to carry their water from public fountains, there was limited distribution of water to public buildings (particularly baths) and some private residences and apartment houses; private and semiprivate baths and latrines became fairly common. The wastewater drainage system was limited, with no treatment of sewage, which was simply discharged into a nearby river. But even these fairly modest applications of public sanitation far exceeded those of previous cultures and would not be equaled until the 19th century.

Another material that the Romans applied to buildings was glass, which had been developed by the Egyptians who used it only for jewelry and small ornamental vessels. The Romans devised many kinds of coloured glass for use in mosaics to decorate interior surfaces. They also made the first clear window glass, produced by blowing glass cylinders that were then cut and laid flat. Seneca (*c.* 4 BC–AD 65) described the sensation caused by the appearance of glazed sun porches in the villas near Rome. Although no Roman glass installations have survived, glass apparently became fairly common in public buildings and was even used in middle-class apartment houses in the capital.

Hypocaust heating

In most Roman buildings, the central open fire remained the major source of heat—as well as annoying smoke—although the use of charcoal braziers made some improvement. A major innovation was the development of hypocaust, or indirect radiant, heating, by conducting heated air through flues in floors and walls. The heated masonry radiated a pleasantly uniform warmth, and smoke was eliminated from occupied spaces; the same method was used to heat water for baths. The Basilica of Constantine at Trier has a well-preserved example of hypocaust heating, where the stone slabs of the floor are supported on short brick columns, creating a continuous heating plenum beneath it.

ROMANESQUE AND GOTHIC

The disappearance of Roman power in western Europe during the 5th century led to a decline in building technology. Brickmaking became rare and was not revived until the 14th century. Pozzolanic concrete disappeared entirely, and it would not be until the 19th century that man-made cements would equal it. The use of domes and vaults in stone construction was also lost. Building technics fell to Iron Age levels, exemplified by log construction, packed clay walls, mud brick, and wattle and daub.

Advanced building technologies were developing in China in this same period during the Sui (581–618) and T'ang (618–907) dynasties. In the 3rd century BC the completion of the Great Wall, about 6,400 kilometres (4,000 miles) in length and following a sinuous path along the contours of rugged terrain, had demonstrated remarkable achievements in masonry technology, logistics, and surveying methods. The An-Chi Bridge, built about AD 610 in Hopei province, had a stone arch with a span of 37.5 metres (123 feet), far exceeding the Roman bridge at Alcántara. Extensive work was also done in the development of heavy timber framing (primarily for temples), and stone tower pagodas up to 60 metres (200 feet) high were built; fired brick was also widely used. These elements of Chinese building technology set a high standard of quality that would be maintained until the 19th century.

Stone construction. Beginning in the 9th century there were the first stirrings of the revival of stone construction in Europe; the Palatine Chapel of Charlemagne at Aachen (consecrated 805), with its octagonal segmented dome spanning 14.5 metres (47 feet), is an early example of this trend. But the Romanesque style, building "in the Roman manner" with stone arches, vaults, and domes to span interior spaces, did not really begin until the later part of the 11th century. Vaults reappeared in such structures as the cathedral of Santiago de Compostela in Spain (begun 1078) and Saint Sernin at Toulouse (begun 1080). The cross vault raised on columns was seen again at Speyer Cathedral (1030–65, reconstructed *c.* 1082–1137) and Durham Cathedral (1093–1133), and the domes of St. Mark's Basilica in Venice (late 11th century) and the cathedral of Saint-Front in Périgueux (1120–1150) marked the recovery of the complete range of Roman structural forms. All these buildings were built by the Roman Catholic church, which had spread its influence throughout western Europe in this period. One contemporary chronicler wrote that the earth seemed to be "clothing itself with a white robe of churches," white because they were new and built of stone. From 1050 to 1350 more stone was quarried in France alone than in the whole history of ancient Egypt—enough to build 80 cathedrals, 500 large churches, and tens of thousands of parish churches. The great building campaign of medieval times has been called the "cathedral crusade," an equally impassioned counterpart of the great military adventures to recover the Holy Land. This vast undertaking required many masons, who worked as free craftsmen, organizing themselves into societies or guilds. They oversaw the quarrying of stone, supervised the process of apprenticeship by which new members were trained, and did all the cutting and placing of stone at the building site. The basic tools of the medieval masons were little changed from those of Egypt, but they had large saws driven by waterwheels to cut stone as well as considerable machinery for raising and moving materials. Their knowledge of technics was a closely held secret; it included the rules of proportion for overall planning and for determining the safe dimensions of structural members. One extant sketchbook of drawings, from the master mason Villard de Honnecourt, shows a keen sense of observation, a love of mechanical devices, and above all the notion of geometric form that underlay the work; but it gives only tantalizing bits of information about actual building construction. Jean Mignot, one of the master masons of Milan Cathedral, summed up their approach with the phrase *ars sine scientia nihil est,* "art without science is nothing"; that is, skill in building derived from practical experience (*ars*) must be tempered and guided by precise principles (*scientia*), which were seen as being embodied in the theorems of geometry, the only science of medieval times. But with these limited means the masons were able to realize great achievements.

The "cathedral crusade"

Romanesque masons had two patrons, church and state. The state built mostly for military purposes, and Roman stonework, once recovered, was adequate for castles and fortifications. But the church had other interests that propelled the development of stone construction in new and daring directions. St. Augustine had written that light is the most direct manifestation of God. It was this idea that led the search for ways to introduce more and more light into churches, opening ever larger windows in the walls until a new kind of diaphanous stone skeleton evolved.

The Roman-inspired circular cross vaults and arches in

The Gothic arch

stone were heavy and needed heavy walls and piers to receive their thrusts; the windows they offered were small. Medieval masons found that there was a more efficient form for the arch than the classical circle; this form is a catenary curve—that is, one formed by a chain when it hangs under its own weight. But the masons' belief in geometry and the perfection of circular forms led them to approximate the catenary shape with two circular segments that met in a point at the top, the so-called Gothic arch. Such arches could be made thinner since they more efficiently channeled the compressive forces that flowed through them and allowed larger openings in the walls. The heavy piers that took the lateral thrust of the roof vaults were soon hollowed out into half arches or flying buttresses, which allowed even more light to enter the nave. To absorb the forces flowing down through the stone frame, massive foundations were required; often the volume of stone below ground was greater than that above. To further lighten the loads, the vaults themselves were made thinner by introducing ribs at the intersections of their curved surfaces, called groins. The ribs were built with supporting formwork or centring made of timber; close cooperation was needed between the carpenters and the masons. The curved surfaces of stones between the ribs were probably laid with little formwork, using only mortar; brick vaults are still built this way in the Middle East. The mortar was used not only for adhesion as a construction device but also later to check for tension cracks, which were signs of possible failure; the mortar thus served as a means of quality control to help keep the structure in compression. The naves of cathedrals were made higher to gather more light; Amiens Cathedral (begun 1220) was 42 metres (140 feet) high (Figure 5), and finally in 1347 Beauvais Cathedral reached the maximum height of 48 metres (157 feet), but its vaults soon collapsed and had to be rebuilt. The spans of the naves of Gothic churches remained fairly small, about 13 to 16 metres (45 to 55 feet); only a few late examples have longer spans, the greatest being 23 metres (74 feet) at Gerona Cathedral (completed 1458).

After the enthusiasm of the cathedral crusade ebbed in the 14th century and the basic fabric of most cathedrals was completed, a new element appeared to further test the skill of masons and carpenters: the spire. The spire was more a symbol of local pride than a part of the theological quest for more light, but it raised interesting technical problems. At Salisbury Cathedral the spire was built over the crossing of the nave and transept, which had not been designed to accommodate it; the tall crossing piers began to buckle under the added weight. Strainer arches had to be added between the piers to brace them against buckling; this was apparently the first time that stone columns were slender and heavily loaded enough to be observed to bend or buckle—later, such action would be a major concern in the design of metal columns. Salisbury's spire is an ingenious composite structure of stone cladding laid over a timber frame and tied together at the base with iron bands to resist spreading; it rose to a total height of 123 metres (404 feet) when it was finished in 1362. Strasbourg Cathedral added a 144-metre (475-foot) spire in 1439, and the upper limit was reached at Beauvais Cathedral in 1569 when its 157-metre (516-foot) spire was completed; the Beauvais spire collapsed in 1573 and was never rebuilt, a last sad epilogue to the cathedral crusade.

Half-timber construction

Construction in timber and brick. Timber construction underwent slow development in this period. Scandinavian stave churches of heavy timber were built in the 8th to 10th centuries, prior to the triumph of the stone church, and a few have survived to the present day. In western Europe, particularly from the 14th century onward, half-timber construction emerged as a new form of house building. The continental type had a frame of squared timbers, with vertical posts spaced about one metre apart and horizontal girts spaced at the same distance; diagonal braces were run through the outside walls for lateral stability. The roof beams spanned between the ridgepole and the walls; floor beams were supported on the walls and interior partitions. The English half-timber frame was similar, but it eliminated the horizontal girts and diagonal bracing by using closely spaced verticals about one-half metre apart. In both systems the space in the outside wall was filled with an enclosure material to impart added rigidity to the frame; brick or wattle and daub were often used. All the timbers of the frame were attached together by elaborate dovetail, or mortise-and-tenon, joints. Half-timber framing would remain the standard way of building with wood in Europe until the 19th century. There was also considerable use of heavy timber for the roofs and floors of masonry buildings, which was influenced by shipbuilding technology. A particular instance of this is the English hammer-beam roof, which was a kind of corbeled truss that could span quite long distances. The roof of King Richard II's Westminster Hall in London (1402), with a 21-metre (70-foot) span, is an excellent example of this type.

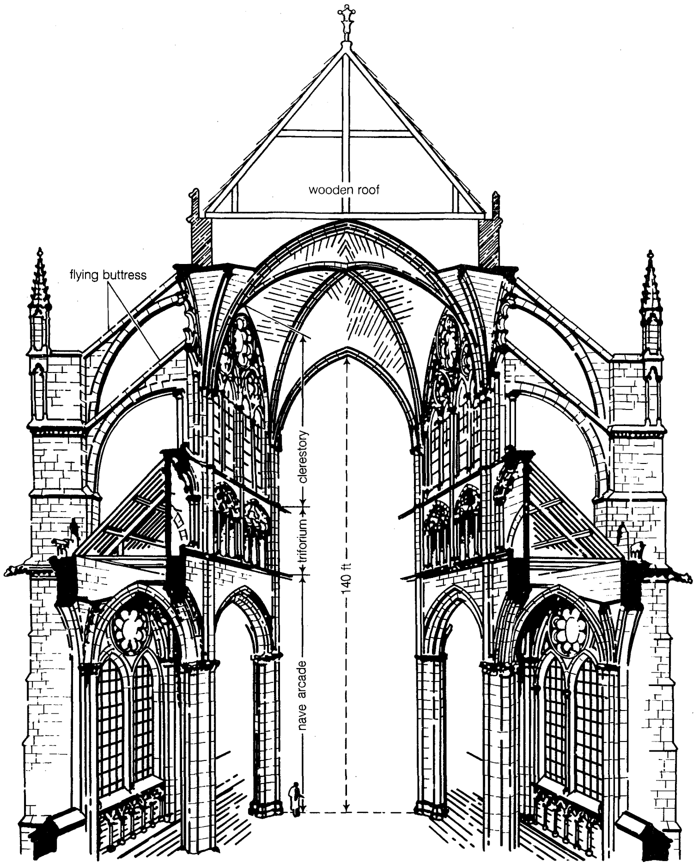

Figure 5: Transverse section of Amiens, a typical Gothic cathedral (1220–88).

The British Architectural Library, RIBA, London

Fired brick began to be made again in Europe in the 14th century, preceded in many areas by the use of salvaged Roman brick. The 14th-century bricks were not as precise as the Roman and were often distorted in firing. Therefore, large lime-mortar joints were needed for regular course lines. Bricks became nearly standardized at something close to the present size, about 20.3 × 9.5 × 5.7 centimetres (8 × 3.75 × 2.25 inches), and bonding systems based on this approximately 2 : 1 proportion were developed. These bonding patterns reduced continuous vertical mortar joints, because the mortars were of substantially lower strength than the bricks and vertical joints could form planes of weakness in the walls where cracks might develop. The best bonding pattern was English bond, in which all the bricks in each course overlapped the ones below and vertical joints were entirely eliminated. Brick remained quite expensive because of the cost of the fuel needed to fire it, and it was used mainly where there was no readily available stone. In the late medieval period and mostly in northern Europe, brick was adapted to Gothic stone forms to build so-called hall churches, with naves and aisles of equal height.

Building services. Although Roman hypocaust heating disappeared with the empire, a new development in interior heating appeared in western Europe at the beginning of the 12th century: the masonry fireplace and chimney began to replace the central open fire. The large roof openings over central fires let in wind and rain, so each house had only one and larger buildings had as few as possible. Therefore, heated rooms tended to be large and semipublic, where many persons could share the fire's warmth; the roof opening did not effectively remove all the smoke, some of which remained to plague the room's occupants. The chimney did not let in much air or water and could remove most of the smoke. Although much of the heat went up the flue, it was still a great improvement, and, most significantly, it could be used to heat both small and large rooms and multistory buildings as well. Houses, particularly large ones, were broken up into smaller, more private spaces each heated by its own fireplace, a change that decisively altered the communal life-style of early medieval times.

THE RENAISSANCE

Reintroduction of dome construction. The waning of the cathedral crusade in the late 14th century led to a decline in the International Gothic style practiced by the master masons. In this period the emerging nation-states of Europe began to compete with the church as centres of power. To these new nations, the Roman Empire was the model nation-state, and it seemed appropriate that they use Roman building forms as symbols of their power—particularly the round arch, the vault, and, above all, the dome, following the powerful example of the Pantheon. From 1350 until 1750 much of building technology was focused on the domed church, which developed as a symbol not only of religious belief but also of national and urban pride. There was a conscious rejection of Gothic forms in favour of the ideological appeal of Rome. This attitude led to a split between the processes of design and construction and to the appearance of the first architects (a word derived from the Greek *architekton,* meaning a chief craftsman), who conceived a building's form, as opposed to the builder, who executed it. The first building in which the designer and the builder were separate persons was the Campanile, or bell tower, of the cathedral of Florence. The design was made by the painter Giotto and constructed by cathedral masons from 1334 to 1359.

The Duomo

The cathedral of Florence itself had been begun in the Gothic style by Arnolfo di Cambio in 1296. But in 1366 the City of Florence, following the advice of certain painters and sculptors, decided that the Gothic should no longer be used and that all new work should follow Roman forms, including an octagonal dome 42 metres (138 feet) in span to be built at the east end of the nave. The dome was not built until the early 15th century, when Filippo Brunelleschi, a goldsmith and sculptor, began to make statues for the cathedral. Gradually he became interested in the building itself and built some smaller parts of it. In about 1415 he prepared a design for the dome that he daringly proposed to build without the aid of formwork, which had been absolutely necessary in all previous Roman and Gothic construction. He built a 1 : 12 model of the dome in brick to demonstrate his method; the design was accepted and built under his supervision from 1420 to 1436. Brunelleschi was thus the first real architect to conceive the building's form and the methods to execute it and to guarantee its performance; he pointedly refused membership in both the masons' and carpenters' guilds. Brunelleschi's dome (Figure 6) consists of two layers, an inner dome spanning the diameter and a parallel outer shell to protect it from the weather and give it a more pleasing external form. Both domes are supported by 24 stone half arches, or ribs, of circular form, 2.1 metres (seven feet) thick at the base and tapering to 1.5 metres (five feet), which meet at an open stone compression ring at the top. To resist outward thrust, tie rings of stone held together with metal cramps run horizontally between the ribs. There are also tie rings of oak timbers joined by metal connectors. The spaces between the ribs and tie rings are spanned by the inner and outer shells, which are of stone for the first 7.1 metres (23 feet) and brick above. The entire structure was built without formwork, the circular profiles of the ribs and rings being maintained by a system of measuring wires fixed at the centres of curvature. Brunelleschi obviously understood enough about the structural behaviour of the dome to know that, if it were built in horizontal layers, it would always be stable and not require timber centring. He also designed elaborate wooden machines to move the needed building materials both vertically and horizontally. Having all but equaled the span of the Pantheon in stone, Brunelleschi was hailed as the man who "renewed Roman masonry work"; the dome was established as the paragon of built form.

The next great dome of the Renaissance was that of St. Peter's Basilica in Rome, begun by Pope Julius II in 1506. The technology was very similar to that of Brunelleschi, and the diameter is nearly the same. The dome's design went through many changes and extended over a period of nearly 80 years. The major contributors to the design were the painter and sculptor Michelangelo, who served as architect from 1546 to 1564, and the architects Giacomo della Porta and Domenico Fontana, under whose direction it was finally built during the 1580s. The dome was considerably thinner than that of Florence and was reinforced by three tie rings made of continuous iron chains. It developed numerous cracks, and in the 1740s five more chains were added to further stabilize it. Since the dome used a proven technology, most of the design was done on paper with drawings.

St. Paul's Cathedral

Another large dome of this period was that of St. Paul's Cathedral in London, which was built from 1675 to 1710 by the English architect Sir Christopher Wren. In the early stages of the design process only two physical models were used; later efforts included extensive drawings and apparently also mathematical modeling with numerical calculations. Wren had begun his career as a mathematician and physical scientist and was professor of astronomy at Oxford from 1661 to 1673 before becoming a full-time architect. With this background he was thus able to profit from the first theoretical determination of the catenary curve as the most efficient profile of the arch and dome, which was published by the Scottish mathematician David Gregory in 1697. Wren's solution to the dome, which has a diameter of 34.5 metres (113 feet), was a series of three nested shells, of which the middle one is the true structure. This middle dome is built of brick in a nearly

Adapted from F.D. Prager and G. Scaglia, *Brunelleschi: Studies of His Technology and Inventions* (1970), Massachusetts Institute of Technology Press

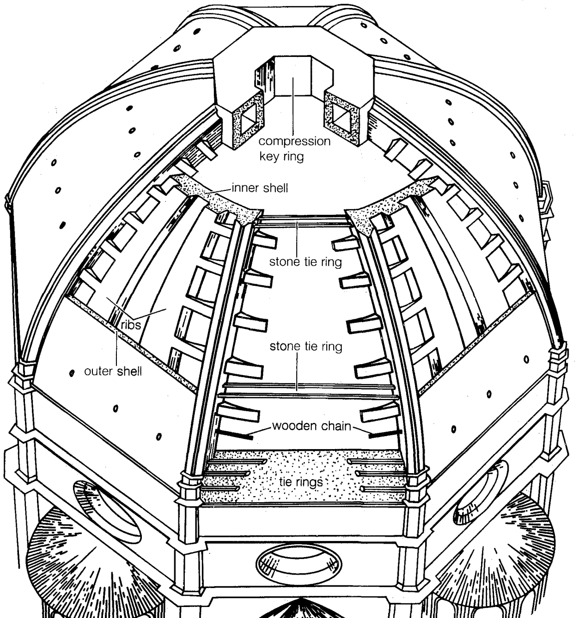

Figure 6: Dome construction of the Cathedral of Santa Maria del Fiore, Florence; Filippo Brunelleschi, architect (1420–36).

conical catenary form, due to the large concentrated load of the lantern on top, and constrained by iron chains; it supports a triangularly braced timber framework to which is attached the exterior surfacing of lead sheets. Within the middle dome is a shallower catenary dome that carries only its own weight and serves as a ceiling for the interior space. Wren's concealed structure, to which were applied the desired internal and external forms, has become a standard architectural technique.

Revival of Roman technics and materials. In addition to Roman forms in masonry, the Renaissance recovered other Roman technologies, including timber trusses. Giorgio Vasari used king-post timber trusses for a 20-metre (66-foot) span in the roof of the Uffizi, or Municipal Office Building, in Florence in the mid-16th century. At the same time, the Venetian architect Andrea Palladio used a fully triangulated timber truss for a bridge with a span of 30.5 metres (100 feet) over the Cimone River. Palladio clearly understood the importance of the carefully detailed diagonal members, for in his diagram of the truss in his *Four Books on Architecture* he said that they "support the whole work." The tension connections of the timber members in the truss were joined with iron cramps and bolts.

Trussed spans in the range 20–26 metres (65–85 feet) became fairly common in building roofs. In 1664 Wren used timber trusses with a span of about 22 metres (73 feet) in the roof of the Sheldonian Theatre at Oxford. But a precise theoretical understanding of the truss, and major use of it in buildings, would not come until the 19th century.

Reintroduction of clear glazing

Another Roman material that was revived and much improved in the Renaissance was clear glass. A new technique for making it was perfected in Venice in the 16th century. It was known as the crown glass method and was originally used for making dinner plates. Glassblowers spun the molten glass into flat disks up to a metre in diameter; the disks were polished after they had cooled and were cut into rectangular shapes. The first record of crown glass windows is their installation in double-hung counterweighted sliding-sash frames, at Inigo Jones's Banqueting House in London in 1685. Large areas of such glass became common in the 1700s, pointing the way toward the great glass and iron buildings of the 19th century.

The efficiency of interior heating was improved by the introduction of cast-iron and clay-tile stoves, which were placed in a free-standing position in the room. The radiant heat they produced was uniformly distributed in the space, and they lent themselves to the burning of coal—a new fuel that was rapidly replacing wood in western Europe. When European builders had recovered the technology of the classical world in brick, stone, and timber, a stable plateau was reached in the development of the building arts; these materials and technics were well-suited to the churches, palaces, and fortifications that their patrons required. The Industrial Revolution, however, brought new materials and the demand for new building types that completely transformed building technology.

THE FIRST INDUSTRIAL AGE

Development of iron technology. The last half of the 18th century saw the unfolding of a series of events, primarily in England, that later historians would call the first Industrial Revolution, which would have a profound influence on society as a whole as well as on building technology. Among the first of these events was the large-scale production of iron, beginning with the work of Abraham Darby, who in 1709 was the first to use coke as a fuel in the smelting process. The ready availability of iron contributed to the development of machinery, notably James Watt's double-acting steam engine of 1769. Henry Cort developed the puddling process for making wrought iron in 1784, and in the same year he built the first rolling mill, powered by a steam engine, to produce rolled lengths of wrought-iron bars, angles, and other shapes. Cast iron, which has a higher carbon content than wrought iron but is more brittle, was also produced on a large scale. Standard iron building elements soon appeared, pointing the way to the development of metal buildings.

Early applications of iron in construction are found several centuries prior to the industrial age. There are records of iron chain suspension bridges with timber decks in China from the early Ming dynasty (1368–1644); some of them, such as the Liu-Tung Bridge, the object of a famous battle on Mao Zedong's (Mao Tse-tung's) Long March in 1935, have survived in a much-restored condition. The iron tension chains in the domes of St. Peter's and St. Paul's cathedrals are other examples. But the first large cast-iron structure of the industrial age was the bridge over the River Severn at Coalbrookdale. Built by the iron founders Abraham Darby III and John Wilkinson between 1775 and 1779, it has a span of 30 metres (100 feet), using five circular-form arches that are reduced to a spidery web of slender iron ribs. Each arch was cast in two pieces with a maximum dimension of 21 metres (70 feet), which were difficult to move from the foundry to the site and to set in place. Smaller, more easily handled pieces characterized the rapid application of iron to buildings that followed. Solid cast-iron columns were used in St. Anne's Church in Liverpool as early as 1772, and hollow tubular columns of increased efficiency were developed in the 1790s. The first use of wrought-iron trusses, which were made of flat bars riveted together, was in a 28-metre (92-foot) span for the roof of the Théâtre-Français in Paris in 1786 by the architect Victor Louis; there iron was used not so much for its strength as its noncombustibility, which, it was hoped, would reduce the hazard of fire. For the same reason, in about 1800 the British textile industry began to use partial metal framing in mill buildings up to seven stories high. Hollow cast-iron cylindrical columns were spaced at about three metres (10 feet) on centre and supported cast-iron tee beams spanning up to 4.5 metres (15 feet); the floors were bridged by brick arches resting on the bottom flanges of the tee beams; at the perimeter the beams rested on masonry bearing walls, which gave the structure its lateral stability. This prototype of the iron-frame building with exterior masonry walls soon set a standard that would continue to the end of the century.

The iron bridge at Coalbrookdale

The completely independent iron frame without masonry adjuncts emerged slowly in a series of special building types. The first modest example was Hungerford Fish Market (1835) in London. Timber was forbidden because of sanitation requirements; the cast-iron beams spanned 9.7 metres (32 feet) with three-metre (10-foot) cantilevers on either side, and the hollow cast-iron columns also served as roof drains. All lateral stability was provided by the rigid joints between columns and beams. The next type to use the full iron frame was the greenhouse, which provided a controlled luminous and thermal environment for exotic tropical plants in the cold climate of northern Europe. Among the first of these was the Palm House at Kew Gardens near London; it was built by the architect Decimus Burton in the 1840s.

A spectacular series of iron and glass buildings for conservatories and exhibition halls continued to the end of the century. The most important of these was the Crystal Palace, built in London's Hyde Park to house the Great Exhibition of 1851. This vast building, 564 metres (1,851 feet) long, was built entirely of standardized parts. Cast-iron columns carried iron trusses of three different spans—7.3 metres (24 feet), 14.6 metres (48 feet), and 21.9 metres (72 feet)—in riveted wrought iron; spanning between the trusses were ingenious "Paxton gutters" made of wooden compression members above iron tension rods that prestressed the wood to reduce deflection. All these prefabricated elements were simply bolted or clipped together on the site to enclose a space of 90,000 square metres (1,000,000 square feet) in only six months. But the major triumph of the Crystal Palace was its all-glass enclosure, made of standard panes 25 × 124 centimetres (10 × 49 inches) in size; the huge space was flooded with light that was scarcely interrupted by the diaphanous metal framing—it resembled a great secular cathedral realizing the ultimate ambition of the medieval masons.

The French also produced a number of fine iron and glass exhibition halls, including one with a 48-metre (160-foot) span in 1855. Others with somewhat smaller spans, but larger enclosed areas than the Crystal Palace, followed in 1867 and 1878. Iron trusses with glazed roofs were also used in the train sheds of railway stations that were built throughout western Europe. The New Street Station in Birmingham, Eng. (1854), had a train shed with an iron truss roof spanning 64 metres (211 feet). It was apparently the first building to exceed the span of the Pantheon. One of the largest was St. Pancras Station (1873) in London, which featured a glazed hall spanned by 74-metre (243-foot) trussed iron arches. After the brilliant successes of midcentury, iron and glass construction was applied in a more prosaic series of buildings that continued to be built until 1900.

Manufactured building materials. The production of brick was industrialized in the 19th century. The laborious process of hand-molding, which had been used for 3,000 years, was superseded by "pressed" bricks. These were mass-produced by a mechanical extrusion process in which clay was squeezed through a rectangular die as a continuous column and sliced to size by a wire cutter. There was also a proliferation of elaborately shaped and stamped masonry units. Periodically fired beehive kilns (stoked by coke) continued to be used, but the continuous tunnel kiln, through which bricks were moved slowly on a conveyor belt, had appeared by the end of the century. The new methods considerably reduced the cost of brick, and it became one of the constituent building materials of the age.

The balloon frame

Timber technology underwent rapid development in the 19th century in North America, where there were large forests of softwood fir and pine trees that could be harvested and processed by industrial methods; steam- and water-powered sawmills began producing standard-dimension timbers in quantity in the 1820s. The production of cheap machine-made nails in the 1830s provided the other necessary ingredient that made possible a major innovation in building construction, the balloon frame; the first example is thought to be a warehouse erected in Chicago in 1832 by George W. Snow. There was a great demand for small buildings of all types as the North American continent was settled, and the light timber frame provided a quick, flexible, and inexpensive solution to this problem. In the balloon frame system, traditional heavy timbers and complex joinery were abandoned. The building walls were framed with 5 × 10-centimetre (2 × 4-inch) vertical members, or studs, placed at 40 centimetres (16 inches) on centre (that is, measured between the centre points of each); these in turn supported the roof and floor joists, usually 5 × 25 centimetres (2 × 10 inches) also placed 40 centimetres (16 inches) apart and capable of spanning up to six metres (20 feet). Lateral stability was achieved by light diagonal braces let into the studs or, more commonly, by two-centimetre (0.75-inch) thick diagonal boards applied to all exterior walls and to floor and roof joists, creating a rigid, light box. Openings were cut through the framing and sheathing as required. All connections were made with machine-made nails, which were easily driven through the soft, thin timbers. A wide variety of interior and exterior surfacing materials could be applied to the frame, including timber siding, stucco, and brick veneer. The balloon frame building, made with manufactured materials and requiring only a few hand tools and little skill to build, has remained a popular and inexpensive form of construction to the present day.

Building science. A significant achievement of the first industrial age was the emergence of building science, particularly the elastic theory of structures. With it, mathematical models could be used to predict structural performance with considerable accuracy, provided there was adequate quality control of the materials used. Although some elements of the elastic theory, such as the Swiss mathematician Leonhard Euler's theory of column buckling (1757), were worked out earlier, the real development began with the English scientist Thomas Young's modern definition of the modulus of elasticity in 1807. Louis Navier published the elastic theory of beams in 1826, and three methods of analyzing forces in trusses were devised by Squire Whipple, A. Ritter, and James Clerk Maxwell between 1847 and 1864. The concept of a statically determinate structure—that is, a structure whose forces could be determined from Newton's laws of motion alone—was set forth by Otto Mohr in 1874, after having been used intuitively for perhaps 40 years. Most 19th-century structures were purposely designed and fabricated with pin joints to be statically determinate; it was not until the 20th century that statically indeterminate structures became readily solvable. The elastic theory formed the basis of structural analysis until World War II, when bomb-damaged buildings were observed to behave in unpredicted ways and the underlying assumptions of the theory were found to require modification.

Emergence of design professionals. The coming of the industrial age also marked a major change in the role of the architect. The artist-architects of the Renaissance had the twin patrons of church and state upon whom they could depend for commissions. In the rising industrial democracies the market for large-scale buildings worthy of an architect's attention widened, and the different users asked for a bewildering range of new building types. The response of the architect was to develop the new role of licensed professional on the model of professions such as law and medicine. In addition, with the coming of building science, there was a further division of labour in the design process; structural engineering appeared as a separate discipline specializing in the application of mathematical models in building. One of the first buildings for which the architect and engineer were separate persons was the Granary (1811) in Paris. Societies representing the building design professions were founded, including the Institution of Civil Engineers (1818) and the Royal Institute of British Architects (1834), both in London, and the American Institute of Architects (1857). Official government licensing of architects and engineers, a goal of these societies, was not realized until much later, beginning with the Illinois Architects Act of 1897. Concurrent with the rise of professionalism was the development of government regulation, which took the form of detailed municipal and national building codes specifying both prescriptive and performance requirements for buildings.

Gas lighting

Improvements in building services. Environmental control technologies began to develop dramatically in the first industrial age. The first major advance was the use of coal gas for lighting. Coal gas was first made in the 1690s by heating coal in the presence of water to yield methane, and in 1792 William Murdock developed the gas jet lighting fixture. The first large building to have gas lighting (from a small gas plant on the site) was James Watt's foundry in Birmingham in 1803. The Gas Light and Coke Company was founded in London in 1812 as the first real public utility, producing coal gas as a part of the coking process in large central plants and distributing it through underground pipes to individual users; soon many major cities had gasworks and distribution networks. Gas was expensive, however, and was used mainly for lighting, not for heating or cooking; it also contained many impurities that produced undesirable products of combustion (particularly carbon soot) in occupied spaces. Relatively pure methane in the form of natural gas would not be available until the exploitation of large oil fields in the 20th century.

The stove and fireplace continued as the major sources of space heating throughout this period, but the development of the steam engine and its associated boilers led to a new technology in the form of steam heating. James Watt heated his own office with steam running through pipes as early as 1784. During the 19th century, systems of steam and later hot-water heating were gradually developed; these used coal-fired central boilers connected to networks of pipes that distributed the heated fluid to cast-iron radiators and returned it to the boiler for reheating. Steam heat was a major improvement over stoves and fireplaces because all combustion products were eliminated from occupied spaces, but heat sources were still localized at the radiators.

Plumbing and sanitation systems in buildings advanced rapidly in this period. Public water-distribution systems were the essential element; the first large-scale example of a mechanically pressurized water-supply system was the great array of waterwheels installed by Louis XIV at Marley on the Marne River in France to pump water for the fountains at Versailles, about 18 kilometres (10 miles)

Advances in plumbing

away. The widespread use of cast-iron pipes in the late 18th century made higher pressures possible, and they were used by Napoleon in the first steam-powered municipal water supply for a section of Paris in 1812. Gravity-powered underground drainage systems were installed along with water-distribution networks in most large cities of the industrial world during the 19th century; sewage-treatment plants were introduced in the 1860s. Permanent plumbing fixtures appeared in buildings with water supply and drainage, replacing portable basins, buckets, and chamber pots. Joseph Bramah invented the metal valve-type water closet as early as 1778, and other early lavatories, sinks, and bathtubs were of metal also; lead, copper, and zinc were all tried. The metal fixtures proved difficult to clean, however, and in England during the 1870s Thomas Twyford developed the first large one-piece ceramic lavatories as well as the ceramic washdown water closet. At first these ceramic fixtures were very expensive, but their prices declined until they became standard, and their forms remain largely unchanged today. The bathtub proved to be too large for brittle ceramic construction, and the porcelain-enamel cast-iron tub was devised about 1870; the double-shell built-in type still common today appeared about 1915.

THE SECOND INDUSTRIAL AGE

Introduction of steel building technology. If the first industrial age was one of iron and steam, the second industrial age, which began in about 1880, could be called one of steel and electricity. Mass production of this new material and of this new form of energy also transformed building technology. Steel was first made in large quantities for railroad rails. Rolling of steel rails (which was adapted from wrought-iron rolling technology) and other shapes such as angles and channels began about 1870; it made a much tougher, less brittle metal. Steel was chosen as the principal building material for two structures built for the Paris Exposition of 1889: the Eiffel Tower and the Gallery of Machines. Gustave Eiffel's tower was 300 metres (1,000 feet) high, and its familiar parabolic curved form has become a symbol of Paris itself; its height was not exceeded until 1929. The Gallery of Machines (Figure 7) was designed by the architect C.-L.-F. Dutert and the engineer Victor Contamin with great three-hinged arches spanning 114 metres (380 feet) and extending more than 420 metres (1,400 feet). Its glass-enclosed clear span area of 48,727 square metres (536,000 square feet) has never been equaled; in fact, it was so large that no regular use for it could be found after the exposition closed, and this magnificent building was demolished in 1910.

Early high-rise construction in steel. While these prodigious structures were the centre of attention, a new and more significant technology was developing: the steel-framed high-rise building. It began in Chicago, a city whose central business district was growing rapidly. The pressure of land values in the early 1880s led owners to demand taller buildings. The architect-engineer William Le Baron Jenney responded to this challenge with the 10-story Home Insurance Company Building (1885), which had a nearly completely all-metal structure. The frame consisted of cast-iron columns supporting wrought-iron beams, together with two floors of rolled-steel beams that were substituted during construction; this was the first large-scale use of steel in a building. The metal framing was completely encased in brick or clay-tile cladding for fire protection, since iron and steel begin to lose strength if they are heated above about 400° C (750° F). Jenney's Manhattan Building (1891) had the first vertical truss bracing to resist wind forces; rigid frame or portal wind bracing was first used in the neighbouring Old Colony Building (1893) by the architects William Holabird and Martin Roche. The all-steel frame finally appeared in Jenney's Ludington Building (1891) and the Fair Store (1892; Figure 8).

The Home Insurance Company Building

The foundations of these high-rise buildings posed a major problem, given the soft clay soil of central Chicago. Traditional spread footings, which dated back to the Egyptians, proved to be inadequate to resist settlement due to the heavy loads of the many floors, and timber piles (a Roman invention) were driven down to bedrock. For the 13-story Stock Exchange Building (1892), the engineer Dankmar Adler employed the caisson foundation used in bridge construction. A cylindrical shaft braced with board sheathing was hand-dug to bedrock and filled with concrete to create a solid pier to receive the heavy loads of the steel columns.

By 1895 a mature high-rise building technology had been developed: the frame of rolled steel I beams with bolted or riveted connections, diagonal or portal wind bracing, clay-tile fireproofing, and caisson foundations. The electric-powered elevator provided vertical transportation, but other environmental technologies were still fairly simple. Interior lighting was still largely from daylight, although supplemented by electric light. There was steam heating but no cooling, and ventilation was dependent on operating windows; thus these buildings needed narrow floor spaces to give adequate access to light and air. Of equal importance in high-rise construction was the introduction of the internal-combustion engine (which had been invented by Nikolaus Otto in 1876) at the building site; it replaced the horse and human muscle power for the heaviest tasks of lifting. Over the next 35 years, higher steel-frame buildings were built; in Chicago the Masonic Building (1892) of Daniel Burnham and John Root reached 21 stories (91 metres or 302 feet), but then the leadership shifted to New York City with the 26-story St. Paul Building (1899). The Singer Building (1907) by the architect Ernest Flagg rose to 47 stories (184 metres or 612 feet), Cass

Support systems in high-rise buildings

Gilbert's Woolworth Building (1913) attained a height of 238 metres (792 feet) at 55 stories, and Shreve, Lamb & Harmon's 102-story Empire State Building (1931) touched 378 metres (1,239 feet). The race for higher buildings came to an abrupt halt with the Great Depression and World War II, and high-rise construction was not resumed until the late 1940s.

Long-span construction in steel. Long-span structures in steel developed more slowly than the high-rise in the years from 1895 to 1945, and none exceeded the span of the Gallery of Machines. Two-hinge (made of a single member hinged at each end) and three-hinge (made of two members hinged at each end and at the meeting point at the crown) trussed arches were widely used, the largest examples being two great airship hangars for the U.S. Navy in New Jersey—the first built in 1922 with a span of 79 metres (262 feet), the second in 1942 with a span of 100 metres (328 feet). The flat truss was used also, reaching a maximum span of 91 metres (300 feet) in the Glenn L. Martin Co. Aircraft Assembly Building (1937) in Baltimore. Electric arc welding, another important steel technology, was applied to building construction at this time, although the principle had been developed in the 1880s. The first-all-welded multistory buildings were a series of factories for the Westinghouse Company, beginning in 1920. The welded rigid frame became a new structural type for medium spans, reaching a length of 23 metres (77 feet) in the Cincinnati Union Terminal (1932), but widespread use of welding did not come until after 1945.

Reintroduction of concrete. The second industrial age also saw the reemergence of concrete in a new composite relationship with steel, creating a technology that would rapidly assume a major role in building construction. The first step in this process was the creation of higher-strength artificial cements. Lime mortar—made of lime, sand, and water—had been known since ancient times. It was improved in the late 18th century by the British engineer John Smeaton, who added powdered brick to the mix and made the first modern concrete by adding pebbles as coarse aggregate. Joseph Aspdin patented the first true artificial cement, which he called Portland Cement, in 1824; the name implied that it was of the same high quality as Portland stone. To make portland cement, Aspdin burned limestone and clay together in a kiln; the clay provided silicon compounds, which when combined with water formed stronger bonds than the calcium compounds of limestone. In the 1830s Charles Johnson, another British cement manufacturer, saw the importance of high-temperature burning of the clay and limestone to a white heat, at which point they begin to fuse. In this period, plain concrete was used for walls, and it sometimes replaced brick in floor arches that spanned between wrought-iron beams in iron-framed factories. Precast concrete blocks also were manufactured, although they did not effectively compete with brick until the 20th century.

Portland cement

The invention of reinforced concrete. The first use of iron-reinforced concrete was by the French builder François Coignet in Paris in the 1850s. Coignet's own all-concrete house in Paris (1862), the roofs and floors reinforced with small wrought-iron I beams, still stands. But reinforced concrete development began with the French gardener Joseph Monier's 1867 patent for large concrete flowerpots reinforced with a cage of iron wires. The French builder François Hennebique applied Monier's ideas to floors, using iron rods to reinforce concrete beams and slabs; Hennebique was the first to realize that the rods had to be bent upward to take negative moment near supports. In 1892 he closed his construction business and became a consulting engineer, building many structures with concrete frames composed of columns, beams, and slabs. In the United States Ernest Ransome paralleled Hennebique's work, constructing factory buildings in concrete. High-rise structures in concrete followed the paradigm of the steel frame. Examples include the 16-story Ingalls Building (1903) in Cincinnati, which was 54 metres (180 feet) tall and the 11-story Royal Liver Building (1909), built in Liverpool by Hennebique's English representative, Louis Mouchel. The latter was Europe's first skyscraper, its clock tower reaching a height of 95 metres (316 feet). Attainment of height in concrete buildings progressed slowly due to the much lower strength and stiffness of concrete as compared to steel.

Between 1900 and 1910 the elastic theory of structures was at last applied to reinforced concrete in a scientific way. Emil Morsch, the chief engineer of the German firm of Wayss and Freitag, formulated the theory, which was verified by detailed experimental testing at the Technical University of Stuttgart. These tests established the need for deformed bars for good bonding with concrete and demonstrated that the amount of steel in any member should be limited to about 8 percent of the area; this assures the slow elastic failure of the steel, as opposed to the abrupt brittle failure of the concrete, in case of accidental overloading. In 1930 the American engineer Hardy Cross introduced relaxation methods for the approximate analysis of rigid frames, which greatly simplified the design of concrete structures. In the Johnson-Bovey Building (1905) in Minneapolis, the American engineer C.A.P. Turner employed concrete floor slabs without beams (called flat slabs or flat plates) that used diagonal and orthogonal patterns of reinforcing bars. The system still used today—which divides the bays between columns into column strips and middle strips and uses only an orthogonal arrangement of bars—was devised in 1912 by the Swiss engineer Robert Maillart.

The concrete dome. Concrete was also applied to long-span buildings, an early example being the Centennial Hall (1913) at Breslau, Ger. (now Wrocław, Pol.), by the architect Max Berg and the engineers Dyckerhoff & Widmann; its ribbed dome spanned 65 metres (216 feet), exceeding the span of the Pantheon. More spectacular were the great airship hangars at Orly constructed by the French engineer Eugène Freyssinet in 1916; they were made with nine-centimetre- (3.5-inch-) thick corrugated parabolic vaults spanning 80 metres (266 feet) and pierced by windows. In the 1920s Freyssinet made a major contribution to concrete technology with the introduction of pretensioning. In this process, the reinforcing wires were stretched in tension, and the concrete was poured around them; when the concrete hardened, the wires were released, and the member acquired an upward deflection and was entirely in compression. When the service load was applied, the member deflected downward to a flat position, remaining entirely in compression, and it did not develop the tension cracks that plague ordinary reinforced concrete. Widespread application of pretensioning was not made until after 1945.

Shell construction in concrete also began in the 1920s; the first example was a very thin (6 centimetres) hemispherical shell for a planetarium (1924) in Jena, Ger., spanning 25 metres (82 feet). In 1927 an octagonal ribbed shell dome with a span of 66 metres (220 feet) was built to house a market hall in Leipzig. Many variations of thin shells were devised for use in industrial buildings. The shell emerged as a major form of long-span concrete structure after World War II.

Development of building service and support systems. *Vertical transportation.* Elisha Graves Otis developed the first safe steam-powered roped elevators with toothed guide rails and catches in the late 1850s. The steam-powered hydraulic elevator, which was limited to buildings of about 15 stories, was developed in 1867 by the French engineer Léon Édoux. The development of the electric motor by George Westinghouse in 1887 made possible the invention of the high-speed electric-powered roped elevator (called "lightning" elevators in comparison to the slower hydraulics) in 1889 and the electric-powered moving staircase, or escalator, in the 1890s.

Lighting. In the second industrial age, environmental technologies developed rapidly. Most of these technologies involved the use of electric power, which declined in cost during this period. The carbon-arc electric light was demonstrated as early as 1808, and the British physicist Michael Faraday devised the first steam-powered electric generator to operate a large carbon-arc lamp for the Foreland Lighthouse in 1858. But the carbon-arc lamp was so bright and required so much power that it was never widely used and was rapidly superseded by the simultaneous invention of the carbon-filament bulb by Thomas Edison and Joseph Swan in 1879. The carbon-filament bulb was highly inefficient, but it banished the soot and fire hazards of coal-gas jets and soon gained wide acceptance. It was succeeded by the more efficient tungsten-filament incandescent bulb, developed by George Coolidge of the General Electric Company, which first appeared in 1908; the double-coiled filament used today was introduced about 1930.

Carbon-arc light

Edison experimented with gas-discharge light tubes in 1896, and Georges Claude in France and Moore in England produced the first practical discharge tubes using noble gases such as neon and argon; these tubes were first used to outline the facade of the West End Cinema in London in 1913 and were rapidly exploited for signs and other decorative purposes. In 1938 General Electric and Westinghouse produced the first commercial fluorescent discharge lamps using mercury vapour and phosphor-coated tubes to enhance visible light output. Fluorescent tubes had roughly double the efficiency of tungsten lamps and were rapidly adopted for commercial and office use. Light intensity increased in all buildings as electric costs decreased, reaching a peak in about 1970. Gaseous-discharge lamps using high-pressure mercury and sodium vapour were developed in the 1960s but found only limited application in buildings; they are of such high intensity and marked colour that they are used mostly in high-ceilinged spaces and for exterior lighting.

Heating and cooling systems. Steam and hot-water heating systems of the late 19th century provided a reasonable means for winter heating, but no practical methods existed for artificial cooling, ventilating, or humidity control. In the forced-air system of heating, air replaced steam or water as the fluid medium of heat transfer, but this was dependent on the development of powered fans to move the air. Although large, crude fans for industrial applications in the ventilation of ships and mines had appeared by the 1860s, and the Johns Hopkins Hospital in Baltimore had a successful steam-powered forced-air system installed in 1873, the widespread application of this system to buildings only followed the development of electric-powered fans in the 1890s.

Important innovations in cooling technology followed. The development of refrigeration machines for food storage played a role, but the key element was Willis Carrier's 1906 patent that solved the problem of humidity removal by condensing the water vapour on droplets of cold water sprayed into an airstream. Starting with humidity control in tobacco and textile factories, Carrier slowly developed his system of "man-made weather," finally applying it together with heating, cooling, and control devices as a complete system in Graumann's Metropolitan Theater, Los Angeles, in 1922. The first office building air-conditioned by Carrier was the 21-story Milam Building (1928) in San Antonio, Texas. It had a central refrigeration plant in the basement that supplied cold water to small air-handling units on every other floor; these supplied conditioned air to each office space through ducts in the ceiling; the air was returned through grills in doors to the corridors and then back to the air-handling units. A somewhat different system was adopted by Carrier for the 32-story Philadelphia Savings Fund Society Building (1932). The central air-handling units were placed with the refrigeration plant on the 20th floor, and conditioned air was distributed through vertical ducts to the occupied floors and horizontally to each room and returned through the corridors to vertical exhaust ducts that carried it back to the central plant. Both systems of air handling, local and central, are still used in high-rise buildings. The Great Depression and World War II reduced the demand for air-conditioning systems, and it was not until the building of the United Nations Secretariat in New York City in 1949 that Carrier produced a method of air conditioning that could deal effectively with the large heat loads imposed by the building's all-glass curtain walls. The conditioned air was delivered not only from the ceiling but also through pipe coil convector units just inside the glass wall. The pipe coil convectors contained centrally supplied warm or cold water to further temper the heat loss or gain at the perimeter; conditioned air and water were centrally supplied from four mechanical floors spaced within the building's 39-story height.

Carrier's "man-made weather"

Carrier's "Weathermaster" system was energy-intensive, appropriate to the declining energy costs of the time, and it was adopted for most of the all-glass skyscrapers that followed in the next 25 years. In the 1960s the so-called dual-duct system appeared; both warm and cold air were centrally supplied to every part of the building and combined in mixing boxes to provide the appropriate atmosphere. The dual-duct system also consumed much energy, and, when energy prices began to rise in the 1970s, both it and the Weathermaster system were supplanted by the variable air volume (VAV) system, which supplies conditioned air at a single temperature, the volume varying according to the heat loss or gain in the occupied spaces. The VAV system requires much less energy and is widely used.

In the early 1950s, air-conditioning systems were reduced to very small electric-powered units capable of cooling single rooms. These were usually mounted in windows to take in fresh air and to remove heat to the atmosphere. These units found widespread application in the retrofitting of existing buildings—particularly houses and apartment buildings—and have since found considerable application in new residential buildings.

The relatively high energy costs of the 1970s also prompted interest in various forms of solar heating, both for interior spaces and for domestic hot water, but, except for residential passive solar heating, the relative decline in energy prices in the 1980s made such systems unattractive.

Use of thermal insulation

The study of thermodynamics in the late 19th century included the heat-transfer properties of materials and led to the concept of thermal insulation—that is, a material that has a relatively low rate of heat transfer. As building atmospheres became more carefully controlled after 1900, more attention was given to the thermal insulation of building enclosures (envelopes). One of the best insulators is air, and materials that trap air in small units have low heat-transfer rates; wool and foam are excellent examples. The first commercial insulations, in the 1920s, were mineral wools and vegetable-fibreboards; fibreglass wool appeared in 1938. Foam glass, the first rigid insulating foam, was marketed in the 1930s, and after 1945 a wide variety of plastic foam insulations was developed. Since the 1970s most building codes have set minimum requirements for insulation of building envelopes, and these have proved to be very cost-effective in saving energy.

Glass as a building material. Glass underwent considerable development in the second industrial age. The making of clear plate glass was perfected in the late 19th century, as were techniques of sandblasting and etching it. In the United States in 1905 the Libbey Owens Glass Company began making sheet glass by a continuous drawing process from a reservoir of molten glass; its surface was somewhat distorted, but it was much cheaper than plate glass. Prefabricated panels of double glazing about 2.5 centimetres (one inch) thick were first made in the 1940s, although the insulating principle of air trapped between two layers of glass had been recognized much earlier. Hollow glass blocks were introduced by the Corning Company in 1935. In 1952 the Pilkington Brothers in England developed the float glass process, in which a continuous 3.4-metre- (11-foot-) wide ribbon of glass floated over molten tin and both sides were fire finished, avoiding all polishing and grinding; this became the standard method of production. Pilkington also pioneered the development of structural glass mullions in the 1960s. In the 1950s the rise of air conditioning led to the marketing of tinted glass that would absorb and reduce solar gain, and in the 1960s reflective glass with thin metallic coatings applied by the vacuum plating process was introduced, also to reduce solar gain. Heat-mirror glass, which has a transparent coating that admits the short-wavelength radiation from the Sun but tends to reflect the longer-wavelength radiation from within occupied spaces, was introduced in 1984; when combined with double glazing its insulating value approaches that of a wall.

Curtain-wall construction

High-rise construction since 1945. *Use of steel and other metals.* The second great age of high-rise buildings began after the end of World War II, when the world economy and population again expanded. It was an optimistic time with declining energy costs, and architects embraced the concept of the tall building as a glass prism. This idea had been put forward by the architects Le Corbusier and Ludwig Mies van der Rohe in their visionary projects of the 1920s. These designs employed the glass curtain wall, a non-load-bearing "skin" attached to the exterior structural components of the building. The earliest all-glass curtain wall, which was only on a single street facade, was that of the Hallidie Building (1918) in San Francisco. The first multistory structure with a full glass curtain wall was the A.O. Smith Research Building (1928) in Milwaukee by Holabird and Root; in it the glass was held by aluminum frames, an early use of this metal in buildings. But these were rare examples, and it was not until the development of air conditioning, fluorescent lighting, and synthetic rubber sealants after 1945 that the glass prism could be realized.

The paradigm of the glass tower was defined by the United Nations Secretariat Building (1949) in New York City; Wallace Harrison was the executive architect, but Le Corbusier also played a major role in the design. The UN building, which featured a Weathermaster air-conditioning system and green-tinted glass walls, helped set the standard for tall buildings around the world. Several other influential buildings—such as Mies van der Rohe's 26-story 860–880 Lake Shore Drive Apartments (1951) in Chicago and Skidmore Owings & Merrill's 21-story Lever House (1952) in New York City—helped to further establish the technology of curtain walls. Perhaps the most important element was the development of extruded-aluminum mullion and muntin shapes to support the glass. Aluminum began to be produced in quantity in the United States by the Hall process in 1886; this process for separating the metal from the ore required large amounts of electricity, and declining energy costs after World War II influenced the development of this building technology. Aluminum forms a coating of transparent oxide that protects it against corrosion; this oxide layer can be artificially thickened and coloured through a process called anodizing. Anodized aluminum was first used in the windows of the Cambridge University Library in England in 1934. Aluminum became the principal material of curtain-wall framing because of its corrosion resistance and ease of forming by means of the extrusion process, in which the metal is forced through a series of dies to create complex cross-sectional shapes. Formed sheet aluminum is also used for opaque curtain-wall panels. Other metals used in curtain walls are stainless steel (a compound of 82 percent iron and 18 percent chromium) and so-called weathering steel, copper-bearing steel alloys that form an adherent oxide layer. The bronze curtain wall of Mies van der Rohe's Seagram Building (1954–58) in New York City proved to be an isolated example. Probably of equal importance in curtain-wall construction was the development of cold-setting rubbers during World War II; these form the elastic sealants that successfully seal the joints between glass and metal and between metal and metal against wind and rain. In the late 1970s the development of artificial diamonds made possible cutting tools that slice stone wafer-thin, and it became an important component of curtain walls.

The bundled tube

Following the development of the curtain wall, new forms of structure appeared in high-rise buildings. As environmental control systems increased in cost, economic pressures worked to produce more efficient structures. In 1961 the 60-story Chase Manhattan Bank Building, designed by Skidmore, Owings & Merrill, had a standard steel frame with rigid portal wind bracing, which required 275 kilograms of steel per square metre (55 pounds of steel per square foot), nearly the same as the Empire State Building of 30 years earlier. Economy of structure in tall buildings was demonstrated by the same firm only nine years later in the John Hancock Building in Chicago. It used a system of exterior diagonal bracing to form a rigid tube devised by the engineer Fazlur Khan; although the Hancock building is 100 stories and 343 metres (1,127 feet) high, its structure is so efficient that it required only 145 kilograms of steel per square metre (29 pounds per square foot). The framed tube, which Khan developed for concrete structures, was applied to other tall steel buildings. Khan used a steel system of nine bundled tubes of different heights—each 22.5 metres (75 feet) square with columns spaced at 4.5 metres (15 feet)—to form the structure of the 110-story Sears Tower (1974), also in Chicago (Figure 9). Its height of 443 metres (1,454 feet) has not been exceeded, and, although present technology would undoubtedly permit higher structures to be built, the large floor areas they provide seem to be unfavourable for economic considerations.

Use of reinforced concrete. Parallel to the development of tall steel structures, substantial advancements in high-rise structural systems of reinforced concrete have been made since 1945. The first of these was the introduction of the shear wall as a means of stiffening concrete frames against lateral deflection, such as results from wind or earthquake loads; the shear wall acts as a narrow deep cantilever beam to resist lateral forces. In 1958 the ar-

Ezra Stoller © Esto

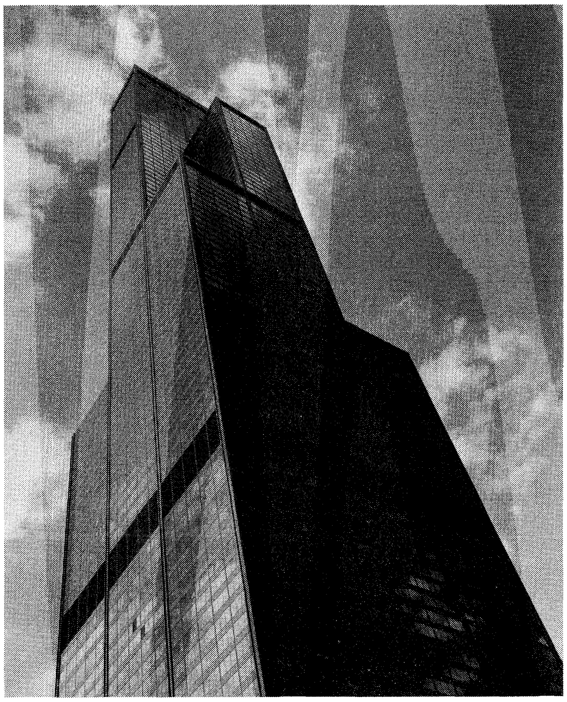

Figure 9: Bundled tube construction with termination of tubes at various heights, Sears Tower, Chicago, 1974.

chitect Milton Schwartz and engineer Henry Miller used shear walls to build the 39-story Executive House in Chicago to a height of 111 metres (371 feet). Of equal importance was the introduction of the perimeter-framed tube form in concrete by Fazlur Khan in the DeWitt–Chestnut Apartments (1963) in Chicago; the building rises 43 stories (116 metres, or 387 feet). Lateral stability was achieved by closely spaced columns placed around the building perimeter and connected together by deep beams. The next step in concrete high-rise construction was the combination of the perimeter-framed tube with a largely solid-walled interior tube or shear walls to give further lateral stability. This was employed by Eero Saarinen and Kevin Roche in the 35-story CBS Building (1964) in New York City, and the system was further developed by Khan in the 221-metre (725-foot) Shell Oil Building (1967) in Houston. Another new structural form in concrete was introduced by Khan in the 174-metre (570-foot) 780 Third Avenue Office Building (1983) in New York City. This is a framed tube with diagonal bracing achieved by filling in diagonal rows of window openings to create exterior bracing members; this is a very efficient system and may lead to yet taller buildings of this type. Three further innovations helped the rapid rise in height of concrete buildings. One was the development of lightweight concrete, using blast-furnace slag in place of stone as aggregate for floor construction; this reduced the density of the concrete by 25 percent, with a corresponding reduction in the loads the building columns needed to carry. The second was the increase in the ultimate strength of concrete used for columns. Third, the use of pumps to move liquid concrete to the upper floors of tall buildings substantially reduced the cost of placement.

Another important technique developed for concrete high-rise construction is slipforming. In this process, a continuous vertical element of planar or tubular form is continuously cast using a short section of formwork that is moved upward with the pouring process. Slipforming has been used to build a number of very tall structures in Canada, including several industrial chimneys 366 metres (1,200 feet) high and the world's tallest occupied structure, the Canadian National Railroad Tower in Toronto, which contains only an observation deck and a television antenna but has a total height of 553 metres (1,814 feet). Concrete has shown itself to be a serious competitor with steel in high-rise structures; it is now used for the great majority of tall residential buildings and for a substantial number of tall office buildings.

Postwar developments in long-span construction. After 1945 the dome and the shell vault continued to be the major forms of long-span structures. One innovation was the geodesic dome, which was devised by the architect and engineer R. Buckminster Fuller in the 1940s; in this form the ribs are placed in a triangular or hexagonal pattern and lie on the geodesic lines, or great circles, of a sphere. A very shallow spherical form with aluminum trussed members was used by Freeman Fox & Partners for the Dome Discovery built in London in 1951. Fuller's own patented forms were used in 1958 to build two large hemispheric domes 115.3 metres (384 feet) in diameter using steel tube members. These are used as workshops for the Union Tank Car Company in Wood River, Ill., and Baton Rouge, La. The largest geodesic dome is the Poliedro de Caracas, in Venezuela, built of aluminum tubes spanning 143 metres (469 feet).

The geodesic dome

Another form of steel trussed dome is the lamella dome, which is made of intersecting arches hinged together at their midpoints to form an interlocking network in a diamond pattern. It was used for the first two examples of the great covered sports stadiums built in the United States since the 1960s: the Harris County Stadium, or Astrodome, built in Houston, Texas, in 1962–64 with a span of 196 metres (642 feet) and the 207-metre- (678-foot-) diameter Superdome in New Orleans, La., designed by Sverdrup and Parcel and completed in 1973. The steel truss continued to be used and was extended to three dimensions to form space trusses. The longest span of this type was the Narita Hangar at Tokyo International Airport, which used a tied portal truss to span 190 metres (623 feet) supporting a space-truss roof spanning 90 metres (295 feet).

The concrete dome or shell developed rapidly in the 1950s. The St. Louis Lambert Airport Terminal (1954), designed by Hellmuth, Yamasaki and Leinweber, has a large hall 36.6 metres (120 feet) square, spanned by four intersecting thin-shell concrete barrel vaults supported at the four corners; the thickness of the shell varies from 20 centimetres (eight inches) at the supports to 11.3 centimetres (4.5 inches) at the centre. Another example is the King Dome, in Seattle, Wash., which covers a sports stadium with a thin single shell concrete parabolic dome stiffened with ribs 201 metres (661 feet) in diameter.

New forms of the long-span roof appeared in the 1950s based on the steel cables that had long been used in suspension bridges. One example was the U.S. Pavilion at the 1958 Brussels World's Fair, designed by the architect Edward Durell Stone. It was based on the familiar principle of the bicycle wheel; its roof had a diameter of 100 metres (330 feet), with a steel tension ring at the perimeter from which two layers of radial cables were tightly stretched to a small tension ring in the middle—the double layer of cables gave the roof stability against vertical movement. The Oakland–Alameda County Coliseum (1967), by Skidmore, Owings & Merrill, extended this system to 126 metres (420 feet) in diameter, but only a single layer of cables, stiffened by encasing ribs of concrete, connects the inner and outer rings.

Another system derived from bridge construction is the cable-stayed roof. An early example is the TWA Hangar (1956) at Kansas City, Mo., which shelters large aircraft under a double cantilever roof made of semicylindrical shells that reach out 48 meters (160 feet); deflection is reduced and the shells kept in compression by cables that run down from central shear walls to beams in the valleys between the shells. Another example of the cable-stayed roof is the McCormick Place West Exhibition Hall (1987) in Chicago, by Skidmore, Owings & Merrill. Two rows of large concrete masts rise above the roof, supporting steel trusses that span 72 metres (240 feet) between the masts and cantilever 36 metres (120 feet) to either side; the trusses are also supported by sets of parallel diagonal cables that run back to the masts.

A third form of long-span roof structures in tension are air-supported plastic membranes, which were devised by Walter Bird of Cornell University in the late 1940s and were soon in use for swimming pools, temporary warehouses, and exhibition buildings. The Osaka World's Fair of 1970 included many air-supported structures, the largest of which was the U.S. Pavilion designed by the engineers Geiger Berger Associates; it had an oval plan 138 × 79 metres (460 × 262 feet), and the inflated domed roof of vinyl-coated fabric was restrained by a diagonally intersecting network of steel cables attached to a concrete compression ring at the perimeter. The system of the Osaka Pavilion was adapted for two large sports stadiums built in the 1980s: the Silverdome at Pontiac, Mich., and the Hubert H. Humphrey Metrodome in Minneapolis. Air-supported structures are perhaps the most cost-effective type of structure for very long spans.

Air-supported structures

Building construction has settled into a period of relative calm after the explosive innovations of the 19th century. Steel, concrete, and timber have become fairly mature technologies, but there are other materials—such as fibre composites—that may yet play a major role in building.

Modern building practices

THE ECONOMIC CONTEXT OF BUILDING CONSTRUCTION

Buildings, like all economic products, command a range of unit prices based on their cost of production and their value to the consumer. In aggregate, the total annual value of building construction in the various national economies is substantial. In 1987 in the United States, for example, it was about 10 percent of the gross domestic product, a proportion that is roughly applicable for the world economy as a whole. In spite of these large aggregate values, the unit cost of buildings is quite low when compared to other products. In the United States in 1987, new building cost ranged from about $0.50 to $2.50 per pound. The lowest costs are for simple pre-engineered metal buildings, and the highest represent functionally complex buildings with many mechanical and electrical services, such as hospitals and laboratories. These unit costs are at the low end of the scale of manufactures, ranking with inexpensive foodstuffs, and are lower than those of most other familiar consumer products. This scale of cost is a rough index of the value or utility of the commodity to society. Food, although essential, is relatively easy to produce; aircraft, at the high end of the scale, perform a desirable function but do so with complex and expensive mechanisms that command much higher unit prices which reflect not only the materials and labour required to produce them but also substantial capital and research investments. Buildings fall nearer to food in value; they are ubiquitous and essential, yet the services consumers expect them to provide can be supplied with relatively unsophisticated technology and inexpensive materials. Thus there has been a tendency for building construction to remain in the realm of low technology, for there has been relatively little incentive to invest in research given consumer expectations.

Building and zoning codes

Within this general economic context, there are a number of specific parameters that affect the cost of buildings. First are government building codes, which are enacted to protect public health and safety; these take the form of both prescriptive and performance requirements. Structural requirements include description of the loads buildings must support, beginning with the constant everyday loads of building contents imposed by gravity and extending to the less frequent but more extreme loadings of wind and earthquake forces. These are specified on a statistical basis, usually the maximum expected to occur with a 100-year frequency. Safety factors for materials are specified to allow for accidental overloading and lapses of quality control. Economic considerations are also reflected; for example, buildings must perform well under normal gravity loads, but no code requires a building to resist direct exposure to the wind and low pressure effects of a tornado, for its cost would be prohibitive.

Planning and zoning requirements provide for height and floor area limitations and building setbacks from lot lines to ensure adequate light and air to adjoining properties. Zoning regulations also establish requirements for permitted building usages, parking spaces, and landscaping and even set standards for the visual appearance of buildings. Another example is requirements for building atmosphere conditions; these include minimum (but not maximum) temperatures and rates of air change to dilute odours and provide an adequate oxygen supply. Life-safety requirements include adequate stairways for emergency exits, emergency lighting, smoke detection and control systems, and fire-resistant building materials. Sanitation requirements include adequate numbers of plumbing fixtures and proper pipe sizes. Electrical requirements include wire sizes, construction requirements for safety, and location of outlets.

Beyond the government standards there are market standards, which reflect user expectations for buildings. One example is elevator systems; elevators are not required by building codes, but in the United States, for example, the number of elevators in office buildings is calculated based on a maximum waiting period of 30 seconds. Cooling of building atmospheres is also not required by code but is provided in climates and building types where the marketplace has shown it to be cost-effective.

Building systems and components are perceived as having two dimensions of value. One is the purely functional dimension: the structure is expected to resist loads, the roof must keep out rain. The other is the aesthetic or psychic dimension: stone is perceived as more durable than wood; an elevator system with a waiting time of 30 seconds is preferable to one with a waiting time of two minutes. For these perceived differences many users are willing to pay more. When symbolic buildings such as temples, cathedrals, and palaces play an important role in society, the aesthetic dimension is important in valuing buildings; for example, the Parthenon of Athens or Chartres Cathedral commanded a level of investment in their economies that might be roughly compared to the U.S. Apollo space program. But in most buildings, the functional dimension of value is dominant.

Because of its relatively low level of technology, wide geographic distribution, highly variable demand, and wide variety of building products, the building industry in industrialized countries is subdivided into many small enterprises. This lack of centralization tends to discourage research and keeps building components sturdy and simple, following well-tried formulas. Within this diversity there are a number of fairly well-defined markets based on building types; these include low-rise residential buildings, low-rise commercial, institutional, and industrial buildings, high-rise buildings, and long-span buildings.

A somewhat similar pattern is found in the Soviet bloc, although the building industry there is more centralized. There is also a much smaller low-rise residential market, with most new housing being provided in high-rise buildings.

In developing countries the major market is for low-rise residential buildings to house rapidly growing populations. Much of the construction is undertaken by local craftsmen using simple building products. Local timber is widely used, and masonry materials still include the ancient mud brick. More sophisticated long-span and high-rise technologies are found only in major cities.

BUILDING DESIGN AND CONSTRUCTION

Design programming. The design of a building begins with its future user or owner, who has in mind a perceived need for the structure, as well as a specific site and a general idea of its projected cost. The user, or client, brings these facts to a team of design professionals composed of architects and engineers, who can develop from them a set of construction documents that define the proposed building exactly and from which it can be constructed.

Building design professionals include those licensed by the state—such as architects and structural, mechanical, and electrical engineers—who must formally certify that the building they design will conform to all governmental codes and regulations. Architects are the primary design professionals; they orchestrate and direct the work of engineers, as well as many other consultants in such specialized areas as lighting, acoustics, and vertical transportation.

Building science

The design professionals draw upon a number of sources in preparing their design. The most fundamental of these is building science, which has been gradually built up over the past 300 years. This includes the parts of physical theory that relate to building, such as the elastic theory of structures and theories of light, electricity, and fluid flow. There is also a large compendium of information on the specific properties of building materials that can be applied in mathematical models to reliably project building performance. There is also a large body of data on criteria for human comfort in such matters as thermal environment, lighting levels, and sound levels that influence building design.

In addition to general knowledge of building science, the design team collects specific data related to the proposed building site. These include topographic and boundary surveys, investigations of subsoil conditions for foundation and water-exclusion design, and climate data and other local elements.

Concurrently with the collection of the site data, the design team works with the client to better define the often vague notions of building function into more precise and concrete terms. These definitions are summarized in a building space program, which gives a detailed written description of each required space in terms of floor area, equipment, and functional performance criteria. This document forms an agreement between the client and the design team as to expected building size and performance.

Design development. The process by which building science, site data, and the building space program are used by the design team is the art of building design. It is a complex process involving the selection of standard building systems, and their adaptation and integration, to produce a building that meets the client's needs within the limitations of government regulations and market standards. These systems have become divided into a number of clear sectors by the building type for which they are intended. The design process involves the selection of systems for foundations, structure, atmosphere, enclosure, space division, electrical distribution, water supply and drainage, and other building functions. These systems are made from a limited range of manufactured components but permit a wide range of variation in the final product. Once the systems and components have been selected, the design team prepares a set of contract documents, consisting of a written text and conventionalized drawings, to describe completely the desired building configuration in terms of the specified building systems and their expected performance. When the contract documents have been completed, the final costs of the building can usually be accurately estimated and the construction process can begin.

The general contractor

Construction. Construction of a building is usually executed by a specialized construction team; it is normally separate from the design team, although some large organizations may combine both functions. The construction team is headed by a coordinating organization, often called a general contractor, which takes the primary responsibility for executing the building and signs a contract to do so with the building user. The cost of the contract is usually an agreed lump sum, although cost-plus-fee contracts are sometimes used on large projects for which construction begins before the contract documents are complete and the building scope is not fully defined. The general contractor may do some of the actual work on the building in addition to its coordinating role; the remainder of the work is done by a group of specialty subcontractors who are under contract to the general contractor. Each subcontractor provides and installs one or more of the building systems—*e.g.,* the structural or electrical system. The subcontractors in turn buy the system components from the manufacturers. During the construction process the design team continues to act as the owner's representative, making sure that the executed building conforms to the contract documents and that the systems and components meet the specified standards of quality and performance.

LOW-RISE RESIDENTIAL BUILDINGS

Low-rise residential buildings include the smallest buildings produced in large quantities. Single-family detached houses, for example, are in the walk-up range of one to three stories and typically meet their users' needs with about 90 to 180 square metres (about 1,000 to 2,000 square feet) of enclosed floor space. Other examples include the urban row house and walk-up apartment buildings. Typically these forms have relatively low unit costs because of the limited purchasing power of their owners. The demand for this type of housing has a wide geographic distribution, and therefore most are built by small local contractors using relatively few large machines (mostly for earth moving) and large amounts of manual labour at the building site. The demand for these buildings can have large local variations from year to year, and small builders can absorb these economic swings better than large organizations. The building systems developed for this market reflect its emphasis on manual labour and its low unit costs. A proportion of single-family detached houses are "factory-built"; that is, large pieces of the building are prefabricated and then transported to the site, where considerable additional work is required to complete the finished product.

Foundations. All foundations must transmit the building loads to a stable stratum of earth. There are two criteria for stability: first, the soil under the foundations should be able to receive the imposed load without more than about 2.5 centimetres (one inch) of settlement and, second, the settlement should be uniform under the entire building. It is also important that the bottom of the foundation be below the maximum winter frost level. Wet soil expands as it freezes, and repeated freeze–thaw cycles can move the building up and down, leading to possible displacement and damage. Maximum frost depth varies with climate and topography. It can be as deep as 1.5 metres (five feet) in cold continental climates and is zero in tropical and some subtropical areas. The foundation systems for low-rise residential buildings are suitable for their light loads; nearly all are supported on spread footings, which are of two types—continuous footings that support walls and isolated pad footings that support concentrated loads. The footings themselves are usually made of concrete poured directly on undisturbed soil to a minimum depth of about 30 centimetres (12 inches). If typical continuous concrete footings are used, they usually support a foundation wall that acts either as a retaining wall to form a basement or as a frost wall with earth on both sides. Foundation walls can be built of reinforced concrete or masonry, particularly concrete block. Concrete blocks are of a standard size larger than bricks and are hollow, forming a grid of vertical planes. They are the least expensive form of masonry—using cheap but strong material—and their large size economizes on the labour required to lay them. Their appearance and weathering properties are inferior to those of fired masonry, but they are satisfactory for foundation walls. In some places timber foundation walls and spread footings are used. Excavation for foundations is the most highly mechanized operation in this building type; it is done almost entirely with bulldozers and backhoes.

Spread footings

Structural systems. *Timber frames.* In these small buildings the ancient materials of timber and masonry are still predominant in the structural systems. In North America, which has abundant softwood forests, light timber frames descended from the 19th-century balloon frame are widely used. These present-day "platform" frames are made of standard-dimension timbers, usually two or four centimetres (0.75 or 1.5 inch) thick, which are joined together by machine-made nails and other metal fasteners using hand tools (Figure 10).

The first step is to construct a floor, which rests on the foundation wall. A heavy timber sill is attached to the wall with anchor bolts, and on top of it are nailed the floor joists, typically 4 × 28 centimetres (1.5 × 11.25 inches) and spaced 40 centimetres (16 inches) apart. The span of the floor joists is usually about 3.6 metres (12 feet), which is the common maximum length of available timbers. The floor may need intermediate supports in the form of interior foundation walls or, if there is a basement, intermediate beams of wood or steel supported by the foundation walls and columns. For longer spans, floor trusses can be made, with members joined by nail grids or nailed plywood gussets or with wood chords and diagonal metal web members. On top of the joists is nailed plywood subflooring, which forms the deck and gives lateral stability to the floor plane.

The exterior bearing walls are made of 4 × 9-centimetre (1.5 × 3.5-inch; "2 × 4") timber verticals, or studs, spaced 40 or 60 centimetres (16 or 24 inches) apart, which rest on a horizontal timber, or plate, nailed to the floor platform and support a double plate at the top. The walls are sheathed on the outside with panels of plywood or particleboard to provide a surface to attach the exterior cladding and for lateral stability against wind. Plywood and particleboard are fabricated in panels of standard sizes. Plywood is made of thin layers of wood, rotary-cut from logs and glued together with the wood grain running perpendicularly in adjoining layers. Particleboard consists of fine wood chips mixed together in an adhesive matrix and allowed to harden under pressure. On top of the wall plate is placed either a second floor or the roof.

Since most of the roofing materials used in these buildings are not fully watertight, the roofs must have sloped surfaces to rapidly drain off rainwater. Sloped forms are created by two methods. The traditional method uses joists similar to those of floor construction to span between exterior walls. Rafters are nailed to the ends of each joist and the rafters meet at a central ridge member, forming a triangular attic space. Where no attic space is needed, it has proved more economical to span the roof with triangular trusses with interior web members. These roof trusses are usually made of narrow timbers joined by nails, glue, or metal connectors, and they are often prefabricated in a workshop. Plywood or particleboard sheathing is then nailed to the roof surfaces to receive the roofing

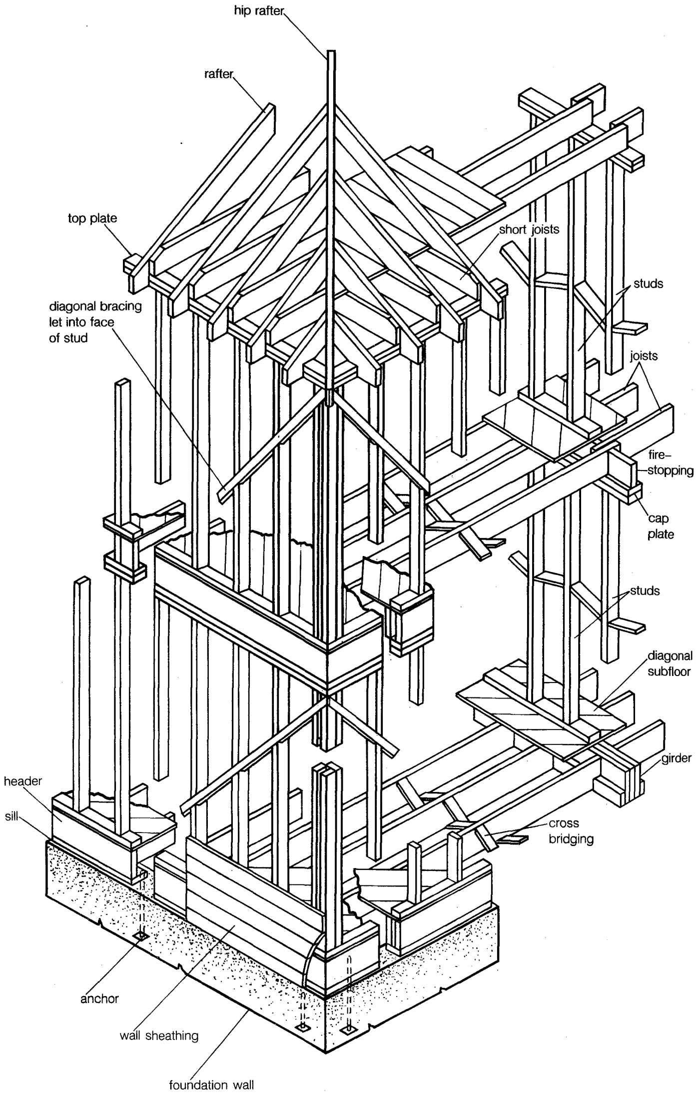

Figure 10: Platform framing for light timber construction, axonometric view.

Adapted from C.G. Ramsay and H.R. Sleeper, *Architectural Graphic Standards* (1970), John Wiley and Sons

and to provide lateral stability, making the entire frame into a rigid box.

Problems of timber framing

Light timber frames are quite flammable, but small one- or two-story buildings are easy to evacuate in case of a fire, and building codes permit the use of these frames with such features as fire-resistant gypsum board on the interiors and fire-stops (short wooden members) between the studs. Timber structures are attacked by certain species of insects—such as termites and carpenter ants—as well as certain fungi, particularly in warm, moist climates. Wood can be chemically treated to discourage these attacks; other precautions include raising the timber above the ground and keeping it dry.

Masonry walls. Structural masonry walls are also used in this building type, primarily in multistory buildings, where they offer greater load-bearing capacity and fire resistance. Brick and concrete block are the major materials, brick being favoured for exterior surfaces because of its appearance and durability. Solid brick walls are rarely used, due to the higher labour and material costs; composite walls of brick and block or block alone are common. Cavity walls are used in colder climates; in these, two wythes (vertical layers) of masonry are built on either side of a layer of rigid insulation. The wythes are joined together by steel reinforcement that runs through the insulation and is laid in the horizontal masonry joints at intervals. Cavity walls have a heat-flow rate that is 50 percent of that of a solid wall. Timber floor and roof construction, similar to balloon framing, is used with masonry construction; and there is also some use of precast prestressed hollow concrete panels, which are fireproof and can span up to nine metres (30 feet).

Enclosure systems. Enclosure systems for this building type are varied. For roofs, traditional wood shingles or, more commonly, felt asphalt shingles are used, as are semicylindrical clay tiles and standing-seam metal roofs. Rainwater from roofs is usually caught in metal gutters and directed to exterior downspouts that discharge onto splash blocks or into underground drains connected to storm sewers.

The wall surfaces of low-rise residential buildings are clad with a range of different materials. Traditional wood elements such as shingles and horizontal shiplap, or clapboard siding, are used on light timber frames as are vertical tongue-and-groove siding and boards and battens. Aluminum and vinyl sidings have been adapted from these wooden forms. Brick and stone veneer are also applied over timber and anchored to it with metal fasteners. Cement plaster, or stucco, is another traditional material used to enclose both timber and masonry structures, and its semiliquid application allows great plasticity of form. A more recent development is a very thin synthetic resin stucco applied directly to the surface of rigid plastic foam insulation.

Insulation

Insulation, which slows the rate of heat transfer through the enclosure, is usually applied at all exterior building surfaces that are exposed to air. There are two major types of insulation, rigid and nonrigid. Rigid insulations are primarily plastic foams (the dead air in the foam cells is the true insulator), which vary in thickness from 2.5 to five centimetres (one to two inches). They include styrofoam, used primarily below grade behind frost walls due to its low fire resistance; urethane foam; isocyanurate foam, which has the best fire resistance; and foam glass. Nonrigid insulations are usually made of fibre—glass fibre being the most common—often with a foil-backed paper on one side. Fibre insulations are made in thicknesses up to 23 centimetres (9.25 inches). The effectiveness of an insulation material is measured in terms of its heat-transfer rate, or U-value, often expressed as the number of BTUs passing through a given unit of insulating material each hour at an expressed temperature differential across the material. Low U-values indicate good insulating properties of the material. U-value is an inverse function of thickness, so that there is a limit to the cost-effectiveness of increasing the amount of insulation on a surface. Rigid insulation panels are applied to vertical wall sheathing and the surfacing material is fastened through the insulation, or it is applied to horizontal roof decks. Glass fibre is usually applied in the spaces between wall studs and between roof joists or the bottom chords of roof trusses.

Most low-rise residential buildings have a limited number of transparent openings in their exteriors, because of the traditional requirements of interior privacy and the relatively higher cost of windows compared to opaque walls. The traditional wooden frames of domestic windows are often clad in extruded vinyl or aluminum cladding, and frames made entirely of extruded aluminum are common. Residential windows are a major means of ventilation, and there are a variety of operating actions for their movable sections: sliding or double-hung windows are still the major form, but hinged types—including casement, hopper, and awning forms—are also used. Sliding glass panel doors are also used, particularly in warmer regions. Glazing is still largely of clear glass. Double glazing, with two panes bonded to a metal tubular separator that contains a desiccant, is cost-effective in northern climates, but triple glazing is used commonly only in regions above about 55° to 60° latitude. A recent development is heat-mirror glass, in which a low-emissivity coating enhances the relative opacity of the glass to infrared radiation and slows the rate of internal heat loss in winter.

Interior finishes. Interior finishes and space-division systems define the living spaces within residential buildings with a range of both natural and synthetic materials. The most widely used wall finish is gypsum board, a prefabricated form of traditional wet plaster. Wet gypsum plaster is cast between paper facings to form large panels that are nailed to light timber or metal frameworks. The joints between the panels are filled with a hard-setting resin compound, giving a smooth seamless surface that has considerable fire resistance. Gypsum board forms the substrate to which a number of other materials, including thin wood-veneered plywood and vinyl fabrics, can be applied with adhesives. In wet areas such as kitchens and bathrooms, water-resistant gypsum board is used, sometimes with the addition of adhesive-applied ceramic tile.

Doors in residential buildings are usually of the hollow-core type, with thin veneers of wood glued over a honeycomb paper core and solid wood edge strips; door frames are typically made of machined timber shapes. Plastic laminates bonded to particleboard are extensively used for built-in cabinets and countertops. The most common floor finish is carpeting, most of which is now made of synthetic fibres, displacing the traditional wool and cotton. It can be easily maintained, and its soft visual and tactile texture, as well as its sound-absorbing qualities, make it attractive for residential use. Hardwoods—primarily oak, birch, and maple—are also used for floors, both in the traditional narrow planks nailed to plywood decks and as prefabricated parquet elements, which are applied with adhesives. In wet or hard-use areas vinyl-composition tiles or ceramic tiles are used.

Mechanical and electrical systems. *Plumbing.* Domestic water-supply systems for low-rise residential buildings have two sources, either municipal water-distribution systems or, where these are not available, wells that are drilled to underground aquifers which are free of contamination. Water is drawn from the wells with small submersible electric pumps, which are lowered through the well casing to the intake. Underground exterior water-supply pipes are usually cast-iron with threaded connections to contain the pressures applied to the fluid, which is typically sufficient to raise it four stories. Within the building, copper tubing with soldered connections is used for distribution because of its corrosion resistance and ease of fabrication; in some areas plastic pipe is also used. The domestic water supply is divided into cold and hot systems, the cold water being piped directly to the fixtures. The hot-water system first draws the supply through a hot-water heating tank, which raises its temperature to about 60° C (140° F) using electric resistance or gas heat. Domestic water heaters that use solar radiation to heat water in coils exposed to the sun on a glass-covered black metal plate (flat-plate solar collectors) are found in areas where there is ample sunshine and relatively high energy costs. The hot water is then distributed from the heater to the fixtures in a recirculating loop pipe system, in which gravity and temperature differentials maintain a constant temperature in period of low demand.

Domestic plumbing service

The primary residential use of water is in the bathroom, which typically includes a bathtub of cast iron or pressed steel with a ceramic porcelain coating (although fibreglass-reinforced resin is also used), a ceramic lavatory, and a ceramic tank-type water closet. The bath and lavatory are supplied with hot and cold water through faucets with lever or screw-type valve controls. The valve of the water closet supply is also lever-operated and relies on the gravity power of the water in the tank for its flushing action. Shower baths are also common, often incorporated into bathtub recesses or in a separate compartment finished with ceramic tile. In some countries a bidet is included.

Other widely used plumbing fixtures include kitchen sinks, usually of cast iron or pressed steel with a ceramic porcelain coating, or of stainless steel; automatic dishwashing machines; and automatic washing machines for laundry. Kitchen sinks can be fitted with garbage disposals, which grind solid waste into a fluid slurry that is flushed out with wastewater. Where the possibility of back siphonage of wastewater into the water supply exists, a vacuum breaker must be provided at the supply to prevent this happening, but most domestic plumbing fixtures are designed to avoid this possibility.

Drainage systems to remove wastewater are made of cast-iron pipe with threaded joints or bell-and-spigot joints sealed with molten lead or with plastic pipe with solvent-welded joints. The waste pipe of every plumbing fixture is provided with a semicircular reverse curve, or trap, which remains constantly filled with water and prevents odours from the drainage system from escaping into occupied spaces. Immediately downstream from each trap is an opening to a vent pipe system, which lets air into the drainage system and protects the water seals in the traps from removal by siphonage or back pressure. When wastewater leaves the building, it is drained through a backflow-prevention valve and into underground ceramic pipes. It then flows by gravity to either a private sewage treatment plant, such as septic tank and tile field, or to the public sewer system. If the discharge level of the wastewater is below the level of the sewer, a sewage ejector pump is required to raise the wastewater to a higher level, where gravity carries it away.

Heating and cooling systems. Atmosphere-control systems in low-rise residential buildings use natural gas, fuel oil, or electric resistance coils as central heat sources; usually the heat generated is distributed to the occupied spaces by a fluid medium, either air or water. Electric resistance coils are also used to heat living spaces directly with radiant energy. Forced-air distribution moves the heat-bearing air through a treelike system of galvanized sheet-metal ducts of round or rectangular cross section; electric-powered fans provide a pressure differential to push the air from the heat source (or furnace) to the living spaces, where it is expelled from grills located in the walls or floors. The negative pressure side of the fan is connected to another treelike system of return air ducts that extract air from living spaces through grills and bring it back to the furnace for reheating. Fresh outside air can be introduced into the system airstream from an exterior intake, and odour-laden interior air can be expelled through a vent, providing ventilation, usually at the rate of about one complete air change per hour. To conserve energy, air-to-air heat exchangers can be used in the exhaust–intake process. The heated air is usually supplied in constant volume, and the ambient temperature is varied in response to a thermostat located in one room. Central humidity control is rarely provided in this building type.

Forced-air heating

Another common heating system is the radiant hot-water type. The heat source is applied to a small boiler, in which water is heated and from which it is circulated by an electric pump in insulated copper pipes similar to a domestic hot-water system. The pipes can be connected to cast-iron or finned tube steel radiators within the living spaces. The radiators are placed near the areas of greatest heat loss (such as windows or outside walls) where their radiant energy heats the surrounding air and creates a convection cycle within the room, producing a roughly uniform temperature within it. The hot water can also be conducted through narrow pipes placed in a continuous looping pattern to create a large radiant surface; this pattern of pipes may be cast in a concrete floor slab or placed above a ceiling to heat the adjoining living space. Temperature control in hot-water systems uses a thermostat in the living space to adjust the pumped flow rate of the water to vary the heat supplied.

Radiant electric resistance heating systems use coils in baseboard units in the rooms, which create convection cycles similar to hot-water radiators, or resistance cables in continuous looped patterns embedded in plaster ceilings. Local temperature control can be much more precise with electric heating, because it is possible to install a thermostatically controlled rheostat to vary the energy output of relatively small sections of baseboard units or cable.

A type of space heating that is increasing in use in residential buildings is passive solar radiation. On sunny winter days, south-facing windows let in substantial amounts of energy, often enough to heat the entire building. Wood-burning fireplaces with chimneys are still widely provided in residential buildings, but their use is mostly for aesthetic effect.

The cooling of atmospheres in low-rise residential buildings is often done locally with unit air conditioners, which penetrate the exterior wall of the space to be cooled; this permits the intake of fresh air when desired and the ejection of heat pumped from the space to the exterior air. Less often, forced-air heating systems have cooling coils

Air-conditioning systems

introduced into the airstream to provide a centrally cooled interior. A compressive cooling process is used, similar to that in a domestic refrigerator. A refrigerant, which is a liquid at room temperature, is pumped through a closed system of coiled copper tubes. An electric pump maintains a low pressure in the cooling coils, and the liquid refrigerant passes through an expansion valve from a region of high pressure to the low-pressure coils. This change in pressure results in a phase change of the refrigerant; it turns from a liquid into a gas and absorbs heat in the process, just as water absorbs heat when it is boiled and converted into steam. The heat absorption of the liquid-to-gas transition cools air passing over the cooling coils. The cooled air is circulated through the building by the forced-air system. When the low-pressure gaseous refrigerant leaves the cooling coils, it goes through the pump and is pressurized. The refrigerant travels through condensing coils, which are located outside the building; there the phase change is reversed as the gas turns to a high-pressure liquid and liberates heat to the exterior air passing over the condensing coils. The liquid refrigerant returns to the expansion valve to repeat the cooling cycle. The refrigeration machine is thus a "heat pump" that moves heat out of the building to the exterior atmosphere. Heat pumps can also be run in reverse in the winter months to pump heat from the outside air into the building interior; they work best in mild climates with fairly warm winter temperatures. The use of heat pumps in cold climates poses many difficult technological problems.

Interior atmospheres are also ventilated by operating windows, as well as by unintended leakage at all types of exterior openings. Bathrooms, kitchens, and laundries generate odours and heat and often have separate exhaust systems powered by electric fans that are operated intermittently as required. Residential atmosphere quality is also protected by the smoke detector, which sounds an alarm to warn of possible danger when smoke reaches even a very low level in living spaces.

Electrical systems. Electrical systems in residential buildings are supplied from public utility power grids, starting from a step-down transformer near the building that reduces the high line voltage to a safer level. An underground or overhead cable from the transformer leads to the building, where it is connected to a meter that records the energy used by the subscriber. Immediately beyond the meter is a fused main switch to protect the building against an accidental power surge from the grid. The main service is then broken down into a number of circuits by a panelboard, each circuit having a fused switch. From the panelboard the wires of each circuit distribute the electricity to different areas of the building. The wires are usually copper, although aluminum is also used, and are covered with thermoplastic insulation. The wires must be contained in conduit, which is either metal or plastic tubing, to protect against damage and reduce the possibility of fire in the case of accidental overloading of the wires. Conduits are usually concealed in finished spaces within the framing of partition walls or above ceilings and terminate in junction boxes flush with a wall surface. The junction boxes contain terminal devices such as the convenience outlet, control switches, or the connection point for built-in light fixtures.

Residential lighting

Residential lighting is provided primarily by movable incandescent fixtures plugged into convenience outlets, but there is often built-in lighting in kitchens, bathrooms, corridors, and closets, mostly of the incandescent type. There is also some use of fluorescent lighting, particularly in built-in fixtures. Overall interior light levels in residential uses are low, about 20–40 footcandles. Exterior lighting is used for entrances, walkways, and exterior living spaces.

The power densities of dwelling units are fairly low and are declining because of the increased use of fluorescent lighting fixtures and improvement of efficiency in electrical appliances. The decline in power consumption enhances the prospect of the widespread appearance of dwellings—particularly detached houses—with their own independent electric power generation and storage systems, unconnected to public utility grids. Photovoltaic cells, which convert sunlight directly into electricity, in combination with storage batteries can offer these residences a new kind of energy autonomy.

LOW-RISE COMMERCIAL, INSTITUTIONAL, AND INDUSTRIAL BUILDINGS

The size of buildings in the commercial, institutional, and industrial market segment ranges from a few hundred to as much as 45,000 square metres (500,000 square feet). All of these buildings have public access and exit requirements, although their populations may differ considerably in density. The unit costs are generally higher than those for dwellings (although those of simple industrial buildings may be lower), and this type includes buildings with the highest unit cost, such as hospitals and laboratories. Residential buildings are fairly static in their function, changing only at long intervals. By contrast, most commercial, institutional, and industrial buildings must respond to fairly rapid changes in their functions, and a degree of flexibility is required in their component systems. In addition, these buildings are built by contractors who utilize heavy mechanized equipment not only for foundations (pile drivers and caisson augers) but also for lifting heavy components (a wide variety of cranes and hoists). Semimanual machines such as cement finishers, terrazzo grinders, and welding generators are also used, but a large percentage of the work is done manually; the human hand and back remain major instruments of the construction industry, well adapted to the nonrepetitive character of building.

Foundations. The foundations in these buildings support considerably heavier loads than those of residential buildings. Floor loadings range from 450 to 1,500 kilograms per square metre (100 to 300 pounds per square foot), and the full range of foundation types is used for them. Spread footings are used, as are pile foundations, which are of two types, bearing and friction. A bearing pile is a device to transmit the load of the building through a layer of soil too weak to take the load to a stronger layer of soil some distance underground; the pile acts as a column to carry the load down to the bearing stratum. Solid bearing piles were originally made of timber, which is rare today; more commonly they are made of precast concrete, and sometimes steel H-piles are used. The pile length may be a maximum of about 60 metres (200 feet) but is usually much less. The piles are put in place by driving them into the ground with large mechanical hammers. Hollow steel pipes are also driven, and the interiors are excavated and filled with concrete to form bearing piles; sometimes the pipe is withdrawn as the concrete is poured. An alternative to the bearing pile is the caisson. A round hole is dug to a bearing stratum with a drilling machine and temporarily supported by a steel cylindrical shell. The hole is then filled with concrete poured around a cage of reinforcing bars; and the steel shell may or may not be left in place, depending on the surrounding soil. The diameter of caissons varies from one to three metres (three to 10 feet). The friction pile of wood or concrete is driven into soft soil where there is no harder stratum for bearing beneath the site. The building load is supported by the surface friction between the pile and the soil.

Bearing piles and caissons

When the soil is so soft that even friction piles will not support the building load, the final option is the use of a floating foundation, making the building like a boat that obeys Archimedes' principle—it is buoyed up by the weight of the earth displaced in creating the foundation. Floating foundations consist of flat reinforced concrete slabs or mats or of reinforced concrete tubs with walls turned up around the edge of the mat to create a larger volume.

If these buildings do not have basements, in cold climates insulated concrete or masonry frost walls are placed under all exterior nonbearing walls to keep frost from under the floor slabs. Reinforced concrete foundation walls for basements must be carefully braced to resist lateral earth pressures. These walls may be built in excavations, poured into wooden forms. Sometimes a wall is created by driving interlocking steel sheet piling into the ground, excavating on the basement side, and pouring a concrete wall against it. Deeper foundation walls can also be built by the slurry wall method, in which a linear series of closely spaced caissonlike holes are successively drilled, filled with concrete, and allowed to harden; the spaces between are excavated by special clamshell buckets and also filled with concrete. During the excavation and drilling operations, the holes are filled with a high-density liquid slurry, which braces the excavation against collapse but still permits extraction of excavated material. Finally, the basement is dug adjoining the wall, and the wall is braced against earth pressure.

Structural systems. *Timber.* The structures of these buildings are mostly skeleton frames of various types, because of the larger spans their users require and the need for future flexibility. Timber is used, but on a much-reduced scale compared to residential buildings and primarily in regions where timber is readily available. The public nature of commercial and institutional buildings and the hazards of industrial buildings generally require that they be of noncombustible construction, and this largely excludes the use of light timber frames. Heavy timber construction can be used where the least dimensions of the members exceed 14 centimetres (5.5 inches); when timbers are this large they are charred but not consumed in a fire and are considered fire-resistant. Because most harvested trees are fairly small, it is difficult to obtain solid heavy timbers, and most large shapes are made up by glue laminating smaller pieces. The synthetic glues used are stronger than the wood, and members with cross sections up to 30 × 180 centimetres (12 × 72 inches) are made; these may be tapered or otherwise shaped along their length. Skeletons of glue-laminated beams and columns, joined by metal connectors, can span 30 to 35 metres (100 to 115 feet). Heavy decking made of tongue-and-groove planks up to 9.4 centimetres (3.75 inches) thick is used to span between beams to support floors and roofs.

Steel. Steel is a major structural material in these buildings (Figure 11). It is a strong and stiff material and yet relatively inexpensive, and it can be quickly fabricated and erected, which saves construction time. Although steel is noncombustible, it starts to lose strength when heated above 400° C (750° F), and building codes require it to be fireproofed in most multistory buildings; in small and low-hazard buildings, however, it can be left unprotected.

Types of structural steel

Nearly all structural steel—including sheets, round or square bars, tubes, angles, channels, and I beam or wide flange shapes—is formed by the hot-rolling process. Steel roof and floor deck panels are fabricated from sheet metal by further cold-rolling into corrugated profiles four to eight centimetres (1.5 to three inches) deep and 60 centimetres (24 inches) wide. They are usually welded to the supporting steel members and can span up to 4.5 metres (15 feet). The lightest and most efficient structural shape is the bar (or open web) joist, a standard truss made with angles for the top and bottom chords, joined by welding to a web made of a continuous bent rod. It is used almost exclusively to support roofs and can span up to 45 metres (150 feet). The standard rolled shapes are frequently used as beams and columns, the wide flange, or W shape, being the most common. The widely separated flanges give it the best profile for resisting the bending action of beams or the buckling action of columns. W shapes are made in various depths and can span up to 30 metres (100 feet). Where steel beams support concrete floor slabs poured onto a metal deck, they can be made to act compositely with the concrete, resulting in considerable economies in the beam sizes.

The connections of steel shapes are of two types: those made in the workshop and those made at the building site. Shop connections are usually welded, and site or field connections are usually made with bolts due to the greater labour costs and difficulties of quality control in field welding. Steel columns are joined to foundations with base plates welded to the columns and held by anchor bolts embedded in the concrete. The erection of steel frames at the building site can proceed very rapidly, because all the pieces can be handled by cranes and all the bolted connections made swiftly by workers with hand-held wrenches.

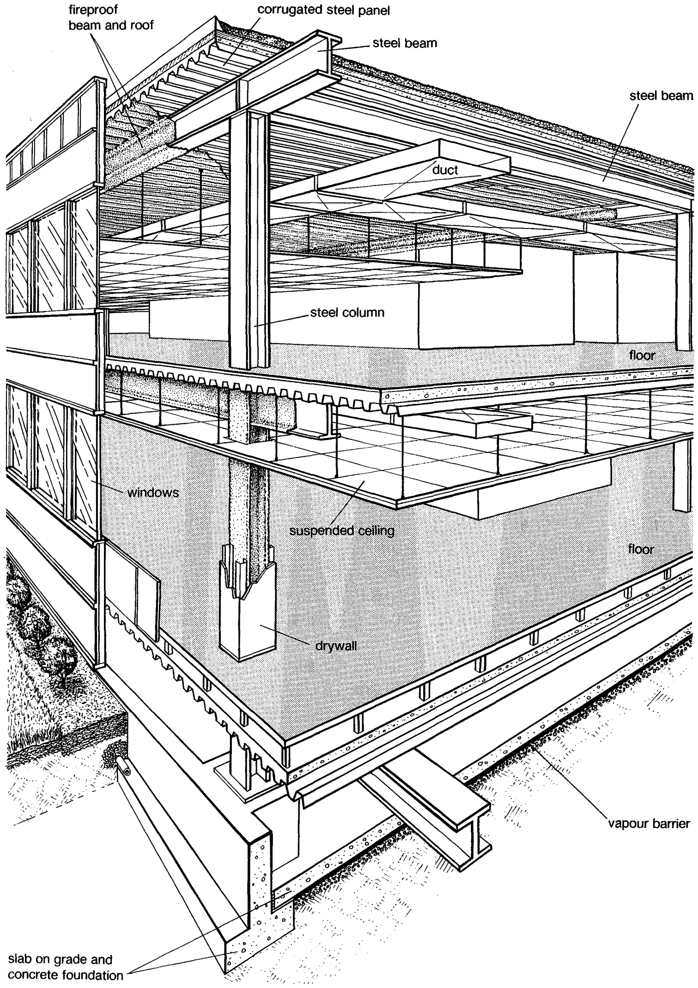

Figure 11: Low-rise steel-frame office building, corner perspective.

Adapted from R. Rush (ed.), *Building Systems Integration Handbook* (1986), John Wiley and Sons

A large proportion of steel structures are built as prefabricated, pre-engineered metal buildings, which are usually for one-story industrial and commercial uses. They are manufactured by companies that specialize in making such buildings of standard steel components—usually rigid steel bents or light trusses—which are assembled into frames and enclosed with corrugated metal siding. The configurations can be adapted to the needs of individual users. The metal building industry is a rare example of a successful application of prefabrication techniques in the construction industry in the United States, where its products are ubiquitous in the suburban and rural landscape.

Concrete. Reinforced concrete is also a major structural material in these buildings. Indeed, outside of North America and western Europe, it is the dominant industrialized building material. Its component parts are readily available throughout the world at fairly low cost. Portland cement is easily manufactured by burning shale and limestone; aggregates such as sand and crushed limestone can be easily obtained. Steel minimills, which use scrap iron to feed their electric furnaces, can mass-produce reinforcing bars for regional use. In industrialized countries the mixing and delivery of liquid concrete to building sites has been mechanized with the use of central plants and mixing trucks, and this has substantially reduced its cost. In barely 100 years, reinforced concrete has risen from an experimental material to the most widespread form of building construction.

In situ and precast concrete

There are two methods of fabricating reinforced concrete. The first is to pour the liquid material into forms at the building site; this is so-called in situ concrete. The other method is called precast concrete, in which building components are manufactured in a central plant and later brought to the building site for assembly. The components of concrete are portland cement, coarse aggregates such as crushed stone, fine aggregates such as sand, and water.

In the mix, water combines chemically with the cement to form a gel structure that bonds the stone aggregates together. In proportioning the mix, the aggregates are graded in size so the cement matrix that joins them together is minimized. The upper limit of concrete strength is set by that of the stone used in the aggregate. The bonding gel structure forms slowly, and the design strength is usually taken as that occurring 28 days after the initial setting of the mix. Thus there is a one-month lag between the time in situ concrete is poured and the time it can carry loads, which can significantly affect construction schedules.

In situ concrete is used for foundations and for structural skeleton frames. In low-rise buildings, where vertical gravity loads are the main concern, a number of framing systems are used to channel the flow of load through the floors to the columns for spans of six to 12 metres (20 to 40 feet). The oldest is the beam and girder system, whose form was derived from wood and steel construction: slabs rest on beams, beams rest on girders, and girders rest on columns in a regular pattern. This system needs much handmade timber formwork, and in economies where labour is expensive other systems are employed. One is the pan joist system, a standardized beam and girder system of constant depth formed with prefabricated sheet-metal forms. A two-way version of pan joists, called the waffle slab, uses prefabricated hollow sheet-metal domes to create a grid pattern of voids in a solid floor slab, saving material without reducing the slab's strength. The simplest and most economical floor system is the flat plate, where a plain floor slab about 20 centimetres (eight inches) thick rests on columns spaced up to 6.7 metres (22 feet) apart. If the span is larger, the increasing load requires a local thickening of the slab around the columns. When these systems are applied to spans larger than nine to 12 metres (30 to 40 feet), a technique called posttensioning is often used. The steel reinforcing takes the form of wire cables, which are contained in flexible tubes cast into the concrete. After the concrete has set and gained its full strength, the wires are permanently stretched taut using small hydraulic jacks and fastening devices, bending the entire floor into a slight upward arch. This reduces deflection, or sagging, and cracking of the concrete when the service load is applied and permits the use of somewhat shallower floor members. Concrete columns are usually of rectangular or circular profile and are cast in plywood or metal forms. The reinforcing steel never exceeds 8 percent of the cross-sectional area to guard against catastrophic brittle failure in case of accidental overloading.

Prestressing

Precast concrete structural members are fabricated under controlled conditions in a factory. Members that span floors and roofs are usually pretensioned, another prestressing technique, which is similar in principle to posttensioning. The reinforcement is again steel wire, but the wires are put into tension (stretched) on a fixed frame, formwork is erected around the taut wires, and concrete is poured into it. After the concrete has set and gained its full strength, the wires are cut loose from the frame. As in posttensioning, this gives the precast floor members a slight upward arch, which reduces deflection and permits the use of shallower members. Precast prestressed floor elements are made in a number of configurations. These include beams of rectangular cross section, hollow floor slabs 15 to 30 centimetres (six to 12 inches) deep and spanning up to 18 metres (60 feet), and single- and double-stem T shapes up to 1.8 metres (six feet) deep and spanning up to 45 metres (150 feet). Precast concrete columns are usually not prestressed and have projecting shelves to receive floor members. At the building site, precast members are joined together by a number of methods, including welding together metal connectors cast into them or pouring a layer of in situ concrete on top of floor members, bonding them together. Precast prestressed construction is widely used, and it is the dominant form of construction in the Soviet Union and eastern Europe.

Masonry. Masonry finds only a limited structural use in these buildings. Concrete block walls with brick facing and punched openings (discrete windows entirely surrounded by the facing material) spanned by concealed steel lintels can be used for exterior bearing walls where the interior is a skeleton frame of steel or timber. The use of interior bearing walls so greatly reduces the flexibility needed in these buildings that they are only rarely found.

Enclosure systems. Enclosure systems in these buildings range from rather simple forms in industrial uses to quite sophisticated assemblies in the commercial and institutional sectors. Most have in common the use of flat roofs with highly water-resistant coverings, the traditional one being a built-up membrane of at least four layers of coal-tar pitch and felt, often weighted down with a gravel ballast. Such roofs are pitched at slopes of 1 : 100 to 1 : 50 toward interior drains. In recent years the single-ply roof, made of plastic membranes of various chemistries, has found wide application. The seams between the pieces of membrane are heat- or solvent-welded together, and they are either ballasted with gravel or mechanically fastened to the underlying substrate, which is usually rigid foam insulation. Sometimes standing-seam sheet-metal roofs are also used; the best quality is continuously welded stainless steel.

Types of glazing

The choice of transparent surfaces in these enclosures is based on three major considerations: conductive heat transfer, radiant energy transfer, and safety. All the transparent materials used in the low-rise residential sector are found, plus a number of others. In buildings with fully controlled atmospheres, double glazing is common to reduce heat transfer and both interior and exterior condensation on the glass. Commercial and institutional buildings tend to have large internal sources of heat gain, such as people and lighting, so it is desirable to exclude at least some solar gain through the transparent surfaces to reduce energy consumption in cooling. This can be done by reducing the light transmission or shading coefficient of the glass by integrally tinting it in various colours; grey, bronze, and green are common tints. This can also be accomplished by vacuum-plating partial reflective coatings of varying densities to an inner surface of double glazing; this can reflect up to 90 percent of the incident energy. Two kinds of reflecting metal are used: aluminum, which is silver in tone, and rubidium, which is gold-toned. These coatings are perceived as strong tints when the outside world is viewed through them by day: grey for aluminum and green for rubidium.

Skylights or horizontal transparent surfaces have found wide application in these types of buildings. These installations range from purely functional daylighting in industrial uses to elaborate aesthetic forms in commercial structures. In horizontal applications, and in vertical walls where people might blunder into glazed panels, safety glazing is required. Safety glazing is of four types: certain plastics that are flexible and difficult to break; wire-embedded glass, which holds together when broken; tempered glass, which is very strong and breaks into tiny and relatively harmless fragments; and laminated glass, which consists of two layers of glass heat-welded together by an intermediate plastic film. Laminated glass can also be made with tinted lamination film, producing many colours not available in integrally coloured glass.

Because many of these buildings have skeleton structures, their vertical surfaces are enclosed in nonstructural curtain walls that resist wind forces and provide weatherproofing. Curtain walls are of several types; the most common is one supported by a metal (typically aluminum) gridwork attached to the building structure. The vertical members, called mullions, are attached to the building at every floor and are spaced 1.5 to three metres (five to 10 feet) apart; the horizontal members, called muntins, are attached between the mullions. The rectangles between the grid of mullions and muntins are filled with transparent or opaque panels. The transparent surfaces can be any of those just described, and the opaque panels include opaque coloured glass, painted or anodized aluminum sheets, porcelain enameled steel sheets, fibreglass-reinforced cement, and stone wafers of granite, marble, or limestone cut with diamond-edged tools. All of these materials are usually backed up by rigid insulation to slow heat transfer. Metal sandwich panels are also used for economy of material; two thin layers of metal are separated by a core of different material, often with a high U-value for insulating effect.

The separation of the thin layers of strong metal greatly increases the overall stiffness of the panel. The joints between panels and the supporting grid are weatherproofed with elastomeric sealants (cold-setting synthetic rubbers) or by prefabricated rubber gaskets. In glazed areas of curtain walls, mullions of structural glass are an alternative to metal mullions; they are more expensive, but they give an effect of greater transparency where this is desired.

Another type of curtain wall is the panel type. It has no gridwork of mullions and muntins but is made of large prefabricated rigid panels connected to the floors and spanning between them, with transparent openings made as holes cut out of the panel. The panels can be made of precast concrete, aluminum, or steel, often in sandwich form; elastomeric sealants are used to close the joints.

The finishes of metals in curtain walls include anodizing of aluminum, an electrolytic process that builds up the natural colourless oxide of aluminum into a thick adherent layer; it often includes the introduction of colour into the oxide layer itself. Durable paint coatings (with lifetimes of up to 40 years) can be applied to the metal in the factory; more conventional paints that must be renewed at shorter intervals are also used.

Walls and doors

Interior finishes. *Partitions.* Space-division systems in these buildings make use of gypsum board partitions, usually applied to a framework of formed sheet-metal members attached to the building structure. They are readily demolished and rebuilt at relatively low cost, meeting the need for flexibility in such buildings. They are often used for fire-resistive protective enclosures, for which a number of layers are laminated to achieve the specified fire resistance. Transparent and translucent partitions are also used, with different types of glass set in metal frames. Office buildings may contain prefabricated movable metal partitions, which typically use metal sandwich panel construction to create panels with both transparent and opaque surfaces as well as doors. These partitions are expensive compared with gypsum board and must be moved often to justify the greater initial cost. Concrete block is used in unfinished spaces and for fire-resistive partitions. Glazed ceramic block or ceramic tile applied over concrete block or gypsum board is used in wet areas and where cleanliness is a problem, such as in kitchens and toilet rooms. Occasionally walls with wood paneling or stone veneer are used for aesthetic effect. Doors are usually set in formed sheet-metal frames, although some wood frames are used. The doors themselves are usually made of solid timbers glue-laminated together and covered with thin decorative wood veneers; painted hollow sheet-metal doors are used for exterior doors and in areas of hard use.

Ceiling finishes. Ceiling finishes in these buildings create a sandwich space below the roof or floor slab above, which conceals projecting structural elements, recessed light fixtures, electrical wiring conduits, and air-handling ductwork. The ceiling must be accessible to change or maintain the service elements located above it, and the most common ceiling system is composed of wet felted mineral fibre panels, painted and perforated on one side for sound absorption. The removable panels are supported on a grid of formed sheet-metal tee bars or zee tracks, which are suspended by wires from the structure above. Where accessibility is not important and a smooth finish is desired, suspended gypsum board ceilings can be used.

Terrazzo

Floor finishes. Floor finishes in commercial and institutional uses make considerable use of synthetic-fibre carpeting and vinyl composition tile. In areas of higher traffic harder surfaces may be used—for example, cut stone tiles of marble or granite, ceramic tile applied with epoxy adhesive to the substrate, or terrazzo. Terrazzo is made in two ways, traditional and thin-set. In the traditional form a four-centimetre (1.5-inch) layer of cement and sand grout is poured over the substrate; a grid of metal divider strips to control shrinkage cracks is set on the hardened surface, and grout mix of coloured cement and marble chips is poured between the strips. After hardening, the surface is machine polished to expose the marble chips and metal dividers. Thin-set terrazzo is made by placing the metal strips and pouring the binder and marble chips directly onto the subfloor, without the underbed of cement and sand. It is generally possible only when epoxy resins are used in place of cement binders. Terrazzo is available in many colours, and it forms a hard, smooth, and durable surface that is easily cleaned.

Fire-suppression equipment

Building services. *Life-safety systems.* Most important in the hierarchy of interior elements are life-safety systems to protect and evacuate the building population in emergencies. These include life-threatening events, such as fire and smoke and earthquakes, and less critical ones, such as electric power failures. To deal with the threat of fire and smoke there is an array of fire-detection and fire-suppression systems. These include electronic heat and smoke detectors that can activate audible alarm devices to warn the building population and automatically notify local fire departments. For fire suppression hand-operated fire extinguishers must be provided, but many buildings have a separate piping system to provide water for fire fighting. If public water mains cannot provide adequate water pressure, an electric pump is included, and there is also a connection outside the building to attach portable fire truck pumps. The piping terminates in an array of sprinkler heads located throughout the building in the ceiling plane in a density ranging from eight to 18 square metres (90 to 200 square feet) per head. Typically there is always water in the pipes (a wet system), though dry systems are used in unheated buildings or where leakage might damage the contents. The head is opened to spray water by a fusible link made of metal that melts at a fairly low temperature when the air surrounding it is heated by a fire. Sprinkler systems have proved to be a highly reliable and effective means of fire suppression. Smoke can be as dangerous as fire to building occupants, and protective measures include the automatic shutdown of mechanical ventilating systems and the division of the building into smokeproof compartments to prevent the spread of smoke.

The evacuation of occupants in emergencies is accomplished by a system of protected exits leading to the exterior; all building areas must be within a specified travel distance of such an exit, varying from 30 to 90 metres (100 to 300 feet). For one-story buildings the exit usually consists simply of exterior doors, but for multistory buildings the exits are enclosed stairways that also lead to the exterior. The stairways have fire-rated enclosures and are often pressurized to exclude smoke; their width is determined by the maximum predicted number of occupants per floor. Travel paths to the exit must be clearly marked by illuminated directional exit signs, and battery-powered emergency lighting is required in the travel path and in the exit itself, in case of power failure. Some buildings of this type, such as hospitals, have large diesel- or natural gas-powered emergency electric generating systems that provide power and lighting for critical areas (such as operating rooms).

Another of the life-safety elements in these buildings is the fire-resistance requirements for building materials. These include the application of cementitious fireproofing or insulation to structural steel frames, the fire-resistive construction of the enclosures around exits, the flame-spread ratings of finish materials such as carpeting and wall coverings, and the use of such inherently fire-resistant materials as reinforced concrete and heavy timber. The fire-resistive ratings of various construction materials and assemblies are established by laboratory fire tests.

Vertical transportation. Vertical transportation systems in these low buildings include stairways, sometimes only those provided as life-safety exits but more often open, well-lighted ones as well. Where large numbers of people need to be moved vertically a short distance, escalators, or moving stairways, powered by electric motors are often provided. For moving smaller volumes of people and freight, hydraulic elevators are used; the cabs of these elevators are moved by a telescoping tubular piston underneath, which is raised and lowered by pumping oil in and out of it with an electric pump. Hydraulic elevators move slowly, but they are the least expensive type and are well suited for low buildings.

Plumbing. Plumbing systems for water supply and wastewater removal are very similar to those used in residential buildings, but the higher population densities of commercial, institutional, and industrial buildings require larger toilet rooms for public multiperson use. These often include pressure-valve water closets placed in partitioned cubicles and urinals in men's toilet rooms. Some fixtures in each toilet room must be carefully arranged for easy access by handicapped persons.

The internal drainage of large flat roofs introduces another piping system, similar to that for sanitary wastewater, to carry away storm water to separate underground storm sewers. Heavy rainstorms can introduce huge influxes of water into storm sewers, and sometimes this surge effect is tempered by the use of storm water retention ponds on the building site; runoff from the roof and paved areas is temporarily stored in these ponds while it flows into the sewer at a slower rate. Hospitals, laboratories, and factories have many other types of plumbing systems for various gases and liquids; these require special materials and construction. The sites of commercial, institutional, or industrial buildings may have underground networks of irrigation piping that terminate in flush sprinkler heads to water grass and plantings.

Environmental control systems. The atmosphere systems of industrial buildings are usually simple, involving only winter heating and possibly humidity control if the manufacturing process is sensitive to it. A commonly used element is the unit heater, in which an electric fan blows air through a coil heated by hot water, steam, electric resistance, or gas combustion and provides a directed supply of warm air where needed. Another system involves radiant heating using electric resistance coils backed by reflectors or continuous reflector-backed metal pipes that radiate heat from gas burned inside them. Ventilation in industrial buildings is sometimes done with operable windows but more often with unit ventilators, which penetrate walls or roofs and use electric fans to exhaust interior air that is replaced by air flowing in through operable louvres.

Rooftop atmospheric systems

Commercial and institutional low-rise buildings generally have fully controlled atmospheres with heating, cooling, and humidification. An economical method of providing this controlled atmosphere is with rooftop single or multizone package units. Each unit contains an electric fan to move conditioned air; heating elements, which can be gas or oil-fired or electric resistance coils; cooling coils, which use the compressive cooling cycle with compressor, cooling coils, and condensor coils to liberate heat; as well as a fresh-air intake and air exhaust. All of these elements are prefabricated in a rectangular enclosed unit that is simply set on the roof over an opening through which it is connected to the supply and exhaust ducts. The airflow over the heating and cooling elements can be partitioned to provide different conditioned airstreams to serve different zones of the building. The conditioned air is fed at a constant volume into treelike systems of insulated sheet-metal ductwork for transmission to the zones served. The conditioned air enters the occupied space through diffusers placed in the ceiling system and connected to the ducts by flexible spiral reinforced fabric tubes. Thermostats within the space sense temperatures and send signals by electricity or compressed airflow to the unit to adjust heating and cooling as required; relative humidity is held to a range of 20 to 40 percent. The return of air from the occupied space to the unit for reconditioning is sometimes done through a reverse tree of ductwork leading back to the unit, but more often in commercial buildings this is accomplished by placing the entire sandwich space between the ceiling and the structural deck above under negative pressure to make what is called a return-air plenum. The negative pressure is created by an opening into the plenum from the return side of the rooftop unit, and perforated openings or grills in the ceiling plane admit the return air from the occupied space. Return air can also be made to enter the plenum by passing over the lamps of fluorescent light fixtures; this permits the direct recovery of heat generated by the lamps, which can be recycled to the occupied space in winter.

The rooftop unit is best used in one-story buildings or smaller multistory ones. For larger multistory buildings, centralized atmosphere systems are used. These are built up of separate components, most of which are housed in mechanical equipment rooms or in penthouses at roof level. The components include fans for moving air, humidification devices, air-filtering devices, and refrigeration machines. Where large refrigeration machines are used, the condensor coils that liberate heat are no longer placed outside the building as in residential units or rooftop units but are located in a water jacket near the compressor. This water is circulated through a piping system to carry away the heat to a cooling tower outside the building where the water is sprayed into the atmosphere and partially evaporated to liberate heat, then recovered and returned at a lower temperature to the condensor coil jacket. Mechanical equipment rooms for atmosphere systems require a minimum of 5 percent of the floor space in a commercial building and can range up to 20 percent in hospitals and 40 percent in laboratory buildings; if the building is large, there can be more than one fan room with centralized refrigeration machines and cooling towers. The distribution of conditioned air in buildings with centralized atmosphere systems is usually done through an insulated ductwork tree, using the variable air volume (VAV) method. This method supplies conditioned air in variable amounts as required to maintain the desired temperature in occupied spaces; it results in considerable energy economies over constant volume air supply methods. Separate exhaust systems are used for areas generating heat and odours, such as kitchens, laboratories, and toilet rooms.

Electrical systems. Electrical systems in these buildings begin at a step-down transformer provided by the utility company and located within or very close to the building. The transformer reduces the standard line potential to two dual voltage systems, which then pass through master switches and electric meters to record the subscriber's usage. Each of the voltages provided serves a separate category of use; different levels are required for incandescent lights and small appliances, large appliances, ceiling-mounted non-incandescent lighting, and heavy machinery. Each voltage pair has a separate distribution system of wiring leading from the meters and master switches to circuit breaker panels, where it is further broken down into circuits similar to residential uses. Because high-voltage wiring is considered hazardous, the switches controlling overhead lighting use lower voltages, and each heavy machine has its own fused switch. From the circuit breaker panel, low-voltage power conduit and wiring is typically distributed through partitions and ceiling sandwich spaces, but, in large open areas of commercial buildings, there may be wireways embedded in the floor slab. These wireways can be either rectangular metal tubes inserted into the concrete slab before pouring or closed cells of formed steel deck; the wireways are tapped where desired to provide convenience outlets at floor level.

Lighting systems

Lighting in these buildings is predominantly fluorescent. Lamps range in size and wattage, and the available colours can range from warm white to cool white. Incandescent tungsten-filament lamps are used mostly for accent lighting, since their light-output efficiency is low. Mercury-vapour and metal halide-vapour lamps have the same efficiency as fluorescent lamps, but certain types may have longer operating lives. High-pressure sodium-vapour lamps have even higher efficiencies and are used in industrial applications; their marked orange colour and high intensity has limited their commercial and institutional use, however. Each of these types of lamp is used in a variety of fixtures to produce different lighting conditions. Incandescent lamps can be placed in translucent glass globes for diffuse effects, or in recessed ceiling-mounted fixtures with various types of reflectors to evenly light walls or floors. Fluorescent lamps are typically installed in recessed rectangular fixtures with clear prismatic lenses, but there are many other fixture types, including indirect cove lights and luminous ceilings with lamps placed above suspended plastic or metal eggcrate diffuser grids. Mercury-vapour and high-pressure sodium-vapour lamps are placed in simple reflectors in high-ceilinged industrial spaces, in pole-mounted light fixtures for outdoor applications on parking lots and roadways, and in indirect uplighting fixtures for commercial applications.

Mathematical models can accurately predict the performance of lighting in most applications. The zonal cavity method, which takes into account the lamps, fixtures, shape of room, and colours of room surfaces, is one example. The usual measure of light intensity is in footcandles on a horizontal surface, such as the floor of a room or a desk. The intensity ranges from 15 footcandles for a minimum ambient light level to 70 footcandles for an office or classroom and 100–200 footcandles for very precise visual tasks such as drafting; direct sunlight at noon, by comparison, is about 1,000 footcandles. In most of these buildings, the required lighting level is achieved with fixtures mounted at ceiling level; having all lighting at ceiling level allows flexibility in using building spaces. But the intensity of light varies inversely with the square of the distance from the source; thus, if a light fixture gives an intensity of 40 footcandles at a distance of one metre, it will produce an intensity of 10 footcandles at two metres. Therefore, considerable energy savings can be realized by having a minimal ambient light level (say 15 footcandles) produced by ceiling-mounted fixtures and providing task lighting close to work surfaces where higher intensities are needed. Daylighting from windows and skylights is also utilized in these buildings, and mathematical models have been developed that accurately predict its performance.

Communications systems

Communications systems are of growing significance and complexity in commercial, institutional, and industrial buildings. Thus communications wires for telephones, public-address systems, and computer data are free to take many paths through the building, including vertical risers, ceiling sandwich spaces, and wireways in floor slabs similar to those of electrical power wires. Where the density of wires rises to very high levels—for example, in computer rooms or where many small computer terminals are installed—raised floor systems are used. Removable floor panels are mounted on tubular metal frameworks resting on the structural floor slab, creating a plenum space to carry the necessary wiring.

A number of building systems are controlled by computers or microprocessors. In certain atmosphere systems both the interior sensors (such as thermostats) and the exterior weather sensors feed data to a computer that adjusts the system for minimal energy expenditure. Other examples include security, fire, and emergency alarm systems.

HIGH-RISE BUILDINGS

The high-rise building is generally defined as one that is taller than the maximum height which people are willing to walk up; it thus requires mechanical vertical transportation. This includes a rather limited range of building uses, primarily residential apartments, hotels, and office buildings, though occasionally including retail and educational facilities. A type that has appeared recently is the mixed-use building, which contains varying amounts of residential, office, hotel, or commercial space. High-rise buildings are among the largest buildings built, and their unit costs are relatively high; their commercial and office functions require a high degree of flexibility.

Foundations. The foundations of high-rise buildings support very heavy loads, but the systems developed for low-rise buildings are used, though enlarged in scale. These include concrete caisson columns bearing on rock or building on exposed rock itself. Bearing piles and floating foundations are also used.

Structural systems. *Wind loads.* The structural systems of tall buildings must carry vertical gravity loads, but lateral loads, such as those due to wind and earthquakes, are also a major consideration. Maximum 100-year-interval wind forces differ considerably with location; in the interiors of continents they are typically about 100 kilograms per square metre (20 pounds per square foot) at ground level. In coastal areas, where cyclonic storms such as hurricanes and typhoons occur, maximum forces are higher, ranging upward from about 250 kilograms per square metre (50 pounds per square foot). Wind forces also increase with building height to a constant or gradient value as the effect of ground friction diminishes. The maximum design wind forces in tall buildings are about 840 kilograms per square metre (170 pounds per square foot) in typhoon areas.

Effect of wind loads

The effect of wind forces on tall buildings is twofold. A tall building may be thought of as a cantilever beam with its fixed end at the ground; the pressure of the wind on the building causes it to bend with the maximum deflection at the top. In addition, the flow of wind past the building produces vortices near the corners on the leeward side; these vortices are unstable and every minute or so they break away downwind, alternating from one side to another. The change of pressure as a vortex breaks away imparts a sway, or periodic motion, to the building perpendicular to the direction of the wind. Thus, under wind forces there are several performance criteria that a high-rise structure must meet. The first is stability—the building must not topple over; second, the deflection, or sidesway at the top, must not exceed a maximum value (usually taken as 1/500 of the height) to avoid damage to brittle building elements such as partitions; and, third, the swaying motion due to vortex shedding must not be readily perceptible to the building occupants in the form of acceleration, usually stated as a fraction of gravity, or g. The threshhold of perception of lateral motion varies considerably with individuals; a small proportion of the population can sense 0.003 g or 0.004 g. The recommendation for motion perception is to limit acceleration to 0.010 g for wind forces that would recur in 10-year intervals. The fourth criterion involves the natural period of the building structure. This is the vibration period at which the swaying cantilever motions of the building naturally reinforce and enhance each other and could become large enough to damage the building or even cause it to collapse. The natural period of the building should be less than one minute, which is the period of vibration due to the shedding of wind vortexes.

Earthquake loads. Earthquake or seismic forces, unlike wind forces, are generally confined to relatively small areas, primarily along the edges of the slowly moving continental plates that form the Earth's crust. When abrupt movements of the edges of these plates occur, the energy released propagates waves through the crust; this wave motion of the Earth is imparted to buildings resting on it. Timber frame buildings are light and flexible and are usually little damaged by earthquakes; masonry buildings are heavy and brittle and are susceptible to severe damage. Continuous frames of steel or reinforced concrete fall between these extremes in their seismic response, and they can be designed to survive with relatively little damage.

Designing for lateral acceleration

In two major earthquakes involving large numbers of high-rise buildings, in Los Angeles in 1971 and Mexico City in 1985, lateral accelerations due to ground motions in a number of tall buildings were measured with accelerometers and were found to be of the order of 0.100 to 0.200 g. In Los Angeles, where the period of the seismic waves was less than one second, most steel-frame high rises performed well with relatively little damage; continuous concrete frames also generally performed well, but there was considerable cracking of concrete, which was later repaired by the injection of epoxy adhesive. In Mexico City, however, the period of the seismic waves was quite long, on the order of a few seconds. This approached the natural frequency of many tall structures, inducing large sidesway motions that led to their collapse. Based on this experience, determination of the seismic performance criteria of buildings involves the lateral resistance of forces of 0.100 to 0.200 g and consideration of the natural period of the building in relation to the period of seismic waves that can be expected in the locality. Another important factor is the ductility of the structure, the flexibility that allows it to move and absorb the energy of the seismic forces without serious damage. The design of buildings for seismic forces remains a complex subject, however, and there are many other important criteria involved.

Classification of structural systems. The types of structures used for high-rise buildings must meet the lateral load performance criteria outlined above, and they must be reasonably efficient in the use of material and of reasonable cost. The most efficient high-rise structure would meet the lateral load criteria using no more material than would be required for carrying the building gravity load alone; in other words, it would have no premium

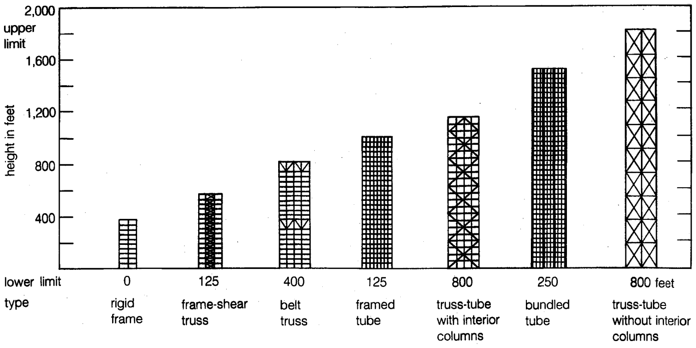

Figure 12: Structural systems for tall buildings.

From A. Swenson/P.-C. Chang, *Architectural Education at IIT, 1938–1978* (1980), Illinois Institute of Technology Press

for height. This economic criterion of "no premium for height" has led to a classification of high-rise structures, each of which has only a small premium for a particular range of height (Figure 12).

High-rise structures begin at the lowest range with the rigid frame in both steel and concrete. Some or all of the joints between the beams and columns are rigidly joined together by welding the steel or pouring the concrete in situ, and lateral resistance is provided by the rigid joints; this system can rise about 90 metres (300 feet) with little premium. The next type is the rigid frame with a vertical shear truss in steel or a shear wall in concrete to provide greater lateral rigidity; it has a range of 38 to 150 metres (125 to 500 feet). The framed tube structure in both steel and concrete brings more gravity load and more structural material to closely spaced columns at the building's perimeter, again increasing lateral rigidity; this type is reasonably efficient from 38 to 300 metres (125 to 1,000 feet) in height. The trussed tube with interior columns, which can also be executed in both steel and concrete, introduces diagonal bracing on all sides of the building's perimeter. The bracing also carries gravity loads and further raises the lateral rigidity, making this a low-premium structure for the region of 240 to 360 metres (800 to 1,200 feet). The bundled tube, which consists of a number of framed tubes joined together for even greater lateral rigidity, begins to be practical at about 75 metres (250 feet). It was the form of the steel structure used for the Sears Tower in Chicago. Beyond this height there is another system that appears to have a low premium: the superframe. In this structure much of the building's gravity load, and therefore its material, is brought to a diagonally braced superframe tube at the perimeter by interior transfer trusses of various configurations. No true superframes have yet been built.

Enclosure systems. The enclosure systems for high-rise buildings are usually curtain walls similar to those of low-rise buildings. The higher wind pressures and the effects of vortex shedding, however, require thicker glazing and more attention to sealants. The larger extent of enclosed surfaces also requires consideration of thermal movements, and wind- and seismic-induced movements must be accommodated. Window washing in large buildings with fixed glass is another concern, and curtain walls must provide fixed vertical tracks or other attachments for window-washing platforms. Interior finishes in high-rise buildings closely resemble those used in low-rise structures.

Building services. *Life-safety systems.* Life-safety systems are similar to those in low-rise buildings, with stairways serving as vertical emergency exits; in case of fire all elevators are automatically shut down to prevent the possibility of people becoming trapped in them. Emergency generator systems are provided to permit the operation of one elevator at a time to rescue people trapped in them by a power failure. Generators also serve other vital building functions such as emergency lighting and fire pumps. Fire-suppression systems often include sprinklers, but, if none are required by building codes, a separate piping system is provided with electric pumps to maintain pressure and to bring water to fire-hose cabinets throughout the building. There are also exterior connections at street level for portable fire-truck pumps. The fire hoses are so placed that every room is accessible; the hoses are intended primarily for professional fire fighters but may also be used by the building occupants.

Vertical transportation. Vertical transportation systems are of vital importance in high-rise buildings. Escalators are used on lower floors for moving high volumes of people over short distances. A few retail or educational buildings have escalators for up to 10 stories. The principal means of vertical transport in tall buildings is the roped elevator. It moves by a direct current electric motor, which raises and lowers the cab in a shaft with wire ropes running over a series of sheaves at the motor and the cab itself; the ropes terminate in a sliding counterweight that moves up and down the same shaft as the cab, reducing the energy required to move the elevator. Each elevator cab is also engaged by a set of vertical guide tracks and has a flexible electric cable connected to it to power lighting and doors and to transmit control signals. Passenger elevators range in capacity from 910 to 2,275 kilograms (2,000 to 5,000 pounds) and run at speeds from 90 to 510 metres per minute; freight elevators hold up to 4,500 kilograms (10,000 pounds). The speed of elevators is apparently limited to the current value of 510 metres per minute by the acceleration passengers can accept and the rate of change of air pressure with height, which at this speed begins to cause eardrum discomfort.

Roped elevators

Elevator movements are often controlled by a computer that responds to signals from call buttons on each floor and from floor-request buttons in each cab. The number of elevators in a building is determined by the peak number of people to be moved in a five-minute period, usually in the early morning; for example, in an office building this is often set at 13 percent of occupancy. The average waiting time for an elevator between pressing the call button and arrival must be less than 30 seconds in an office building and less than 60 seconds in an apartment building. The elevators are usually arranged in groups or banks ranging from one to 10 elevators serving a zone of floors, with no more than five elevators in a row to permit quick access by passengers. In a few very tall buildings the sky lobby system is used to save elevator-shaft space. The building is divided vertically into subbuildings, each with its own sky lobby floor. From the ground floor large express elevators carry passengers to the sky lobby floors, where they transfer to local elevator banks that take them to the individual floors within the subbuildings.

Plumbing. Plumbing systems in tall buildings are similar to those of low-rise buildings, but the domestic water-supply systems require electric pumps and tanks to maintain pressure. If the building is very tall, it may require the system to be divided into zones, each with its own pump and tank.

Environmental control systems. The atmosphere systems in high-rise office buildings are similar to those of low-rise, with conditioned air distributed by a ductwork tree using the VAV system and return air removed through ceiling plenums. The placement of air-handling equipment can be done in two ways. One uses centralized fans placed about every 20 floors, with air moved vertically through trunk ducts to and from each floor; the other uses floor-by-floor fan rooms to provide air separately for each floor. There is usually a central refrigeration plant for the entire building connected with cooling towers on the roof to liberate heat. The central refrigeration machines produce chilled water, which is circulated by electric pumps in a piping system to the air-handling fans in order to cool incoming air as required. Incoming air is heated in winter either by piping coils through which hot water is circulated by pumps and piping from a central boiler, or by electric resistance coils in the air-handling units. In residential high-rise buildings cooling is typically provided by window air-conditioning units, and heating by hot-water or electric resistance radiant systems. There is limited use of centralized cooling, in which chilled water from a central refrigeration plant is circulated to fan-coil units near the building perimeter; a small electric fan within the unit circulates the air of the room over the chilled water coil to absorb heat.

Electrical systems. Electrical systems for high-rise buildings are also very similar to low-rise types. The major difference is that, if the building is exceptionally tall, the utility company may bring its high-voltage lines inside the building to a number of step-down transformers located in mechanical equipment spaces. From each step-down transformer the distribution of electricity is similar to that of a smaller building.

LONG-SPAN BUILDINGS

Types of long-span buildings

Long-span buildings create unobstructed, column-free spaces greater than 30 metres (100 feet) for a variety of functions. These include activities where visibility is important for large audiences (auditoriums and covered stadiums), where flexibility is important (exhibition halls and certain types of manufacturing facility), and where large movable objects are housed (aircraft hangars). In the late 20th century, durable upper limits of span have been established for these types: the largest covered stadium has a span of 204 metres (670 feet), the largest exhibition hall has a span of 216 metres (710 feet), and the largest commercial fixed-wing aircraft has a wingspread of 66.7 metres (222 feet) and a length of 69.4 metres (228 feet), requiring a 75–80-metre- (250–266-foot-) span hangar. In these buildings the structural system needed to achieve these spans is a major concern.

Structural systems. *Structural types.* Structural systems for long-span buildings can be classified into two groups: those subject to bending, which have both tensile and compressive forces, and funicular structures, which experience either pure tension or pure compression. Since bridges are a common type of long-span structure, there has been an interplay of development between bridges and long-span buildings. Bending structures include the girder, the two-way grid, the truss, the two-way truss, and the space truss. They have varying optimum depth-to-span ratios ranging from 1 : 5 to 1 : 15 for the one-way truss to 1 : 35 to 1 : 40 for the space truss. The funicular structures include the parabolic arch, tunnel vault, and dome, which act in pure compression and which have a rise-to-span ratio of 1 : 10 to 1 : 2, and the cable-stayed roof, the bicycle wheel, and warped tension surfaces, which act in pure tension. Within these general forms of long-span structure, the materials used and labour required for assembly are an important constraint along with other economic factors (Figure 13).

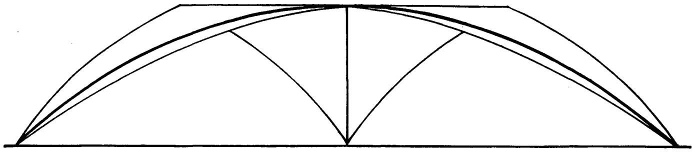
Timber structures. Glue-laminated timber can be used as a long-span material. It can be prefabricated using metal connectors into trusses that span up to 45 metres (150 feet). Its most economical forms, however, are the pure compression shapes of the multiple-arch vault, with spans up to 93 metres (305 feet), and ribbed domes, with spans up to 107 metres (350 feet). These are often used as industrial storage buildings for materials such as alumina, salt, and potash that would corrode steel or concrete. Such timber structures are usually found only near forested areas; transportation of timber to other areas increases its cost.

Steel structures. Steel is the major material for long-span structures. Bending structures originally developed for bridges, such as plate girders and trusses, are used in long-span buildings. Plate girders are welded from steel plates to make I beams that are deeper than the standard rolled shapes and that can span up to 60 metres (200 feet); however, they are not very efficient in their use of material. Trusses are hollowed-out beams in which the stresses are channeled into slender linear members made of rolled shapes that are joined by welding or bolting into stable triangular configurations. The members of trusses act either in pure compression or pure tension: in the top and bottom horizontal members the forces are greatest at the centre of the span, and in the verticals and diagonals they are greatest at the supports. Trusses are highly efficient in bending and have been made up to 190 metres (623 feet) in span. Two-way grids can be made of either plate girders or trusses to span square spaces up to 91 metres (300 feet) in size; these two-way structures are more efficient but more expensive to build.

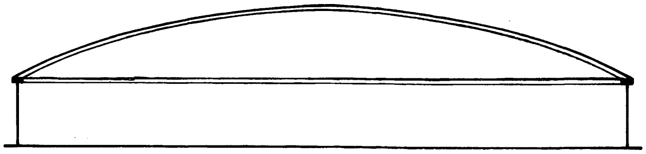
Steel funicular structures

The highly efficient funicular forms are used for the longest spans. Vaults made of rows of parabolic arches, usually in truss form for greater rigidity, have been used for spans of up to 98.5 metres (323 feet). Steel truss domes, particularly the Schwedler triangulated dome, have been the choice for several large covered stadiums, with the greatest span being 204.2 metres (669 feet). Cable-stayed roof construction is another structural system derived from bridge building. A flat roof structure in bending is supported from above by steel cables radiating downward from masts that rise above roof level; spans of up to 72 metres (236 feet) have been built. Another funicular form is the bicycle-wheel roof, where two layers of radiating tension cables separated by small compression struts connect a small inner tension ring to the outer compression ring, which is in turn supported by columns.

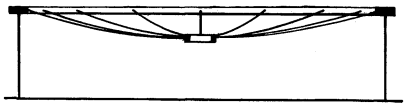
Tension-cable networks use a mesh of cables stretched from masts or continuous ribs to form a taut surface of negative curvature, such as a saddle or trumpet shape; the network of cables can be replaced by synthetic fabrics to form the tension surface. Another fabric structure using tension cables is the air-supported membrane. A network of cables is attached by continuous seams to the fabric, and the assembly of cables and fabric is supported by a compression ring at the edge. The air pressure within the building is increased slightly to resist exterior wind pressure. The increase can be as slight as 1.5 percent of atmospheric pressure, and it is possible to maintain this even in large buildings with relatively small compressors. The cables stiffen the fabric against flutter under uneven wind pressure and support it in case of accidental deflation.



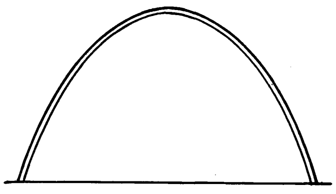
concrete shell 216 m (720 ft)



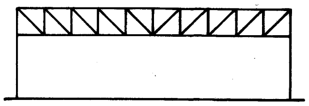
steel dome 204 m (678 ft)



concrete cable dish 126 m (420 ft)



steel truss vault 98.5 m (328 ft)



steel truss 90 m (300 ft)

steel plate girder 60 m (200 ft)

Figure 13: Long-span structures.

Concrete shell vaults

Concrete structures. Reinforced concrete, because of its inherent strength in compression, is primarily used for long spans in funicular compression forms, including vaults, shells, and domes. Thin parabolic shell vaults stiffened with ribs have been built with spans up to about 90 metres (300 feet). More complex forms of concrete shells have been made, including hyperbolic paraboloids, or saddle shapes, and intersecting parabolic vaults. An example of the latter is the CNIT Exhibition Hall in Paris, which consists of six intersecting double-shell parabolic vaults built to span a triangular space 216 metres (708 feet) on a side with supports only at the apexes of the triangle. Reinforced concrete domes, which are usually also of parabolic section, are built either in ribbed form or as thin shells. The maximum span of these domes is about 200 metres (660 feet).

Another funicular form used in concrete, though it is really a composite structure, is the inverted dome, or dish. As in the steel bicycle wheel, a concrete compression ring resting on columns at the perimeter of the structure supports radial steel cables that run inward and downward to a small steel tension ring at the centre, forming the dish shape. The cable network is stiffened against wind forces by encasing it in a poured concrete dish; structures of this type have been built with spans of up to 126 metres (420 feet).

Factors in the built environment. *Acoustics.* Long-span auditoriums involve considerations in acoustics: audiences wish to hear speakers clearly and to hear music with appropriate tonality. Unfortunately, acoustic requirements for speech quality often conflict with those for music, and it is difficult to design an auditorium that is satisfactory for both. The best single measure of acoustic performance for auditoriums is the reverberation time, which is directly proportional to the volume of the hall and inversely proportional to the amount of sound absorbency within it, including wall and ceiling surfaces and the audience itself. Measured in the sound range of 500–1,000 hertz, rooms with short reverberation times of one to 1.5 seconds are good for the intelligibility of speech, while longer reverberation times of 1.5 to 2.5 seconds add richness of tone to musical performances. Thus, adding sound-absorbent material to a hall improves it for speech but detracts from its musical qualities. People are excellent sound absorbers, and thus the audience has a distinct impact on auditorium acoustics; to keep this effect constant with varying audience size, auditorium seats are usually upholstered to serve as surrogate spectators of the same sound absorbency. Curved surfaces, which tend to focus sound, are either avoided in auditoriums or covered with sound-absorbent material. Electronic sound-amplification systems can be used to assist speakers in large halls but generally are not satisfactory for music. Other long-span buildings, such as covered stadiums and exhibition halls, receive only minor acoustical treatment.

Environmental control systems. Atmosphere systems in long-span buildings must handle the considerable heat and odour generation from population densities of less than one square metre (11 square feet) per person. Air must be moved fairly rapidly through the population zone to maintain an acceptable air-change rate.

COWAN (ed.), *Encyclopedia of Building Technology* (1988), is a collection of informative articles by authoritative contributors from 15 countries; and JOSEPH A. WILKES and ROBERT T. PACKARD (eds.), *Encyclopedia of Architecture: Design, Engineering & Construction,* 5 vol. (1988–89), offers an extensive coverage of a broad spectrum of topics. See also CYRIL M. HARRIS (ed.), *Dictionary of Architecture and Construction* (1975); and KORNELIS SMIT (ed.), *Means Illustrated Construction Dictionary* (1985).

History: BANISTER FLETCHER, *Sir Banister Fletcher's A History of Architecture,* 19th ed., edited by JOHN MUSGROVE (1987), is the most comprehensive exploration of comparative methods. The early history of building materials and building techniques is covered in NORMAN DAVEY, *A History of Building Materials* (1961, reissued 1971); RENÉ ALLEAU, *History of the Great Building Constructions* (1967; originally published in French, 1966); HENRY J. COWAN, *The Master Builders: A History of Structural and Environmental Design from Ancient Egypt to the Nineteenth Century* (1977, reprinted 1985); and JOHN FITCHEN, *Building Construction Before Mechanization* (1986). Specific urban cultures are the basis of the analyses in JEAN GIMPEL, *The Cathedral Builders,* trans. by TERESA WAUGH (1983; originally published in French, 1958); JOHN FITCHEN, *The Construction of Gothic Cathedrals: A Study of Medieval Vault Erection* (1961, reissued 1981); FRANK D. PRAGER and GUSTINA SCAGLIA, *Brunelleschi: Studies of His Technology and Inventions* (1970); and E. BALDWIN SMITH, *The Dome: A Study in the History of Ideas* (1950; reissued 1978). For the industrial age, see CARL W. CONDIT, *American Building Art: The Nineteenth Century* (1960), *American Building Art: The Twentieth Century* (1961), *American Building: Materials and Techniques from the First Colonial Settlements to the Present,* 2nd ed. (1982), and *The Rise of the Skyscraper* (1952); SIGFRIED GIEDION, *Mechanization Takes Command: A Contribution to Anonymous History* (1948, reprinted 1969), and *Space, Time, and Architecture: The Growth of a New Tradition,* 5th rev. ed. (1967); REYNER BANHAM, *The Architecture of the Well-Tempered Environment,* 2nd ed. (1984); and HENRY J. COWAN, *Science and Building: Architectural and Environmental Design in the Nineteenth and Twentieth Centuries* (1978).

Modern practices: Standards regulating building construction are covered in BUILDING OFFICIALS AND CODE ADMINISTRATORS INTERNATIONAL, *The BOCA Basic/National Building Code* (triennial); INTERNATIONAL CONFERENCE OF BUILDING OFFICIALS, *Uniform Building Code* (triennial); SOUTHERN BUILDING CODE CONGRESS, *Southern Standard Building Code* (irregular); and AMERICAN SOCIETY OF HEATING, REFRIGERATING, AND AIR-CONDITIONING ENGINEERS, *ASHRAE Guide and Data Book* (annual). See also FREDERICK S. MERRITT (ed.), *Building Design and Construction Handbook,* 4th ed. (1982); and CHARLES A. HERUBIN, *Construction Site Planning and Development* (1988). Standards and data pertaining to architecture, building, and allied fields are illustrated in JOHN RAY HOKE, JR. (ed.), *Ramsey/Sleeper Architectural Graphic Standards,* 8th ed. (1988). See also ALBERT G.H. DIETZ, *Dwelling House Construction,* 4th rev. ed. (1974); JOSEPH D. FALCONE, *Principles and Practices of Residential Construction* (1987); FRANCIS D.K. CHING, *Building Construction Illustrated* (1975); HAROLD B. OLIN, JOHN L. SCHMIDT, and WALTER H. LEWIS, *Construction: Principles, Materials & Methods,* 5th ed. (1983), focusing on low-rise construction; and, for nontraditional building, LESTER L. BOYER and WALTER T. GRONDZIK, *Earth Shelter Technology* (1987).

B.S. BENJAMIN, *Structures for Architects,* 2nd rev. ed. (1984), analyzes the behaviour of structural systems based on physical principles and properties of materials; MARIO SALVADORI, *Why Buildings Stand Up: The Strength of Architecture* (1980), is an illustrated introduction to structural engineering; and MARIO SALVADORI and ROBERT HELLER, *Structure in Architecture: The Building of Buildings,* 3rd ed. (1986), is a broader survey of foundations and structural systems. See also RONALD C. SMITH and CAMERON K. ANDRES, *Principles and Practices of Heavy Construction,* 3rd ed. (1986); IRVING ENGEL, *Structural Steel in Architecture and Building Technology* (1988); E. ERANTI and G.C. LEE, *Cold Region Structural Engineering* (1986); and WOLFGANG SCHUELLER, *High-Rise Building Structures,* 2nd ed. (1986).

The following works focus on building materials: RONALD C. SMITH and CAMERON K. ANDRES, *Materials of Construction,* 4th ed. (1988); PAUL BIANCHINA, *Illustrated Dictionary of Building Materials and Techniques* (1986); EDWARD ALLEN, *Fundamentals of Building Construction: Materials and Methods* (1985); and HENRY J. COWAN and PETER R. SMITH, *The Science and Technology of Building Materials* (1988).

Mechanical and electrical systems are studied in RICHARD D. RUSH, *The Building Systems Integration Handbook* (1986); BUILDING SERVICES RESEARCH AND INFORMATION ASSOCIATION, *Building Services Materials Handbook: Heating, Sanitation, and Fire Protection* (1987); ROGER W. HAINES, *Control Systems for Heating, Ventilating, and Air Conditioning,* 4th ed. (1987); BENJAMIN STEIN, JOHN S. REYNOLDS, and WILLIAM J. MCGUINNESS, *Mechanical and Electrical Equipment for Buildings,* 7th ed. (1986); and ROBERT H. PERRY and TYLER G. HICKS (eds.), *Building Systems Reference Guide* (1987).

(A.Sw./P.-C.C.)

Bulgaria

The People's Republic of Bulgaria (Narodna Republika Bŭlgariya) occupies the eastern portion of the Balkan Peninsula in southeastern Europe. The country is crossed by historically important routes from northern and eastern Europe to the Mediterranean basin and from western and central Europe to the Middle East. Bulgaria is remarkable for its variety of scenery, its rugged mountains and modern Black Sea resorts alike attracting tourists from other countries. Although the Ottoman influence remains visible, Bulgaria's chief historical, cultural, and political ties connect it with the Soviet Union. Long-term alliances with other eastern European countries became uncertain in late 1989 as a sweeping democratic-reform movement dissolved the Soviet bloc. In January 1990 the Bulgarian parliament revoked the Communist Party's constitutionally guaranteed monopoly on political power.

A nation of some 43,000 square miles (111,000 square kilometres), Bulgaria is bounded by Romania on the north, most of the border being marked by the lower Danube River. The Black Sea lies to the east, Turkey and Greece to the south, and Yugoslavia to the west. The capital of the country is Sofia, which lies in a mountainous basin in the west, near the geographic centre of the whole Balkan region.

This article is divided into the following sections:

Physical and human geography

THE LAND

Topographic variety

Relief. Within a relatively small compass, the Bulgarian landscape exhibits striking topographic variety. Open expanses of lowland alternate with broken mountain country, cut by deep river gorges and harbouring upland basins such as that in which Sofia lies. Three basic structural and physiographic divisions run east–west.

The Danubian Plain. All but a short section of the northern frontier of Bulgaria is marked by the lower Danube, the abrupt and often steep banks on the Bulgarian side contrasting with the swamps and lagoons of the Romanian side. A fertile, hilly plain extends southward from the Danube to the foothills of the Balkan Mountains. The average elevation of the region is 584 feet (178 metres), and it covers some 12,200 square miles (31,500 square kilometres). Several rivers cross the plain, flowing northward from the Balkans to join the Danube.

The Balkan Mountains. The Balkan Mountains border the Danubian Plain on the south, their rounded summits having an average height of 2,368 feet and rising to 7,795 feet (2,376 metres) in Botev, the highest peak. Parallel to this principal chain (its Bulgarian name, Stara Planina, means "Old Mountains," "old" signifying its greater extent compared to the adjacent ranges) lies a transitional region of complex relief. Block faulting—the raising or lowering of great structural segments along regular lines of crustal weakness—has produced there the Sredna Mountains (Sredna Gora), the Vitosha Mountains, the Lisa Mountains, a number of sheltered structural basins, and the Upper Thracian and Tundzha lowlands.

The Rila–Rhodope massif. Another mountain mass covers southern Bulgaria. This includes the alpine Rhodope Mountains (Rodopi in Bulgarian, Rodhópis in Greek), which rise to 7,188 feet (2,191 metres) in Golyam Perelik Peak; the Rila Mountains, rising to Musala Peak, at 9,596 feet (2,925 metres) the highest in the country and indeed in the whole Balkan Peninsula; the Pirin Mountains, with Vikhren Peak reaching 9,560 feet (2,914 metres); and a frontier mountain range known as the Belasitsa.

These majestic ranges discharge meltwater from montane snowfields throughout the summer, and their sharp outlines, pine-clad slopes, and, in the Rila and Pirin ranges, several hundred lakes of glacial origin combine to form some of the most beautiful of Bulgarian landscapes.

The Black Sea coast. Trending north–south at the eastern fringe of the other regions is the narrow Black Sea coastal region. The coast has few bays (exceptions being the fine harbours of Varna and Burgas) but does have extensive stretches of sandy beach that have led to the growth of a number of picturesque seaside resorts.

Rivers

Drainage. Bulgaria has a complex drainage pattern characterized, with the notable exception of the Danube, by relatively short rivers. The major rivers are the Maritsa (Marica), the Iskŭr, the Struma, the Arda, the Tundzha, and the Yantra. Overall, more than half of the runoff drains to the Black Sea, and the rest drains to the Aegean Sea. Bulgaria's numerous lakes may be coastal (such as the large lakes around Varna and Burgas, both on the Black Sea), glacial (such as those in the southern mountains), structural, or karst in origin. The country has some 500 mineral springs, half of which are warm or hot (reaching 217° F [103° C] at Sapareva Banya, in the west). Numerous dams have been constructed in the mountains.

Soils. The varied Bulgarian natural environment has produced about 20 soil types and subtypes, which may be grouped into three main regions. Northern Bulgaria is characterized by the fertile black-earth soils known as chernozems and also by gray soils of forest origin. Southern Bulgaria has forest soils with acidic (cinnamonic) traces—by far the most extensive single category—as well as the modified chernozems known as chernozem-smolnitzas (a dark-coloured zonal soil with a deep and rich humus horizon). The rugged high mountain regions have brown forest, dark mountain forest, and mountain meadow soils.

Precipitation

Climate. The greater part of Bulgaria has a moderate continental climate, which is tempered by Mediterranean influences in the south. The average annual temperature is 51° F (10.5° C), but this conceals a wide variation; temperatures as low as −37° F (−38° C) and as high as 113° F (45° C) have been recorded. Mean annual precipitation ranges from about 18 inches (450 millimetres) in the northeast to more than 47 inches in the highest mountains. The lowlands receive snowfall from mid-October to mid-May, with an annual average of 25–30 days of snow cover. Hailstorms occur between May and August.

Plant and animal life. The relatively large number of Bulgarian plant and animal species reflects the country's location adjoining several of the great Eurasian biogeographic zones. During the Ice Age, life in the region was not destroyed by advancing glaciers as occurred in much of Europe but was actually enriched by the immigration of species from the north, some of which still survive. Influences from the steppes of western Asia also penetrated the region at that time. Nonetheless, the greater part of the plant and animal life is central European, mixed with a type that blends Arctic and alpine characteristics in the high mountains. Steppe species are most characteristic of the northeast and southeast, while the south is rich in sub-Mediterranean and Mediterranean species. The Bulgarian government has introduced a number of conservation measures, including steps to protect soil, water, and air from pollution and to establish protected areas of outstanding interest to naturalists.

Settlement patterns. The natural environment of Bulgaria falls into three basic regions: North Bulgaria, including the Danubian Plain and the Balkan Mountains; South Bulgaria, including the Rila–Rhodope massif; and a transitional area between them. Each of these traditional regions over the centuries has been subjected to the actions of humans, whether in the remoter mountains, where national culture was cherished and the seeds of nationalism were sown during the long Ottoman domination, or in the Danubian Plain, where agriculture has been practiced from ancient times. Bulgarian settlements have been officially classified into more than 200 urban areas and 5,000 villages, the latter including hundreds of small hamlets, clusters of farmsteads, and, deep in the mountains, a handful of historic monasteries.

Urban patterns. Many Bulgarian towns have roots in the Middle Ages and in remotest antiquity, although new, modern settlements are being created each year; the urban population overtook the rural for the first time in 1969. Each new or modernized town is required to have its own development plan, and the neighbourhood unit is a characteristic feature of the planning process. Despite the pressure of urban population growth, many Bulgarian towns preserve their ancient charm and are rich in cultural monuments; in the remoter areas, they offer a slower pace of life than can be found in the cities.

Major cities

Sofia, the capital, is the largest city and dominates the national economic and cultural life. Plovdiv, in the south-central region, enjoys a scenic location on the Maritsa River and is another major industrial and cultural centre, where an international trade fair is held annually. Varna is a centre for industry, transport, and tourism on the shores of the Black Sea. The nearby seaside resort of Zlatni Pyassŭtsi ("Golden Sands") attracts an international tourist trade. Burgas is Bulgaria's largest Black Sea port and a major industrial, cultural, and resort centre. Ruse, on the Danube in the north, is the largest Bulgarian river port; there the Friendship Bridge leads to the Romanian city of Giurgiu. Stara Zagora lies on the southern flanks of the central Sredna Mountains and is notable for its archaeological and architectural remains.

Rural patterns. The numerous contemporary Bulgarian villages are either clustered or scattered. Since World War II they have undergone a transformation from the sleepy, backward, and poverty-stricken settlements that typified much of the region for centuries. Almost all of the rural population live in villages supplied with water and electricity; three-quarters of the houses are recent constructions, replacing the older lath and plaster structures. Most of the villages have paved and asphalted streets. Processing plants have been built in many villages, so that rural areas are increasingly industrialized.

THE PEOPLE

The origins of the Bulgarians

Ethnic, religious, and linguistic background. Ethnically, the population is fairly homogeneous, Bulgarians making up about 85 percent of the total. The Slav tribes that settled in the eastern part of the Balkan Peninsula in the 6th and 7th centuries AD, thereby assimilating the local Thracian tribes, formed a basic ethnic group. The group known as the proto-Bulgarians, who, together with the Slavs, formed the Slav-Bulgarian state in 681, formed another component. With the gradual obliteration of fragmented Slav tribes and also of the ethnic differences in the territory of the first Bulgarian state (covering Moesia, Thrace, and Macedonia) in the 9th and 10th centuries, proto-Bulgarians and Slavs consolidated into a unified Slav people who thence retained the name of Bulgarians. This national unity, present in embryonic form during the long Ottoman domination, flowered in the independence struggles of the 19th century.

The Turks, Bulgaria's largest minority, live in some regions of the northeast and in the eastern Rhodope. Gypsies and Macedonians are two other sizable minorities (though the government does not consider Macedonians as such, regarding them as ethnically Bulgarian), and there are a few thousand Armenians, Russians, and Greeks (mostly in the towns) and Romanians and Tatars (mostly in the villages).

The Bulgarian language belongs to the South Slavic group, along with Serbo-Croatian, Slovene, and Macedonian (the last, however, considered to be a dialect of Bulgarian by the government). A number of dialects remain in the common speech.

Following the reforms of 1989–90, the state continued to encourage atheism, but religious activity was increasingly tolerated. The majority of religious Bulgarians are adherents of the Bulgarian Orthodox Church, which pressed the new leadership for greater autonomy and restoration of monastic lands. Minority religious groups include Muslims, Jews, Bulgarian Catholics, Protestants, and Gregorian Armenians.

Demographic trends. *Birth and death rates.* As a result of social and economic changes after World War II, notably the introduction of free medical care and the improvement of working conditions, Bulgaria's death rate dropped significantly, but it began to rise again in the 1970s as the proportion of older people in the population rose. The birth rate has dropped, as has the infant mortality rate.

Emigration and immigration. Emigration since World War II has mostly affected non-Bulgarians. About half a million Turks left the country, 155,000 having been expelled in 1949–51 and a further 300,000 or more having emigrated in 1989. Almost all Czechs and Slovaks returned to their homelands, as did large numbers of Russians and Armenians (to the Soviet Union) and Jews (to Israel). About 35,000 others, mostly Bulgarians, returned from North America and from European countries. Internally, the movement of population has been from rural areas to larger towns and cities. From 1946 to 1988, for example, the population of Sofia trebled; the populations of Varna and Plovdiv increased more than sixfold; and Ruse's population increased more than fivefold.

Population distribution. Bulgaria's geographic variety is reflected in the distribution of its population. The most densely populated areas are the Danubian Plain, the Upper Thracian Basin, the Burgas Plain, and the intermontane basins of southwestern Bulgaria. Areas of lowest density are the east and southeast of the country, the Strandzha and Dobruja regions, and the higher mountain areas.

Urbanization continues to have an effect on the demographic structure; a large segment of the urban population is of a young working—and childbearing—age, leading to natural growth of the towns. Because relatively more older adults remain in the villages, the birth rate there continues to be lower and the death rate higher. These effects thus amplify the shift of population from rural areas to urban centres.

THE ECONOMY

Until the reform movement of the late 1980s, the Bulgarian economy was based solely on the premise that all means of production should be owned by the state. The National Assembly elected in 1990, while dominated by the Bulgarian Socialist Party (formerly called Bulgarian Communist Party), was to draft a new constitution incorporating reforms.

The state's role in agriculture and industry. Beginning in 1990, farmers were paid bonuses for each head of cattle or sheep exceeding the previous year's total; reduction of herds or flocks resulted in fines. Hard-currency exchange rights gave dairy farmers an incentive to maintain high milk-production levels. Supplies of quality wool and hides were to be paid for in hard currency. Farmers in upland and mountainous regions also received incentives. In addition, the government lifted restrictions on private farming and made available loans for the establishment of small farms and food-processing facilities.

Turnover tax

Taxation. The main sources of revenue are the turnover tax and deductions made from the profits produced by public enterprises. The turnover tax, a form of value-added tax, is based on a fixed rate and goes immediately into the budget after the sale of products by state enterprises. In this way the state budget is ensured a regular and uniform source of revenue to finance the undertakings called for in the economic plan. The turnover tax is dependent on the size, variety, and sale of manufactured products; ultimately it is passed on to the consumer. The profit deduction tax from state enterprises, unlike the turnover tax, is not at a fixed rate. It comes from each enterprise's net income after deduction of the turnover tax. The profit shown by an enterprise is the difference between income and maintenance expenses.

Budget. The national budget finances most capital investments, enterprises under direct central management, and a number of social and cultural needs (*e.g.,* higher educational institutions). It also covers defense and the central government departments. People's Council budgets—those of the district, municipality, and village People's Councils—maintain a variety of educational, health, and cultural institutions, urban development and planning, and various other services. The state social insurance budget covers expenditure for matters such as employees' pensions, temporary incapacity to work, maternity leave, maintenance of rest homes, and family allowances.

The national budget allots about half of its revenues to developing the national economy, a large portion of this going to development of heavy industry. It also provides funds for capital investment in industrial enterprises and provides them with turnover funds. Large credits are allocated to agricultural development and the supply of farm equipment. Budgetary credits are also used to finance long-term investment projects (*e.g.,* power generation, forestry, ferrous metallurgy, and land improvement and water conservation projects). About a third of all investment comes from state budgetary credits, and two-thirds is covered by local enterprises' funds and bank credits. About one-fourth of the total budgetary expenditure goes to fund social services.

The role of trade unions. Bulgaria has some 17,000 local trade union organizations made up of 111,000 separate trade union subgroups. Only an insignificant portion of the country's work force does not belong to a trade union. Until it was reconstituted as the Confederation of Independent Bulgarian Trade Unions (S'uz na Nezavisemite B'lgarski Profs'uze) in late 1989, all trade unions belonged to the Central Council of Trade Unions (Tsentralen Sŭvet na Profesionalnite Sŭyuzi), founded in 1944 and allied with the Bulgarian Communist Party. Also in 1989, Podkrepa ("Support"), a leading independent trade union, along with both established and newly formed opposition parties, formed the Union of Democratic Forces (S'uz na Demokraticheskite Sili) in order to press for governmental reform.

Coals

Resources. Bulgaria is relatively well endowed with a variety of both metallic and nonmetallic minerals. Geologic exploration has identified about 40 coal basins, which together contain an estimated 4.1 billion tons of proven recoverable reserves. Of the reserves, more than 99 percent is lignite. The main mining areas are in the Pernik basin southwest of Sofia, the Maritsa basin south of Stara Zagora, the Maritsa basin at Dimitrovgrad in the south, and Lom on the Danube. Lignite and brown coal fuel the country's thermal power stations and are used as fuel and as raw material for many of its industries. Although deposits of bituminous and anthracite coal have been almost exhausted in Bulgaria, other promising deposits of black coking coal have been found in the northeast, in the Dobruja region.

Deposits of iron ore are estimated at 317 million tons; one of the largest reserves is at Kremikovtsi near Sofia, the site of the country's largest metallurgical plant. Smaller quantities of iron ore are mined in the northwest (Mikhaylovgrad), in the central region (Troyan), and in the southeast (Yambol). There are significant deposits of nonferrous ores (copper, lead, and zinc) in the Rhodope Mountains, the Balkan Mountains, and the Sredna Mountains. Bulgaria is also rich in less valuable minerals, including rock salt, gypsum, limestone, dolomite, kaolin, asbestos, perlite, feldspar, fluorite, and barite.

Bulgaria has only small deposits of oil and natural gas; mineralogists have begun offshore exploration of the Black Sea, which is believed to be rich in coal, oil, natural gas, and other minerals.

Bulgaria gets about one-fourth of its electrical power from nuclear plants, and hydroelectric plants supply one-tenth.

Industry. Before World War II, industries were of minor importance in Bulgaria. Under the Socialist system, industrialization became one of the principal aims of economic policy, with particular emphasis on basic industries such as electric power, ferrous and nonferrous metallurgy, and chemicals. Central planning of management, production, and investment channeled into industry a large portion of the national resources.

Postwar industrialization

Before the war, shipbuilding at Varna and foundries at Sofia, Plovdiv, Ruse, and Pernik were the most important metallurgical industries. Those developed after the war include iron and steel works at Pernik, based upon local brown coal and iron ore from the Sofia district; a large steel project at Kremikovtsi; a lead and zinc works at Kŭrdzhali; and a copper and sulfuric acid plant at Pirdop. A chemical industry has developed at Dimitrovgrad, and chemical plants were also built at Stara Zagora, Vratsa, Devnya, and Vidin, and a petrochemical plant at Burgas. The biotechnology sector is increasingly important in the economy.

Machine building is a priority of the national economy. Its relative share of industrial production has jumped dramatically. Machine building and metal processing are widely dispersed throughout the country; the largest plants are located in Sofia, Varna, Ruse, Burgas, and Plovdiv. The production of chemicals and rubber is mainly centred around Sofia, Dimitrovgrad, Varna, Reka Devnya, and Plovdiv.

Since the 1960s three other industries have had marked regional development: food, beverage, and tobacco processing; textiles; and tourism. While food processing and beverage production are found throughout the country, three main industrial regions may be defined. The first, in the south, includes the towns of Plovdiv, Krichim, Pazardzhik, Asenovgrad, and Pŭrvomay, which primarily specialize in canning and tobacco processing. The second region, in northern Bulgaria (Gorna Oryakhovitsa, Veliko Tŭrnovo, and Lyaskovets), concentrates on canning, sugar refining, and meat processing. A third region to the northwest (Pleven, Dolna Mitropoliya, and Cherven Bryag) has become important for flour, paste products, poultry processing, canning, sugar refining, and the processing of vegetable oils. Fishing and fish breeding have also become important industries.

Textile industries before World War II were mainly to be found where the demand for textiles was constant (Sofia, Plovdiv, Varna) or where raw materials were available (Sliven, Vrasta). The industries used locally produced wool, cotton, or silk. Under the republic's five-year plans, large new mills were built at Sofia, Sliven, and Plovdiv, and the total output of textile fabrics rose tremendously.

Tourism in Bulgaria has grown markedly since the 1960s. In addition to the popular Black Sea resorts, tourists are attracted to historical centres such as Sofia, Plovdiv, and Rila Monastery and to winter sports centres such as Borovets in the Rhodope Mountains.

John Launois—Black Star

Harvesting wheat on a state farm near Tolbukhin, in the Dobruja region, northeastern Bulgaria.

The major source of energy in Bulgaria is the Maritsa lignite field, which provides fuel to large thermoelectric plants at Dimitrovgrad and Maritsa-Iztok; there are thermal power stations also at Pernik, Sofia, Plovdiv, and Burgas. The country's first nuclear power station, at Kozloduy, was constructed with Soviet aid. It began operation in 1974 and has since been expanded. Transmission lines carry electric power to most parts of the country.

Agriculture. A cooperative movement developed in the agricultural sector in Bulgaria before World War II, and after the war it spread further, until most of the arable land was in cooperative farms. The cooperative and state farms then merged into large state and collective units. Agriculture grew unevenly, however, and in 1970–71 these units were consolidated into the larger groupings called agro-industrial complexes to take better advantage of integrated systems of automation, supply, and marketing. Agriculture accounts for less than one-fifth of the national income in Bulgaria.

Crops

Cereal crops are grown on almost three-fifths of the sown land. Wheat is by far the most important, followed by corn (maize) and barley; rye, oats, soybeans, and rice are also grown. Industrial crops are important, especially tobacco, which is a good-quality Oriental type and is grown mainly in the south. Sunflower seed is the chief oil-seed crop; after extraction of the oil, the pulp is made into cattle feed. Sunflowers, like sugar beets, grow mainly in the north. Bulgaria has become a leading exporter of grapes and tomatoes. Stock breeding has increased since World War II, and productivity has improved; cattle, sheep, pigs, and poultry are raised.

Finance. As of 1990, the Bulgarian National Bank, the principal banking institution, was to undergo significant reforms. Its 130 branches were to be reorganized to have more operational independence. Sixty separate commercial banks (about half with their own subsidiaries) were to be established for better links between banks and state enterprises. Shares in local enterprises were to be offered for sale in some commercial banks.

Trade. Foreign trade is a state monopoly. Almost two-thirds of all exports are capital goods, such as machinery and equipment, and one-quarter are consumer goods, mainly of agricultural origin (such as fresh and canned fruits, wine, honey, cigarettes, dairy products, and meat and live animals). About two-fifths of all imports are capital goods. There has been some decline in Bulgaria's imports from the Council for Mutual Economic Assistance member countries, while exports to these states have remained steady, creating a trade surplus. Exports to the West have risen, and imports remained steady.

Transportation. *Roads and railways.* The development of the Bulgarian economy has required the expansion of the transportation system. Road transport accounts for a large percentage of all freight carried (on a tonnage basis) as well as most passenger traffic. Roads and railways together account for all but a small fraction of both freight and passengers carried. The E-5 European International Highway, crossing the country toward Istanbul, has undergone reconstruction. The main railway lines connect Sofia with the Black Sea coast.

Airports

Water and air transport. The Danube is used for both internal and international traffic, Ruse, Svishtov, and Lom being the main river ports. The chief seaports are Varna and Burgas, and there is a regular international merchant service on the Black Sea. Bulgaria has international airports at Sofia, Varna, and Burgas, and internal air services have grown; scheduled international service has increased considerably.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Following the overthrow of the veteran Communist Party leader Todor Zhivkov in November 1989, the party gave up its guaranteed right to rule, adopted a new manifesto, streamlined its leadership, and changed its name to the Bulgarian Socialist Party. Attempts to create a broadly based national unity government prior to special elections in mid-1990 failed because the Agrarian

Party (formerly the sleeping coalition partner of the Communist Party) and the multiparty Union of Democratic Forces refused to join the Socialists. Bulgaria's first free elections in 40 years, held on June 10 and 17, 1990, defied the predictions of most observers by granting the Socialists a comfortable majority in the National Assembly, which was to draft a new constitution.

The highest constantly functioning organ of state power is the State Council (Ministerski Sŭvet), which is responsible to the National Assembly. It consists of a president, a varying number of vice presidents, a secretary, and a varying number of members, all elected from the membership of the National Assembly. The State Council manages the day-to-day operations of the organizational and political functions of the country based on decisions made by the National Assembly.

The Council of Ministers is the official executive and administrative body and as such comprises the government of Bulgaria. It consists of a chairman (the country's prime minister), deputy chairman, ministers, and heads of departments (who may be given the rank of minister by the National Assembly). The council is elected from the membership of the National Assembly and is responsible to the Assembly.

The People's Councils express state power at the local government level. The members of the People's Councils are elected for two and a half years. They are responsible for the economy, health, social welfare, communal activities, and cultural and educational facilities within the bounds of their allotted territory.

Political parties

Elections to the various representative bodies are open to all citizens who have attained the age of 18. Prior to the reforms of 1990, the ruling party was the Bulgarian Communist Party (Bŭlgarska Komunisticheska Partiya, or BKP), founded in 1891 as the Bulgarian Social Democratic Party. The other party that was permitted to function was the Bulgarian Agrarian People's Union (Bŭlgarski Zemedelski Naroden Sŭyuz, or BZNS), founded as a peasant organization in 1899. Under the Union of Democratic Forces, founded in 1990, labour, religious, environmental, and other goups joined opposition parties to challenge the Communists, who now called themselves Socialists.

Justice. The judiciary is part of the government structure, ranking below the executive and legislative branches. The system of court organization distinguishes between general (district) courts, special courts (for the armed forces and transport facilities), and a Supreme Court. Supreme Court judges are elected by the National Assembly for terms of five years, judges of district courts for three years; judges of people's courts, on the lowest level, are elected by the general electorate for the same three-year period. All judges are subject to removal by the agency that elected them. The chief public prosecutor is elected for a five-year term by the National Assembly and is empowered to appoint and dismiss deputies and other public prosecutors in the country.

Armed forces and law enforcement. The general management of the Bulgarian military forces is the responsibility of the State Council; the Bulgarian People's Army, consisting of the Ground Forces, the Air Forces, and the Navy, is under the immediate command of the Ministry of National Defense. The term of obligatory national service is two years, except in the naval forces, in which it is three. The army is integrated with the forces of other Warsaw Treaty Organization member countries. The armed forces also include the Border Guards, the Labour Corps, and the Ministry of Transport Corps. The People's Militia and the Organization for Assistance in Defense are paramilitary organizations that also serve as local police. The state security police deal with crimes against national security or those presenting a threat to society.

Education. Primary and secondary education is the responsibility of a hierarchy of educational councils. Higher education is governed by the Ministry of Public Education. Education is free at all levels, and an eight-year elementary program is obligatory for children. Since 1959, general education has included polytechnical subjects and vocational training. The "Kliment Ohridski" Sofia University (founded in 1888 as the Sofia Higher Institute) is the oldest body of higher learning in Bulgaria and was the only university until 1971, when teacher-training institutes in Plovdiv and Veliko Tŭrnovo were elevated to university status. There are numerous technical institutes as well as schools for the arts, including an institute of music, a conservatory, an institute of fine arts, and an institute of dramatic art and cinematography.

Health and welfare. The health service, directed by a government ministry, provides free medical assistance of all types. A number of specialized establishments treat tuberculosis patients, and a highly developed network of pediatric facilities cares for children. Medical social services are supported by an insurance plan that consists of a consolidated fund of contributions from state and cooperative enterprises and institutions and similar bodies. It is directed by the Confederation of Independent Bulgarian Trade Unions and covers practically all of the working population.

Urban housing shortage

Housing. A sizable fraction of the total capital investment in Bulgaria goes into housing, reflecting a program adopted in 1970 to try to alleviate the severe housing shortage caused by rapid urbanization. Another portion is spent on individual housing construction, with the state granting to individuals loans that can be repaid over periods of up to 25 years. More than 80 percent of the housing is owner-occupied.

Social conditions. Because wages and many retail prices are controlled by the government, they are kept relatively stable in relation to one another. The highest annual wages are those in the building trades, the lowest in agriculture. Monthly children's allowances, pensions, and sick pay in some cases add considerably to the income from wages alone.

The rapid industrialization since World War II has had noticeable socioeconomic effects: more than one-third of the people are now engaged in industry, while only one-fifth are in agriculture. The number of people employed in education, in culture and art, and in the health services has risen to more than one-seventh of the active work force. The percentage of women workers has risen to almost half of the total labour force, and women are especially concentrated in finance, banking, and insurance.

CULTURAL LIFE

Contemporary Bulgarian culture is a lively blend of the millennium-old folk traditions of the region; a more formal culture, which played a vital role in the emergence of national consciousness under Ottoman rule and in the development of a modern state; and, since World War II, the development of a strong Socialist element.

Because Bulgaria's population is largely homogeneous, the degree of cultural variation even at the regional level is small. The state encourages cultural development at all levels of society and supports the dissemination of culture, particularly through schools, libraries, museums, publishing and the press, radio, television, and cinema.

Daily life. Outwardly, daily life in Bulgaria has been dominated since World War II by the Socialist political system based on the teachings of Karl Marx. The state has sought to inculcate a new mode of thinking and manner of action, based above all on the need for and benefit of social labour. More inwardly, however, daily life continues to be dominated by a much older tradition and cultural legacy. For example, the Bulgarian family has kept many of its traditional forms of organization. Many households consist of an extended family comprising parents and one of their married sons—usually the youngest—or daughters.

Religious functions are entirely separate from state functions, the postwar constitution prohibiting the use of religion or religious organizations for political purposes. On the other hand, the Bulgarian state tolerates religion and does not attempt to take away the political rights of religious believers; in normal circumstances there is no attempt to persecute religious believers. Nevertheless, the state education system encourages a scientific and atheistic education.

The arts. *Visual arts.* The early impetus of Bulgarian traditions in the arts was cut short by the Ottoman occupation in the 14th century, and many of the early masterpieces were destroyed. Artistic life emerged again in Bulgaria during the national revival in the 18th century: among the most influential works were the secular and realist paintings of Zahari Zograph (1810–53) and Hristo Tsokev (1847–83). At the end of the 19th century, Bulgarian painters such as Anton Mitov (1862–1930) and the Czech-born Ivan Mrkvička (1856–1938) produced memorable works, many of them depicting the daily life of the Bulgarian people. The early part of the 20th century saw further development of both style and subject matter, and the foundations were laid for later artists such as Vladimir Dimitrov (1882–1960), an extremely gifted painter specializing in the rural scenes of his native country; Tsanko Lavrenov (1896–1978), a noted graphic artist and art critic who also painted scenes of old Bulgarian towns; Zlatyo Boyadjiev (1903–76), noted for his village portraits; and Ilya Petrov (1903–75), who painted scenes and themes from Bulgarian history. After World War II, Socialist Realism began to dominate Bulgarian artistic circles; its influence is seen in the broad historical themes adopted by modern artists in genres ranging from cartoons to still-life paintings and regional landscapes.

Bulgarian classical music

Music. The first performances of Bulgarian classical music date from the 1890s, and the earliest Bulgarian opera, by Emanuil Manolov (1860–1902), was performed in 1900. He, along with other Bulgarian composers, concentrated on solo and choral vocal works, although between World War I and World War II several symphonies and works for ballet, in addition to choral and opera works, were created by such composers as Lyubomir Pipkov (1904–74), Petko Stainov (1896–1977), and Pancho Vladigerov (1899–1978). The modern Bulgarian composers have experimented with new tonality in vocal and instrumental music. Recordings and concert tours abroad have won new audiences for traditional Bulgarian vocal music.

Theatre. The Bulgarian theatre remains a popular source of entertainment. In many cases political themes are adopted for modern plays, as evidenced by the works of Georgi Karaslavov (1904–80) in his depictions of the Bulgarian countryside and the socialist struggle for social justice. World classics and modern foreign dramas are also produced.

Literature. Bulgaria's literary tradition may be traced to the 9th century, when saints Cyril and Methodius created the alphabet for Old Bulgarian (Old Church Slavonic). During Ottoman domination, literature could only be preserved in the monasteries and churches. With the national revival in the 18th century, Bulgarian literature flowered once more and was used as a subtle spiritual means of fighting for the country's liberation.

Motion pictures. Bulgaria's motion-picture industry has expanded considerably since World War II. Bulgarian audiences take interest in both domestic and foreign films, and the country's feature and documentary films have a wide export market. Animated cartoons also are popular. Many of the motion pictures are produced at the Cinema Centre near Sofia.

Cultural institutions. Bulgaria has almost 10,000 libraries, with a total holding of about 110,300,000 volumes, and more than 200 museums. There are also a few thousand *chitalishte*s, cultural centres similar to reading rooms, found in even the smallest villages. The major museums in Sofia are the National Archaeological Museum, National Ethnographical Museum, National Museum of the Revolutionary Movement of Bulgaria, and the National Museum of Bulgarian-Soviet Friendship. Plovdiv also has some well-known museums, particularly for archaeology and ethnography, and other important archaeological museums are in Stara Zagora, Burgas, and Varna. Regional specialist museums are also popular. The major state libraries include the Cyril and Methodius National Library and the Central Library of the Bulgarian Academy of Sciences, both in Sofia.

The highest research institution in the country is the Bulgarian Academy of Sciences. It is involved in international cooperative projects and has cultural treaties with other eastern European countries and with some research institutes in the West.

Recreation. *Festivals.* Bulgaria observes many festivals and competitions. Examples are the International Folklore Festival, held early in August in Burgas, and the Varna Summer International Festival, primarily a music festival, held in July. Historical plays are popular, particularly when staged outdoors in summer against the natural backdrop of important monuments or buildings associated with events in the country's history. The local festivals provide an opportunity for new musical and literary works to be performed.

The blossoming of the roses in the Karlovo and Kazanlŭk valleys is celebrated in May and June; the oil-bearing roses are collected for production of attar of roses, which is exported worldwide.

Sport and physical education. The state-run Union of Physical Education and Sport is responsible for building and maintaining sports facilities, training coaches, and overseeing athletics at all educational levels. Athletes have considerable sporting facilities at their disposal, including Vasil Levski Stadium, Universiada Hall, Festivalna Hall, and Students' Sports Complex in Sofia and the Palace of Sport and Culture in Varna; many regional centres also have sports complexes for local use. The major sporting event in the country is the National Spartakiad, which organizes mass participation of sports teams, clubs, and individuals in a variety of sporting activities.

Press and broadcasting. Broadcasting is the responsibility of the Committee for Television and Radio. In addition to national and regional programs Bulgarian Radio also broadcasts in several languages to foreign countries. Bulgarian National Television produces several types of programs, including news coverage and documentaries, arts and education programs, sports broadcasts, programs for children and youth, and programs for visiting tourists. A Soviet channel also broadcasts. All mass media, including printed matter, are strictly censored. (F.W.C.)

For statistical data on the land and people of Bulgaria, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

Evidence of human habitation in the Bulgarian lands dates from the Middle Paleolithic period (100,000 to 40,000 BC). Agricultural communities appeared in the Neolithic period, and in the Bronze Age the lands were inhabited by Thracian tribes. The Thracians were eventually expelled or absorbed by Greek, Persian, and Roman colonies, but traces of their culture remain in their monuments devoted to horse worship and in the mummer (Bulgarian: *kuker*) tradition that still survives in southwestern Bulgaria. In Roman times Bulgaria was divided between the provinces of Moesia (to the north of the Balkan Mountains) and Thrace (to the south of the Balkans) and was crossed by the main land route from the west to the Middle East. The ruins of Roman towns and settlements are numerous, and extensive sites have been excavated at Plovdiv in the southwest, Varna in the northeast, and other locations.

Traces of early Thracian habitation

THE BEGINNINGS OF MODERN BULGARIA

The Slavic invasions. The story of the modern Bulgarian people begins with the Slavic invasions of the Balkan Peninsula in the 6th and 7th centuries AD, a time when Byzantium was absorbed in prolonged conflict with Persia and could not resist the incursions from the north. Ancient sources refer to two Slavic tribes north of the Danube at this time, the Slavenae and the Antae. Evidence suggests that the Slavenae, to the west, were the ancestors of the Serbs and Croatians, while the Antae moved into the regions of Bulgaria, Macedonia, and northern Greece. The Slavic tribes tilled the soil or practiced a pastoral way of life and were organized in patriarchal communities.

Arrival of the Bulgars. The name Bulgaria comes from the Bulgars, a Turkic people who are first mentioned in the sources toward the end of the 5th century AD. Living at that time in the steppes to the north of the Black Sea, the Bulgar tribes were composed of skilled, warlike horsemen governed by khans (chiefs) and boyars (nobles). The Bulgars were subdued by the Avars in the 6th century, but in 635 Khan Kubrat led a successful revolt and organized an independent tribal confederation. After Kubrat's death in 642 the Bulgars were attacked by the Khazars and dispersed. According to Byzantine sources, the Bulgars split into five groups, each under one of Kubrat's sons. One of these, Asparukh (or Isperikh), moved into Bessarabia (between the Dnestr and Prut rivers) and then crossed to the south of the Danube, where his people conquered or expelled the Slavic tribes living north of the Balkan Mountains. The Byzantine emperor Constantine IV led an army against the Bulgars but was defeated, and in 681 Byzantium recognized by treaty Bulgar control of the region between the Balkans and the Danube. This is considered to be the starting point of the Bulgarian state.

THE FIRST BULGARIAN EMPIRE

Asparukh and his successors established their court at Pliska, northeast of modern Shumen, and a religious centre at nearby Madara. Archaeological evidence suggests that the Bulgars kept their settlements distinct from those of the Slavs, from whom they accepted tribute. They maintained a mixed pastoral and agricultural economy, although much of their wealth continued to be acquired through warfare. Asparukh's successor, Tervel (701–718), helped to restore the emperor Justinian II to the Byzantine throne and was rewarded with the title "caesar." On the whole, however, relations with Byzantium were hostile, and the 8th century was marked by a long series of raids and larger campaigns in which the Byzantine forces were usually victorious. Bulgaria recovered under Khan Krum (803–814), who, after annihilating an imperial army, took the skull of the emperor Nicephorus I, lined it with silver, and made it into a drinking cup. Under Krum's successors Bulgaria enjoyed an extended period of peace with Byzantium and expanded its control over Macedonia and what is now western Yugoslavia.

Assimilation of Bulgars by Slavs. Internally, the 8th and 9th centuries saw the gradual assimilation of the Bulgars by the Slavic majority. There are almost no sources that describe this process, but it was certainly facilitated by the spread of Christianity, which provided a new basis for a common culture. Boris I of Bulgaria (852–889) was baptized a Christian in 864, at a time when the conflict between the Roman Church and the Eastern Church in Constantinople was becoming more open and intense. Although Boris' baptism was into the Eastern Church, he subsequently wavered between Rome and Constantinople until the latter was persuaded to grant de facto autonomy to Bulgaria in church affairs. The spread of Christianity was facilitated by the work of saints Cyril and Methodius, who had invented an alphabet in which to write the Slavic language (known as Old Church Slavonic or Old Bulgarian) and who had developed a Slavonic liturgy in Moravia. When Moravia committed to Rome and expelled the disciples of Cyril and Methodius, many of them resettled in Bulgaria, where they were welcomed by Boris and undertook the translation of church books and the training of priests. St. Clement and St. Naum are credited with preparing more than 3,000 priests, and they established an important church and educational centre on the shores of Lake Ohrid (Okhrid) in Macedonia.

Spread of Christianity

Bulgaria's conversion had a political dimension, for it contributed both to the growth of central authority and to the melding of Bulgars and Slavs into a unified Bulgarian people. Boris adopted Byzantine political conceptions, referring to himself as ruler "by the grace of God," and the new religion provided justification for suppressing those boyars of Bulgar origin who clung to paganism and the political and social order with which it was linked. In 889 Boris, whose faith apparently was deep and genuine, abdicated to enter a monastery. When his eldest son, Vladimir, fell under the influence of the old boyars and attempted to reestablish paganism, Boris led a coup that overthrew him. After Vladimir was deposed and blinded, Boris convened a council that confirmed Christianity as the religion of the state and moved the administrative capital from Pliska to the Slavic town of Preslav. The council conferred the throne on Boris' third son, Simeon, and Boris retired permanently to monastic life.

Reign of Simeon I. The reign of Simeon I (893–927) marked the high point of the first medieval Bulgarian state. Educated in Constantinople and imbued with great respect for the arts and Greek culture, Simeon encouraged the building of palaces and churches, the spread of monastic communities, and the translation of Greek books into Slavonic. Preslav was made into a magnificent capital that observers described as rivaling Constantinople. The artisans of its commercial quarter specialized in ceramics, stone, glass, wood, and metals, and Bulgarian tile work in the "Preslav style" surpassed its contemporary rivals and was eagerly imported by Byzantium and Kievan Rus.

Simeon was also a gifted military leader. His campaigns extended Bulgaria's borders, but he ultimately dissipated the country's strength in an effort to take Constantinople. When he died he was master of the northern Balkans, including the Serbian lands, and styled himself "Tsar of the Bulgars and Autocrat of the Greeks," but his country was near exhaustion.

Under Simeon's successors Bulgaria was beset by internal dissension provoked by the spread of Bogomilism (a dualist religious sect) and by assaults from Magyars, Pechenegs, the Rus, and Byzantines. In the campaign of 1014 the Byzantine emperor Basil II won a decisive victory, after which he blinded as many as 15,000 prisoners taken in the battle. (For this act he became known as Basil Bulgaroctonus, or Basil, Slayer of the Bulgars.) Bulgaria lost its independence in 1018, and for more than a century and a half, until 1185, remained subject to Byzantium.

THE SECOND BULGARIAN EMPIRE

With the collapse of the first Bulgarian state, the Bulgarian Church fell under the domination of Greek ecclesiastics who took control of the see of Okhrid and attempted to replace the Bulgarian Slavic liturgy with liturgy in the Greek language. Bulgarian culture was by this time too deeply rooted to be easily removed, and the Byzantine Empire, beset by the attacks of the Seljuq Turks and the disturbances of the crusaders, lacked the power to support a more forcible Hellenization. In 1185 the brothers Ivan and Peter Asen of Tŭrnovo launched a revolt to throw off Byzantine sovereignty. The Asen brothers defeated the Byzantines and forced Constantinople to recognize Bulgarian independence. Their brother and successor, Kaloyan (1197–1207), briefly accepted the supremacy of Rome in church affairs and received a royal crown from the pope. But when the patriarch at Constantinople again recognized the independence of the Bulgarian Church, Kaloyan reverted to Orthodoxy.

The Second Bulgarian Empire, with its centre at Tŭrnovo, reached its height during the reign of Tsar Ivan Asen II (1218–41). Bulgaria was then the leading power in the Balkans, holding sway over Albania, Epirus, Macedonia, and Western Thrace. During this period the first Bulgarian coinage appeared, and in 1235 the head of the Bulgarian Church received the title of patriarch.

The successors of Ivan Asen II could not match his ability. Moreover, Bulgaria was beset by Mongol attacks from the north and by internal upheavals brought on by the growing burdens placed on the peasantry by the powerful nobles. The great peasant revolt of 1277–80 briefly allowed the swineherd Ivaylo to occupy the royal throne at Tŭrnovo before he was defeated with the aid of the Byzantines. The Asen dynasty died out in 1280 and was followed by two others, both of Cuman origin, neither of which succeeded in restoring central authority. The declining state reached its nadir in 1330 when Tsar Mikhail Shishman was defeated and slain by the Serbs at the battle of Velbuzhd (modern Kyustendil). Bulgaria lost its Macedonian lands to the Serbian Empire of Stefan Dušan, which then became the dominant Balkan power. Bulgaria appeared to be on the point of disintegration into feudal states when the invasions of the Ottoman Turks began.

OTTOMAN RULE

The Ottoman Turks first entered the Balkans as mercenaries of Byzantium in the 1340s, and they returned as invaders in their own right during the following decade. Between 1359 and 1362 Sultan Murad I wrested much of

Thrace from Byzantine control and captured Adrianople, commanding the route up the Maritsa Valley into the heart of the Bulgarian lands. In 1364 the Turks defeated a crusade sent by Pope Urban V to regain Adrianople, but not before the crusaders committed so many atrocities against the Orthodox Christians that many Bulgarians came to regard Turkish rule as preferable to alliance with the Roman Catholic West. Although Ivan Shishman, Bulgaria's last medieval tsar, declared himself a vassal of Murad in 1371, the Ottomans continued to seek complete domination. Sofia, in the west, was seized in 1382, and Shumen, in the east, fell in 1388. A year later the defeat of the Serbs on Kosovo Plain sealed the fate of the entire Balkan Peninsula. In 1393, after a three-month siege, Tŭrnovo was taken and burned. Ivan Shishman died in Turkish captivity three years later. With the capture of a rump Bulgarian kingdom centred at Bdin (Vidin) in 1396, the last remnant of Bulgarian independence disappeared.

The "Turkish yoke." The five centuries from 1396 to 1878 are engraved in Bulgarian consciousness as the era of the "Turkish yoke," traditionally seen as a period of darkness and suffering. Both national and ecclesiastical independence were lost. The Bulgarian nobility was destroyed—its members either perished, fled, or accepted Islām and Turkicization—and the peasantry was enserfed to Turkish masters. The "blood tax" took a periodic levy of male children for conversion to Islām and service in the Janissary Corps of the Ottoman army. The picture was not entirely negative, however. Once completed, the Turkish conquest included Bulgaria in a "pax ottomanica" that was a marked contrast to the preceding centuries of war and conflict. While Ottoman power was growing or at its height it provided an acceptable way of life for the Bulgarian population. It was only when the empire was in its decline and unable to control the depredations of local officials or maintain reasonable order that the Bulgarians found Ottoman rule unbearable.

Bulgaria did not change radically in its religious or ethnic composition during the Ottoman period, for the Turks did not attempt to forcibly populate Bulgaria with Turks or to convert all Bulgarians to Islām. With the exception of the people of the Rhodope Mountains who did convert (and thence were called Pomaks), the Bulgarian population remained within the Orthodox Church. Although Turkish administrators were established in the towns and countryside, Turkish peasants were not settled in Bulgaria in large numbers, and those who did immigrate were concentrated in the southern and eastern parts of the country and in some of the valleys of Macedonia and Thrace. In the 15th and 16th centuries Turkish authorities permitted the immigration of Jewish refugees from the Christian West. While the majority were resettled in Constantinople and Salonika, most Bulgarian towns acquired small Jewish communities.

Ottoman administration. At the time Bulgaria was conquered, the Ottoman Empire was divided into two parts for administrative purposes. Bulgaria was part of the European section, called Rumelia, headed by a *beylerbey* ("lord of lords") who resided in Sofia. As the empire expanded, this system proved inadequate, and in the 16th century it was replaced by territorial divisions called *vilayet*s (provinces), further subdivided into *sanjak*s (districts). The borders of these units changed many times over the centuries. Bulgarian lands were assigned as fiefs to Turkish warriors, or *spahi*s, who could impose taxes and other obligations on the subject population. Fiefs were also given to governors and other officeholders to provide their income, and lands in the form of *vakıf*s—designated for the support of religious, educational, or charitable enterprises—were assigned to specific institutions. The *spahi* had no right of lordship or justice over the peasants living in his fief, and the Bulgarians frequently retained their traditional village administration and the customs of local law with regard to issues in which Turkish interests were not involved.

Decline of the Ottoman Empire. The decline of the Ottoman Empire was marked by military defeats at the hands of Christian Europe and by a weakening of central authority. Both of these factors were significant for developments in Bulgaria. As the empire was thrown on the defensive, the Christian powers, first Austria and then Russia, saw the Bulgarian Christians as potential allies. Austrian propaganda helped to provoke an uprising at Tŭrnovo in 1598, and two others occurred in 1686 and 1688 after the Turks were forced to lift the siege of Vienna. Under Catherine the Great, Russia began to assert itself as the protector of the Orthodox population of the Ottoman Empire, a claim that the Sublime Porte (as the government of the empire was called) was forced to recognize in the Treaty of Küçük Kaynarca in 1774. Of greater significance, however, was the inability of the central government to keep the *spahi*s and local officials under control. During the 17th and 18th centuries the *spahi*s succeeded in converting their fiefs to *chifliks*, hereditary estates that could not be regulated by the government. Owners of *chiflik*s were free to impose higher obligations on the peasantry or to drive them off the land. Turkish refugees from lands liberated by Christian states were frequently resettled on *chifliks* in Bulgaria, increasing the pressure on the land and the burden on the peasantry. Occasionally, Turkish refugees formed marauding bands that could not be subdued by central authority and that exacted a heavy toll from their Christian victims. One response among the Bulgarians was a strengthening of the *haiduk* tradition. The *haiduk*s were guerrillas—some would say bandits—who took to the mountains to live by robbing the Turks. Although the *haiduk*s lacked a strong sense of national consciousness, they kept alive a spirit of resistance and gave rise to legends that inspired later revolts.

THE NATIONAL REVIVAL

In the 19th century growing Bulgarian discontent was given direction in a movement of national revival that restored Bulgarian national consciousness and prepared the way for independence. The social foundation of this movement was produced by the quickening of economic life in the late 18th and early 19th centuries and by the influence of the Enlightenment and the French Revolution, echoes of which, however faint, were heard among the people. A growing demand for cotton cloth and other products stimulated urban development. A number of Bulgarian merchant houses were founded, and artisans in the towns began to form guild organizations (*esnafi*). The latter played an important role in sponsoring schools and providing scholarships for young Bulgarians to study abroad.

Paisiy of Khilendar

The monk Paisiy of the Khilendar Monastery on Mount Athos is recognized as the founder of the national revival. Little is known of his life except that he came from a merchant family in Bansko, a town in southwestern Bulgaria that maintained commercial relations with Vienna. In the 1760s Paisiy used texts preserved on Mount Athos to write his "Slaveno-Bulgarian History." It reminded Bulgarians of the greatness of their past empires and called on them to foreswear foreign tongues and customs and to take pride in their race. Sofroniy, Bishop of Vratsa, helped to spread Paisiy's influence. In his own writings he stressed the importance of education, without which his people would remain, in his words, "dumb animals."

Spread of education. The spread of education was in fact the centrepiece of the Bulgarian national revival. In 1835 Vasil Aprilov founded a Lancasterian school, based on the monitorial system of instruction, in Gabrovo. With the monk Neofit Rilski (Neophyte of Rila) as its teacher, it was the first school to teach in Bulgarian. Its work was facilitated by the appearance of a Bulgarian publishing industry and a small but influential periodical press. By the 1870s the guilds, town and village councils, and wealthy groups and individuals founded some 2,000 schools in Bulgaria, each providing free education. The school was supplemented with the *chitalishte,* or "reading room," an institution that first appeared in Svishtov in 1856 but soon spread throughout the country. More than just a small library, the *chitalishte* staged lectures, meetings, plays, concerts, debates, and social events. It was of immense importance for those who did not acquire formal education.

Cultural movement against Greek influence. The cultivation of Bulgarian national consciousness was initially a cultural rather than a political movement. Consequently, it was directed more against the "cultural yoke" of the Greeks than the "political yoke" of the Ottoman Empire. After the Turkish conquest of the Balkans, the Greek patriarch had become the representative of the *Rūm millet,* or the "Roman nation," which comprised all the subject Christian nationalities.

The desire to restore an independent Bulgarian church was a principal goal of the national "awakeners." Their efforts were rewarded in 1870 when the Sublime Porte issued a decree establishing an autocephalous Bulgarian church, headed by an exarch, with jurisdiction over the 15 dioceses of Bulgaria and Macedonia. Although the Greek patriarch refused to recognize this church and excommunicated its adherents, it became a leading force in Bulgarian life, representing Bulgarian interests at the Sublime Porte and sponsoring the further expansion of Bulgarian churches and schools. After the liberation of 1878 it provided a powerful means of spreading Bulgarian national feeling in Macedonia.

The national revolution. The creation of the Bulgarian exarchate was the high point of the national revival as a cultural movement. The inability of the Sublime Porte to maintain order or to carry through its program of reform known as Tanzimat (1839–76), combined with the examples of Greek and Serbian independence, engendered an explicitly revolutionary movement among the Bulgarians. Inspired by the *haiduk* tradition, Georgi Rakovski formed a Bulgarian legion on Serbian territory in 1862 to send armed bands to harass the Turks in Bulgaria. In 1866 Lyuben Karavelov and Vasil Levski created a Bulgarian Secret Central Committee in Bucharest to prepare for a national uprising. It dispatched "apostles" into Bulgaria to spread the message among the people. Levski was captured during one such mission and was hanged in Sofia. He is considered to be the greatest hero of the revolutionary movement.

Uprising of 1876

Against the background of a wider Balkan crisis, the Bulgarian revolutionary committees laid plans for a nationwide uprising in 1876. The April Uprising began prematurely and was violently put down. The atrocities committed against the civilian population by irregular Turkish forces, including the massacre of 15,000 Bulgarians near Plovdiv, increased the Bulgarian desire for independence and outraged public opinion in Europe. A conference of European statesmen proposed a series of reforms, but when the Sultan refused to implement them Russia declared war. In the ensuing campaign Bulgarian volunteer forces fought alongside the Russian army, earning particular distinction in the epic battle for the Shipka Pass.

Treaty of San Stefano (1878). Advancing to the outskirts of Constantinople, the Russians dictated the Treaty of San Stefano, which called for a large independent Bulgaria stretching from the Danube to the Aegean and from the Vardar and Morava valleys to the Black Sea. The boundaries stated in the treaty, signed on March 3, 1878, represented the fulfillment of Bulgaria's territorial aspirations and remained for generations the national ideal of the people. But the creation of a large Bulgaria, perceived as an outpost of Russian influence in the Balkans, was intolerable to Austria-Hungary and Britain, and they forced a revision of the Treaty of San Stefano a few months later at the Congress of Berlin. The new Treaty of Berlin (July 13, 1878) created a much smaller Bulgarian principality, autonomous but under the sovereignty of the Sublime Porte, in the territory between the Danube and the Balkan Mountains. To the south, the treaty created the autonomous province of Eastern Rumelia, subject to the sultan but with a Christian governor. Macedonia was returned entirely to the Ottoman Empire. The treaty also stipulated that Bulgaria would elect an assembly of notables to meet at Tŭrnovo to prepare a constitution and to choose a prince who would be confirmed by the powers.

Land reform after liberation

The liberation of Bulgaria from Turkish rule also functioned as a land reform, for Russian occupation authorities and subsequent Bulgarian governments confiscated the Turkish estates and sold them in small parcels to the peasantry. Bulgaria began its independence as a nation of smallholders with one of the most equalitarian land distributions in Europe.

THE PRINCIPALITY

By the time the constituent assembly convened in Tŭrnovo in February 1879, conservative and liberal political tendencies had emerged and rapidly coalesced into parties. The Liberal Party, under Dragan Tsankov, Karavelov, and Petko Slaveikov, dominated the assembly and created a constitution that was one of the most democratic in Europe. It provided for a single National Assembly elected by universal male suffrage, guarantees of civil rights, and strict limits on the power of the prince.

Political divisions under Alexander of Battenberg. The democratic character of the constitution and sympathies of Liberal Party political leaders were at variance with the views of Bulgaria's first prince, Alexander of Battenberg (a nephew of the Tsar), and with those of the Russian advisers who played a large role in his court. The Prince first formed a Conservative ministry, but he was forced by popular agitation to form a Liberal government under Tsankov. Tsankov's government undertook the construction of judicial and state apparatuses and put an end to the depredations of brigands who had remained active in the mountains after the war. But when the Liberals showed, in the eyes of the Prince, insufficient respect for the institution of monarchy and engaged in a campaign to diminish Russian influence, Alexander dismissed them in favour of a Conservative government led by General Casimir Erenroth, a Finn in Russian service, who had earlier been charged with setting up the Bulgarian Army. Erenroth used rigged elections to select a Grand National Assembly, which agreed in 1881 to suspend the constitution and invest the Prince with absolute powers for seven years. A period of dictatorship followed under the Conservatives and the Russian generals Leonid N. Sobolev and Alexander V. Kaulbars. Alexander, however, soon found his Russian allies harder to deal with than their Liberal predecessors. In September 1883 he compromised with his opponents, dismissed the Russians, restored the constitution, and accepted a coalition Conservative–Liberal government, but the coalition was soon supplanted by an entirely Liberal government under Petko Karavelov, the brother of Lyuben.

Eastern Rumelia's union with Bulgaria

Meanwhile, popular sentiment for union with Bulgaria had been growing in Eastern Rumelia, and the restoration of the constitution provided the Eastern Rumelian allies of Bulgaria's Liberal Party with the stimulus to prepare for a seizure of power in Plovdiv. In September 1885, with the prior approval of Prince Alexander, they staged a bloodless coup d'état and declared the unification of the two states. Turkey did not resist, but Russia, incensed by such independence of action in its diplomatic sphere, refused to approve, and Tsar Alexander III ordered the withdrawal of all Russian officers and advisers in the Bulgarian Army. In these circumstances, King Milan of Serbia, stating that the balance of power in the Balkans was endangered by Bulgarian unification, suddenly declared war. The Serbs advanced as far as Slivnitsa, where they were met and defeated by the untrained Bulgarian army under Prince Alexander's command. Bulgarian forces pursued the Serbs across the frontier but were stopped by the threat of Austrian intervention. Peace and the status quo were restored by the Treaty of Bucharest (March 3, 1886) and the convention of Tophane (April 5, 1886). Prince Alexander was appointed governor general of Eastern Rumelia and the Eastern Rumelian administrative and military forces were merged with those of Bulgaria.

Prince Alexander had little time to enjoy the fruits of his popular triumph. On Aug. 21, 1886, a group of Russophile conspirators and military officers whom Alexander had passed over for promotion seized the Prince in his palace, forced him to sign a statement of abdication, transported him out of the country, and handed him over to the Russians at the Danube port of Reni. The conspiracy was countered, however, by Stefan Nikolov Stambolov, president of the National Assembly, and by Lieutenant Colonel Sava Mutkurov, commander of the Plovdiv garrison, who took control of Sofia and recalled the Prince. Alexander was not detained by the Russians, but he refused to remain in Bulgaria without Russian approval. When the Tsar refused to give it, Alexander abdicated on September 7, appointing a regency composed of Stambolov, Mutkurov, and Petko Karavelov. The regency was successful in preserving order but had great difficulty finding a new prince, for few wished to assume the throne in the face of Russian hostility. A willing candidate was at last found in the person of 26-year-old Prince Ferdinand of Saxe-Coburg-Gotha, a grandson of Louis-Philippe of France, who was then serving as an officer in the Austrian army. Ferdinand was elected prince by the Grand National Assembly in July 1887.

Prince Ferdinand's rule. Because Russia declared Ferdinand a usurper, Europe withheld recognition, the bishops of the Holy Synod would not pay him homage, and conspiracies flourished. However, Stambolov, as prime minister from 1887 to 1894, ruthlessly suppressed all opposition. Stambolov, who was recognized as one of Europe's "strongmen," stabilized Bulgaria's international position, but his methods, which amounted to a virtual dictatorship, alienated much of the population. In 1894 Ferdinand unexpectedly made use of his constitutional right to dismiss Stambolov and replaced him with a Russophile government headed by a Conservative, Konstantin Stoilov. A year later the former prime minister was gunned down on the streets of Sofia, apparently by some of those he had earlier persecuted.

Dismissal and death of Stambolov

The change of course in Sofia and the death of Tsar Alexander III facilitated a reconciliation between Bulgaria and Russia. Ferdinand gained international recognition as prince, and in 1896 Tsar Nicholas II stood godfather to Ferdinand's first son when he was baptized into the Orthodox faith.

The failure of Bulgarian democracy. *Breakdown of two-party system.* From the time of the liberation, political power was exercised by a politically active elite composed of the country's few large landowners, merchants, lawyers, clergy, officers, teachers, and those educated in Bulgarian communities abroad. After the liberation these men staffed the country's civilian and military bureaucracies. By the mid-1880s their number expanded far beyond the capacity of the country to absorb them effectively, and the educational system continued to generate a large surplus of lawyers, journalists, and literati who had little hope for careers outside the government. The result was the breakdown of the two-party system, an intensified struggle for the spoils of office, a proliferation of bureaucracy, and pervasive corruption. Between 1884 and the end of the century, splits in the ranks of Conservatives and Liberals gave rise to nine parties. There were few, if any, differences in principle among them, and they were, in the words of one participant, "partnerships for the exploitation of power." The peasantry, which made up four-fifths of the population, lacked the education, organization, and experience to act as a brake on political degeneration.

Economic stagnation. The loss of free access to Ottoman markets and the lack of available capital largely offset the economic advantages gained by the liberation. Moreover, Bulgarian governments did little to encourage industrialization, preferring to use the state budget to finance the growth of bureaucracy and to maintain as powerful an army as possible in the hope of territorial expansion. Bulgarian military expenditures on a per capita basis were the highest in Europe and brought the country the reputation of being "the Prussia of the Balkans." In the countryside the long-term factors of low agricultural productivity, declining world grain prices, and steady population growth were reinforced by government policies that imposed increasing burdens of taxation and indebtedness.

The Socialist movement and the Bulgarian Agrarian Union. In the last decade of the 19th century these conditions gave rise to two movements of political protest that would significantly affect Bulgaria's future. One was the appearance of a Socialist movement that drew its inspiration from Karl Marx and the European Socialist parties. The schoolteacher Dimitŭr Blagoev, who as a student in Russia had formed the first Marxist group in that country, inspired the creation of a Bulgarian Socialist party in 1891. Given Bulgaria's minuscule proletariat, Marxist socialism had little chance to become a mass movement, but it remained an influential force among the country's intelligentsia. Of greater immediate importance was the emergence in the countryside of an alliance between the peasantry and the rural intelligentsia. This acquired organizational form in 1899 with the founding of the Bulgarian Agrarian Union (later the Bulgarian Agrarian National Union). Created as a nonpartisan interest group to promote peasant welfare, the Agrarian Union was pushed into politics by the unrest and violence that followed the government's attempt to reintroduce the Turkish tithe on agricultural production in 1900. Under the leadership of Aleksandŭr Stamboliyski, who developed a distinct agrarian ideology and program, the Agrarian Union grew rapidly and was the largest opposition party in the country on the eve of the Balkan Wars.

Leadership of Aleksandŭr Stamboliyski

Ferdinand's "personal regime." The period from Stefan Stambolov's fall in 1894 to World War I is known as the era of Ferdinand's "personal regime." By encouraging the fragmentation of the political parties and by skillfully using his powers of patronage to manipulate the party chiefs, Ferdinand became the dominant political figure in the country. In 1908, in conjunction with the Austrian annexation of Bosnia and Hercegovina, he proclaimed the de jure independence of Bulgaria from the Sublime Porte and assumed the title "tsar." Three years later a Grand National Assembly amended the constitution to give him this title officially and to grant him the right to conclude treaties with foreign states without the knowledge of the National Assembly.

Macedonia constituted the principal objective of Ferdinand's diplomacy. On July 20, 1903, the Macedonian Bulgarians revolted against Ottoman rule. Their revolt—known as the Ilinden (St. Elijah's Day) Uprising—and the brutality with which it was put down again focused attention on the problems of Turkish misrule in Macedonia, and in 1908 the revolution of the Young Turks led Balkan statesmen to believe that the time was fast approaching when Macedonia could be wrested from the empire. Greece and Serbia, however, laid claim to portions of Macedonia that Bulgarians regarded as rightfully theirs. It was the great mistake of Bulgarian diplomacy to organize a war against the Ottoman Empire without first clearly resolving these competing claims.

Unresolved claims to Macedonia

In March 1911, against the background of increasing unrest in Macedonia, Ferdinand appointed a new government under Ivan Geshov to begin negotiations for an anti-Turkish alliance. In May 1912 Bulgaria signed a treaty with Serbia providing for military cooperation but leaving a large section of Macedonia as a contested zone, the fate of which would be determined after the war. A quickly made agreement with Greece also made no provision for the future distribution of territory. An arrangement between Greece and Serbia and verbal agreements with Montenegro completed the formation of the Balkan League. Montenegro declared war on the Ottoman Empire on October 8, and the other Balkan states soon entered the conflict.

Bulgaria's participation in the First and Second Balkan wars. The successes of the Balkan League exceeded expectations. Bulgarian forces won major victories at Lozengrad (now Kırklareli) and Lüleburgaz and laid siege to Adrianople and the Çatalca line of fortifications defending Constantinople, while the Greeks took Salonika and Serbian troops won a series of battles in Macedonia. Turkey asked for an armistice, but Ferdinand insisted that the army attempt to capture Constantinople. When the assault on the Çatalca line failed, leaving the Bulgarian army in a weakened state, the Tsar agreed to the armistice, and peace negotiations began in London. On May 30, 1913, Turkey signed the Treaty of London, conceding all but a small strip of its European territory. But it proved impossible to divide the territory peacefully among the victors. Serbia and Greece insisted on retaining most of the Macedonian territory they had occupied, and Romania demanded compensation for its neutrality. When Geshov was not able to negotiate a compromise he resigned in favour of Stoyan Danev, who reflected the Tsar's desire for a military solution. On the night of June 29/30 Bulgarian forces began the Second Balkan War by launching a surprise assault on Greek and Serbian positions in Macedonia. As

Second Balkan War

the Bulgarian attack was being repulsed, Romanian troops began an uncontested march toward Sofia from the north, and Turkey reoccupied the fortress of Adrianople. By the Treaty of Bucharest (Aug. 10, 1913), Romania took the rich lands of the southern Dobruja and the city of Silistra, while Serbia and Greece divided the larger part of Macedonia between them. From its gains in the First Balkan War, Bulgaria retained only a small part of eastern Macedonia, the Pirin region, and a portion of eastern Thrace. This was poor compensation for the loss of the southern Dobruja and of the Bulgarian exarchate in Macedonia. Consequently, the desire to win back what had been lost was the main motivating factor in Bulgaria's diplomacy when World War I began.

WORLD WAR I

Bulgaria's alliance with the Central Powers. When World War I began, Bulgaria declared strict neutrality, but the Tsar and a Germanophile government under Vasil Radoslavov encouraged both sides to bid for Bulgarian intervention. In this contest, the Central Powers (Austria-Hungary and the German Empire) could offer far more at the expense of Serbia, Greece, and, later, Romania, than could the Triple Entente (an alliance of Great Britain, France, and Russia), which had to take the interests of its smaller allies into account. During the summer of 1915, when the military balance swung in Germany's favour, Bulgaria committed to the Central Powers, and Bulgaria declared war on Serbia on October 14. Some of the neutralist and pro-Entente political figures objected, but none went as far as the Agrarian leader Stamboliyski, who threatened the Tsar and issued a call for the troops to resist mobilization. For these acts he was arrested and condemned to life imprisonment.

Bulgaria's losses. By the autumn of 1918 approximately 900,000 men, nearly 40 percent of the male population, had been conscripted. The army suffered 300,000 casualties, including 100,000 killed, the most severe per capita losses of any country involved in the war. In the interior, bad weather and the absence of adult male labour cut grain production nearly in half, while the town population suffered from shortages of food and fuel and from runaway inflation. "Women's riots" for food began early in 1917 and continued to the end of the war. The revolutions in Russia and the hopes inspired by American intervention in the war and by U.S. president Woodrow Wilson's Fourteen Points peace plan further contributed to the breakdown of civilian order and military discipline. In June 1918 the replacement of the pro-German Radoslavov by Alexander Malinov, a leader of the parliamentary opposition, raised hopes for an end to the war, but instead frustration increased as Malinov yielded to Tsar Ferdinand's determination to fight on.

Domestic disorder. On Sept. 15, 1918, the Allied forces on the Macedonian front broke through the Bulgarian lines at Dobropol'ye. The army dissolved as many of the troops deserted to return home while others began a march on Sofia to punish the Tsar and party leaders responsible for the war. Ferdinand turned to Stamboliyski, releasing the Agrarian leader from prison in return for his promise to use his influence to restore order among the troops. Stamboliyski, however, joined the uprising and, at the village of Radomir, where rebel troops were encamped, proclaimed Bulgaria a republic. The Radomir Rebellion was short-lived as the Agrarian-led assault on Sofia was repulsed by German and Macedonian forces that remained loyal to the Tsar. But this provided only a temporary respite. The Bulgarian government asked the Allies for an armistice, which was signed on September 29. Four days later Tsar Ferdinand abdicated in favour of his son Boris III and left the country.

Consequences of the war. Bulgaria was punished for its part in World War I by the Treaty of Neuilly, which assigned the southern portion of the Dobruja region to Romania, a strip of western territory including Tsaribrod and Strumitsa to the Kingdom of Serbs, Croats, and Slovenes (modern Yugoslavia), and the Aegean territories gained in the Balkan Wars to the Allies, who turned them over to Greece at the Conference of San Remo in 1920. Bulgaria was also disarmed and subjected to a heavy burden of reparations.

Postwar politics and government. Defeat and the hardships of war broke the hold of Bulgaria's traditional parties on the government. In the first two postwar elections the Agrarians, Communists, and Socialists together polled first 59 percent and then 65 percent of the ballots. These parties were not united, however, and a Communist-led general strike in the winter of 1919–20 was ruthlessly put down by Stamboliyski, who became prime minister first in coalition with smaller conservative parties and then as head of an all-Agrarian cabinet.

Programs of the Agrarian Union. The years from 1920 to 1923 represented a remarkable period in which the Agrarian Union sought to translate into reality the beliefs and ideas developed in its years in opposition. The Agrarian government introduced a progressive income tax and a land reform directed against the country's few large estates and against absentee ownership, sponsored the spread of cooperative organizations in agriculture and other branches of the economy, and undertook a massive expansion of the school system, providing, among other things, for free, compulsory secondary education. The Agrarians also introduced the practice of compulsory labour service, by which all young men were required to contribute a year's labour on state projects in lieu of military conscription.

Stamboliyski's foreign policy. Stamboliyski abandoned the traditional Bulgarian goal of territorial expansion, which had required huge military budgets, a standing army and professional officer corps, and the patronage of the great powers. His policy aimed, above all, to cultivate good relations with the Kingdom of Serbs, Croats, and Slovenes by accepting the status quo in Macedonia.

Stamboliyski's policies alienated the old political leaders, the Military League (composed of active and reserve officers), and Tsar Boris' court. Influenced by the successes of Benito Mussolini's Fascist organization (known as the Blackshirts) in Italy, the rightist parties united in the National Alliance (later called Democratic Alliance) and planned to march on Sofia to wrest control of the country. On the left, the Communists viewed the Agrarian government as their principal opponent. But the most dangerous enemies were the Military League and the Internal Macedonian Revolutionary Organization (IMRO). IMRO established effective control over the Pirin region and launched terrorist attacks across the border into Yugoslav and Greek Macedonia. It also assassinated several Agrarian leaders. Unable to rely on the Bulgarian military against the Macedonian terrorists, Stamboliyski turned to Yugoslavia; by signing the Treaty of Niš he permitted Yugoslav forces to pursue the Macedonian bands into Bulgarian territory. This treaty, combined with an overwhelming Agrarian election victory in early 1923, led Stamboliyski's opponents to plan a coup d'état. The coup was organized by the Military League, IMRO, and the old parties, and it probably had the support of Tsar Boris III. When it was launched on the night of June 8–9, 1923, it took the Agrarian government by surprise. Stamboliyski was captured a few days later and brutally murdered, and a right-wing government under Aleksandŭr Tsankov took his place.

Stamboliyski's overthrow

The Communist Uprising. The Bulgarian Communists, who had declared their neutrality when the coup occurred, were chastised by Moscow and directed to prepare an armed revolt against the Tsankov regime. The Communists' September Uprising was put down with great brutality and provided Tsankov with a pretext for outlawing the party. The Communists struck back in 1925 with an attempt to assassinate the Tsar and leaders of the government by blowing up Sofia's Sveta Nedelya Cathedral during services. Although 123 people were killed and hundreds more wounded, the main targets escaped, and the government exacted brutal reprisals. As a result of the defeats suffered in 1923 and 1925, many of Bulgaria's Communist leaders escaped abroad, finding positions in the Soviet Union or the Comintern (Communist International), and one, Georgi Mikhailovich Dimitrov, achieved international fame as the chief defendant in the Reichstag

Fire trial of 1933. So great was his standing that, following his acquittal, Stalin had him appointed secretary general of the Comintern, a position he held until that body was dissolved in 1943.

Attempts to stabilize government. After 1925 Bulgarian political life began a slow recovery. In January 1926 Tsankov yielded the premiership to the more moderate Andrei Liapchev. A gradual and qualified return to a free press and parliamentary politics marked his five-year tenure, although assassinations and other terrorist acts by IMRO continued and soured Bulgaria's relations with Yugoslavia and Greece. In 1931 a reconstituted opposition called the Popular Bloc, a coalition that included the Agrarian Union, defeated the Democratic Alliance and pledged to restore full democracy.

The Popular Bloc government came to power during a period of economic crisis brought on by the world depression. Its inability to alleviate the economic situation led to further political instability and a rising tide of labour unrest. On the night of May 18–19, 1934, the Military League carried out a peaceful coup d'état that installed Kimon Georgiev as prime minister. The ideology of the new regime was supplied by an elitist group called Zveno ("a link in a chain"), which drew its membership from intellectual, commercial, and military circles. Inspired by the former Socialist Dimo Kazasov, Zveno advocated "national restoration" through an authoritarian, technocratic regime. The "divisive forces" associated with parliamentary politics were eliminated by the suspension of the constitution and the suppression of all political parties. A new assembly was created, composed of individuals without party affiliation and elected from approved government lists.

The new regime was able to suppress IMRO gangsterism and restore the government's authority over Pirin Macedonia, but its political base was too narrow to allow it to consolidate power firmly. The real beneficiary of the 1934 coup was Tsar Boris III. By the end of 1935 he had relied on his own clique in the army to unseat and jail Georgiev, purge the Military League, and install a subservient government under Georgi K'oseivanov. Bulgaria thus ended the 1930s as a royal-military dictatorship, the form of government that had become nearly universal in eastern Europe.

WORLD WAR II

Boris' alliance with Germany. When World War II began in Europe, Bulgaria proclaimed neutrality. Tsar Boris, however, appointed a new government under a notorious Germanophile, Bogdan Filov, and moved steadily closer to the German orbit, particularly after Germany forced Romania to restore the southern Dobruja to Bulgaria in August 1940. The desire for territorial expansion at the expense of Yugoslavia and Greece and the expectation of a German victory led Boris to join the Axis on March 1, 1941. German troops used Bulgaria as a base from which to attack Yugoslavia and Greece, and in return Bulgarian forces were permitted to occupy Greek Thrace, Yugoslav Macedonia, and part of Serbia. After the German invasion of the Soviet Union and the Japanese attack on the U.S. naval installation at Pearl Harbor, Bulgaria yielded to German pressure to declare war on Great Britain and the United States, a move that was regarded as of only symbolic importance, but Tsar Boris avoided joining the war against the Soviet Union, fearing that this would lead to popular unrest.

Bulgaria was relatively untouched by military operations until the summer of 1943, when Allied bombers began to attack rail and industrial centres. The government complied with German requests to deport the Jews of the occupied territories to the concentration camp at Treblinka, but Tsar Boris cancelled orders for the deportation of the rest of Bulgaria's Jews in the face of protests led by prominent political figures and Metropolitan Stefan, head of the Bulgarian Orthodox Church.

Bulgarian resistance to the Axis alliance. Some attempts at forming a resistance were made by Agrarian leaders when Bulgaria joined the Axis. After the German attack on the Soviet Union, however, it was the Bulgarian Communist Party that assumed the initiative inside the country. Until the final stage of the war, the tactics of the resistance emphasized sabotage and small-group operations. About 10,000 persons are estimated to have participated, making it the largest resistance movement among any of Germany's allies. Politically, the Communists sought the cooperation of other opposition groups, and in August 1943 the Fatherland Front was formed, composed of Communists, left-Agrarians, Zveno, the Socialists, and some independent political figures. The Front's influence grew as the military situation of Germany deteriorated.

Many Bulgarians expected Tsar Boris to break with the German alliance when circumstances permitted. On Aug. 28, 1943, however, the Tsar suffered a fatal heart attack. Because his son and heir, Simeon II, was only six years old, Filov established a Regency Council headed by himself and appointed a new government under Dobri Bozhilov that remained loyal to the German alliance. In May 1944, faced with the continuing German collapse and stern Allied threats that Germany's allies would be severely punished, Bozhilov resigned. He was replaced with the right-Agrarian Ivan Bagrianov, who began secret negotiations for surrender with the Allies but at a snail's pace. At the end of August, the sudden surrender of Romania, which brought Soviet troops to the Danube months before they had been expected, created panic in Sofia. When Bagrianov's attempt to proclaim Bulgarian neutrality was rejected as insufficient by both Britain and the Soviet Union, the prime minister resigned and was replaced by Kosta Muraviev of the Agrarian Union, who reiterated a proclamation of neutrality. Four days later, on Sept. 5, 1944, the Soviet Union declared war on Bulgaria, and Soviet forces began to enter the country unopposed. Simultaneously, the Fatherland Front began preparations for a coup d'état. Despite Muraviev's declaration of war against Germany on September 8, during that night military forces organized by Zveno and partisan detachments occupied key points in Sofia and toppled Muraviev's government in the name of the Fatherland Front. Kimon Georgiev of Zveno became the new prime minister and sought an immediate armistice with the Soviet command.

THE POSTWAR ERA

Consolidation of Communist power. The consolidation of Communist power in Bulgaria was carried out by 1948, coinciding with the completion of the peace treaty with the Allies and the presence of Soviet occupation forces. In the coalition Fatherland Front government, the Communists enjoyed control of the interior and judicial ministries, which were crucial in setting up the new state. Taking advantage of the popular feeling that those who were responsible for Bulgaria's involvement in the war should be punished, the regime established "people's courts" to prosecute the political leaders of the wartime period. The first mass trial, lasting from Dec. 20, 1944, to Feb. 1, 1945, resulted in death sentences for three of the Tsar's former regents, 28 former ministers, 68 members of parliament, and an adviser to the Tsar. Other defendants received long prison sentences. According to official statistics, by the time the people's courts completed their work in April 1945, they had tried 11,122 people, of which 2,730 were condemned to death, 1,305 to life imprisonment, and 5,119 to terms of up to 20 years. Unofficial estimates suggested that as many as 30,000 political opponents were killed.

The army, which was under overall Soviet command but was not yet under direct Communist control, was engaged in the final stages of the campaign against Germany. The Communists insisted on the immediate appointment of officers drawn from the partisan movement, and by the time the regular army returned, the party was in a position to carry through a purge of the officer corps.

Return of Dimitrov from exile

On Nov. 4, 1945, Georgi Dimitrov returned to Bulgaria after 22 years of exile. The belligerent tone with which he referred to the opposition in his first public address was a clear indication of his party's intentions.

Given the Communist Party's control of the instruments of power, the hopes of the non-Communist opposition rested on the Western democracies. Indeed, during the summer of 1945 the regime postponed parliamentary elections after Great Britain and the United States protested the undemocratic character of the proposed electoral laws. Bulgaria, however, did not have a high priority on the diplomatic agenda of the West. As early as October 1944 British prime minister Winston Churchill had shown his willingness to consign the country to Soviet control during his "percentages discussion" with Soviet premier Joseph Stalin. As the Bulgarian Communists and their Soviet sponsors became aware that the Western states were not concerned with events in Bulgaria, they moved more forcefully to eliminate the internal opposition. Elections held in November 1945 returned a substantial majority in favour of the Communists and their allies. In September 1946 a referendum decided by a 93-percent majority to proclaim Bulgaria a republic, and Tsar Simeon II and the Queen Mother were required to leave the country.

Elections of 1946

Elections for a Grand National Assembly to prepare a new constitution were held on Oct. 27, 1946. Although they produced a large Communist majority, the opposition polled more than one million votes, which amounted to 28 percent of the total. When the Assembly opened in November, the Agrarian leader Nikola Petkov emerged as the opposition's principal spokesman. He was charged by the police with plotting to overthrow the government and was expelled from parliament along with most of his associates. In June 1947 Petkov was arrested, and on September 23 he was executed. One week later the United States extended diplomatic recognition to the new regime; Great Britain had already done so in February.

The defeat of the political opposition coincided with or was followed by the elimination of nearly all elements of pluralism in Bulgarian society. This seems to have been accelerated after the founding congress of the Communist Information Bureau (Cominform) on Sept. 22–27, 1947, at Szklarska Poredba in Poland, where Andrey Aleksandrovich Zhdanov and Georgy Maksimilianovich Malenkov delivered the message that Stalin desired a more rapid transformation of the Socialist camp along Soviet lines. In Bulgaria the "intensification of the revolutionary process" saw increased pressure on the remaining non-Communist parties. Some Socialists applied to join the Bulgarian Communist Party, and those who remained in opposition were crushed by police repression. The Socialist Party was formally absorbed by the Communists in August 1948. The Agrarian leader, Georgi Traikov, repudiated his party's traditional ideology and defined a new role for it as the helpmeet or "little brother" of the Bulgarian Communist Party in the countryside. Zveno and the remaining smaller parties announced their "self-liquidation" by the beginning of 1949. They were dissolved into the Fatherland Front, which in turn was converted into a broad patriotic organization under Communist control.

The "Dimitrov Constitution"

In the Grand National Assembly a team of Soviet jurists assisted in the preparation of the "Dimitrov Constitution," which went into effect on Dec. 4, 1947. Modeled closely on the Soviet constitution of 1936, it provided a legal foundation for the reconstruction of the state on Communist principles.

Reforms under the Fatherland Front. The Fatherland Front regime had launched an assault on private property almost immediately after the coup of Sept. 9, 1944, employing a variety of legislative measures aimed at confiscating the wealth of "fascists" or "speculators." The Dimitrov Constitution provided for even larger measures of nationalization. All large-scale industries, banks, and insurance companies were nationalized, and government monopolies were established over the major items of retail trade. By the end of 1948 approximately 85 percent of industrial production was in the hands of the state, with another 7 percent carried on by cooperative organizations. The party also sponsored a reorganization of the country's trade unions, creating the General Workers' Trade Union and gradually forcing all workers' organizations into it. Similarly, the youth organizations of the various parties were incorporated into the Dimitrov Communist Youth League.

Exarch Stefan, head of the Bulgarian Orthodox Church, sought to adapt to the new political regime, but he resisted the efforts of the Bulgarian Communist Party to control church affairs directly. In September 1948 Stefan resigned his office under mysterious circumstances and retired to a monastery. His successor offered no resistance to legislation adopted in March 1949 that subjected all religious orders to state supervision. At the time this law was adopted, 15 pastors from evangelical Protestant churches were arrested, tried, and executed for espionage on behalf of the United States and Britain and for other alleged crimes. Soon afterward a number of Bulgarian Catholic clergy were tried for spying for the Vatican and for disseminating anti-Communist propaganda. The nearly 50,000 Bulgarian Jews who survived the war were encouraged to emigrate to Israel. The regime also attempted to deport ethnic Turks and Gypsies, causing the Turkish government to seal the border.

Stalinism and de-Stalinization. Traicho Kostov, who had been instrumental in supervising the defeat of the opposition, was accused of treason and of collaborating with Yugoslavia's Communist leader Josip Broz Tito against Stalinism. Kostov's execution in December 1949 was followed by the purge of thousands of "Kostovites" and others alleged to be criminals and spies.

Economic developments

Georgi Dimitrov died in office in July 1949. His immediate successor, Vasil Kolarov, died early in 1950 and was followed by Vulko Chervenkov. Known as Bulgaria's "Little Stalin," Chervenkov followed policies aimed at developing Bulgaria according to the Soviet model. These included rapid industrialization, with an emphasis on heavy industry, the forced collectivization of agriculture, heavy reliance on the police and security apparatus to control the country, and isolation from nations outside the Soviet bloc.

Stalin's death in 1953 and the inauguration of the "New Course" in the Soviet Union had repercussions in Bulgaria. In 1954 Chervenkov accepted the Soviet model of collective leadership, remaining prime minister but yielding his post as party leader to Todor Zhivkov. The government also released several thousand political prisoners and moderated its economic policies in favour of raising living standards. The beginning of open de-Stalinization at the Soviet Union's 20th Communist Party Congress in February 1956 was followed in Bulgaria by the April Plenum of the Bulgarian Communist Party, at which Chervenkov was accused of having created a personality cult and of having violated the norms of legality. Chervenkov was removed from the premiership, there was some relaxation of censorship, and the victims of the Kostovite trials, including Kostov himself (posthumously), began to be rehabilitated.

Rise of Todor Zhivkov. In the years after the April Plenum, party leader Zhivkov became the dominant figure in political life. In 1962 he became prime minister, and he continued to hold the positions of head of state and head of party until 1989. An attempted putsch led by General Ivan Todorov-Gorunya in 1965 was easily put down, and Zhivkov consistently managed to purge or undercut party leaders regarded as potential rivals.

During the era of Zhivkov's ascendancy, Bulgaria modeled its domestic policies on those of the Soviet Union. Treaties linked Bulgaria's economic development with that of the Soviet Union through the end of the 20th century. Bulgaria gave the highest priority to participation in the modern scientific-technological revolution and pursued policies aimed at industrialization and the development of a population with the education and skills appropriate to an industrial state. In 1948 approximately 80 percent of the population drew their living from the soil. In 1988 the government reported that 19 percent of the labour force was engaged in agriculture, with the rest concentrated in industry and the service sector.

In its foreign relations after the 1950s, Bulgaria abandoned the isolationism that characterized the Chervenkov period. Although remaining steadfast in its commitments to the Warsaw Pact and the Council for Mutual Economic Assistance, Bulgaria improved relations with its Balkan neighbours, particularly Greece, and expanded its economic and cultural relations with most Western states. Relations with Yugoslavia remained strained, however, over the persistence of the Macedonian issue. In 1979

Bulgaria proposed a treaty with Yugoslavia that would guarantee the inviolability of the borders established after World War II; this proposal was rejected, however, because of Bulgaria's refusal to admit the existence of a distinct Macedonian nationality. From the Bulgarian point of view, such an admission would both fly in the face of historical reality and legitimize Yugoslav claims on the Pirin region.

During the 1970s, in spite of the country's economic growth, a serious concern appeared about the low birth rate of the ethnic Bulgarian population. Numerous measures were adopted to encourage larger families, but without apparent effect. In late 1984 the government began a major effort to convert the country's ethnic Turks into Bulgarians. Measures aimed at the Turkish population, estimated to number approximately 800,000, included the abandonment of Turkish-language publications and radio broadcasts and the requirement that Turks adopt Bulgarian names. Despite these policies, the ethnic Turkish population was not assimilated, and clashes with the authorities continued. During the spring and summer of 1989, when the government of Turkey offered to accept refugees from Bulgaria, more than 300,000 ethnic Turks fled or were driven from the country in a wave of violence that focused worldwide attention on Bulgaria's violations of human rights.

The era of reforms launched by Mikhail Gorbachev in the Soviet Union had a major impact on Bulgaria, inspiring greater demands for openness and democratization. The growth and greater aggressiveness of Bulgarian dissidents, a declining economic situation, and internal party rivalries led Zhivkov's colleagues to force his resignation on Nov. 10, 1989. He was soon subjected to intense criticism for corruption and abuse of power, placed under detention, and held while a state commission prepared formal charges against him.

Post-Zhivkov reforms. Zhivkov's successors endorsed a policy of openness, pluralism, and respect for law, halted repression of the ethnic Turks, and took the first steps toward separating the Communist Party from the state. Article One of the constitution, guaranteeing the party a monopoly of power, was repealed. After some shuffling of positions, Petar Mladenov was named head of state, Andrey Lukanov prime minister, and Alexander Lilov head of the Communist Party. In early 1990 the party held an extraordinary congress that enacted significant changes in party structure and purged many of the old guard. To symbolize its break with the repressive policies of the past, it abandoned the name Communist and renamed itself the Bulgarian Socialist Party.

Bulgarian Socialist Party

In the meantime, dissident groups took advantage of the country's new freedoms to organize opposition political parties. Many of these joined the Union of Democratic Forces (UDF), a coalition led by the sociologist Zheliu Zhelev. By the spring of 1990 the UDF and the Socialists came to an agreement on the holding of free elections for a Grand National Assembly that would prepare a new constitution for the country. In these elections and subsequent runoffs, held June 10 and June 17, the Socialists won 47 percent of the vote and a narrow majority (211 of 400 seats) in the Assembly. In July 1990 Mladenov resigned after unsuccessfully attempting to conceal the fact that he had recommended a military crackdown on protesters in late 1989. Because their majority was too small to allow them to govern alone, the Socialists supported the election of opposition leader Zhelev in August. (J.D.B.)

Business Law

Business law—also called commercial law, or mercantile law—is not recognized specifically as a branch of common law but, in popular usage, is frequently an omnibus term given to titles of textbooks and academic courses on such commercial subjects as contract, agency, commercial transactions, bankruptcy, and labour. In most continental European legal systems based on Roman law, however, "commercial law," or "mercantile law," designates a branch of law distinct from "civil law"—the commercial law governing merchants or businesses engaged in acts of commerce and the civil law governing ordinary consumer transactions or other acts of persons not engaged in trade. In continental European law, the rules for the two branches differ.

The sections below deal with major branches of law relevant to business and commercial practices. The law of business partnerships and limited-liability companies, or corporations, is covered in BUSINESS ORGANIZATION. Allied branches of law may be found under PROPERTY LAW; additional aspects of labour law are treated in the article WORK AND EMPLOYMENT.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 553.

This article is divided into the following sections:

Contracts

The nature of contract law

A contract, in the simplest definition, is a promise enforceable by law. The promise may be to do something or to refrain from doing something. The making of a contract requires the mutual assent of two or more persons, one of them ordinarily making an offer and another accepting. If one of the parties fails to keep the promise, the other is entitled to legal recourse against him. The law of contracts considers such questions as whether a contract exists, what the meaning of it is, whether a contract has been broken, and what compensation is due the injured party.

HISTORICAL DEVELOPMENT

Contract law is the product of a business civilization. It will not be found, in any significant degree, in precommercial societies. Most primitive societies have other ways of enforcing the commitments of individuals; for example, through ties of kinship or by the authority of religion. In an economy based on barter, most transactions are self-enforcing because the transaction is complete on both sides at the same moment. Problems may arise if the goods exchanged are later found to be defective, but these problems will be handled through property law—with its penalties for taking or spoiling the property of another—rather than through contract law.

Even when transactions do not take the form of barter, primitive societies continue to work with notions of property rather than of promise. In early forms of credit transactions, kinship ties secured the debt, as when a tribe or a community gave hostages until the debt was paid. Other forms of security took the form of pledging land or pawning an individual into "debt slavery." Some credit arrangements were essentially self-enforcing: livestock, for example, might be entrusted to a caretaker who received for his services a fixed percentage of the offspring. In other cases—constructing a hut, clearing a field, or building a boat—enforcement of the promise to pay was more difficult but still was based on concepts of property. In other words, the claim for payment was based not on the existence of a bargain or promise but on the unjust detention of another's money or goods. When a worker sought to obtain his wages, the tendency was to argue in terms of his right to the product of his labour.

A true law of contracts—that is, of enforceable promises—implies the development of a market economy. Where a commitment's value is not seen to vary with time, ideas of property and injury are adequate and there will be no enforcement of an agreement if neither party has performed, since in property terms no wrong has been done. In a market economy, on the other hand, a person may seek a commitment today to guard against a change in value tomorrow; the person obtaining such a commitment feels harmed by a failure to honour it to the extent that the market value differs from the agreed price.

Roman law. The Roman law of contracts, as found in Justinian's law books of the 6th century AD, reflected a long economic, social, and legal evolution. It recognized various types of contracts and agreements, some of them enforceable, others not. A good deal of legal history turns upon the classifications and distinctions of the Roman law. Only at its final stage of development did Roman law enforce, in general terms, informal executory contracts—that is, agreements to be carried out after they were made. This stage of development was lost with the breakup of the empire. As western Europe declined from an urbanized, commercial society into a localized, agrarian society, the Roman courts and administrators were replaced by relatively weak and imperfect institutions.

The rebirth and development of contract law was a part of the economic, political, and intellectual renaissance of western Europe. It was everywhere accompanied by a commercial revival and the rise of national authority. Both in England and on the Continent, the customary arrangements were found to be unsuited to the commercial and industrial societies that were emerging. The informal agreement, so necessary for trade and commerce in market economies, was not enforceable at law. The economic life of England and the Continent flowed, even after a trading economy began to develop, within the legal framework of the formal contract and of the half-executed transaction (that is, a transaction already fully performed on one side). Neither in continental Europe nor in England was the task of developing a law of contracts an easy one. Ultimately, both legal systems succeeded in producing what was needed: a body of contract doctrine by which ordinary business agreements, involving a future exchange of values, could be made enforceable.

The law merchant

The new contract law began to grow up throughout Europe through the practices of merchants; these were at first outside the legal order and could not be upheld in courts of law. Merchants developed informal and flexible practices appropriate for active commercial life. By the 13th century, merchants' courts had been established at the international trade fairs. The merchant courts provided expeditious procedures and prompt justice and were administered by men who were themselves merchants and thus fully aware of mercantile problems and customs.

In the 12th and 13th centuries the development of the law of contracts on the Continent and in England began to diverge. In England the common law of contracts developed pragmatically through the courts. On the Continent the process was very different, with speculative and systematic thinkers playing a much larger role.

Common law. From perhaps the 13th century on, English common law dealt with contractual problems primarily through two actions: debt and covenant. When a fixed sum of money was owed, under an express or implied agreement, for a thing or a benefit given, the money was recoverable through a simple action at debt. Other debt action was available for breach of a promise, made in an instrument with a seal, to pay a fixed sum of money. A so-called action at covenant could also be brought, but only for breach of a promise under seal. These actions did not, however, provide a remedy for the breach of an informal agreement to do something. In the 15th century the common-law courts started to develop a form of action that would render such agreements enforceable, and by the middle of the 16th century they had done so through the form of action known as assumpsit ("he has undertaken"). Originating as a form of recovery for the negligent performance of an undertaking, it came step by step to cover the many kinds of agreement called for by expanding commerce and technology. Having established in principle a comprehensive remedy, it was necessary for the courts to limit its scope. The courts found the limiting principle in the doctrine of "consideration," according to which a promise as a general rule is not binding unless something is given or promised in exchange. This consideration need not be of commensurate value, but it must be of some value, must be bargained for, and cannot be simply a formality.

Civil law. On the Continent, the revived study of classical Roman law had an immense influence upon the developing law of contract. It stimulated the rediscovery or construction of a general law concerning the validity of agreements. The Roman law, however, as crystallized in Justinian's law books, tended to confirm the notion that something more than an informal expression of agreement was required if a contract was to be upheld by a court. Another significant influence in the development of contract law on the Continent was the Roman Catholic Church. The church in its own law (canon law) strongly supported the proposition that a simple, informal promise should be binding (*pacta sunt servanda*). This attitude was to encourage the development of informal contracts. The natural-law philosophers took up such ideas as *pacta sunt servanda,* although they were slow to abandon the view that some contracts, especially contracts of exchange, should require part performance if they were to be held enforceable. By the 18th century the speculative and systematic thought of jurists and philosophers had finally and fully carried the day. The legal writers and legislators of the period generally considered informal contracts as enforceable in the courts. Thus in the French Civil Code of 1804, contract was approached essentially in terms of agreement; obligations freely assumed were enforceable except when the welfare of society or the need to protect certain categories of persons, such as minors, dictated otherwise. With the generalization that contract rests ultimately on agreement, the civil-law systems achieved a foundation quite different from the common law's view that contract is basically a promise supported by a consideration.

Flexibility of modern contracts

All the Western systems of modern contract law provide mechanisms through which individuals can voluntarily assume, vis-à-vis others, legally binding obligations enforceable by the other person. Contract law strives to give legal expression to the endlessly varying desires and purposes that human beings seek to express and forward by assuming legal obligations. The resulting system is open-ended; in principle, no limits are set in modern contract law to the number of possible variations of contracts.

THE SETTING OF STANDARDS

In theory, contractual obligations should be concluded between parties of substantially equal awareness and bargaining power and for purposes fully approved by society. The law reflects this utopian idea in the sense that it tends to conceive of contract as an arrangement freely negotiated between two or more parties of relatively equal bargaining power. The manifestations of intention required to form a contract are accordingly thought of as indicating real willingness, although in fact they may simply represent acquiescence.

Fairness and social utility. Much of the law of contract is concerned with ensuring that agreements are arrived at in a way that meets at least minimum standards respecting both parties' understanding of, and freedom to decide whether to enter into, the transactions. Such provisions include rules that void contracts made under duress or that are unconscionable bargains; protection for minors and incompetents; and formal requirements protecting against the ill-considered assumption of obligation. Thus, section 138 of the German Civil Code renders void any contract "whereby a person profiting from the distress, irresponsibility, or inexperience of another" obtains a disproportionately advantageous bargain. In addition, more general social requirements and views impinge upon contracts in a number of ways. Certain agreements are illegal, such as—in the United States—agreements in restraint of trade. Others, such as an agreement to commit a civil wrong, are held by the courts to be contrary to the public interest. Certain systems discourage some purposes, such as the assumption of a legally binding obligation to confer a gift of money or other gratuitous benefit upon another, by various special requirements.

Legal systems often have recourse to interpretation in the interest of fairness and social utility. Many litigated cases in which a remedy is sought for breach of contract are concerned with the meaning to be attached to the verbal expressions and acts of the parties in their dealing with each other. Ambiguities, for example, may be resolved against the party thought to have the superior bargaining position. This decision is common in cases in which one party is able to set the terms of a contract without bargaining. Again, a written agreement may be interpreted against the party who drafts or chooses the language. Or the court may prefer an interpretation it finds to be in accord with the public interest.

Although all legal systems try to achieve a reasonable approach to freedom of contract, there are bound to be contractual obligations that depart in some degree from the ideal. No one seeking to enforce a contract is required to show affirmatively that it advances specific ends desired by society or that the contracting process is without blemish. Such a requirement would be administratively cumbersome and expensive. In addition, it would reduce the general usefulness of the contract as an economic and social instrument. Differences in the economic resources available to individuals are found in most societies; to the extent that these differences flow from general conditions and are reflected in, rather than produced by, individual contracts, it is usually not feasible to take remedial action through the law of contracts. A single contract, moreover, is often only one element in a complex of economic and legal relations. Thus, in times of severe inflation or deflation, it may simply not be feasible to seek to deal with the resulting inequities in terms of redoing individual contracts.

Big industry and the public interest

Contracts of adhesion. There are large areas of economic life in which the parties to contracts have such unequal bargaining positions that little real negotiation takes place. These contracts are often known as contracts of adhesion. Familiar examples of adhesion contracts are contracts for transportation or service concluded with public carriers and utilities and contracts of large corporations with their suppliers, dealers, and customers. In such circumstances a contract becomes a kind of private legislation, in the sense that the stronger party to a large extent assigns risks and allocates resources by its fiat rather than through a reciprocal process of bargaining. Enforcement of such standard contracts can be justified on the ground that they are economically necessary. The question then becomes whether these decisions are to be made by private enterprise or by other agencies of society—in particular, government—and to what extent the interest of those who deal with such economic enterprises can be represented and protected in the decision-making process.

Contract law in such cases provides only what can be called the legal relationship. The content of the relationship derives not from bargaining between the parties but from the fiat of the large enterprise often offset by the fiat of some government agency. In a sense, the socially regulated contract of adhesion seeks to eat the cake of bureaucratic rationality while having, as well, the cake of individual choice and decision. Doubtless both cakes are diminished in the process, but the result may well be more satisfying than if only one had to be chosen. At all events, the resulting legal-economic phenomenon is radically different from that envisaged by traditional contract law. In the late 20th century legislative attempts have been made in a number of countries, such as West Germany (1976), the United Kingdom (1977), and France (1978), to strike a balance between the general freedom to contract and the protection of the weaker party.

THE RULES OF DIFFERENT LEGAL SYSTEMS

Traditional contract law developed rules and principles controlling the voluntary assumption of obligations, regulating the performance of obligations so assumed, and providing sanctions for failure to perform.

The question of whether a contract exists

Offer and acceptance. Some of the rules respecting offer and acceptance are designed to operate only when a contrary intention has not been indicated. Thus, in German law an offeror cannot withdraw his offer until the time stipulated in the offer or, if no time is stipulated, until a reasonable time has passed; but this rule yields to a statement in the offer to the effect that it shall be revocable. In Anglo-American common law, when parties contract by correspondence the acceptance takes place on dispatch of the letter, but the offeror can stipulate that no contract will be formed until the acceptance has reached him. These rules serve to fill in points on which the parties in their negotiations have not, for one reason or another, been specific.

Another function of rules relating to offer and acceptance is to enable the parties to understand and to mark when their discussions pass from an exploratory stage to the stage of commitment. The concepts of offer and acceptance are somewhat formal; they assume that the negotiations pass through clearly distinguishable phases, which is often not the case. But they help the parties to distinguish negotiation from commitment. The two words offer and acceptance become firmly associated with the assumption of obligations.

Different legal systems frequently advance comparable policies in quite different ways. Several distinctly different patterns are found in the approach of modern legal systems to the problems of whether an offeror is free to revoke his offer before acceptance, and of when an acceptance is effective to form a contract. Perhaps the polar extremes are represented by the West German civil law, on one hand, and the Anglo-American common law on the other. In the German view, an offer binds the offeror for any stipulated period or, when the offer is silent as to time, for a reasonable period unless the offeror has expressly made the offer revocable. The common-law rule is the opposite: an offer is revocable until it has been accepted. The two systems also have sharply divergent rules with respect to the point at which, when the parties are contracting by correspondence, the acceptance takes effect to conclude the contract. In German law, the acceptance takes effect when it reaches the offeror, in the sense that he either knows or can learn of it. In the common law, on the other hand, if the offeree uses an appropriate means of communication, the acceptance is effective on dispatch unless the offeror stipulated the contrary in his offer. (A revocation by the offeror, however, does not take effect until received by the offeree.)

How are these divergencies in the rules respecting offer and acceptance to be explained? In particular, do they reflect fundamental policy differences or simply different techniques designed to forward quite similar purposes? An examination of a typical problem posed when parties contract by correspondence suggests the latter explanation. Upon receipt of an offer, the offeree frequently changes his position by, for example, refusing or ignoring other offers, neglecting to seek additional offers, or himself making propositions based on the offer made to him. For this reason the legal system sees a need to provide the offeree with a secure point of departure for his decision, in order both to protect him and to facilitate commerce generally. The German system provides this protection by making the offer in principle irrevocable. The common law, on the other hand, found this solution excluded by its doctrine of consideration; as the offeree does not give anything in exchange for the offer's irrevocability, consideration is lacking to support an obligation not to revoke. (On the other hand, the Uniform Commercial Code, which has been adopted everywhere in the United States except in parts of Louisiana, provides that a firm offer made by a merchant is irrevocable even though the other party has given no consideration.) The common law is not entirely insensitive to the offeree's predicament. The rule that the acceptance is effective upon dispatch creates a situation in which the offeror who wishes to revoke his offer is uncertain whether or not he can still do so, since his revocation is not effective until receipt, whereas the offeree's acceptance, if one is made, takes effect on dispatch. This uncertainty makes the consequences of an attempted revocation unpredictable and thereby inhibits an offeror who might otherwise seek to revoke. In sum, the German and Anglo-American systems both try to achieve, and in a measure succeed in achieving, a fair balance between the offeror and the offeree.

The criteria of a legal contract

Unenforceable transactions. In all systems of contract law, certain classes of transactions are treated as unenforceable by the judicial process because they are thought to involve unusual hazards for a contracting party or to be of marginal social utility. There are, in both civil-law and common-law systems, four kinds of concern that lead the systems to treat certain types of transaction as unenforceable. These four kinds of concern may be called evidentiary, cautionary, channeling, and deterrent. The evidentiary concern springs from the desire to protect both the individual citizen and the courts against manufactured evidence and insufficient proof. The cautionary concern seeks to safeguard the individual against both his own rashness and the importuning of others. The channeling concern seeks to mark off or label obligations that may be enforceable and to direct attention to the problem of the extent and kind of the legal obligation, so that the individual will know the legal significance that his action may have. Finally, the deterrent concern refers to those types of transaction that are discouraged because they are felt to be of doubtful value to society.

Two quite different techniques are used to delineate types of transaction that are unenforceable in their natural, or normal, state. The first proceeds by describing the type in functional or economic terms. The common-law Statute of Frauds enacted by the English Parliament in 1677 provided that the following six kinds of contracts should be unenforceable unless expressed in writing: contracts to sell goods exceeding a certain value; contracts to sell any interest in land; agreements that are not to be performed within a year of their making; agreements upon consideration of marriage; suretyship agreements; and undertakings by an executor or administrator to be surety on a debt of the deceased for which the estate is liable. Civil-law systems typically describe as unenforceable in the absence of an appropriate formality noncommercial contractual obligations exceeding a certain value; mortgages created by contract; noncommercial compromise agreements; marriage contracts; agreements binding a party to transfer all, or a fractional part of, his property; leases to run for more than a year; assumptions of the obligation to stand as surety, at least when the operation is not a commercial one on the surety's part; promise of an annuity; and promises to make gifts.

Another less direct technique for delineating unenforceable types of transaction derives from the common law's doctrine of consideration. It holds transactions unenforceable in the absence of a bargained-for exchange. This class would include, for example, promises to make gifts. The approach tends to be too all-embracing, treating certain types of transaction as suspect when there is little or no practical justification for doing so. It is not clearly demonstrated, for example, that an option agreement made by two businessmen should be handled differently from many other kinds of commercial dealings. A strong argument exists that the common law's handling of commercial options, business compromises, and other business transactions lacking an element of exchange is more a logical deduction from the general doctrine of consideration than an expression of justifiable policy concerns.

Except in cases where the ground for unenforceability is radical, when a given transaction type is considered unenforceable the legal system should prescribe an extrinsic element the addition of which will cure the defect—for example, expressing the agreement in writing, performing it in part, or having a document drawn up with the participation of a legally qualified notary or other public official who holds a special appointment from the state and is charged with handling and recording various types of transactions.

Decline of the use of seal

A complex situation has arisen with respect to the two most generally available extrinsic elements, the seal and the payment of a nominal consideration. Various states of the United States no longer consider the seal as an effective extrinsic element. The seal's decline is rooted in its changed significance in the modern, literate, democratic world. The seal was originally an impression, usually in wax, of a device, or design, representing an individual or a family. In modern times, the courts, with legislative assistance in a fair number of the states of the United States, have recognized easy-going substitutes for the wax seal, such as simple writing presumed to have been made for sufficient consideration or, in special circumstances, parol agreement for valid consideration. The effect has been to render the seal progressively less effective, particularly from the cautionary perspective, and many courts now refuse to accept it as a satisfactory formality.

Nominal consideration is a subtle and ingenious formality. Its essence is the introduction of a contrived element of exchange into the transaction. Thus A, desiring to bind himself to give B $10,000, requests B to promise to give (or to give) A a peppercorn in exchange. B's promise (or performance) is an element, extrinsic to a normal gift promise, introduced by the parties in an effort to render the transaction enforceable (since the law does not treat normal gift promises as enforceable). Common-law courts often accept nominal consideration when used in a business context, such as in an option arrangement or a compromise agreement; its effectiveness is understandably more doubtful in the context of a gift promise, since such a transaction involves greater dangers for one party and is socially more marginal.

Civil-law systems have less need than the common law for a formality such as nominal consideration; they prescribe methods directly in their statutes. Interestingly enough, however, in some civil-law systems an analogous, judicially developed formality has emerged—the disguised donation (*donation déguisée*) of French law, in which the parties cast a gift promise in the form of an onerous transaction, such as a sale. It can be argued that both the nominal considerations and the disguised donation serve at least the cautionary and channeling functions of formalities mentioned above.

Reliance

Another kind of extrinsic element recognized by some courts, especially in the common-law countries, is one party's reliance upon the promise of the other. The fact of reliance argues in favour of enforcement because it indicates that an underlying understanding existed between the parties and because the relying party may suffer as a consequence of his change of position. Some courts will enforce initially suspect transactions when several extrinsic elements are present in combination. A common-law court, for example, may enforce a gift promise in which the element of reliance was present in addition to a seal or a nominal consideration. Other extrinsic elements, either alone or in combination with reliance, a seal, or a nominal consideration, may also render a transaction enforceable. Cases, for example, in which the promisor dies without attempting to revoke a gift promise could be enforced, as distinguished from cases in which the promisor seeks to revoke.

Performance. Contract law seeks to protect parties to an agreement not only by requiring formalities but in many other ways as well. Thus rules respecting deceit, fraud, and undue influence are designed to ensure that contractual obligations are assumed freely and without one party misleading the other. Other rules regulate the modification of ongoing contractual relations with a view to preventing a party with considerable bargaining power from unfairly imposing changes in the contract.

The law also allows contractual relations to be adjusted when they have been thrown out of balance by unforeseen circumstances. The task of adjustment is relatively easy in cases in which both parties made a mistake or in which one party laboured under a mistaken assumption that was, or plainly should have been, known to the other. The problem of mistake becomes more intractable when the error is chargeable to only one party. The solutions reached for such situations are complex and defy general statement.

Catastrophic events such as inflation, political upheaval, or natural disasters may upset the economy of a contract. In the case of natural catastrophes, relief is frequently available under theories of force majeure (action by a superior or irresistible force) and "act of God" (act of nature that is unforeseeable and unpreventable by human intervention). When the unsettling circumstances are economic in their nature, as with severe inflation or deflation, a solution is difficult to find. A party who benefits from inflation in one contractual or economic relation may suffer from it in another. A general readjustment in contracts would be enormously complicated and time-consuming and would interject an undesirable element of uncertainty into economic and business activity. Only under exceptional circumstances—and usually in the form of special legislation—are contractual relations adjusted for the effects of severe economic dislocations.

Sanctions for nonperformance

Failure to perform. Another branch of contract law deals with the sanctions that are made available to a contracting party when the other party fails to perform his contractual obligations. When these sanctions take the form of money damages—as they usually do in practice, even though some civil-law systems have a theoretical preference for specific relief—the system must decide whether the plaintiff is to be put in the same position economically that he would have been in had the contract been performed (expectancy damages) or simply reimbursed for the actual losses, if any, flowing from his reliance on the contract (reliance damages). Reliance damages can, of course, be very large. A subcontractor who fails to deliver parts required for the construction of an ocean liner (or delivers faulty parts) may be responsible for heavy reliance damages resulting from delay in the work or actual damage to the vessel. Legal systems utilize various techniques to limit both reliance and expectancy damages when otherwise they would be unreasonably large.

If a person has agreed to buy an article from a merchant, his refusing to take delivery will not ordinarily produce substantial reliance damages. Delivery costs will have been incurred, but the merchant will presumably not have lost sales elsewhere. In such circumstances, the merchant will seek to recover not his delivery costs but his lost profit—his expectancy damages. The law allows relief on the basis that the expectancy created by an enforceable promise has a current economic value, measured by the economic gain that the party would derive if the particular agreement were performed.

In some circumstances, performance is not measureable in terms of market value—as, for example, when one relative has agreed to sell to another a family painting of sentimental value but of little intrinsic worth. Many legal systems in such a case require specific performance (that is, compliance with the precise terms agreed upon in the contract). The availability of specific relief varies among contemporary legal systems, for reasons that seem more historical and doctrinal than practical.

Multiparty contracts

Other problems of contract law. Many contracts involve more than two persons. The law of contracts provides special rules for regulating claims by multiparty plaintiffs or claims against multiparty defendants, or for determining rights among the parties. Multiparty problems arise in other contexts as well. There is the problem of whether the immediate parties to a contract can enter into an agreement that will confer rights upon a person not an original party to the contract. Probably because the dogmatic structure of contract law was largely formed on the model of the simpler two-party situation, and because the contract for the benefit of third parties did not have great practical importance until such relatively modern developments as the emergence of life insurance, many systems of contract law have encountered difficulty in working out the relationship between the third party and the underlying contract. English law took the view that, as a rule, a person cannot acquire a right on a contract to which he is not a party. Some of the problems posed are difficult to resolve: under what circumstances and to what extent should the third party control the underlying contract when, for example, the original parties desire to rescind or modify it?

Another variation of the party problem is presented by efforts to add or substitute parties to a contract. In the absence of an express regulation of the problem in the basic contract, the law works with the notion of the presumed intention of the contracting parties, based on considerations of fairness and practicality. A contracting party cannot, in principle, assign to another his right under a contract if the assignment would result in a significant change in the burden assumed by the other contracting party. A contractual right to receive money or goods is a different matter; it can ordinarily be assigned because the resulting burden on the person under obligation is not great, and because society as a whole benefits from having this flexible economic and legal instrument.

One problem of contract law that has been mentioned above deserves further consideration—the problem of interpretation. Many rules of contract law are simply presumptions, based on experience and tradition, as to what the parties ordinarily intend; if they clearly intend otherwise, the rules are not mandatory. Problems of interpretation frequently arise with respect to the particulars of a given agreement; thus the court seeks to determine what the parties actually had in mind. The effort to ascertain intention may encounter difficulties arising from the law of evidence. Many legal systems limit the use of testimonial evidence to explain the essential elements of a written contract.

CONTEMPORARY TENDENCIES

Arbitration. Modern commercial practice relies to a growing extent on arbitration to handle disputes, especially those that arise in international transactions. There are several reasons for the growing use of arbitration. The procedure is simple, it is more expeditious, and it may be less expensive than traditional litigation. The arbitrators are frequently selected by a trade association or business group for their expert understanding of the issues in the dispute. The proceedings are private, which is advantageous when the case involves trade or business secrets. In many legal systems, the parties can authorize arbitrators to base their decision on equitable considerations that the law excludes. Finally, when the parties are from different countries, an international panel of arbitrators may offer a greater guarantee of impartiality than would a national court. Despite these advantages of arbitration, the development of contract law may suffer considerably by a withdrawal from the courts of litigation involving some of the most significant and difficult problems of the present day, all the more so because the reasoning in arbitral awards is usually not made public.

U.S. Uniform Commercial Code

Codification. Trade and commerce flow increasingly across national and state boundaries. In response to this there have been many efforts to unify the traditional legal systems. In the United States, the Uniform Commercial Code has replaced earlier uniform statutes such as the Sales Act and the Negotiable Instruments Law; by 1970 it had been adopted by every state including, although in part only, Louisiana. Internationally, the decade of the 1960s saw significant progress toward uniform regulation of the law of sales. The creation of a uniform body of substantive rules is, of course, easiest when the communities involved have roughly similar rules and principles. In addition, the greater the volume of multistate transactions, the greater the pressure for uniform regulation. It is understandably easier to achieve a Uniform Commercial Code within the United States than to create such a system internationally.

When a transaction has a significant relationship with more than one legal order, difficult problems of private international law often arise with respect to which law shall govern. A kind of halfway point between legal diversity and unification—the creation of uniform rules for choice of law—is of some help, and in this area the Hague Conference on Private International Law has done significant work. (A.T.v.M.)

Agency

The law of agency governs the legal relationship in which one person (the agent) deals with another (third party) on behalf of still another (the principal). The competent agent is legally capable of acting for this principal vis-à-vis the third party. Thus, the process of concluding a contract through an agent involves a twofold relationship. On the one hand, the law of agency is concerned with the external business relations of an economic unit and with the powers of the various representatives to affect the legal position of the principal. On the other hand, it rules the internal relationship between principal and agent as well, thereby imposing certain duties on the representative (diligence, accounting, good faith, etc.). The two relationships need not be in full conformity. Thus, an agent's effective powers in dealing with outsiders may extend to transactions that he is under a duty to his principal not to undertake, leading to a situation characterized as "apparent authority."

Agency is recognized in all modern legal systems as an indispensable part of the existing social order. It fulfills the most diverse functions in both public and private law; in particular, it assists in organizing the division of labour in the national and international economy by making it possible for a principal greatly to extend his individual sphere of activity by having one or more persons act for him. In addition to the individual principal, a principal may be composed of a group of persons carrying on a trade or business by way of a partnership, a registered company, or another kind of corporate entity. The need for legal representation in some form has therefore increased as business units have come to involve transactions conducted at a distance (through the use of factors, or commercial agents) or have grown in size (as in the case of the firm, the house, and the corporation). Continental law additionally allows the use of legal representatives, such as the father, mother, guardian, or curator (*curateur, tuteur*), to enable minors, insane persons, and other legally incapacitated persons to act. Although a similar category of "authority by law" is not unknown in common law, powers based on family relationships are scarce and appear in only a few cases.

HISTORICAL DEVELOPMENT

Roman law. Because concepts grow primarily out of specific situations that have occurred and social needs that have arisen, the doctrine of legal representation developed differently in different times and places, sometimes even within a single legal system. At first it seemed unthinkable that an agent, by making a contract with a third party, could create obligatory rights and duties between a third party and a principal. Even the official law of the Roman Empire never fully recognized the principle of representation. The explanation for this rejection lies mainly in the early Roman conception of a contractual obligation as a personal relationship binding the parties in some quasi-mystical way. This type of relationship allowed creditors in some instances to seize the possessions—and in very early times also the person—of the debtor. Usually the formation of such a relationship between two parties took place in a solemn ceremony at which both parties had to be present, certain formal words spoken, and definite acts performed. In such a situation it was impossible to confer right or duties on a third party. On the other hand, the head of the household could transact business through his slaves or his dependent sons, who were not conceived of as agents but as "long arm" extensions of the contracting master or father. Because of the wide prevalence of slavery, there was no great need for a true agency relationship. As Roman law later developed, the formalities connected with creating legal relationships became less important, and the need for personal representation in commerce increased. In the meantime, however, legal theory and practice had developed so many ways to evade the problem that there was no longer an urgent need for Roman law to overcome its stark conservatism and to develop a legal institution that it had earlier opposed.

Conception of contract

Medieval influence of canon law and Germanic law. Labouring under the influence of Roman law, legal development in the Middle Ages strove to overcome disadvantages in daily commercial life caused by the Roman rejection of the principle of agency. Through the efforts of legal scholars (glossators and commentators), Roman law was further developed by means of extensions, emphases, and exceptions—a process already sanctioned by the Romans themselves. Additional impetus for change came from Roman Catholic Church canon law. Although manifestly structured after Roman civil law, canon law had its own special development, influenced by Hebraic theological concepts. Certain writers succeeded as early as 1200 in constructing a type of agency relationship based on the position of *procurator,* a relationship intended to solve the representation problem in all except legal matters. The issue nevertheless remained in dispute.

About this time, the doctrine of principal and agent developed in England as an outgrowth or expansion of the doctrine of master and servant. Anglo-Norman law created the figures of *ballivus* and *attornatus.* His position in the household of his master empowered the *ballivus* to transact commercial business for his master, reminiscent of the power of the slave to bind his master under Roman law. Later the *ballivus* was given more authority, especially in his frequent role as land administrator, gradually becoming competent to act independently for his master. On the other hand, the *attornatus,* originally just a representative of one of the parties in litigation, soon assumed a position of broader importance. Certain contracts were effective only when made in a judicially prescribed manner. For this reason, the formation of this type of contract always had to be concluded in a court proceeding in which an *attornatus* represented each party. This was the beginning of the role of the *attornatus* as a general agent.

Modern developments. Recognition of the principle of agency in the field of civil law was finally achieved in continental Europe during the ascendancy of natural law in the 17th century. By this time, however, new objections grounded in state law, feudal law, and the question of the general reasonableness of agency had to be overcome. Hugo Grotius in his best-known work, *De Jure Belli ac Pacis* (1625; *On the Law of War and Peace*), explained that on the basis of his mandate a *procurator* could acquire rights directly for his principal. He thereby overcame the Roman rule that allowed slaves and dependent sons, but not free persons, with two exceptions, to act directly for the head of the household. Grotius simply maintained that this rule did not contradict natural law. In another work, *Defensio Fidei Catholicae,* Grotius added, in a theological context, that the principle of agency is based not on essential natural law but on nonessential natural law; that is, agency is not demanded by the nature of things but must only correspond to and be adapted to the nature of things.

The codifications of the subsequent age of rationalism recognized the principle of representation. The Prussian Civil Code (1794), the French Napoleonic, or Civil, Code (1804), and the Austrian General Civil Code (1811) nevertheless regarded agency as an aspect of mandate and the power to act as an agent to be derived solely from that concept.

The master–servant theory

A similar dualism governed the English development of the doctrine of principal and agent, in large part because of the new doctrine's dependence upon that of master and servant. The jurists of the 18th century, employing the phrase *qui facit per alium, est perinde ac si facit per se ipsum* ("whoever acts through another acts as if he were doing it himself"), made much use of the fiction of identity. In contrast, 18th-century commercial law, which at the end of the Anglo-Saxon period had split off from the main body of common law and had been allowed to develop under less-stringent controls, modified numerous feudal common-law concepts. In particular, it brought a legal flexibility allowing the law of agency, which had grown from three independent common-law roots—one relating to actions of debt and assumpsit (informal contract), another connected with the action of account, and the third deriving from deeds—to adapt itself to the peculiar problems and requirements of an individual case. Through this commercial influence, the concept of undisclosed agency, an especially important mode of representation in commercial transactions in which the agent appears to be the principal, developed alongside open agency representation in English law. Thus, even when a principal with the real economic interest in the transaction remained concealed, claims for and against him began to be recognized, whereas in continental law the necessity for the agent to act openly in the name of the principal retained a more fundamental importance in the general doctrine of contracts. English law attempted to relate agency rules more closely to the everyday needs of the principal–agent relationship, in contrast to the conceptually systematic and more narrowly confining treatment of agency in continental European law. As Alfred Conard, a modern writer, has observed, agency came to be a legal institution in English and North American law, "knitting together the whole subject of the employment of one man by another, whether for one job or for life, and whether on commission or on payroll."

While the first practical treatises on agency in England, by William Paley, and in the United States, by Samuel Livermore and Joseph Story, appeared early in the 19th century, in continental Europe the doctrines of the theoretical jurists continued to play their traditional leading role in the development of this branch of the law. A particularly important distinction in the European law of agency was made in the second half of the 19th century by the legal scholars Rudolf von Jhering and Paul Laband. Before them, agency was viewed solely in terms of the relationship binding the principal, the person being represented, and the agent, the person representing; that is, agency was equated with the relationship created by the mandate given to the agent. Jhering and, especially, Laband were the first to distinguish sharply between the agent's power to create legal rights and obligations for his principal and the inner contractual relationship governing the personal rights and duties between principal and agent. This distinction was largely adopted by the continental European legal systems and was codified in several countries.

Nineteenth-century legal theory also strengthened the so-called disclosure principle (*Offenheitsprinzip*), according to which the acts of an agent have direct legal implications for the principal only when the agent makes it known to the third party by acting in the name of his principal that he acts for him and not for himself. Only in such a case can there be direct representation—where the principal alone is the party to the contract—in contrast to indirect representation. Thus, this distinction became, to varying degrees, a common element in the individual civil-law systems.

Anglo-American law, more realistic in this area and standing on different dogmatic grounds, was not influenced to the same degree by such principles, although it was also long plagued by refined doctrinal distinctions, such as the contrast between general agents, with whom an outsider could deal with moderate safety, and special agents, whose powers the courts viewed very narrowly. At this stage of development the remaining feudal elements in the English law of agency, whose prototypes had remained the servant and the steward of a lord, were largely eliminated. Because of the increasing complexity of most modern commercial transactions, the significance of the various types of representatives grew to the point where agency had become one of the most important of modern legal relationships. The agent had come to be seen as an instrument of the principal without personal responsibility, a view which developed still further the responsibility of the principal for the misconduct of his agent.

Reflecting the generally more realistic attitude of contemporary private law, the modern treatment of agency has retreated from the somewhat artificial conceptualism of the 19th century and has emphasized the actual commercial and social context. Tendencies both to apply general solutions to broad types of cases and to provide specific solutions in the more unique individual cases have produced further refinements in the law of agency. The continuing shift to more complex business units, accompanied by developments in marketing practices, has required solutions more appropriate to modern business necessities. In addition to a reassessment of the relationship between mandate and authority to act for the principal, new questions are being asked concerning the proper role of this kind of authority in relation to the legal and social functions of representation that it serves. Accordingly, the mere fact of one's external position, which without authority cannot properly be used, has been increasingly acknowledged as an independent ground for recognizing an agent's power of representation.

Authority and action

At the same time that modern society's concern for third persons' rights has led to recognition of powers of position, thereby making an agent's power of representation less dependent upon the will of his principal (the latter being bound in these cases whether or not he wishes to be), a better view of private autonomy, as expressed in the act of authorization, sees a fundamental connection between the agent's act and the will of his principal in the legal transaction as a whole. In this view the authorization by the principal and the act of the agent are not two independently complete legal transactions carried out in isolation from each other. Rather, they are two parts of an extended legal event, which would consist of a single act if no agency were involved. Thus, when the principal uses the help of an agent, the offer, which is usually made by a single act, becomes divisible into two parts (the authorization and the action of the agent). Without such a connection, agency in private law, as it is understood today, would be largely incompatible with the principal's own autonomy.

THE RULES OF DIFFERENT SYSTEMS

In order to compare agency in continental and Anglo-American law, the principal types of agency that have developed in practice should be noted.

The continental "commercial agent" and his functions. The four main types of agent engaged in business activities in continental Europe can be identified as follows:

Commission agent (German *Kommissionär,* French *commissionaire,* Italian *commissionario*). The commission agent accepts or sells goods for the account of his principal, but in his own name. He is independent of his principal, has a claim for his commission, and, except in France, has the right when dealing with certain goods to conduct the transaction as he sees fit. The forwarding agent (German *Spediteur,* French *commissionaire de transport,* Italian *spedizioniere*) ships goods in his own name for the account of his principal and therefore is a type of commission agent.

Commercial agent (German *Handelsvertreter;* French *agent commercial,* or *voyageur,* or *représentant et placier;* Italian *agente*). The commercial agent negotiates and concludes contracts on behalf of his principal. Although the degree of his independence from the principal varies, he is never totally independent. While Italian law limits such an agent's activities to a specific geographic region, German law has such limitations only for the *Agent,* a subclassification of the general commercial agent who remains unrestricted in this regard. Apart from several protective rules, the French commercial agent is subject to the general rules governing the mandate.

Broker (German *Mäkler,* French *courtier,* Italian *mediatore*). The broker is a business agent who is completely independent of his principal. In the area of employment brokerage or placement services, most European countries have passed special regulatory legislation to protect the interests of those persons using such services to seek employment.

Sales representative. The sales representative is a dependent employee of a merchant who concludes contracts for the merchant outside the business establishment. Most European legal systems have no special provisions governing such an agent but rather treat the position under the general rules governing dependent commercial employees (*e.g.,* those governing German shop assistants, or *Handlungsgehilfen*).

The variety of Anglo-American agents. Various kinds of agency relationships are evident in Anglo-American commercial life. The factor and the broker are the most common mercantile agents dealing in transactions involving personal property. The factor is entrusted with possession of the chattels to be sold, or the documents of title thereto, and is empowered to conclude the sale at the best price obtainable. The broker, on the other hand, has no possession of the object of sale but is empowered to make contracts for the purchase or sale of personal property on behalf of his principal. More limited are the powers of the real estate agent, who may show the land and state the asking price to the potential buyer without ordinarily being empowered to make further representations. The store salesman is similarly restricted in his power to represent his principal and can usually do no more than make customary warranties and sell at the price fixed by his employer. In contrast, the traveling salesman not in possession of the goods normally has authority only to take orders, which are in effect mere offers to buy and are not binding on either party until the principal has accepted. The auctioneer is usually empowered to do no more than sell at the highest price bid.

Managerial and administrative agents

The common function of a second large class of agents is managerial or administrative. The manager of a business has the widest authority of all business agents and normally has complete control of all normal operations of the business. The agent employed to manage investments has a duty to deal only as would a prudent investor with reference to the principal's personal financial situation. The powers of the agent entrusted with his principal's land or chattels is more administrative; he has full power to protect the property and to make it profitable, but he may not sell or encumber it. Finally, the attorney at law may do what is necessary to advance his client's interests and may incur the necessary expenses in so doing but, unless specifically authorized, may not release any substantive rights of his client.

Apparent authority and related questions. If the principle of private autonomy were uncompromisingly applied to the law of agency, only an actually authorized agent could create legal rights and obligations for his principal. The will of the principal would then precisely define the boundaries of the agent's competence; however, a third party cannot always make a reliable determination of whether the agent has acted within the scope of this authority. Rather, he must often rely upon the principal's manifestation of the agent's authority, which may go beyond the more restricted authority actually communicated by the principal to the agent. Often he must rely upon the fact that the agent holds a certain position, such as wife, partner, or employee, in the belief that the normal incidents of authority implied by such a position are present, even though special restrictions on the agent's authority may have been made. And sometimes a third party must rely upon an earlier declared authorization that has since been revoked internally by the principal. Obviously, a third party cannot be expected to check all the details of the agent's internal authorization, especially since representation makes sense only when it functions efficiently and since use of an agent is also for the benefit of the principal. Therefore, the risk that the agent has acted without power of representation must be apportioned between the principal and the third party, with individual factors determining who must bear it in a particular case. This compromise is the subject of the doctrine of apparent authority.

It is obvious that the expression apparent authority is inappropriate since in none of the above cases is the competence of the agent illusory. With respect to the third party, at least, the authority of the agent is no less real than it would be if it were in conformity with the will of the principal. The distinction between apparent and real lies rather in the justification of the agent's acts in relation to the principal. In contrast to apparent authority, real authority is more than mere power of an agent, for along with the agent's legal power "looking out" (*posse*) stands his privilege "looking in" to the lawfulness of his conduct (*licere*). In the case of a real authority, power and privilege to exert the power are coextensive as against the principal, while, in the case of apparent authority, the agent has only the external legal power to perform without the corresponding internal justification vis-à-vis the principal.

Although the expression apparent authority spread from continental Europe, where it was used by, among others, the influential French classicist Robert Pothier (1699–1772), into English law, where Lord Ellenborough applied it in *Pickering* v. *Busk* (1812), its development in the two legal systems was independent and went systematically different ways. Nevertheless, the results obtained in concrete situations by the courts of both systems often seem rather similar. A similar disparity marked the development of the doctrine within Europe itself, with the formulation of different rules in the French system, which largely identifies authority and mandate, and in the German system, which distinguishes the two ideas. Another general tendency that has arisen in both legal systems has been to objectify the more subjective aspects of the doctrine, thus making the legal consequences more certain and predictable. Today both Anglo-American and continental courts permit the legal consequences of an agency relationship to result even when the principal is not willfully responsible for the appearance of authority.

Similar situations can also lead to opposite approaches in some matters. Here also it depends in the first instance upon whether the principal or the third party must bear the risk, since in general an agent acting without authority is not personally responsible. The question arises as to whether and to what degree the authority of the agent to bind his principal is affected by the death of the principal. According to the traditional English view (*Campanari* v. *Woodburn;* 1854), this event automatically terminates the agent's powers, irrespective of whether the agent or the third party knew or should have known of the death. While the rule originally might have rested upon the "fiction of identity" between principal and agent, today it is supported more by the technical argument that what a dead man cannot himself do, he cannot do through another, with further support garnered from the so-called doctrine of the meeting of the minds that is necessary for concluding a contract.

The death of the principal

In contrast, the continental legal systems have evolved less doctrinaire solutions to this question based more on considerations of protection of the concerned parties. Article 2008 of the French Civil Code even goes so far as to treat all transactions of an agent who acts in ignorance of the death of his principal as valid. The more balanced solution offered by the courts on the Continent, however, is to make the good faith of the third party the determinative factor, since in the usual case the real interest of the agent is simply to avoid any personal obligation.

Disclosed and undisclosed agency. Continental European laws restrict the application of agency rules to cases where the agent acts openly in another's name. Thus, French jurists infer from article 1984 of their Civil Code, according to which agency is the act of the agent *pour le mandant et en son nom* ("for and on behalf of the principal"), the negative conclusion that in case an agent does not disclose that he is acting as an agent for a principal, the consequences touch only the "agent" himself. The hidden principal is not concerned by the effects of the transaction at all. Section 164 of the West German Civil Code expressly provides that "an agent, who acts without disclosing the fact that he is acting as agent, is the only one to acquire any rights and is exclusively personally liable."

Undisclosed principal

In contrast to the continental view, when an agent contracts in his own name without disclosing his principal, the common law allows the undisclosed principal under certain conditions to sue or be sued by the third party. Such conditions include that the agent had power to make the contract and that the parties eventually learn their respective identities. This wider concept of agency has no counterpart in continental legal tradition.

The use of this basic doctrine in the common-law countries gives rise to questions regarding the identity of the undisclosed principal, the election of remedies that must be made by the third party, the extent of the respective liabilities, the right of the third party to setoff (the amount of its own damages from any sum that might be awarded it), etc. A solution to these conflicts of interests must in final analysis rest upon an evaluation of the extent to which the relationship between the undisclosed principal and the agent should influence the contract made by the agent with a third party.

The external, unilateral act of authorization. It is still a characteristic feature of the French Civil Code and of other codifications following its model (for instance, those of Spain, Portugal, Romania, and Brazil and other Latin-American countries) that agency is not recognized as an isolated institution. These legal systems conceive of agency only as a subordinate instance or external effect of mandate. The result is that they consider the power to act as an agent as a mere part of mandate and do not have a general concept of authorization as a distinct legal institution. In contrast to this approach, the more modern codifications of Scandinavia and of such countries as West Germany, Switzerland, Japan, Poland, Czechoslovakia, Italy, and Greece draw a sharp distinction between the unilateral organizational act on the part of the principal authorizing the agent to act and the internal contractual relations between the principal and the agent. This distinction, one of the major achievements of 19th-century European legal scholars, is also followed by modern English and American legal writers, even though the classical concept of mandate is unknown in the common law.

The insight that authority can exist independent of the underlying contract, and even without it, opens several new practical possibilities. For example, it explains the rule that the authorization of a minor can be valid if he is in fact mentally and physically capable of transacting business, even though the minor is not competent himself to conclude the (internal) contract of employment for himself that establishes fiduciary duties. Thus, the minor is not subject to the liabilities *ex contractu* (from or out of a contract) of an adult agent although he is authorized.

A few countries still prescribe a special form for every authorization. According to the Russian (RSFSR) and Brazilian codes, for example, an authorization must be given in written form. This general rule, which has been mitigated to some extent by the courts, is influenced by a distrust of informality and by a concern "to protect the individual and to be better able to examine the lawfulness of a legal transaction." The opposite tendency is followed to the extreme by the German Civil Code. It not only adopts the general principle of "freedom of form"—with the rare exception that a special form is required in those cases where a statutory article expressly prescribes it—but even states that the granting of authority need not be in the form prescribed for the judicial act to which the agency power relates. In spite of this express statutory language, West German courts do require compliance with formalities in certain extreme situations under pressure of practical necessity, in order to avoid frustration of the aim of the formal requirement in the principal contract. This attitude thereby approaches the English rule according to which, in most cases, no particular formalities are required, even if the agent is to make an agreement for the sale or lease of land, an agreement that must be in writing. More attention to the connection between the authorization and the act of the agent appears in provisions like that of the Greek Code of 1940, which says that the authorization must take the form required for the legal transaction for which the authority is issued unless the particular circumstances lead to a different solution. Other modern codes like those of Poland and Italy do not even contain the "unless" clause and prescribe only that an agent's power of attorney must be granted with the formalities prescribed for the contract that is to be entered into by the agent.

The internal agency contract. The internal bilateral relationship between principal and agent—apart from agency of necessity—rests upon what is commonly termed a "contract of agency." This term encompasses all sorts of contracts of employment including gratuitous services (in those cases in which the agent is willing to render a friendly favour).

This internal relationship between principal and agent must begin with an agreement, since otherwise the principal would have no rights against the agent—even the right to beneficial service presupposes the agent's consent to serve. The consent of the principal may be given expressly by a written power of attorney or implied by his conduct, such as an established course of dealing. Generally, the formation of the contract of agency requires no formal ritual. Moreover, in many cases the obligation to act as agent is only a part of the greater complex of duties that forms a person's job, profession, or office (for example, those of factors, bailiffs, attorneys, or brokers).

Consent of principal

The basic principle of agency is that the agent, in fulfilling his obligation, concludes legal transactions on the part of his principal. When these transactions result from the authorized legal acts of the agent, the result is that only the principal is bound by them. The competent agent himself remains outside the contractual relations with the third party (but compare "undisclosed agency" above) provided he has not also contracted for himself at the same time—for example, when the third party is not content with the principal's credit and insists upon having the agent's liability in addition to the principal's; in such a case the agent binds both his principal and himself. This general rule that the agent does not become involved may change in the exceptional case of an authorization conferred for the benefit of the agent. Thus, such an agent has been held personally liable by German courts for mistakes made in the course of contract negotiations (*culpa in contrahendo*).

Rights and duties between principal and agent. Continental European codifications generally do not treat the contract of agency as a special, separate type of contract. The standards governing the principal–agent relationship must therefore be derived from the general legal rules governing the mandate, the contracts for performing work, employment contracts, and partnership contracts, together with the more specific rules (*e.g.,* of the commercial codes) regulating particular agency relations and the individual transaction at hand.

Differing from this general approach, the common law has recognized a number of more specific rights and duties between principal and agent. The principal must provide the agent with a regular opportunity for service under the contract of employment and has a positive duty to aid, and not inhibit, the agent's performance of such service. He must compensate the agent for his services, provided they are not gratuitously rendered (the agent's right of remuneration), and must account for those amounts due to the agent, including indemnification for economic loss suffered by the agent on account of the agency relationship (right of indemnity and right of lien by way of charge on the principal's goods in his possession). The principal also has the more abstract duty to conduct himself so as not to harm the agent's reputation.

Remuneration, indemnity, and lien: the agent's rights

The primary duties of the agent to the principal are those of care, obedience, and loyalty—similar to those of a trustee. More specifically, the agent must act solely for the interests of his principal and therefore must account for any financial benefit ("secret profit") he might derive from a transaction. It follows that it is a violation of an agent's fiduciary duty to his principal to have unrevealed interests adverse to those of his principal. He must not compete with his principal and may not use or disclose confidential information except for his principal's benefit. If an agent has received money or other property from or for his principal, he must account for it. An agent also may not normally delegate his task to a subagent, since the principal is assumed to have placed his confidence in the person of the agent and not in a subagent. Finally, the agent also has the abstract duty of conducting himself so as not to bring disrepute upon the principal.

Liability of principal for acts of agents. Continental European law classifies the undertaking of transactions in the place of another as agency only when the transactions are legal. It excludes other acts, including unlawful acts, so that when dealing with the law of agency, the rules concerning the liability of a master for the torts of his servant do not come into consideration.

Following the lead of Justice Oliver Wendell Holmes, Jr., the opposite view has been taken in English and American literature. The predominant opinion treats the liability of a master for the tortious conduct of his servant as a part of agency law since these cases logically come within the maxim *qui facit per alium, facit per se* ("he who acts through another, acts himself"). The doctrine of *respondeat superior* ("that the master must answer") is therefore treated as a part of agency law, even though the rationale behind the master's liability is that he has assigned to a servant under his control a task that unforeseeably results in damage to a third person. On the other hand, consequences flowing from an agency relationship rest on the idea that an authorized person performs legal acts within his competence not on his own behalf, but for the principal. A growing view in the modern literature recognizes, however, that "the two basic relations are strange bedfellows."

According to English and American law, the liability of a principal for his agent's torts in the ordinary course of his employment depends upon the existence of a master–servant relationship. If the principal and agent stand in a master–servant relationship to each other, the master is vicariously liable for his servant's tortious conduct committed within the course of his employment irrespective of any personal fault on his own part. This doctrine of *respondeat superior* arose from the belief that since the head of the household or economic enterprise exercises control, he should pay for the harm caused by its members.

Such a relationship presupposes a degree of physical control by the master over his servant, which may exist, for example, over the driver of the principal's delivery truck but is lacking over the principal's factor or broker. The other major limitation to the doctrine is that the servant's tortious conduct must be committed within the servant's course of employment. Generally, this includes conduct that is not a serious departure from that authorized, both in manner and space, by the master and that is actuated at least in part by a motive to serve the master. Under this principle, the master's vicarious liability extends in some instances even to claims arising from the servant's intentional torts.

If no master–servant relationship exists between the parties, the principal's liability for the torts of his agent is far more restricted. For example, a principal is not liable for the harm caused by the negligent physical conduct of his nonservant agent. He is liable, however, for any other torts of his agent that either are authorized or the commission of which normally are made possible by the agent's position. The chief example of such conduct is tortious misrepresentation by the agent.

Termination of agency. With the termination of actual authority, questions often arise as to whether the authority was usual, was special or general, arose out of necessity or was also apparent. Questions concerning the external and internal agency relationships create special problems, particularly in this area. A principal's termination of the agency relationship does not necessarily have the same effect vis-à-vis the agent as it has with respect to the third party. It may be that the principal can terminate the real authority but not the apparent authority toward a third party.

Termination in breach of agreement

In theory, the principal may revoke the real authority of his agent or the agent may terminate his authority by renunciation or revocation at any time. If the revoking party has previously agreed not to do so, the revocation remains valid, but the other party may maintain a breach of contract action against him. The agency relation can also terminate by operation of law in case of death, insanity, bankruptcy, or war, particularly where the principal is concerned. The question then arises as to whether the unknowing agent is protected by the law, since he might be personally liable on the contract.

A major exception to the principal's power of revocation occurs when the agent possesses "authority coupled with an interest." Here the agent who has part ownership in something that is to be disposed of has power also to dispose of his principal's remaining interest in this thing. Such a power for the purpose of effectuating any security or of protecting or securing any interest of the agent cannot be revoked without the agent's consent. (W.M.-F.)

Commercial transactions

Law of exchange of values

The law of commercial transactions comprises the core of the legal rules governing business dealings. The most common types of commercial transactions, involving such specialized areas of the law and legal instruments as sale of goods and documents of title, are discussed below. Despite variations of detail, all commercial transactions have one thing in common: they serve to transmit economic values such as materials, products, and services from those who want to exchange them for another value, usually money, to those who need them and are willing to pay a countervalue. It is the purpose of the relevant legal rules to regulate this exchange of values, to spell out the rights and obligations of each party, and to offer remedies if one of the parties breaches its obligations or cannot perform them for some reason.

The law of commercial transactions thus covers a wide range of business activities. It does not, however, govern such essentially noncommercial relationships as those involved in succession and family law. Historically, land was of such prime importance that it was not subject to frequent disposition and therefore was also excluded from the category of commercial transactions.

In some countries the term commercial transactions is merely descriptive. In Anglo-American law especially, it is merely a collective name for those rules that relate to business dealings. The term itself has no legal consequences. It serves only as a convenient and illustrative shelter under which certain legal rules may be assembled.

Many countries, however, have established a technical concept of commercial transactions with precise definitions and important legal consequences. This is most often the case in the civil-law countries. In these countries the term commercial transactions thus has more than a merely descriptive function. It designates in part those rules that are peculiar to commercial transactions. In France, for example, bankruptcy is open only to individuals who are merchants and to business organizations, and there are special rules applying to commercial cases. In West Germany, similarly, the general rules on consumer sales are in part superseded by special rules on commercial sales. A commercial transaction thus results in a number of specific legal consequences that differ from those of ordinary consumer transactions. Such a special commercial regime exists usually because it is thought that the ordinary citizen should not be exposed to the rigours of commercial rules that presuppose a knowledgeable, versatile individual who does not need as much protection against the legal risks and consequences of his dealings.

In those countries in which specific legal consequences attach to commercial transactions, it is necessary to develop a precise definition of what constitutes a commercial transaction. Although such definitions are more or less closely related, they are peculiar to each country. Most of them, found usually at the beginning of a special "commercial code," combine two elements: definitions of a "merchant" and of a "commercial transaction." In certain countries—West Germany, for example—the emphasis is on the definition of the merchant; in others, such as France, the emphasis is on that of the commercial transaction (*acte de commerce*). This latter criterion, the so-called objective test, was adopted in the 19th century for ideological reasons, the French wanting to avoid any repetition of the pre-Revolutionary differentiation of legal rules according to the social condition of persons. But whatever the test, the results are similar, for the gist of the various definitions is that a transaction is "commercial" if it is concluded by a merchant in the exercise of his profession.

Socialist economic law

It should be mentioned that the Socialist countries of eastern Europe and of East Asia do not recognize the concept of commercial transactions. This is because such a concept is somewhat suggestive of a capitalistic form of the economy. The implication would be the more invidious since the state, directly or through the various forms of state enterprises, is practically the only trader in Socialist countries. All the Socialist countries have developed a mixed system, combining more or less obligatory state planning with the autonomous fixing of the remaining terms of their exchanges. The breach of these so-called economic contracts may entail the payment of damages to the other contracting state enterprise, thus drawing the attention of the state bank to violations of plan and contract discipline. These special rules for dealings between state enterprises within each country and also for enterprises from different Socialist countries are called "economic" laws.

HISTORICAL DEVELOPMENT

Only a few traces of rules on commercial transactions in antiquity have survived. The most notable is a rule developed by the seafaring Phoenicians and named after the island of Rhodes in the eastern Mediterranean. The "Rhodian Law" provided that losses incurred by a sea captain as a result of trying to save ship and cargo from peril must be shared proportionately by all owners of cargo and by the shipowner. If, for example, one merchant's cargo was thrown overboard in order to save the ship from sinking, the loss would be shared among the shipowner and all the other merchants with cargoes aboard. This rule applied in the entire Mediterranean and is today known in the maritime law of all nations as general average.

Another important rule, also of maritime character, arose in connection with the maritime loan that developed in Athens. A capitalist would lend money for a marine trading expedition. The loan would be secured by ship and cargo, but repayment of the capital and payment of interest were conditional on the ship's safe return. The interest rate of 24–36 percent, considerably beyond normal rates, reflected the highly speculative risks involved. This transaction later developed into marine insurance.

Roman law influences

Much more is known of the commercial law of the Romans. It was in Rome that for the first time a separation developed between the ordinary civil law and special rules for foreign (that is, primarily trade) relations. Since the civil law applied only to Roman citizens, trade and other relations with and among noncitizens were subject to a separate set of rules—the jus gentium, or law of nations. The latter exhibited two traits that have become characteristic of the law of commercial transactions: it was more liberal than the strict rules of the civil law, and it was applied uniformly in various parts of the world.

As far as specific rules are concerned, the Romans received and preserved the two institutions of the general average and the maritime loan that had been developed earlier. They added two other rules of maritime law: the liability of the shipowner for contracts concluded by the ship's master (an early recognition of an agency relationship that was later generalized) and the liability of the ship's master for damage to or loss of the passengers' luggage and equipment. Innkeepers were charged with the same liability. Banking transactions and bookkeeping were well developed, and some prohibitory rules were enacted against capitalist excesses. Thus, the legal interest rate was lowered. In the postclassical period an attempt at achieving a "just price" was made by introducing a rule that a sale could be annulled by the seller if the price paid to him was less than 50 percent of the value of the goods sold.

In the Middle Ages the Christian Church attempted to enforce certain moral commands adverse to commercial transactions. The taking of interest for loans of money was considered income without true work and, therefore, sinful and prohibited. There was also an attempt to generalize the idea of a just price. Although both rules, and especially the former, influenced the law and the economy for centuries, neither of them finally prevailed in the secular world.

Emergence of the law merchant

Another feature of the medieval period was the development of a separate commercial law—the law merchant. Like the jus gentium of early Roman days, the law merchant was different from the existing ordinary rules that varied from place to place. The need for certainty and uniformity in the provisions governing trade motivated the growth of one set of rules for commercial transactions, valid everywhere in Europe. These rules were disseminated and applied in special courts conducted at the numerous international fairs held in various countries of Europe and attended by local and foreign merchants. The main sources of the law merchant were the customs of the most developed commercial communities of the time—the northern Italian cities. Later, in the 13th and 14th centuries, Italian, French, and Spanish cities made the first attempts at codifying certain branches of commercial law.

The medieval period saw the development of company and banking law. The *compagnia* and the *comenda,* forerunners of the partnership and limited partnership, were in frequent use. The Italians created a sophisticated system of bills of exchange used partly for the transfer and exchange of money, partly (by means of endorsement) for payment, and partly (by discounting) for credit purposes. They also invented bankruptcy as a method for dealing equally with an insolvent merchant's creditors.

In the period following the medieval era, but before the French Revolution, the law of commercial transactions lost its universal character. The birth of pronouncedly national states in Europe provoked a "nationalization" of the law. In 1673 and 1681 the French king Louis XIV enacted ordinances on land and maritime commerce. These were precursors of the French Commercial Code of 1807, which set the pattern for national codification of the law of commercial transactions in the Latin countries of Europe and America. In England the chief justice Lord Mansfield began from about 1756 to blend the law merchant into the common law. Only maritime law, although nationally codified, preserved some of its universal traits.

Of great consequence for the later development of commercial law was the foundation of colonial companies, usually through royal charter, for the exploitation and administration of the colonies of the European countries. The first, the Dutch East India Company, was chartered in 1602. Only such companies were able to attract the immense amounts of capital that were needed. The liability of each member was limited to his contribution, which was represented by share certificates that were transferable. Limited liability of shareholders and negotiability of shares were in fact fundamental to the operation of these companies. They were adopted and refined later into the most important vehicle of modern capitalism—the corporation.

ELEMENTS OF THE LAW OF COMMERCIAL TRANSACTIONS

In the 20th century, domestic as well as international commerce has experienced an expansion far beyond any earlier dimensions. With the multiplication of commercial transactions the demand for legal certainty has increased, especially for transactions across national boundaries.

Contractual relations. The first response to the multitude of practically identical transactions was the standardization of contracts. Printed standard contracts or forms lay down those provisions that are essential in the eyes of the drafting party. It depends upon the relative economic strength of the other party whether departures from the printed form can be negotiated. Trade associations as well as individual enterprises have developed and elaborated forms and standard contracts for their members.

The same technique of standardization has been adopted for international transactions. The forms and standard contracts of certain well-known trade associations, especially British ones, such as the London Corn Trade Association, are used by exporters and importers in many countries. The same is true of many shipping transactions. Even international bodies, such as the United Nations Economic Commission for Europe, have elaborated printed forms for certain international contracts. Apart from standardizing the contract practices of a particular party, these uniform conditions also help to bridge the gap between the many different national rules. They are a means of achieving partial uniformity of law for international trade.

International unification of commercial law

The development of uniform legislative rules for international transactions has been another distinctive feature in the 20th century. This trend resulted from the uncertainties to which international commercial transactions that came under two or more national jurisdictions were exposed. International conventions have resulted in the unification of numerous rules, especially in the areas of transportation, industrial property (patents and trademarks), copyright, and commercial paper (bills of exchange and checks). Less successful so far have been attempts in the fields of sale of goods and the conclusion of contracts.

Despite considerable progress in the field of unification, none of the uniform rules is really worldwide in scope, many being limited to a continent or to narrower regional groups such as the countries of the European Economic Community or the Council for Mutual Economic Assistance (of eastern Europe).

Sale of goods. The sale is the most common commercial transaction. All the rights that the seller has in a specific object are transferred to the buyer in return for the latter's paying the purchase price to the seller. The objects that may thus be transferred may be movable or immovable and tangible or intangible. (Patents are an example of intangibles.)

The essence of a sales transaction

Not all transfers of goods to another person for any purpose whatsoever constitute a sale. Goods may be transferred for use only (lease), for safekeeping or storage (bailment), as a present (gift), or in exchange for another good (barter). They may also be transferred as security. A sale is involved only if the seller intends to part with the object completely and conceivably forever and to receive instead a sum of money as the price.

The seller's complete parting with all his rights in the object sold means, in legal parlance, transfer of ownership to the buyer. One may say that the transfer of ownership for a price is the essence of a sale. But this rule applies only in countries with a free economy, not for the Socialist states in eastern Europe and East Asia, where the sale of goods among state enterprises transfers not ownership but merely the right of administration. Such sales are therefore designated as "delivery contracts." For most practical purposes, however, a sales contract and a delivery contract can be equated.

Obligations of the seller. The seller's duties are three: he must deliver the goods, transfer ownership in them, and warrant their conformity to the specifications of the contract.

Delivery of the goods sold to the buyer must be at the time and place and in the manner agreed upon by the parties. Nondelivery is sanctioned by the various legal systems in three different ways. Anglo-American law does not, in general, permit the buyer to sue for delivery of the merchandise but requires him to buy elsewhere and to demand damages from the original seller. The buyer is entitled to a decree for delivery (specific performance) only if damages are an inadequate remedy because the buyer cannot obtain substitute goods in the market. On the European continent, by contrast, a buyer may always demand delivery. Merchants do not usually go to the trouble of suing for delivery, however, but act voluntarily as their English and American counterparts are by law enjoined to act: they buy the same or similar goods in the market and then sue the nonperforming seller for damages. The measure of damages is usually the difference (if any) between the original contract price and the market price at the time of the substituted purchase. This covers the loss arising directly from the seller's nondelivery. Additional loss, such as expense arising from the substituted purchase or a loss on the intended resale of the goods, may also usually be claimed as damages from the seller.

Delayed delivery

From the point of view of the buyer, delayed delivery is connected with nondelivery in two ways. After the time for delivery has passed, the buyer may not know whether the seller is failing to deliver at all or whether delivery has merely been delayed. Further, the delay in delivery may be as harmful to the buyer's interests as outright nondelivery. This latter situation is particularly likely to arise if the agreed time for delivery was of the essence of the contract (that is, if it constituted so vital a stipulation that without compliance the contract could not be fulfilled). Even if the parties did not agree expressly that prompt delivery was crucial, such a condition may have been implicit because of the nature of the goods sold (for example, in a contract for the sale of raw materials subject to marked fluctuations in market price or for the sale of perishable or seasonal goods).

Countries differ considerably in the treatment of delayed delivery. Most legal systems require a more or less formal request for delivery or information by the buyer from the seller if a precise delivery date had not been agreed upon. If a precise time had been fixed but was not essential, such a request for information is usually unnecessary, except in France and some other Latin countries. But even if the buyer is not obligated to make inquiries of the seller, additional steps may be necessary in order to obtain remedies for nondelivery. In France and some other Latin countries, the buyer must bring suit for dissolution of the contract, and the judge may grant days of grace to the seller for performance. In West Germany, the buyer must grant the seller a reasonable period of time and declare unambiguously that he will refuse acceptance thereafter. Neither Anglo-American nor Scandinavian law protects the seller with such a period of grace. If the time element was crucial, the buyer's remedies in these countries are the same as for nondelivery. If, however, the seller did in fact deliver, although belatedly, the buyer may claim general damages for the loss arising from the delay.

Under certain circumstances the seller may be excused from his obligation to deliver on time. This is generally the case if prompt delivery becomes impracticable because of an unforeseeable and unavoidable obstacle. But if the seller owes a quantity of a certain kind of product and has not by the time delivery is due appropriated specific pieces for the purpose of delivery, he is rarely excused. In major contracts the parties usually make specific provisions concerning the conditions under which the seller is to be exempted from liability for late delivery.

Delivery must be accompanied by transfer of ownership to enable the buyer to enjoy full legal rights over the objects sold. The method of transferring ownership varies in two main ways. In most countries, ownership in a specific object is transferred with the conclusion of the contract of sale unless the parties agree otherwise. Such a transaction in Anglo-American law is called a "sale," as distinct from a mere "contract to sell." In the case of generic goods (any goods within a class rather than specifically designated goods; for example, 10 tons of coal), ownership cannot pass to the buyer until the seller has specified those goods which he intends to deliver (by transferring 10 tons of coal to a carrier for transportation to the buyer). But the parties may delay the transfer of ownership, perhaps until delivery to the buyer or until payment of the purchase price. If nothing has been agreed, the seller, although no longer the owner, may refuse to deliver or stop the goods en route to the buyer if the latter's solvency has become doubtful after conclusion of the contract. If the seller resells the same goods to a second buyer, the first buyer's claim to the goods prevails unless the second buyer has received the goods. In the central and eastern European countries ownership does not usually pass to the buyer until he receives the goods.

Although it would appear to be logical that a buyer cannot become the full owner unless the seller had unrestricted ownership, the demands of commercial expediency have carved out important exceptions in favour of a purchaser in good faith. Details vary considerably from country to country. At least between merchants, the acquisition of goods from one in possession of them who can in good conscience be regarded by the other as their owner, or at least as being entitled to their disposition, usually confers ownership on the buyer, even if the seller was not in fact the owner.

Remedies for defective title

The sanctions available to the buyer who does not obtain unrestricted ownership vary from country to country. Some countries impose upon the seller the outright obligation to procure ownership in the goods sold to the buyer. A violation of this duty is a breach of contract and opens the same remedies as those for nondelivery, including a suit for transfer of ownership. But in most countries the seller's obligation is limited to warranting "quiet possession"; that is, guaranteeing enjoyment of the goods undisturbed by claims of third parties. In some countries the warranty of quiet possession entitles the buyer who is sued by a third party to call the seller into the proceedings or even to turn the proceedings over to the seller so that the latter may defend the action. Everywhere the buyer may claim damages from the seller, covering not only the difference between the contract and the market price of the goods but also the expenses of defense against the claims of the third party. The buyer's rights are usually excluded if he knew of the seller's defective title at the time of contracting or if he became aware of it at some later time but nevertheless accepted the goods.

Caveat emptor

Goods sold must conform to the specifications of the contract as to their physical qualities, kind, and quantity. The rules on the delivery of goods of defective quality have a long history. Roman as well as English law originally denied the buyer the right of any claims as to quality under the doctrine of caveat emptor ("let the buyer beware"). This general rule did not apply, however, if the buyer had received express guarantees from the seller. Gradually the law developed various "implied warranties," the breach of which gave rise to certain special rights. As a result, the quality of goods is generally considered defective if they are unfit for the ordinary purposes for which such goods are used or unfit for the buyer's special purpose, provided the latter was known to the seller. As soon as possible after delivery the buyer must examine the goods for defects and must notify the seller if any are found. The buyer may then accept the goods but make a deduction from the purchase price for the defect. In most legal systems the buyer may alternatively reject the goods and dissolve the contract of sale. The buyer may also claim damages from the seller, but usually only under special conditions. A third remedy open to the buyer is to demand delivery of conforming goods, but this right is usually limited to generic goods. The buyer's rights are vitiated if he knew of the defect at the time of contracting or if he failed to avail himself of his rights immediately on delivery or within a limited time thereafter. Remedies for defective goods are often widely modified by contractual agreement between the parties.

Obligations of the buyer. The buyer's main duties are simple: payment of the purchase price and acceptance of delivery. Contemporary legal systems are no longer concerned with enforcing a just price. Only a few European countries (including Italy and France) still have rules on exorbitant prices and only in certain special fields. The buyer is strictly responsible for payment of the agreed price and cannot excuse himself by invoking his financial straits. Only war, revolution, exchange restrictions, and other unforeseeable and unavoidable obstacles to performance may, under certain circumstances, excuse the buyer from his duty to pay.

Just as the buyer is often unable to secure specific performance of the seller's duty to deliver, so the seller is not always able to enforce his claim for acceptance of delivery against a buyer who refuses to take delivery. Most countries do not object to such a claim, but in England and the United States the remedy is rather to refer the seller to the market: as long as he is still the owner of the goods, he should at least attempt to resell them at a reasonable price. Only if this is impossible or impracticable may he sue the buyer. In many other countries the seller, though not obliged, is at least entitled to resell the goods. The proceeds of the resale diminish the seller's loss; but the original buyer remains responsible for the difference. The seller may also, without actual resale of the goods, claim this difference as damages. If the buyer merely delays payment, the seller may usually claim compensation for any resulting loss. Very often this loss is calculated in a lump sum and takes the form of interest on the outstanding purchase price, the rate of which is in many countries provided for by statute. Additional damages for any further loss usually may be claimed. The buyer is, in general, excused from the payment of interest as well as additional damages if the delay of payment was due to unforeseeable and unavoidable obstacles.

The buyer's obligation to take delivery of the goods depends, as regards details, on the precise agreement of the parties: if steel plates, for example, have been sold "free on board vessel," the seller must load the plates on board the vessel named by the buyer. If the latter does not name a ship, the seller cannot perform his duty of delivery.

If the buyer fails to make provision for taking delivery, the seller still must preserve the goods, although he is no longer fully responsible for their fate. In many countries the seller may deposit the goods; in others he has the right to resell or a choice between the two. The proceeds of the resale take the place of the goods and have, therefore, to be paid to the buyer. The seller may claim damages arising from the buyer's breach of duty.

Mutual obligations of the seller and buyer. The duties of seller and buyer do not exist separately and independently from each other but are mutual and concurrent. Both parties assume duties in anticipation of the performance promised by the other party. It is a major consequence of the principle of mutuality of obligations that the duties of seller and buyer must be performed in general at the same time unless the parties agree otherwise. In international sales transactions it is often agreed that the seller must ship the goods to the buyer, so that the latter need not pay until he has received the goods and has thus been able to inspect them. Sellers may reestablish the time balance by demanding "payment against documents"; that is, payment when the buyer receives the documents of title, although the goods themselves may still be with the seller or in transit. The law everywhere protects the time sequence agreed upon by the parties by allowing a party to refuse its own performance as long as the agreed advance performance has not been made by the other party. The technical legal means used to achieve this result vary considerably. In exceptional circumstances the party that is obligated to perform first may refuse to do so. This may be justified if the other party's financial situation after conclusion of the contract has become so aggravated that payment is doubtful.

Time sequence of performance

Various countries differ widely in determining when risk for lost or damaged goods passes to the buyer. In several countries risk passes at the conclusion of the contract to sell; in others, notably France and England, risk is tied to the transfer of ownership in the goods; in West Germany and most eastern European countries, risk passes at the time of delivery; and in the United States and the Scandinavian countries, risk passes when the seller has essentially performed his duties. In all countries, the parties may, expressly or implicitly, agree to some other suitable arrangement.

Unification of sales law. The many differences in the sales laws throughout the world are a serious obstacle to an effective and smooth international trade. In view of the great volume of international trade, attempts at unification of sales law have been undertaken for many years. The most thorough results may be expected from a unification of the diverging rules on sales themselves. A more modest approach, however, has been to develop common rules on how to proceed when a conflict between the divergent national sales laws occurs. Efforts at unification have in fact followed both lines.

A considerable degree of unification of sales rules has been achieved by the wide acceptance of certain form contracts. But however successful some of these form contracts have proved, they have two important drawbacks: their validity depends on their acceptance by both contracting parties, and they cannot override the mandatory rules of national law.

These drawbacks can only be overcome by unifying national legislation. This method has been used with great success by the Socialist countries of eastern Europe. These have agreed, within the framework of the Council for Mutual Economic Assistance, on Uniform Conditions for Contracts of Delivery Between Foreign Trade Enterprises (1958, revised 1968 and 1975). The elaborate "conditions" have the force of law; the enterprises may not deviate from them except under special circumstances. For cases not expressly covered by the conditions, there is a uniform conflicts rule that declares the law of the seller's country applicable.

Other countries have had much less success. After almost 40 years of preparation, an international conference at The Hague adopted in 1964 a Uniform Law on International Sales. Under the auspices of the United Nations Commission on International Trade Law (UNCITRAL) a revised Convention on Contracts for the International Sale of Goods was signed in 1980 and entered into force on Jan. 1, 1988, in some countries.

A much more modest approach to the harmonization of legal divergences is the unification of the conflicts rules relating to international sales. A convention to this effect concluded in The Hague in 1955 has been ratified by eight European countries. According to this convention, the parties are free to choose the applicable law; if they do not do this, the law at the seller's place of business will, in general, govern the sales contract. The effect of these rules is, however, limited. They merely ensure that the courts in the participating countries will apply the same law to an international sales contract: the divergences between the different sales laws are not overcome.

Negotiable instruments. The negotiable instrument, which is essentially a document embodying a right to the payment of money and which may be transferred from person to person, developed historically from efforts to make credit instruments transferable; that is, documents proving that somebody was in their debt were used by creditors to meet their own liabilities. Thus a promise of A to pay B a certain sum at a specified date in the future could be used by B to pay a debt to C. This "negotiability of credit" was facilitated by the development of a variety of negotiable instruments including promissory notes, checks, and drafts (bills of exchange). These are in fact the most common negotiable instruments in use, and the following discussion will be confined to them.

Negotiable instruments are used for purposes of payment or credit and as security. Sometimes one instrument may perform all three functions. A typical "trade bill" used in connection with an inland or an export sale serves as an example of this: the seller, according to a clause of the contract of sale, may draw a bill on the buyer (that is, prepare a "promise to pay" that the buyer must sign) or, in the case of an overseas buyer, on a bank acting for the buyer, payment to be made within the agreed time (such as 30, 60, or 90 days after delivery). The buyer or his bank signs the bill as drawee and thereby becomes acceptor. On return of the instrument the seller may use this accepted bill to pay his own debts or may sell it to his bank (discounting). The buyer may also, although this is not typical for commercial transactions, draw a check on his own bank and send it to the seller.

Drafts as negotiable instruments

The most common and most complex form of negotiable instrument is the draft, or bill of exchange. It has been defined in England as an unconditional order in writing addressed by one person to another, signed by the person giving it (the drawer), and requiring the person to whom it is addressed (the drawee) to pay on demand or at a fixed or determinable future time a certain sum of money to, or to the order of, a specified person (the payee) or to the bearer. In the United States the definition is the same, except that an instrument may only be made payable "to order or to bearer." If the drawee assents to the order and accepts the bill, which is done by signing his name, or his name with the word "accepted," across the face of the paper, he is called an acceptor. The person to whom a bill is transferred by endorsement is called the endorsee. Any person in possession of a bill, whether as payee, endorsee, or bearer, is termed a holder and, if he is a bona fide purchaser, a holder in due course.

The basic rule applying to drafts is that any signature appearing on a draft obligates the signer to pay the amount drawn. It is the characteristic feature of a draft that it is not limited to the three-cornered relationship among drawer, drawee, and the named or unnamed creditor. Rather, the creditor may transfer it (for purposes of payment or borrowing) to a fourth party, and the latter may transfer it to a fifth, and so on, in a long chain. The means of accomplishing a transfer from one creditor to another is by endorsement or delivery. If an instrument is payable "to order," the signature (endorsement) of the transferor is required. The draft is then delivered to the new creditor. If the instrument is payable "to bearer," delivery alone suffices. Endorsement transfers the rights of the endorser to the new holder and also creates a liability of the endorser for payment of the amount of the draft if the drawee does not meet payment when the draft becomes due.

A failure to pay a draft must be more or less formally ascertained (in continental Europe through a formal "certificate of dishonour"). Upon due notice of dishonour, the holder of the draft may claim payment from any endorser whose signature appears on the instrument, and he in turn may claim from prior endorsers, from the drawee, and from the drawer.

The necessity of unifying the legal rules relating to negotiable instruments used in international trade has long been felt, and considerable success in this direction has been achieved. The principal rules in English law are laid down in the Bills of Exchange Act of 1882. This act spread through the whole Commonwealth and also influenced the United States Negotiable Instruments Act proposed in 1896 and eventually adopted throughout the United States. This latter act has since been replaced by article 3 of the Uniform Commercial Code. On the Continent uniformity between the French and the German approach was first achieved at two conferences held at The Hague in 1910 and 1912 and finally by two Geneva conventions of 1930 and 1931 on uniform laws for drafts, promissory notes, and checks. These latter agreements included some uniform provisions on conflicts of law. These have been adopted by most European countries and by many states in other parts of the world. Neither England nor the United States accepted these conventions, however, partly for fear of upsetting the uniformity already achieved in the Anglo-American orbit.

Documents of title. Whereas negotiable instruments embody a claim for the payment of money, documents of title embody claims to goods. The most common such documents are the bill of lading and the warehouse receipt.

Bills of lading

A bill of lading is a receipt for goods delivered for transportation by a ship. On receiving the goods alongside or on board, a dock or mate's receipt is issued and is later turned in for the bill of lading proper. The bill of lading may certify receipt of the goods either on board the ship ("shipped on board") or alongside ("received for shipment"). This latter form of bill of lading is less valuable since it does not prove the fact and date of loading. Apart from proving receipt of the goods to be shipped, the bill of lading incorporates the terms of the contract concluded between the carrier and the consignor for the transportation of the goods to the port of destination. A great many of the printed clauses on a bill of lading purport to excuse the carrier from liability for delayed delivery or from liability for damage to or loss of the goods. These clauses are valid, however, only if and insofar as they comply with the applicable national law or, in the case of ocean transport, with the Brussels Convention on Limitation of Liability (1923, amended 1968) that incorporates the Hague Rules, which have been adopted by the major shipping nations. Subject to these contractual terms, the consignee (the person to whom the goods are being shipped) may, by virtue of the bill of lading, demand delivery of the transported goods at the port of destination. In the simplest case the consignor sends the bill of lading by airmail to the consignee so that the latter may claim the goods on the arrival of the ship. The carrier may only deliver the goods to a person holding a duly negotiated bill of lading.

A bill of lading and the claim it represents may be transferred to another person by endorsement and delivery of the document. If made out to bearer (which happens rarely), the bill may even be transferred by mere delivery. By such transfer all the rights and obligations embodied in the document are transferred to the new holder. The latter is entitled to demand delivery of the goods unless the carrier proves that the holder knew or through gross negligence was unaware of the transferor's lack of title to the bill. In contrast with the rules on negotiable instruments, an endorsement of a bill of lading does not make the endorser liable for any default of the carrier or previous endorsers. The bill represents the goods, and transfer of the bill is, therefore, equivalent to delivery of the goods to the transferee.

It depends on the intention of the parties whether ownership in the goods or merely a security interest in them is to be transferred. A security interest is typically acquired by a bank, which gives credit on the security of the shipped goods. The above rules on bills of lading, though not formally unified, are essentially the same in all the seafaring nations. Most of them apply also to bills of lading issued in river navigation.

Warehouse receipts

The warehouse receipt is a document that shares the essential traits of a bill of lading, except that the duty to transport the goods is replaced by an obligation to store them. This receipt also embodies the claim for delivery of the goods and may, therefore, if made out to order, be transferred by endorsement and delivery. According to the intention of the parties, such a transfer may pass ownership in the stored goods or create other rights, such as a security interest, in them.

Letters of credit. Of great importance in international trade is the letter of credit. A letter of credit is essentially an authorization made by a buyer to his agent (usually a bank) to make payment to a seller. The letter of credit comes into use when there is a substantial time lag between the dispatch of goods by a seller and their receipt by the buyer. The seller, having sent the goods off, has fulfilled his part of the contract and seeks payment. The buyer, not having received the goods and being unable to inspect them, will be reluctant to pay. To overcome this difficulty the buyer and seller make arrangements to have intermediaries operating in each of the two countries involved make settlement. The buyer instructs his bank to issue a letter of credit authorizing payment to be made to the seller when the latter's part of the contract has been fulfilled (usually when the seller has dispatched the correct quantity of conforming goods). The buyer's (or issuing) bank ascertains whether or not this has been done by obtaining the cooperation of a bank in the seller's country. This bank (the "corresponding" bank), having inspected all of the relevant documents of title and bills of lading to ensure that the seller has performed, makes payment to the seller, often by means of a bill of exchange or other credit device. The document of title, bills of lading, and so forth are then mailed to the buyer. The buyer then reimburses his bank, which in turn reimburses the corresponding bank for making payment to the seller.

In no other branch of international trade have the efforts at unification of law been more successful than in that of letters of credit. In 1933 the International Chamber of Commerce in Paris published the *Uniform Customs and Practice for Documentary Credits,* which was revised in 1951, 1962, and 1983. It has been adopted by banks and banking associations in almost all countries of the world.

Loan of money. Second only to sales, the lending of money is one of the most frequent types of commercial transaction. No developed economy could exist without the credit financing of industrial investments, of commercial transactions, or of private acquisitions. A lender gives money to the borrower, who is obliged to repay it and to pay interest as well. Interest is thus the price for the utilization of the lender's money. The payment of such a price has not, however, always been regarded as permissible. For centuries the medieval Christian Church stigmatized interest as income without true work and, therefore, sinful. Religious restrictions on interest are, to this day, of great importance in the Islāmic countries. In the Socialist countries of eastern Europe and East Asia, the lending of money against interest, except through state banks, is strongly discouraged.

A loan is a contract between lender and borrower. It may consist of the immediate giving of money against the borrower's promise of repayment, or the contract may contain a promise of the lender to give the money at a future date. In the latter case it may sometimes happen that a borrower must sue an unwilling lender for performance of the promise to make the loan. As in the comparable situation of nondelivery in a sales contract, Anglo-American law (and also that of some other countries) refuses an action for specific performance and provides merely for damages, whereas most of the legal systems of continental Europe admit such an action. Specific performance of an agreement to take a loan may similarly be enforced against a borrower in most civil-law countries but not under Anglo-American law.

Interest on loans is today generally admitted. Among merchants it often must be paid even if not expressly agreed by the parties, since no merchant is regarded as willing to lend money without receiving interest thereon. Many countries fix the rate of interest to be applied in such cases. This legal rate has frequently been somewhere between 4 and 7 percent. Modern legislation sometimes establishes flexible rates, such as 2 percent above the (fluctuating) official discount rate of the country. Many countries also limit the maximum amount of interest that may be charged even if both parties have agreed on a higher rate. The maximum figure has frequently been between 6 and 12 percent, but in certain countries goes up to 30 percent or more. These "usury statutes" are likely to be circumvented by lenders who may demand considerable sums as commissions or "expenses." More flexible, but also less certain, are general laws declaring certain "usurious" transactions null and void.

Legal and maximum rates of interest

If a borrower does not repay a loan by the agreed date, he must reimburse the lender for his loss. Without even having to prove loss, the lender is at least entitled to default interest (that is, interest accruing after the due date of repayment). Some countries permit the lender to claim additional damages, whereas others exclude them.

A few countries, notably the United States, have established special rules regulating loans to consumers. This has usually been in response to abuses to which consumers have been exposed in connection with installment sales (hire-purchase agreements).

Security on loans. In the event of a borrower's bankruptcy, the lender may have to share the borrower's assets with competing creditors and may receive only partial satisfaction or even none at all. Lenders, therefore, urge borrowers to give security for the loan unless the credit standing of a specific debtor is free from any doubt. A security interest on goods (called collateral) entitles the creditor to satisfy his outstanding claim from the charged good to the exclusion of the other creditors of the borrower. Hence a security interest gives the secured creditor a right of preferential satisfaction from the goods charged with the security interest.

The demand for security on loans varies from country to country. In general, the demand is greater the more developed the credit system is. But even among countries having a comparable credit structure there are variations. Thus, certain countries, especially France, put legal obstacles in the way of modern forms of security, whereas others have recourse to various forms of personal security.

The oldest security device that is common everywhere is the pledge (or pawn). The borrower delivers the goods to be charged to the lender, who keeps them until repayment of the secured loan. This security device has become rather outmoded today and is utilized only in relatively few situations. But pawnbrokers continue to operate on a minor scale, and banks keep documents of title (such as property deeds) as security.

The decisive drawback of the pledge is the necessity of transferring the goods to be charged to the lender. Hence the borrower cannot use them for production, sale, or lease. There has thus been a trend away from the pledge to other forms of security by which the goods charged remain in the hands of the borrower. Many new devices have been introduced in the last hundred years, and they vary considerably in their operation. For want of a common descriptive name they will be referred to as "no-pledge devices." They all attempt to overcome the problem posed by the fact that third persons, relying on the outer appearance of a well-funded borrower, have no means of knowing whether or not the borrower's assets are in reality already charged in favour of another lender.

Creation of security interests

The most common method of warning third persons against existing security interests has been by their registration. Goods so charged are entered in a public register together with details about the goods themselves and the security agreement. A simpler method of giving publicity to a security interest is by marking the charged goods. This is still sometimes used in the case of cattle. Some countries also employ the method of "privileging" specific lenders. They endow the loans of certain lenders (usually publicly held or controlled banks) with a security interest or a right of preferential satisfaction. All the borrower's goods, or at least those that have been acquired by means of the loan, are automatically charged.

In the absence of any of the above three methods, various indirect techniques are usually employed. The need for sellers to retain a security interest in the goods sold until the purchase price has been paid has been particularly acute. In some, especially Latin, countries, the rules on sales provide the seller with a statutory right of preferred satisfaction. But in most jurisdictions, the seller must make his own arrangements. Since the transfer of ownership in the goods is subject to the agreement of the parties, the seller may retain his ownership in them until he has received the full purchase price. Such a "conditional sale" is recognized in many countries even without registration, since it is regarded as a modified sales transaction. If the seller himself is using credit to finance his credit sales, the financer can usually be secured by transferring to him the seller's retained ownership. In some countries, including Great Britain, the so-called hire-purchase method is widespread, especially in sales to consumers. The seller retains ownership but surrenders the goods that the buyer intends to acquire on hire to him against a down payment and a monthly rental. If in due course the rental payments accumulate to the sale price, ownership is transferred to the purchaser. Here again registration is usually not required since the transaction is cast into the form of a lease.

In the case of lenders who are not at the same time sellers it has been more difficult to find adequate security devices. One of the most successful methods has been developed in close analogy to hire-purchase sales transactions. The borrower transfers ownership in the goods financed by the loan to the lender but retains them in his possession by means of a lease agreement between him and the lender. After repayment of the secured loan the borrower reacquires title from the lender.

The disposition of charged goods

Under modern economic conditions it is rarely feasible to deprive the borrower of charged goods, as the rise of no-pledge security interests demonstrates. But the goods frequently do not even rest in the borrower's hands. This is especially likely to be the case if the borrower is a trader; he will probably want to sell the goods that he has charged. A manufacturer may similarly wish to replace charged machinery. In these instances the need arises to allow the borrower the desired disposition of the goods and at the same time to maintain the lender's security interest. A number of legal systems, however, do not yet recognize the legitimate interests of both parties in this situation. They prohibit any disposition by the borrower and may not admit a security interest in goods that remain in the borrower's hands for purposes of resale. This problem has been solved in the United States and Great Britain, although on slightly different lines in the two countries. In the United States the original registration may provide that the security interest is to extend to the proceeds from the disposition of the goods or to products of the charged goods. In Great Britain the right to a "floating charge," granted against its assets by a borrowing company to a lender, has the same effect.

A security interest proves its legal value when under attack by third parties. If it is to fulfill its function of guaranteeing to the lender preferential satisfaction of his claim, the charged goods must be immunized as much as possible against the rights of other persons. The third party is frequently a person who has unknowingly purchased charged goods: borrowers in financial straits may be unable to resist the temptation of selling charged goods left in their hands to a third person without the consent of the lender and without making the proceeds of the sale available to him. Most countries tend to protect the buyer, provided he neither knew nor ought to have known of the existing security interest. If the charged goods are marked, the buyer can hardly claim to have purchased in good faith. But mere registration does not usually give the buyer sufficient notice, since sales transactions cannot be burdened by requiring the buyer to search a register in a distant place.

The borrower's other creditors are also likely to have an interest in charged goods. But creditors, as distinct from buyers, are usually expected to search existing registers of charged goods. If they have neglected to do this, they must suffer the consequence of being subordinated to the lender's security interest.

Enforcement of security interests

Failure of repayment. If the borrower does not make payment after the secured loan has fallen due, the lender may pursue two different courses. He may enforce his claim for repayment before the courts just as any other creditor or he may enforce his preferred position as a secured lender. The rules to be followed in enforcing a security interest differ considerably from country to country and even within a country according to the type of security interest involved. Very often the lender must sell the charged goods by public sale; occasionally he is permitted to acquire the charged goods himself. If the proceeds of a sale exceed the amount of the secured loan, the surplus must be paid to the borrower, whereas the borrower remains liable for any deficit. All legal systems frown upon clauses that permit a lender to acquire the charged goods automatically on the borrower's failure to pay.

The rules on security interests are still strongly national in character. The need for unification has, except in a few specialized areas, not been very urgent. This is largely because, in the great bulk of international sales transactions, the seller, wherever necessary, may secure himself by insisting on payment by letter of credit. But of some international concern was the question of the protection of security interests in those means of transportation that move constantly from one country to another. Two international conventions on security interests in ships and aircraft have, therefore, been concluded. They do not provide uniform rules on security interests but merely guarantee that an interest validly created in one contracting state will be recognized in any other contracting state. The number of countries that have adopted these conventions is, however, limited. (U.M.D.)

Bankruptcy and insolvency

Bankruptcy laws were enacted to provide and govern an orderly and equitable liquidation of the estates of insolvent debtors. This purpose has remained an important aim of bankruptcy legislation since the Middle Ages. Because in the past bankruptcy was coupled with the loss of civil rights and imposition of penalties upon fraudulent debtors, the designation bankrupt came to be associated with dishonesty, casting a stigma on persons who were declared bankrupts. Eventually, however, bankruptcy legislation was extended to provide procedures for the adjustment of debts so as to avoid liquidation and for the rehabilitation of insolvent debtors. Modern bankruptcy laws, therefore, include detailed provisions for preventive compositions, arrangements, or corporate reorganizations of various types. In fact, the salvage of an enterprise in financial difficulties has become the principal focus of insolvency legislation with particular concern for the maintenance of employment opportunities and the protection of members of the labour force.

In addition, the bankruptcy laws of England, the United States, and the British Commonwealth nations traditionally came to include provisions for the unpaid portions of debts incurred prior to bankruptcy in order to give honest but unfortunate debtors a new start in life. The bankruptcy laws of the European and Latin-American countries, by contrast, did not have such provisions. In the late 20th century, however, legislation in some of these countries (*e.g.,* Argentina and France) provided for the discharge of the unpaid portion of pre-bankruptcy creditors under certain conditions.

Since bankruptcy laws aim at the liquidation or rehabilitation of insolvent estates, bankruptcy proceedings involve all nonexempt assets of the debtor, and all creditors entitled to share in the proceeds of the liquidation or in the adjustment of their claims are called to participate. Accordingly, bankruptcy proceedings are viewed as general or universal collection procedures as distinguished from individual collection remedies available to particular creditors for the enforcement of their claims.

HISTORY OF BANKRUPTCY LAW

Early developments

Modern bankruptcy law has been formed from a number of distinct historical strands. In ancient Roman law an unpaid judgment creditor could have the debtor's estate sequestered (*missio in bona*) and sold for the benefit of all creditors (*venditio bonorum*). Proceedings of this type caused loss of civil rights. To alleviate this hardship a debtor was given the privilege of relinquishing voluntarily his assets to his creditors by petitioning a magistrate (*cessio bonorum*).

During the Middle Ages both institutions underwent a revival and development. The medieval Italian cities enacted statutes dealing with the collection and distribution of the assets of debtors, especially merchants, who had absconded or fraudulently caused insolvency. Such bankrupts (*rumpentes et falliti*) were subjected to severe penalties, and their estates were liquidated. In addition, medieval Spanish law restored the judicial *cessio bonorum.* The Siete Partidas, a codification published by authority of Don Alfonso X the Wise, king of Castile and León, during the second half of the 13th century, contained detailed provisions relating to insolvent debtors, applicable to merchants and nonmerchants alike, enabling them to secure a voluntary liquidation of their assets under judicial supervision. An unpaid creditor could insist on either payment or assignment of his estate by the debtor to all creditors.

Laws dealing with the property of absconding and fraudulent debtors, modeled after the statutes of the medieval Italian cities, spread throughout western Europe. Provisions of this type were adopted in the commercial centres of France, Brabant, and Flanders during the 15th and 16th centuries. The customs of Antwerp, printed in 1582, contained comprehensive rules on the treatment of bankrupts and their estates. The emperor Charles V, as count of Flanders, inserted stringent provisions for the repression of bankruptcies in his Decree for the Administration of Justice and Good Order of 1531. There can be no doubt that the first English "acte againste suche persones as doo make Bankrupte," passed in 1542/43, was inspired by the northern European models, as the title reproduces the Flemish expression. It governed proceedings instituted against absconding or concealed debtors. It was replaced by a more detailed act of 1571 that applied only to merchants and other traders. Voluntary proceedings were not provided in England until 1844 and not in the United States until 1841.

In France, national rules on insolvency and bankruptcy were inserted into the Ordonnance du Commerce of 1673. It regulated both voluntary assignments for the benefit of creditors made by merchants (Title X) and the proceedings and effects flowing from bankruptcy (Title XI). It was interpreted to restrict bankruptcy proceedings to merchants only, and the laws of many other countries followed the French lead. Thus in Spain the limitation of bankruptcy to merchants was adopted by the Ordinances of Bilbao, which were sanctioned in 1737 and subsequently applied in Latin America, especially Argentina.

The restriction of bankruptcy legislation to persons engaged in commerce created a need for liquidation proceedings applicable to other debtors. As mentioned above, the Siete Partidas contained provisions for voluntary liquidation proceedings applicable to all classes of debtors. On that basis a Spanish jurist of the 17th century, Salgado de Somoza, elaborated detailed rules for the initiation and conduct of voluntary liquidation proceedings, which were styled "concourse of creditors." His tract, entitled *Labyrinthus Creditorum,* influenced the course of Spanish law and also had great impact on the common law of the German states. As a result, Spanish law developed two classes of liquidation proceedings, one for merchants and one for nonmerchants. Spanish law in that respect was the model for the legislation in Portugal, Argentina, Brazil, and other Latin-American countries. Other nations, including Austria, Germany, England, the United States, and nations influenced by English laws, brought both merchants and nonmerchants under their bankruptcy laws. More recent laws in Latin America (*e.g.,* in Argentina and Peru) likewise have established a unified system. France, Italy, and a few countries in Latin America, however, do not provide true insolvency proceedings for ordinary debtors.

Avoidance of bankruptcy

The dire consequences of bankruptcy for the debtor, such as the loss and liquidation of his assets, criminal penalties, and loss of civil rights, resulted in the need for procedures avoiding such sanctions. A remedy was found in the right of a deserving debtor to reach an agreement for an extension or reduction of his debts with a majority of his creditors that was binding on dissenters. The cradle of this institution was again the statutes of the medieval cities. Provisions to that effect were also contained in the Siete Partidas. In England, similar procedures were developed by the Privy Council through bills of conformity, but this practice ended with the abolition of the council's civil jurisdiction in 1641. In France the Ordonnance du Commerce of 1673 recognized majority compositions as a legitimate means of handling the estates of insolvents without liquidation. The Commercial Code of 1807, however, and following it the laws of other countries, restricted them to a method of terminating rather than preventing bankruptcy proceedings. Preventive compositions were reintroduced as legitimate means of dealing with embarrassed or insolvent estates only during the second part of the 19th century; they are now recognized in most countries as important devices for economic rehabilitation.

At one time all bankrupts were considered defrauders and criminals. They were subjected to severe social and professional sanctions, including even a degrading form of dress. In recent times, however, great efforts have been made to remove the disgrace attached to bankruptcy. Even the terms bankrupt and bankruptcy (or their equivalents in other languages) are used less and less frequently in the statutory language. Modern French legislation, for example, totally suppresses the traditional term *faillite* as the name of liquidation proceedings and restricts it to special procedures entailing the imposition of disqualifications on insolvents guilty of commercial misconduct.

LIQUIDATION OF THE ESTATES OF INSOLVENT DEBTORS

Most nations with private-enterprise economies have legislation providing for liquidation of hopelessly insolvent estates. Socialist countries treat financial difficulties of their economic organizations in a manner aiming at rehabilitation rather than elimination. By the late 20th century, however, many countries not considered Socialist likewise were resorting to liquidation of enterprises only as an ultimate measure and instead favoured techniques to rescue distressed enterprises, sometimes by direct financial intervention. Conversely, Yugoslavia and, more recently, Hungary have enacted legislative measures in the nature of bankruptcy laws. The People's Republic of China has introduced draft legislation governing the liquidation of insolvent enterprises by way of experiment.

Liquidation proceedings are often referred to as "straight" bankruptcy, in contradistinction to other insolvency proceedings aiming at arrangements or reorganizations. Recent insolvency laws, such as those enacted in Argentina and France, provide for a unified procedure in which liquidation is decreed only after the possibility of reorganization has been found not to exist or an attempted reorganization has failed.

Differences in coverage of laws

Persons subject to judicial liquidation of their estates. Bankruptcy or insolvency laws vary considerably in their applicability to particular classes of persons. The West German act and, following its example, the Austrian and Japanese acts extend bankruptcy proceedings to all natural and legal persons, whether or not they are engaged in commerce and without differentiating between petitions by the bankrupt himself or by creditors. In the United States, individuals, whether merchants or nonmerchants, as well as private corporations, with the exception of certain financial institutions, are subject to the Bankruptcy Code. Involuntary petitions, however, cannot be filed against farmers and nonprofit corporations. Moreover, proceedings for debt adjustment of individuals cannot be initiated by creditors. Canada likewise applies its act to individuals and corporations. It excludes, however, certain financial institutions and nonbusiness corporations in general. In England the former Bankruptcy Act covered only individuals, whether merchants or not. Registered companies were liquidated under the winding-up provisions of the Company Law. A great number of the provisions of the Bankruptcy Act, however, were made applicable in such proceedings. The dual system still governs in Australia, New Zealand, and India. A number of nations, following the model of the French law of 1838, extend their bankruptcy laws only to persons qualifying as merchants or engaging in trade but do not differentiate between individuals and corporations. To that class belong the bankruptcy laws of Italy (with the exception of small enterprises), Spain, Portugal, Switzerland, and a number of Latin-American countries, including Bolivia, Brazil, Colombia, Mexico, and Venezuela. Argentina, Chile, and

Peru, however, follow the German pattern and subject to their bankruptcy laws all individuals and corporations, whether merchants or not. A number of the countries that restrict bankruptcy to merchants have, however, inserted provisions for insolvency proceedings governing nonmerchants in their codes of civil procedure. France extends its new insolvency law (1985) to merchants, artisans, and all legal persons even if not merchants.

Persons entitled to initiate liquidation proceedings. Modern bankruptcy laws provide for the initiation of liquidation proceedings upon petition by either the bankrupt himself or his creditors. There are differences as to the number of creditors who must join in a creditor's petition. A great number of laws are satisfied with a petition by a single creditor regardless of the amount of his claim, the total number of creditors, or the amount of the outstanding indebtedness, so long as the debtor is unable to meet his current payments or has committed a so-called act of bankruptcy. Petition by a single creditor suffices according to the law of Germany (1877) and, following it, of Japan; the laws of Austria, France, Italy, Portugal, Spain, and Switzerland; and the laws of such Latin-American countries as Argentina, Brazil, Chile, and Mexico. In Austria at least one other creditor must exist, although he need not join in the petition; but the sufficiency of one unpaid creditor is provided expressly in the Chilean and Mexican acts.

A somewhat different regime exists in the common-law countries. In England, Canada, Australia, and New Zealand, as well as India, a single creditor may be a petitioner if the unsecured part of his claim equals or exceeds a specified amount. Otherwise, other creditors must join until the aggregate amount of their claims equals the requisite sum. In the United States in 1978, the unsecured indebtedness of the bankrupt had to be at least $5,000, and a petition by three or more creditors with unsecured claims aggregating at least that amount was required if the total number of creditors was 12 or more; otherwise one or two creditors with such claims totaling at least that amount might be petitioners.

In some countries the initiation of liquidation may also be decreed by the court ex officio or upon petition by public officials. Ex officio action by the court is provided, for example, in Italy, France, and Mexico. Moreover, these countries and, in addition, East Germany and Portugal authorize public officials to file petitions for the liquidation of bankrupt estates. In a number of countries, following in that respect the traditional French approach, a bankrupt debtor is under a duty to file a petition, and his initiation is not left to his own judgment as in the common-law countries.

Substantive prerequisites of liquidation proceedings. The bankruptcy laws of the various nations differ materially as to the definition of the substantive grounds for the institution of insolvency proceedings, especially those initiated by creditors. The majority of laws employ general formulas, such as cessation of payments (Argentina); impossibility to meet current indebtedness with disposable assets (France); lack of ability to pay all debts, taking account of contingent and prospective liabilities (England); general nonpayment of debts, not subject to a bona fide dispute, as they mature (United States); inability to pay or excess of liabilities over assets (West Germany); or inability to satisfy regularly one's liabilities (Italy). Some of the common-law countries, including Australia, Canada, India, and New Zealand, require a creditor's petition upon commission by the debtor, within a specified period prior to the petition, of one or more "acts of bankruptcy" or "acts of insolvency" listed in the respective statutes. These acts, which vary among statutes, include public manifestations of insolvency as well as conduct that endangers the collectibility of debts or entails preferential treatment of certain creditors by an insolvent. Some jurisdictions have mixed systems. Liquidation is decreed if the debtor has either resorted to cessation of payments or committed specified acts manifesting insolvency. Laws of that type apply in Spain, Portugal, Brazil, Chile, and Mexico. In some of these laws (*e.g.,* that of Mexico) the commission of these specific acts raises merely a presumption of a cessation of payments. In Brazil and Chile even a single default in the payment of a liquid and exigible indebtedness warrants proceedings if the obligation has remained unpaid after demand. In Switzerland institution of liquidation proceedings likewise can be based on cessation of payments or on the commission of other specified acts of bankruptcy.

Acts of
bankruptcy

Assets subject to liquidation proceedings. One of the most important aspects of bankruptcy legislation is the determination of the assets to be seized and sold for the purpose of distributing the proceeds among the creditors. Various legal systems have vastly different approaches. The disparities relate mainly to the status of assets acquired by the bankrupt subsequent to his adjudication or conveyed away by him prior to that date.

The
bankrupt's
estate

In West Germany all nonexempt assets belonging to the bankrupt at the date of the adjudication form the bankrupt estate. Assets that are no longer owned by the bankrupt at the time of the adjudication are not included in the bankrupt estate unless their sale, transfer, or other disposal is voidable under special rules permitting the avoidance of fraudulent or preferential transactions. The Bankruptcy Code of the United States follows a similar approach, except that the "date of cleavage" is not the date of the adjudication but the date of the filing of the petition. Postpetition acquisitions are part of the bankrupt estate under the U.S. law only if they constitute narrowly defined "windfalls," such as inheritances or bequests settled on the bankrupt within six months from the filing date. On the other hand, many other bankruptcy laws include within the estate subject to distribution all nonexempt assets acquired after the adjudication and during the period of the proceedings. Thus the English Insolvency Act, 1986, provides that in individual bankruptcies the bankrupt's estate comprises all nonexempt property owned by the debtor on the day on which the bankruptcy order is made and any property claimed by the trustee (the person charged with the administration and liquidation of the bankrupt's estate) that has been acquired by or devolved upon the bankrupt since that time and until the date of his discharge. Similar provisions exist in Canada, Australia, and New Zealand, except that in Australia and New Zealand the date for determining what is property of the bankrupt estate relates back to (*i.e.,* is retroactive to) the date of the earliest commission within a specified period of an act of bankruptcy by the bankrupt. This "relation-back" theory, however, is qualified by numerous exceptions.

In the majority of civil-law countries that follow the traditional French model the bankrupt estate likewise includes all nonexempt property owned by the debtor at the date of the adjudication and all property acquired during the course of the proceedings until the close of the case or the rehabilitation of the debtor. Subject to variations in details, laws of that type operate in, for example, Argentina, Austria, Brazil, Italy, Portugal, Spain, and Switzerland. Some of these laws (*e.g.,* those of Chile and Italy) make special exceptions for future earnings to the extent that they are necessary for the debtor's maintenance. The 1985 French law on economic rehabilitation and liquidation also includes in the bankrupt estate all property acquired on whatever grounds until the close of the proceedings. With the exception of Austria, Italy, and Switzerland, the countries listed above retract the effective date of adjudication to the date of the cessation of payments.

The insolvency or bankruptcy laws of England and other countries that follow the English model give title to the property forming the bankrupt estate to the trustee or assignee in bankruptcy. In the United States the estate is a separate legal entity represented by a trustee. In the other countries liquidation proceedings divest the bankrupt of his power of administration and disposition, but he retains the title to the assets of the estate. The estate, however, forms a separate unit, often called the mass.

The
bankrupt's
estate

As indicated above, a number of bankruptcy laws contain a relation-back effect, dating the bankrupt estate as of the time of the petition, the earliest commission of an act of bankruptcy, or the cessation of payments. The model for that approach in the civil-law countries whose laws were based on the French codes was the French Commercial

Code of 1807. It required the decree of adjudication to fix the date of the cessation of payments and provided that transactions by the bankrupt after that time and before the adjudication (called the critical, or suspect, period) did not affect the estate. In 1838 France replaced the general relation-back theory with a catalog of transactions, mostly various types of gratuitous or preferential transfers, that were rendered ineffective against the mass if made during the critical period. The law of 1985 in essence retains that approach. Most countries limit the duration of the period of possible retroactivity. Spain is one of the countries still adhering to the general invalidation of transactions following the cessation of payments. Italy abolished the relation-back effect in 1942.

Preferences. One of the cardinal principles governing the liquidation of insolvent estates is the equal treatment of creditors—the classical *par condicio creditorum.* Debtors on the eve of bankruptcy, either on their own volition or under pressure, may accord preferential treatment—by way of payment or security—to certain creditors. The bankruptcy laws of most, if not all, countries therefore contain rules aiming at the reintegration of the bankrupt estate through avoidance of preferences given after insolvency or cessation of payments or even earlier. These provisions are included in, in lieu of, or cumulative with a general relation back of the effects of the adjudication. Again, the laws of the different countries vary greatly with respect to the elements, especially those of a subjective character such as intent on the part of the debtor or knowledge of the debtor's financial status on the part of the creditor, that must be present to make a transfer voidable as a preference.

In the United States, except in the case of insiders, the preference period is 90 days before the date of the petition; transfers to existing creditors made within that period that have a preferential effect are voidable, unless the debtor was neither insolvent at the time of the preferential transfer nor rendered insolvent thereby, or the payment was made in the regular course of business. In England a preference given by an insolvent, or an individual rendered insolvent thereby, to a creditor other than an associate of the debtor is voidable if it was made within six months prior to the filing of the bankruptcy petition and was motivated by the desire to give a preference. In Canada, in cases other than preferences to creditors related to the debtor, the preference period is three months prior to the receiving order (*i.e.,* the order initiating the proceedings). The transfer must have been made or suffered by an insolvent with a view to giving the creditor a preference; but this element is presumed to exist if the transfer in fact had a preferential effect. In Australia the preference period commences six months prior to the petition. A transfer within such preference period by the bankrupt to a creditor that gives the creditor a preference is voidable if the debtor was insolvent at that time, unless the creditor had no reason to suspect that the debtor was insolvent at that time and that the transfer would give him a preference. The New Zealand law differentiates between preferences made by an insolvent with the view of giving a preference and preferences made without such purpose. In the first alternative the preference period is two years prior to the date of adjudication, in the second it is one month.

Presumption of intent

The French law of 1985, preserving vestiges of the traditional relation-back theory, invalidates payments of debts made after their due date and the date of the cessation of payments if the recipient had knowledge of the cessation of payments. In addition, anticipatory payment of unmatured debts, payment of debts made by other than ordinary means of payment, or the grant of security interests for preexistent debts are invalid if made after the cessation of payments, regardless of the creditor's knowledge. Rules of the latter type also govern in Latin-American countries (*e.g.,* Argentina, Brazil, Chile, and Mexico). In Argentina the payment of matured debts with ordinary means may be voidable if the creditors knew of the cessation of payments. The laws of these countries vary as to the outer limits of the suspect period, ranging from two years in Argentina and Chile to 60 days in Brazil.

In the civil-law countries that do not adhere to a general relation-back doctrine, such as West Germany, Italy, or Portugal, preferential transfers to creditors prior to an adjudication may be voidable, but the governing laws vary materially as to the relevant time frames and types of preferences. In West Germany transfers by the debtor granting a security interest or satisfaction to which the creditor at that time was not entitled are voidable if made within 10 days prior to or after a cessation of payments or filing of a bankruptcy petition, unless the creditor shows that at that time he knew neither of the cessation of payments or petition nor of a preferential intent on the part of the debtor. The voidable act may not precede the adjudication by more than six months. In addition, security interests or satisfaction obtained by the creditor after a cessation of payments or filing of a petition are voidable if the trustee shows that the creditor knew of the cessation of payments or petition. In that case the date of the adjudication is irrelevant. Similar rules governing preferences apply in Austria. Voidability is provided if the preference was obtained within 60 days prior to or after the petition or within one year prior to the adjudication after insolvency. Moreover, in the case of transfers to the creditor in conformity with an obligation, the trustee must prove the preferential intent of the debtor and knowledge thereof by the creditor, whereas in the case of payments made or security interests granted not in conformity with an existing obligation, the only defense is lack of preferential effect. In Italy anticipatory payments of debts that fall due only on the day of or after the adjudication are *ipso jure* (by the law itself) invalid if made within two years prior to the adjudication. Payments, effected by normal means, of debts that were payable at the time of such payment are voidable as preferences provided that the payment was made within one year prior to the adjudication, while the debtor was insolvent, and the trustee shows that the creditor knew the debtor's state of insolvency. Payment of matured debts made by other than normal means and security interests granted for preexisting unmatured debts are voidable if made within two years prior to the adjudication unless the creditor shows that he was ignorant of the debtor's state of insolvency. In Switzerland voidable preferences consist in the grant, without prior obligation to that effect, of security interests for existing debts; satisfaction of debts by other than usual means of payment; or premature payment of debts, if the respective acts were committed within six months prior to the adjudication, while the debtor was insolvent. The creditor can defeat the avoidance by showing lack of knowledge of the debtor's financial condition. In addition, all acts committed with the intent to prefer a creditor are voidable for five years after their execution, if the intent was recognizable by the creditor.

Creditors entitled to share in the distribution of the estate. One of the principal objectives of bankruptcy is the distribution of the proceeds of the estate among the creditors. The designation of the categories of claims entitled to share in such distribution, the order of distribution, and the regulation of the procedures for their establishment form an important ingredient of modern bankruptcy legislation. At the outset a distinction must be made between secured and unsecured creditors. The recognition and assertion of security interests is subject to rules that aim at the separate satisfaction of the secured party from the proceeds of the collateral. To the extent that a secured creditor holds a claim that exceeds the value of the collateral—a so-called undersecured creditor—the creditor must comply with the rules governing unsecured debts. Many laws also require timely claim of security interests to permit orderly distribution of the estate. Moreover, the separate enforcement of security interests may be barred by the institution of bankruptcy proceedings. Security interests may be voidable as fraudulent or preferential transfers or because of inconsistency with overriding policies of the bankruptcy legislation. Except for these limitations, a security interest will remain unimpaired by bankruptcy and provide priority over creditors who do not possess a right of satisfaction from the specific property. The French law of 1985, however, subordinates all types of security interests to the rights of creditors originating during the period between the order instituting the procedure for economic rehabilitation or liquidation and the order of liquidation, and there is a general complaint against the consumption of the assets by secured creditors.

Provable claims

Generally speaking, "bankruptcy debts" or "provable claims" are based on transactions or occurrences prior to the date of bankruptcy. Creditors whose claims result from acts in, or expenditures for, the administration of the bankrupt estate are not creditors of the bankrupt and are paid before the latter. Post-bankruptcy debts incurred by the debtor are not payable from the estate. The line that divides provable post-bankruptcy claims from non-provable post-bankruptcy claims varies. In England, Australia, and Canada debts provable in bankruptcy (bankruptcy debts) include any debt or liability to which the bankrupt is subject at the date of the bankruptcy or to which he may become subject before his discharge by reason of an obligation incurred before the date of bankruptcy. In England liabilities accruing after the debtor's discharge on an obligation incurred before bankruptcy are also provable. The date of bankruptcy within the meaning of these laws is that of the adjudication or making of the sequestration or receiving order, respectively. In the United States the date of the petition controls the determination of provable debts, but "gap creditors" are included if the adjudication follows an involuntary petition. In continental European and Latin-American countries and countries influenced by their laws, such as Austria, France, West Germany, Italy, Portugal, Spain, Argentina, Brazil, Chile, and Japan, creditors entitled to share in the estate are likewise those whose claim originated prior to the adjudication, while subsequent creditors are relegated to assets not entering into the estate.

Under most modern bankruptcy laws provable debts include all types of pre-bankruptcy obligations, whether matured or unmatured, liquidated or unliquidated, unconditional or contingent. A provable unliquidated liability may be based on contract or tort, including personal injury as well as damages to property. This also holds true for most common-law countries, in particular England, the United States, Canada, and New Zealand. In Australia, however, demands for unliquidated damages arising other than by reason of contract or breach of trust are not provable. In Brazil creditors with unliquidated claims are entitled to the setting aside of a reserve. If at the time of proof the amount of the liability is still undetermined, many laws provide that it may be estimated.

In principle, bankruptcy laws aim at equality among creditors. Nevertheless, for social or fiscal reasons bankruptcy laws recognize or grant preferential rights to certain categories of claims. These rights are not security interests in particular assets but priorities in the distribution of the proceeds from their sale. These priorities may attach either to the proceeds from the entire estate or only to those from certain classes of assets. Some bankruptcy laws establish complex hierarchies of priority. The most common general priorities relate to tax claims and claims of or for the benefit of the labour force. In some countries labour claims not only have priority over all other provable claims but outrank even the rights of secured creditors. Examples of the latter approach are the laws of Brazil and France.

Discharge of debts. An English statute of 1705 provided for a discharge (release) of all debts owed by the bankrupt and due at the time of bankruptcy provided the bankrupt had faithfully complied with his statutory duties. Since that time relief of the honest but unfortunate debtor from his provable debts has become one of the main objectives of bankruptcy legislation in countries influenced by the English system. The right to a discharge is not unqualified and may be forfeited by the commission of acts that the particular legislation considers as meriting this sanction. Moreover, certain debts are excepted from the operation of the discharge, as, for example, liabilities for support under the governing family-law provisions or for certain types of personal injury.

In England discharges are automatic after the expiration of specified periods, usually three years, unless the court has suspended or conditioned the running of the period. In the United States a discharge requires a court order, but the debtor is entitled to a discharge unless he has engaged in conduct defined by law that disqualified him from receiving it and the trustee or a creditor has objected to the discharge. There is no statutory waiting period.

In Australia and New Zealand a debtor is automatically discharged three years after the date of adjudication, unless an objection to the discharge has been entered by the trustee or a creditor. In addition, the bankrupt may obtain an earlier discharge by court order upon application, which may be subject to conditions. Conditional discharges also may be ordered under Canadian law. Provisions for discharge exist in South Africa and in an increasing number of civil-law countries. Japan introduced discharge provisions modeled after U.S. law in 1952. Brazil, Argentina, and, most recently, France adopted provisions for the extinction of debts to the extent that they remain unsatisfied by dividend payments. In France that rule is absolute; in Argentina and Brazil it is subject to specified conditions and qualifications.

Roles of the court, the administrator, and the creditors in bankruptcy proceedings. Since insolvency proceedings aim at a judicially approved or supervised rehabilitation or liquidation of the estate of an insolvent, the proceedings must be initiated in a court having the necessary judicial powers. The bankruptcy laws of different countries, however, vary considerably with respect to the jurisdiction of the bankruptcy court over the phases of a case and the relative roles assigned to judicial officers, administrators, and creditors in the conduct of a case.

Jurisdiction of the bankruptcy court

During the formative period of bankruptcy law in the 18th and 19th centuries the courts developed the doctrine of the "force of attraction" of bankruptcy proceedings, resulting in the concentration in the bankruptcy court of all litigation relating to the creditors or the assets of the estate. Modern statutes still adhere to that idea, but with considerable variation. The laws of England, the United States, Australia, Canada, and New Zealand contain very broad jurisdictional grants to the bankruptcy courts relating to the collection and administration of the property of the estate and the rights of secured and unsecured creditors. A number of civil-law countries, following French and Spanish models, provide equally extensive powers to the bankruptcy courts. In some of these countries, however, the jurisdiction of special labour courts limits the judicial powers of the bankruptcy courts. In West Germany the settlement of individual controversies, such as the determination of contested claims or the rights of third parties to or in property claimed as part of the bankrupt estates, is left to the regular courts. In Austria, however, the bankruptcy court has exclusive or concurrent jurisdiction in disputes of that type.

In most countries many functions of the bankruptcy court are conferred upon special judicial officers who may be either actual members of the judiciary (as in France) or judicial officers without full judicial status. In England registrars of the courts vested with insolvency jurisdiction, especially the bankruptcy registrars of the High Court, have jurisdiction over the initiation of insolvency proceedings and a long catalog of matters not requiring hearing in open court. Similar rules apply in Canada and New Zealand. In the United States special bankruptcy judges may exercise most judicial functions involved in the conduct of a case. Since these judges are not appointed for life and with Senate approval, some functions are reserved to the regular judiciary. Similar reasons limit the delegation of judicial functions in Australia. In West Germany, conversely, a wide range of judicial functions in bankruptcy are delegated to court registrars (called *Rechtspfleger*) who perform judicial functions outside the regular judiciary.

Growing power of the courts

Creditors have traditionally played an important part in the conduct of insolvency cases. In most countries, however, they are no longer the dominant parties. The courts, assisted by official administrators, have emerged as the key figures. Under the 1985 French law even the creditor's representative is a functionary of the administration of justice, appointed by the court from an approved panel. In England the system of creditors' control that existed from 1706 to 1831 and from 1869 to 1883 was replaced in the latter year by a system of joint control, or creditor participation, a scheme that in attenuated form is retained by the Insolvency Act of 1986. The administration of bankrupts' estates is undertaken by an official receiver—an office established in 1883—unless a general meeting of creditors or the secretary of state for trade and industry, upon reference by the official receiver, appoints another person qualified to act as an insolvency practitioner to the post of trustee. In cases of summary administration (a simplified procedure that may be ordered by the courts if unsecured debts fall below a certain level) the appointment may be made by the court. Official receivers exist also in Australia and Canada. In Australia the official receiver functions as official trustee only when there is no registered trustee. Since 1981 a registered trustee is the initial trustee if he consents to the appointment prior to the adjudication. He may be removed by the court upon petition by a creditor. The official trustee may be replaced by a registered trustee upon resolution by a creditors meeting. In addition the creditors may appoint a committee to advise and superintend the trustee. In Canada official receivers, appointed by the governor in council, are not trustees of the insolvent estate but exercise supervisory authority. The initial trustee is appointed by the court from a list of licensed trustees but is subject to being replaced by another licensed trustee by means of a special resolution adopted at any meeting of the creditors. In New Zealand the administration of insolvent estates is entrusted to official assignees, appointed under the State Services Act. The creditors may appoint a committee to assist the assignee in the exercise of his functions. In the United States the court appoints an interim trustee to serve until the creditors elect another qualified person to serve as trustee in the case; if the creditors fail to act, the interim trustee remains in office. By way of experiment, administrative officers, called U.S. trustees, are appointed for some districts to serve as interim trustees and, if the creditors make no other election, as trustees. In Chile trustees are licensed and supervised by a governmental agency. In the order of adjudication the judge appoints an interim trustee who remains in office if his appointment is ratified in the first meeting of the creditors, though they may appoint another licensed person as definitive trustee. Chile's bankruptcy act of 1982 has restored creditors' control to some extent. In Switzerland bankruptcy offices are established for each of the bankruptcy districts created by the individual cantons. The bankruptcy office is in charge of the progress of the proceedings and acts as trustee unless the creditors select one of their choice. In Italy the bankruptcy judge appoints the trustee and selects a committee from among the creditors. The committee has merely advisory and supervisory functions. A meeting of creditors is summoned only for the determination of provable debts.

REHABILITATION AND REORGANIZATION OF INSOLVENT ESTATES

The principal focus of modern insolvency legislation no longer rests on the liquidation and elimination of insolvent estates, but on the remodeling of the financial and, if necessary, organizational structure of a debtor in economic difficulties so as to permit the continuation of the economic activities. Procedures for the conclusion of binding preventive accords with creditors, requiring approval by a qualified majority of them and confirmation by the courts, were provided by legislation in a number of countries during the second half of the 19th century. Economic crises during the 20th century gave rise to further legislative measures, providing a breathing spell for the debtor by means of a postponement or reduction of his liability, coupled if necessary with a change in ownership. Thus a German law of 1916 provided for avoidance of bankruptcy and executions by a procedure placing the debtor, upon his petition, under judicially supervised management. Similar procedures were introduced subsequently into the companies acts of South Africa and Australia and are now incorporated into the English Insolvency Act, 1986, as a new avenue of relief for debtors threatened with insolvency (administration orders procedure). In addition, the laws of England, Canada, Australia, and New Zealand outline procedures for preventive composition and schemes of arrangement with creditors by companies or individual debtors. Procedures for preventive accords also exist in many civil-law countries—*e.g.,* Austria, West Germany, Italy, Portugal, Spain, Argentina, Brazil, Chile, and Mexico. Italy has enacted special legislation for the extraordinary management of large enterprises in economic difficulties. Usually judicial compositions affect only the rights of unsecured creditors. Secured creditors must specifically and individually assent to any modification of their rights. In the case of corporate debtors, however, effective restoration of the viability of the enterprise may require much more drastic measures. Therefore, the United States, Japan, and, more recently, Argentina and Chile have enacted laws establishing procedures to permit the formulation and judicial confirmation of reorganization plans, the provisions of which may include elimination of ownership rights and significant curtailments of the rights of secured creditors. Austria reformed its composition act in 1982 by adding a preliminary procedure, resembling the old German management supervision order, to facilitate voluntary reorganization, especially refinancing. The most comprehensive legislation aimed at the salvage of distressed enterprises is the French insolvency legislation of 1985. This law provides a unified procedure establishing a mandatory period of observation to determine whether the insolvent enterprise can be rescued, if necessary at the expense of the owners and existing creditors, or whether liquidation is unavoidable.

Preventive accords

INTERNATIONAL ASPECTS

Normally the existing bankruptcy laws do not differentiate between foreign and domestic creditors in proceedings involving the estates of residents, at least if reciprocity exists between the countries of the parties involved. Provisions to that effect exist in West Germany and Japan and, by implication, in Italy. A number of Latin-American countries, however, give priority to local creditors if there are concurring bankruptcies (simultaneous proceedings in more than one country) involving the same debtor. Equally controversial is the extraterritorial effect of releases resulting from compulsory compositions or discharges in bankruptcy.

Bankruptcy treaties

Because of the difficulties arising from multiple bankruptcies or the principle of territoriality of bankruptcy legislation, some countries have regulated that subject among themselves by regional conventions. Among the Latin-American countries are three treaties, binding different parties: the two treaties of Montevideo on International Terrestrial Commercial Law, concluded in 1889 and 1940, respectively, and the treaty of Havana on Private International Law (the so-called Bustamante Code) of 1928. The five Scandinavian countries concluded the Copenhagen Convention on bankruptcy on Nov. 7, 1933. In the late 1980s the members of the European Economic Community were studying the draft of a bankruptcy treaty, proposed in 1980, which superseded a preliminary draft of 1970. In addition, there exist a number of bilateral treaties between different nations on the subject—*e.g.,* the West German–Austrian bankruptcy treaty of 1979, which entered into force in 1985. (S.A.Ri.)

Labour

Labour law is the varied body of law applied to such matters as employment, remuneration, conditions of work, trade unions, and industrial relations. In its most comprehensive sense the term also includes social security and disability insurance. Unlike the laws of contract, tort, or property, the elements of labour law are less homogeneous than the rules governing a particular legal relationship. In addition to the individual contractual relationships growing out of the traditional employment situation, labour law deals with the statutory requirements and collective relationships that are increasingly important in mass-production societies, the legal relationships between organized economic interests and the state, and the various rights and obligations related to some types of social services.

Labour law has won recognition as a distinctive branch of the law within the academic legal community, but the extent to which it is recognized as a separate branch of legal practice varies widely depending partly on the extent to which there is a labour code or other distinctive body of labour legislation in the country concerned, partly on the extent to which there are separate labour courts or tribunals, and partly on the extent to which an influential group within the legal profession practice specifically as labour lawyers.

In the early phases of development the scope of labour law is often limited to the most developed and important industries, to undertakings above a certain size, and to wage earners; as a general rule, these limitations are gradually eliminated and the scope of the law extended to include handicrafts, rural industries and agriculture, small undertakings, office workers, and, in some countries, public employees. Thus a body of law originally intended for the protection of manual workers in industrial enterprises is gradually transformed into a broader body of legal principles and standards, which have basically two functions: the protection of the worker as the weaker party in the employment relationship, and the regulation of the relations between organized interest groups (industrial relations).

Statute versus contract

The general tendency in the modern development of labour law has been the strengthening of statutory requirements and collective contractual relations at the expense of rights and obligations created by individual employment relationships. How important these latter remain depends, of course, on the degree of personal freedom in the given society as well as the autonomy of both employer and worker allowed by the actual operation of the economy. In such matters as hours of work, health and safety conditions, or industrial relations, the statutory or collective elements may define most of the substance of the rights and obligations of the individual worker, while with respect to such things as the duration of his appointment, his level and extent of responsibility, or his place in the scale of remuneration, these elements may provide what is essentially a framework for individual agreement.

HISTORICAL DEVELOPMENT OF LABOUR LAW

Impact of the Industrial Revolution

The origins of labour law can be traced back to the remote past and the most varied parts of the world. While European writers often attach importance to the guilds and apprenticeship systems of the medieval world, some Asian scholars have identified labour standards as far back as the Laws of Hammurabi and rules for labour–management relations in the Laws of Manu; Latin-American authors point to the Laws of the Indies promulgated by Spain in the 17th century for its New World territories. None of these can be regarded as more than anticipations, with only limited influence on subsequent developments. Labour law as it is known today is essentially the child of successive industrial revolutions from the 18th century onward. It became necessary when customary restraints and the intimacy of employment relationships in small communities ceased to provide adequate protection against the abuses incidental to new forms of mining and manufacture on a rapidly increasing scale at precisely the time when the 18th-century Enlightenment, the French Revolution, and the political forces that they set in motion were creating the elements of the modern social conscience. It developed rather slowly, chiefly in the more industrialized countries of western Europe, during the 19th century and has attained its present importance, relative maturity, and worldwide acceptance only during the 20th century.

The first landmark of modern labour law was the British Health and Morals of Apprentices Act of 1802, sponsored by the elder Sir Robert Peel. Similar legislation for the protection of the young was adopted in Zürich in 1815 and in France in 1841. By 1848 the first legal limitation of the working hours of adults was adopted by the Landsgemeinde (citizens' assembly) of the Swiss canton of Glarus. Sickness insurance and workmen's compensation were pioneered by Germany in 1883 and 1884, and compulsory arbitration in industrial disputes was introduced in New Zealand in the 1890s. The progress of labour legislation outside western Europe, Australia, and New Zealand was slow until after World War I. The more industrialized states of the United States began to enact such legislation toward the end of the 19th century, but the bulk of the present labour legislation of the United States was not adopted until after the Depression of the 1930s. There was virtually no labour legislation in Russia prior to the October Revolution of 1917. In India children between the ages of seven and 12 were limited to nine hours of work per day in 1881 and adult males in textile mills to 10 hours per day in 1911, but the first major advance was the amendment of the Factory Act in 1922 to give effect to conventions adopted at the first session of the International Labour Conference at Washington, D.C., in 1919. In Japan rudimentary regulations on work in mines were introduced in 1890, but a proposed factory act was controversial for 30 years before it was adopted in 1911, and the decisive step was the revision of this act in 1923 to give effect to the Washington Convention on hours of work in industry. Labour legislation in Latin America began in Argentina in the early years of the century and received a powerful impetus from the Mexican Revolution, which ended in 1917, but, as in North America, the trend became general only with the impact of the Great Depression. In Africa the progress of labour legislation became significant only from the 1940s onward.

The legal recognition of the right of association for trade union purposes has a distinctive history. There is no other aspect of labour law in which successive phases of progress and regression have been more decisively influenced by political changes and considerations. The legal prohibition of such association was repealed in the United Kingdom in 1824 and in France in 1884; there have been many subsequent changes in the law and may well be further changes, but these have related to matters of detail rather than to fundamental principles. In the United States freedom of association for trade union purposes remained precarious and subject to the unpredictable scope of the labour injunction, by means of which the courts helped restrain trade union activity until the 1930s. The breakthrough for trade unionism and collective bargaining was achieved by the National Labor Relations Act of 1935. In many other countries the record of progress and regression with respect to freedom of association falls into clearly distinguished periods separated by decisive political changes. This has certainly been the case with Germany, Italy, Spain, Japan, and much of eastern Europe; there have been many illustrations of it, and there may well be more in the developing world.

Labour codes or other forms of comprehensive labour legislation and ministries of labour were not introduced until the 20th century. The first labour code (which, like many of its successors, was a consolidation rather than a codification) was projected in France in 1901 and promulgated in stages from 1910 to 1927. Among the more advanced formulations affecting the general condition of labour were the Mexican Constitution of 1917 and the Weimar Constitution of Germany of 1919, both of which gave constitutional status to certain general principles of social policy regarding economic rights. Provisions of this kind have become increasingly common and are now widespread in all parts of the world.

Departments or ministries of labour responsible for the effective administration of labour legislation and for promoting its future development were established in Canada in 1900, in France in 1906, in the United States in 1913, in the United Kingdom in 1916, and in Germany in 1918. They became general in Europe and were established in India and Japan during the following years and became common in Latin America in the '30s. A labour office was established in Egypt in 1930, but only in the '40s and '50s did similar arrangements begin to take root elsewhere in Asia and Africa. Under differing political circumstances there continue, of course, to be wide variations in the authority and effectiveness of such administrative machinery.

ELEMENTS OF LABOUR LAW

The basic subject matter of labour law can be considered under nine broad heads: employment; individual employment relationships; wages and remuneration; conditions of work; health, safety, and welfare; social security; trade unions and industrial relations; the administration of labour law; and special provisions for particular occupational or other groups.

Employment. Employment considered as a basic concept and category of labour law is a relatively recent development. Prior to the Great Depression and World War II the emphasis was upon the prevention or reduction of excessive unemployment rather than upon long-term employment policy as part of a comprehensive scheme to promote economic stability and growth. The new approach, arising from changes in political outlook and contemporary economic thought, has increasingly found expression in legal provisions that establish the creation of employment opportunities as a general objective of policy. To this end, legislation has established the necessary legal framework for the forecasting of manpower needs and availability and the provision of employment services including placement, recruitment, vocational training, and apprenticeship. Freedom from forced labour, equality of treatment in employment and occupation, and unemployment benefits may, in a broad sense, be regarded as part of the same general subject.

The worker in new economic thought

Individual employment relations. The making, modification, and termination of individual employment relations and the resulting obligations for the parties form a second branch of labour law. It may also involve certain aspects of promotion, transfer, and dismissal procedures and compensation. Historically speaking, the law on these matters was at one time described as the law of master and servant. It implied a contractual relation in which one party agreed to be under the control of the other in the sense that the servant was bound to obey orders not only as to the work that he would execute but also as to the details of the work and the manner of its execution. In return, the master had to pay a wage and grant certain minimum conditions for the protection of the worker. As the law developed, the implied terms and statutory incidents attached to this relationship concerning such matters as termination of employment, dismissal procedures and compensation, minimum wages, conditions of work, and social security rights began to limit freedom of contract. The individual employment relationship continues, however, to be the subject matter of labour law to which general legal principles, as opposed to statutes and collective agreements, apply. Legally speaking, the individual contract of employment plays a more important role in the civil-law countries than in common-law countries.

Wages and remuneration. The substantive law on wages and remuneration covers such elements as forms and methods of payment, the protection of wages against unlawful deductions and other abuses, minimum wage arrangements, the determination of wages, fringe benefits, and, in highly sophisticated economies, incomes policies. The concept of wage regulation as a restraint upon extreme social evils has gradually been superseded by wage policies as deliberate instruments of positive management designed to promote economic stability and growth.

Wage protection and abuse

Legal requirements concerning the forms of wages and methods of wage payment deal with such matters as the proper notification of wage conditions, the payment of wages in legal tender or by check, the limitation and proper valuation of payments in kind, the freedom of the worker to dispose of his wages, regularity in wage payments, the treatment of wages as a privileged, or secured, debt, and restrictions upon the attachment or assignment of wages.

Minimum-wage regulation takes varied forms; it may, following the pattern originally set by the British Trades Boards Acts from 1909 onward, provide for wages councils or similar bodies to fix wages in trades that have no arrangements for collective agreements and where wages are exceptionally low; it may consist, as in Australia and New Zealand, essentially of arbitration arrangements; or it may, as in the United States under the Fair Labor Standards acts, provide a statutory rate or criteria for determining such a rate. Statutory provisions and collective agreements for determining wages may embrace such varied matters as skill differentials, the elimination of race and sex differentials, payment according to results and the relationship of wages to productivity, and wage guarantees for agreed periods of time. Fringe benefits, such as bonuses payable in varying contingencies, are typically a matter for collective agreements. Incomes policies remain the subject of much controversy. Their general purpose, sometimes embodied in legislation and sometimes expressed in collective agreements or statements of government policy, is to restrain inflationary pressures resulting from wage increases unrelated to increased productivity and to do this in a manner that promotes a fairer distribution of income.

Conditions of work. The conditions of work involve hours, rest periods, and vacations; the prohibition of child labour and regulation of the employment of young persons; and special provisions concerning the employment of women. This part of the law originated in legislation for the protection of children, young persons, and women against the worst evils of the Industrial Revolution. It originally dealt particularly with such matters as admission to employment, night work, and excessive hours, but the elements of its content and their relative importance have been wholly transformed during the 20th century.

As economic and educational progress and changed social habits have limited child labour in the industrialized countries, and increasingly in the modernized sectors of developing economies, the special concern of labour law with regard to the young has shifted to such areas as vocational guidance and training, career planning and advancement, and medical protection.

As employment opportunities for women have become more varied and responsible, there has been a similar shift of emphasis from protective legislation, which has come to be regarded as discriminatory since it tends to limit such opportunities, to legal guarantees of equal pay and equal employment, coupled with adequate maternity protection and the provision of facilities to enable women with family responsibilities to continue to be employed.

Whereas previously any statutory limitation of the hours of work of adult males was regarded as being highly questionable, except in mines where it had been introduced on safety grounds, in a society of much increased leisure it has now become a general practice to fix maximum hours of work by statute or collective agreement. In many countries the eight-hour day has been superseded by the 40-hour week as the statutory maximum for a wide range of occupations, and collective agreements providing for substantially shorter working hours are not uncommon. The details of hours regulation, whether by statute or collective agreement, include such matters as exceptions and adjustments necessary for continuous shift working. In addition, such regulations cover the extensions permitted for preparatory, complementary, and intermittent work; the special rules for force majeure (work of absolute necessity), accident, maintenance, and repair work; and the limitation, authorization, and remuneration of overtime.

The principle of resting one day of the week, sanctioned as it is by religious practice in many places, was widely incorporated in legislation at an early date; the lengthening of this weekly rest through the creation of the five-day week has been strongly influenced by statutory requirements and collective agreements.

Holidays

Legislation granting annual holidays with pay and collective agreements providing for such holidays are almost entirely a development of the mid-20th century but are increasingly common; moreover, there is a marked tendency for the minimum annual holiday to be increased.

Complex questions may arise concerning the qualifying period of service required for entitlement, breaks in the continuity of service, the calculation of average or normal remuneration for the purpose of the holidays, the extent to which holidays may be divided, and the liability for holidays where there has been a change of employer.

Health, safety, and welfare. Such general matters as occupational health and accident prevention regulations and services; special regulations for hazardous occupations such as mining, construction, and dock work; and provisions concerning such health and safety risks as poisons, dangerous machinery, dust, noise, vibration, and radiation constitute the health, safety, and welfare category of labour law. The efforts of organized safety movements and the progress of occupational medicine have produced comprehensive occupational health and accident-prevention services and regulations no longer limited to a few specially acute risks but covering the full range of dangers arising from modern industrial processes. Major developments include increased concern with the widespread use of chemicals and increasing provision for welfare facilities related to employment, including feeding, rest, recreation, and transport facilities.

Social security. Social security ranges from basic employers' liability for occupational accidents to comprehensive schemes that include income security in the form of sickness, unemployment, retirement, employment injury, maternity, family, invalidity, and survivors' benefits and medical care. As with other aspects of labour law, a progression from the particular to the general has been characteristic of the development of social security legislation. By the time of World War I, workmen's compensation schemes were general in industrialized and industrializing countries, but they were highly restrictive in their provisions for specific cases. Pension insurance was part of Otto von Bismarck's legacy to Germany, but elsewhere there was little more to be found than pension funds for the privileged or noncontributory pensions for the aged. Great Britain had been the pioneer in health and unemployment insurance. But social insurance remained a pragmatic experiment limited to a few countries advanced in both economic development and social policies. The coverage was limited to specific risks for certain categories of protected persons. Its object was to protect the worker against the hazards of life for which preindustrial societies provide by some form of community or family responsibility, but the approach was piecemeal and was limited to the most manageable cases of acute hardship. Eventually, the impact of the world economic depression of the 1930s and World War II in the industrial nations and the increasingly apparent inadequacy of earlier forms of community responsibility in developing countries transformed the position. The concept of social security, first given statutory expression in the United States in 1935 and in New Zealand in 1938, superseded that of social insurance, and the Beveridge Report of 1943 developed it even further to provide a basic income for all in need of such protection, in addition to providing comprehensive medical care. The concept has continued to broaden since that time, and social security has found increasing acceptance, though necessarily with varying degrees of practical application, in countries in the most varied stages of economic development.

The right to security

Acute, sometimes highly controversial, problems, particularly in the cost and efficiency of administrative organization of social security programs and of medical care, remain almost everywhere. But many countries have made progress in making higher standards of medical care available as a legal right and in converting the guarantee of a basic income as a protection against want into provision for effective income maintenance in the event of unemployment or loss of the family breadwinner. The idea is still developing. The trend is to broaden it to the point at which it includes all the varied hazards of life, including accidents of any kind, with the idea of facilitating economic growth by reducing the human cost of structural change. The pattern varies widely in different countries, partly as a reflection of different relationships between social security and private life, retirement, and health insurance, and partly because of differences in economic and social conditions.

Trade unions and industrial relations. A number of complex legal relationships fall under the heading of industrial relations, including the legal status, rights, and obligations of trade unions and employers' organizations, collective bargaining and collective agreements, the representation of employees at plant and enterprise level (including joint consultation and, where it exists, codetermination and other forms of workers' participation in management, even to the extent of workers' representation on company boards), and the prevention and settlement of various types of labour disputes in general and of strikes and lockouts in particular. There are wide variations both in the extent to which such matters as the representative character and capacity of trade unions, their legal status, the obligation to recognize and bargain with them, the enforceability of collective agreements, the scope of activities permitted to trade unions, and their obligations in contract and tort are subject to legal rules and in the content of such rules. In the United States, for instance, there is a considerable body of law on these subjects, the most important enactments being the National Labor Relations Act of 1935 (the Wagner Act) and the Labor Management Relations Act of 1947 (the Taft–Hartley Act); in the United Kingdom the law has hitherto remained marginal to most of these trade union issues, except for legislation of 1871, 1875, and 1906, which had provided certain "immunities," or "privileges," as they are sometimes called, for trade unions, particularly in connection with trade disputes. Legislation enacted in the early 1980s restricted some of these immunities or privileges, the trend being to expand the role of law in labour–management relations to reduce the increasing disruption caused by industrial conflict in a complex society. How to reconcile freedom of association and collective bargaining with the stability and growth of the economy remains the most challenging and difficult problem of labour law.

The administration of labour law. Another feature of labour law involves the organization and functioning of administrative authorities such as labour departments, labour inspection services, and other organs of enforcement. Administration of the law also encompasses the operation of labour courts and other bodies for the settlement of grievances arising from existing contracts or collective agreements and of industrial disputes arising between labour and management.

Labour law and the economic goal

The principal problem in many countries is to relate the process of labour administration and its special intimacy with labour and management to overall economic and social planning in a manner that gives proper weight to social considerations in economic policy. This problem falls mostly outside the scope of labour law, but its solution does depend in part on the extent to which labour law provides for and secures effective standards of administration.

Special categories of workers. Labour law includes many provisions for particular occupational or other groups. These sometimes appear as special parts of a general code, special legislation, or provisions that limit specific legislative provisions with regard to particular groups. These special provisions are common and important in mining, transportation (and in particular maritime transport), commercial occupations, and agriculture. Cutting across these broad sectors of economic activity are the traditional legal distinctions made in some countries between blue-collar workers and salaried employees and certain newer distinctions, such as that between employees who earn annual salaries and have rights of tenure and persons with no such rights engaged and remunerated on a monthly, weekly, or even daily basis.

THE RULES OF DIFFERENT SYSTEMS

Among the distinctive elements of labour law that reflect the political, socioeconomic, and legal differences among countries are variations in the relative importance of statutory regulation and collective agreements, the prevalence of national or industrial collective agreements as opposed to company or plant agreements, the importance in certain countries of arbitral awards, and the extent to which labour law has been affected by a country's constitutional structure, especially with regard to judicial review of constitutionality of legislation and judicial interpretation of constitutional powers, limitations, and guarantees.

In the United Kingdom, for instance, the tradition has been to allow a maximum of initiative and freedom to employers' and workers' organizations in the regulation of their mutual relations and the determination of conditions of work. Most countries on the Continent, by contrast, have detailed legislative provisions on these matters.

In the United Kingdom, however, the reluctance to legislate is becoming less marked; there is now legislation concerning industrial training and discrimination in employment, formerly matters for collective agreement; and legislation concerning collective bargaining, safeguards against unfair dismissal, and certain trade union practices was enacted in the late 1970s and early 1980s. In virtually all of the developing countries the absence of an established tradition of collective bargaining and the importance of the part played by the state in economic development have placed a premium on legislative action.

Variations in collective agreements

The coverage and scope, term of validity, and legal effect of collective agreements vary widely. In Sweden there has been a practice of national negotiations covering the whole of industry; in the United Kingdom agreements generally cover an industry or occupation in the country as a whole or a particular industrial area; in the United States and in Japan the unit of negotiation is generally the company or plant. The contrast may be less significant in practice than in principle, since an important company or plant agreement tends to set an industry-wide pattern of negotiation (*e.g.,* in the automobile industry of the United States); nevertheless, the difference is important.

In Australia and New Zealand conciliation and arbitration tribunals determine by awards matters normally dealt with in other countries by legislation or collective agreement, such as wages, hours, and conditions of work. The example has had some influence on systems of arbitration courts established in developing countries, notably in Asia and East Africa, but with this exception there is no tendency for it to be widely imitated elsewhere except as a device for avoiding deadlocks in negotiation, especially in essential public services.

Constitutional impediments

In the United States and Canada the development of labour law has been affected by questions of constitutionality, which not only influenced its ultimate form but also retarded its development. In the United States the constitutionality of workmen's compensation laws was much debated until it was favourably settled by the Supreme Court in 1917; child-labour and minimum-wage regulations were delayed by judicial decisions holding them to be outside federal competence and, in some cases, inconsistent with the constitutional guarantee against deprivation by the state of life, liberty, and property without due process of law (the guarantee here applying to the factory owner). The first attempt of President Franklin Roosevelt's administration to regulate hours and wages by codes of fair competition during the Great Depression was also held to be unconstitutional as an improper delegation of legislative power by Congress to the executive branch. But thereafter the temper of judicial review changed and the validity of federal legislation guaranteeing free collective bargaining, regulating wages and hours, and establishing social security was upheld. In Canada, a pioneer in establishing a labour department, restrictive judicial interpretations of the powers of the federal government had a similar effect, and only after World War II did federal–provincial cooperation afford a basis for achieving greater uniformity and more rapid progress.

UNIFYING TENDENCIES

The range of possible solutions for similar problems often consists of variations of detail on a limited number of options, and certain common elements, often expressed in identical or almost identical texts, recur in the law of different countries. These elements derive partly from the legislation of other nations but increasingly from the influence on the law of the international standards evolved by the International Labour Organisation (ILO).

From the beginnings of modern labour legislation in the early 19th century, the law of certain countries has been extensively used by other countries as a model. For example, British factory legislation was widely copied at an early date and German social-insurance legislation provided a prototype from the time of Bismarck's reforms. British legislation has continued to serve as a model for the basic legislation of many states that were formerly British dependencies and remains in force subject to modifications made since independence. Much of the French Labour Code became applicable through the 1952 Labour Code for Overseas Territories to the states that were formerly French dependencies and remains the basis of their labour law. The United States legislation of the period from the 1930s onward has been exported to Japan, the Philippines, Liberia, and other countries. The Mexican Labour Law of 1931, varied by elements derived primarily from European models, had considerable influence on the early development of labour law in a number of Latin-American countries. Through quite another process, the labour law of the Soviet Union has reshaped without replacing some of the earlier elements in the labour law of the other Socialist states. But on the whole these national influences of particular countries and legal systems are declining.

The ILO: international standards

During the mid-20th century the standards evolved by the ILO became the leading external influence upon the labour law of many countries. They have had a far-reaching impact in virtually all of the advanced countries except the United States and the Soviet Union, where external influences have been secondary. In much of the developing world they were of great importance even before independence, since much of the legislation sponsored there by the colonial powers was based on ILO standards.

The ILO, created in 1919 as an autonomous partner of the League of Nations, and since 1946 a specialized agency associated with the United Nations, adopts international standards in the form of conventions and recommendations. Conventions when ratified become binding obligations of the member states ratifying them; recommendations are designed as guides for legislation, collective agreements, administrative measures, etc. Elaborate follow-up arrangements, including examination of regular reports and commissions of enquiry into complaints, are provided to ensure that the obligations assumed are fulfilled. These standards, which already cover, in varying degrees of detail and at varied stages of development, virtually all the more important branches of labour law, are constantly amplified and revised at the annual sessions of the International Labour Conference.

Unification or, as the process is often called, harmonization of labour law is one of the professed purposes of a number of regional organizations in different parts of the world, but only in the Council of Europe, the European Communities, and the Organization of American States have tangible measures been taken, largely based on ILO standards. The more important instruments adopted are the European Social Charter, the European Social Security Code, the Social Security Regulations of the European Economic Community, and the Central American Convention on Social Security for Migrant Workers. The Conferences of American and African Labour Ministers, sponsored by the Organization of American States and the Organization of African Unity respectively, and the Conference of Asian Labour Ministers, which has developed without any comparable sponsorship, discuss matters of general policy and the coordination of action in the ILO rather than the formulation of specific standards. An Arab Labour Organization was created in 1970.

CONTEMPORARY TENDENCIES

Labour law differs from the older branches of the law in that its history has been in some cases so much influenced by the ebb and flow of political change, its development so rapid, and its expansion on a world scale so recent, that it is difficult to predict its future. But the trend is clear. In no place is labour law losing importance. While some types of protective legislation, notably special provision for the protection of women workers, are losing their importance, the tendency is toward more comprehensive legislation embracing a wider range of subjects and often dealing with matters previously left to collective agreement, individual contract, or the discretion of the employer.

The transition everywhere has been from a class law protecting the weakest segment of society to a community law designed to serve the common interest. This development is seen in the elimination of limitations and exceptions to the law and in the increasing emphasis given to matters of general interest, including full employment, equitable distribution of wealth, and community responsibility for the incidence of misfortune in individual lives.

The place of labour law in legal evolution

Labour law must also be said to serve the social interest in promoting constructive industrial relations and reducing the occurrence of open conflict. This evolution of labour law is an important contribution to the evolution of the law as a whole, from a law for the propertied and trading classes with a special chapter for the working class to a common law for the entire community.

The importance of a body of law that has a dynamic and progressive impact rather than a restrictive influence is now widely understood, and the need for legal flexibility to facilitate economic and social development and change is increasingly appreciated. In addition, the value of delegated powers and procedures of consultation with interested groups and organizations to achieve such flexibility is more generally recognized. Social objectives remain the test of the validity of economic policy, and labour law plays a major part in defining these objectives and ensuring that economic policy respects them in the interest of the whole community. (C.W.J./J.Sch./Ed.)

BIBLIOGRAPHY

Contracts: E. ALLAN FARNSWORTH, "The Past of Promise: An Historical Introduction to Contract," *Columbia Law Review,* 69(4):576–607 (April 1969), is a survey of the development of contract law from its beginnings in primitive societies. C.H.S. FIFOOT, *History and Sources of the Common Law: Tort and Contract* (1949, reprinted 1970), is a historical treatment of the common law of contract. Treatises on Anglo-American contract law include: JOHN D. CALAMARI and JOSEPH M. PERILLO, *The Law of Contracts,* 3rd ed. (1987); G.C. CHESHIRE and C.H.S. FIFOOT, *Cheshire and Fifoot's Law of Contract,* 10th ed. by M.P. FURMSTON (1981); ARTHUR LINTON CORBIN, *Corbin on Contracts: A Comprehensive Treatise on the Rules of Contract Law,* 8 vol. in 12 (1950–51); and SAMUEL WILLISTON, *A Treatise on the Law of Contracts,* 18 vol., 3rd ed. by WALTER H.E. JAEGER (1957–78). A discussion of French and German contract law is found in ARTHUR TAYLOR VON MEHREN and JAMES RUSSELL GORDLEY, *The Civil Law System,* 2nd ed. (1977). A classic discussion of the law of contract damages is found in L.L. FULLER and WILLIAM R. PERDUE, JR., "The Reliance Interest in Contract Damages," parts 1 and 2 *Yale Law Journal,* 46(1):52–96 (November 1936), and 46(3):373–420 (January 1937). See also HANS SMIT, NINA M. GALSTON, and SERGE L. LEVITSKY, *International Contracts* (1981). (A.T.v.M.)

Agency: OLIVER WENDELL HOLMES, "Agency," in *Collected Legal Papers* (1920, reprinted 1985), pp. 49–116, is an Anglo-American treatment written from a historical point of view. Labour: Important labour laws from countries throughout the world are reproduced in the International Labour Office's *Legislative Series* (3/yr.). International standards are published in C. WILFRED JENKS (ed.), *The International Labour Code, 1951,* 2 vol. (1952). For the impact of ILO standards, see DAVID A. WAUGH, "The ILO and Human Rights," *Comparative Labor Law,* 5(2):186–196 (Spring 1982); and C. WILFRED JENKS, *International Protection of Trade Union Freedom* (1957), *Human Rights and International Labour Standards* (1960), and *Social Justice in the Law of Nations: The ILO Impact After Fifty Years* (1970). Annual summaries of international judicial decisions in labour law appear in the January–February issue of *International Labour Review.* Descriptions of the labour law systems of many countries (with bibliographical references) are contained in R. BLANPAIN, *International Encyclopaedia of Labour Law and Industrial Relations,* 8 loose-leaf vol. (1977–81); shorter treatments can be found in R. BLANPAIN (ed.), *Comparative Labour Law and Industrial Relations,* 2nd rev. ed. (1985). The documentation published in connection with the international congresses organized by the International Society for Labour Law and Social Security contains comparative studies of particular aspects of labour law in various parts of the world; see, for example, *Reports and Proceedings,* 3 vol. (1984). (C.W.J./J.Sch.)

Business Organization

In the widest sense, all social groupings are organized for some form of business. This article, however, is restricted to the contemporary concept of an organization formed for the purpose of carrying on commercial enterprise. Such a concept is predicated on systems of law governing contract and exchange, property rights, and incorporation. In this narrower sense, business enterprises customarily take one of three forms: individual proprietorships, partnerships, or limited-liability companies (or corporations). In the first form, a single person holds the entire operation as his personal property, usually managing it on a day-to-day basis. Most businesses are of this type. Of the nearly 15,000,000 business establishments in the United States in the late 20th century, for example, more than three-quarters were individual proprietorships; they tended to be small operations, most of them with annual receipts of less than $50,000. The second form, the partnership, may have from two to 50 or more members, as in the case of large law and accounting firms, brokerage houses, and advertising agencies. This form of business is owned by the partners themselves; they may receive varying shares of the profits depending on their investment or contribution. Whenever a member leaves or a new member is added, the firm must be reconstituted as a new partnership. The third form, the limited-liability company, or corporation, denotes incorporated groups of persons—that is, a number of persons considered as a legal entity (or fictive "person") with property, powers, and liabilities separate from those of its members. This type of company is also legally separate from the individuals who work for it, whether they be shareholders or employees or both; it can enter into legal relations with them, make contracts with them, and sue and be sued by them. Most large industrial and commercial organizations are limited-liability companies, or corporations.

This article deals primarily with the large private business organizations made up chiefly of partnerships and limited-liability companies—called collectively business associations. Some of the principles of operation included here also apply to large individually owned companies and to public enterprises.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 553, and the *Index.*

The article is divided into the following sections:

Types of business associations

Business associations have three distinct characteristics: (1) they have more than one member (at least when they are formed); (2) they have assets that are legally distinct from the private assets of the members; and (3) they have a formal system of management, which may or may not include members of the association.

Essential features of business associations

The first feature, plurality of membership, distinguishes the business association from the business owned by one individual; the latter does not need to be regulated internally by law because the single owner totally controls the assets. Because the single owner is personally liable for debts and obligations incurred in connection with the business, no special rules are needed to protect its creditors beyond the ordinary provisions of bankruptcy law.

The second feature, the possession of distinct assets (or a distinct patrimony), is required for two purposes: (1) to delimit the assets to which creditors of the association can resort to satisfy their claims (though in the case of some associations, such as the partnership, they can also compel the members to make good any deficiency) and (2) to make clear what assets the managers of the association may use to carry on business. The assets of an association are contributed directly or indirectly by its members—directly if a member transfers a business or property or investments of his own to the association in return for a share in its capital, and indirectly if a member pays his share of capital in cash and the association then uses his contribution and like contributions in cash made by other members to purchase a business, property, or investments.

Limited participation of shareholders

The third essential feature, a system of management, varies greatly. In a simple form of business association the members who provide the assets are entitled to participate in the management unless otherwise agreed. In the more complex form of association, such as the company or corporation of the Anglo-American common-law countries, members have no immediate right to participate in the management of the association's affairs; they are, however, legally entitled to appoint and dismiss the managers (known also as directors, presidents, or administrators), and their consent is legally required (if only pro forma) for major changes in the company's structure or activities, such as reorganizations of its capital and mergers with other associations. The role of a member of a company or corporation is basically passive; he is known as a shareholder or stockholder, the emphasis being placed on his investment function. The managers of a business association, however, do not in law comprise all of the persons who exercise discretion or make decisions. Even the senior executives of large corporations or companies may be merely employees, and, like manual or clerical workers, their legal relationship with the corporation is of no significance in considering the law governing the corporation. Whether an executive is a director, president, or administrator (an element in the company or corporation's legal structure) depends on purely formal considerations; if he is named as such in the document constituting the corporation, or if he is subsequently appointed or elected to hold such an office, it is irrelevant whether his actual functions in running the corporation's business and the power or influence he wields are great or small. Nevertheless, for certain purposes, such as liability for defrauding creditors in English law and liability for deficiencies of assets in bankruptcy in French law, people who act as directors and participate in the management of the company's affairs are treated as such even though they have not been formally appointed.

PARTNERSHIPS

The
imited
artnership

The distinguishing features of the partnership are the personal and unrestricted liability of each partner for the debts and obligations of the firm (whether he assented to their being incurred or not) and the right of each partner to participate in the management of the firm and to act as an agent of it in entering into legal transactions on its behalf. The civil-law systems of most continental European countries have additionally always permitted a modified form of partnership, the limited partnership (*société en commandite, Kommanditgesellschaft, società in accomandita*) in which one or more of the partners are liable for the firm's debts only to the extent of the capital they contribute or agree to contribute. Such limited partners are prohibited from taking part in the management of the firm, however; if they do, they become personally liable without limit for the debts of the firm, together with the general partners. English common law refused to recognize the limited partnership, and in the United States at the beginning of the 19th century only Louisiana, which was governed by French civil law, permitted such partnerships. During the 19th century most of the states enacted legislation allowing limited partnerships to be formed, and in 1907 Great Britain adopted the limited partnership by statute, but it has not been much used there in practice. Another distinction between kinds of partnership in civil law—one that has no equivalent in Anglo-American common-law countries—is that between civil and commercial partnerships. This distinction depends on whether or not the purposes for which the partnership is formed fall within the list of commercial activities in the country's commercial code. These codes always make manufacturing, dealing in, and transporting goods commercial activities, while professional and agricultural activities are always noncommercial. Consequently, a partnership of lawyers, doctors, or farmers is a civil partnership, governed exclusively by the civil code of the country concerned and untouched by its commercial code. No such distinction is made in the common-law countries, where professional and business partnerships are subject to the same rules as trading partnerships, although only partners in a trading partnership have the power to borrow on the firm's behalf.

LIMITED-LIABILITY COMPANIES, OR CORPORATIONS

The company or corporation, unlike the partnership, is formed not simply by an agreement entered into between its first members; it must also be registered at a public office or court designated by law, or otherwise obtain official acknowledgment of its existence. Under English and American law the company or corporation is incorporated by filing the company's constitution (memorandum and articles of association, articles or certificate of incorporation) signed by its first members at the Companies Registry in London or, in the United States, at the office of the state secretary of state or corporation commissioner. In France, West Germany, and Italy and the other countries subject to a civil-law system, a notarized copy of the constitution is filed at the local commercial tribunal, and proof is tendered that the first members of the company have subscribed the whole or a prescribed fraction of the company's capital, and that assets transferred to the company in return for an allotment of its shares have been officially valued and found to be worth at least the amount of capital allotted for them. English and American law, together with the laws of The Netherlands and the Scandinavian countries, provide only one category of business company or corporation (in The Netherlands the *naamloze vennootschap,* in Sweden the *aktiebolag*), although all these systems of law make distinctions for tax purposes between private, or close, companies or corporations on the one hand and public companies or corporations on the other. English law also distinguishes between private and public companies for some purposes of company law; for example, a private company cannot have more than 50 members and cannot advertise subscriptions for its shares. Under the civil-law systems, however, a fundamental distinction is drawn between the public company (*société anonyme; Aktiengesellschaft; società per azioni*) and the private company (*société à responsabilité limitée, Gesellschaft mit beschränkter Haftung* [*G.m.b.H.*], *società a responsabilità limitata*), and in West Germany the two kinds of company are governed by different enactments, as they were in France until 1966. For practical purposes, however, public and private companies function the same way in all countries. Private companies are formed when there is no need to appeal to the public to subscribe for the company's shares or to lend money to it, and often they are little more than incorporated partnerships whose directors hold all or most of the company's shares. Public companies are formed—or more usually created by the conversion of private companies into public ones—when the necessary capital cannot be supplied by the directors or their associates and it is necessary to raise funds from the public by publishing a prospectus. In Great Britain, the Commonwealth countries, and the United States, this also requires the obtaining of a stock exchange listing for the shares or other securities offered or an offer on the Unlisted Securities Market (USM). In a typical public company the directors hold only a small fraction of its shares, often less than 1 percent, and in Great Britain and the United States, at least, it is not uncommon for up to one-half of the funds raised by the company to be represented not by shares in the company but by loan securities such as debentures or bonds.

Public and
private
companies

In Anglo-American common-law countries, public and private companies account for most of the business associations formed, and partnerships are entered into typically only for professional activities. In European countries the partnership in both its forms is still widely used for commercial undertakings. In West Germany a popular form of association combines both the partnership and the company. This is the G.m.b.H. & Co., which is a limited partnership whose general partner (nominally liable without limit for the partnership's debts) is a private company and whose limited partners are the same persons as the shareholders of the company. The limited partners enjoy the benefit of limited liability for the partnership's debts, and by ensuring that most of the partnership's profits are paid to them as limited partners and not to them as shareholders in the private company, they largely avoid the incidence of corporation tax.

Shares and other securities. Under all systems of law a partner may assign his share or interest in a partnership to anyone he wishes unless the partnership agreement forbids this, but the assignment does not make the assignee a partner unless all of the other partners agree. If they do not, the assignee is merely entitled to receive the financial benefits attached to the share or interest without being able to take part in the management of the firm, but neither is he personally liable for the debts of the firm.

How
company
shares
differ from
those in a
partnership

The shares of a company are quite different. In the first place, they are freely transferable unless the company's constitution imposes restrictions on their transfer, or, in French and Belgian law, unless the company is a private one, in which case transfers require the consent of the holders of three-quarters of the company's issued shares. The constitution of an English private company must always restrict the transfer of its shares for the company to qualify as private. The restriction is usually that the directors may refuse to register a transfer for any of several reasons, or that the other shareholders shall have the right to buy the shares at a fair price when their holder wishes to sell. In American law similar restrictions may be imposed, but unreasonable restrictions are disallowed by the courts. According to French and West German law, the transfer of shares in public companies may be restricted only by being made subject to the consent of the board of directors or of the management board, but under French law if the directors do not find an alternative purchaser at a fair price within three months their consent is considered as given.

Limited liability. The second significant difference between share holding and partnership is that shares in a company do not expose the holder to unlimited liability in the way that a partner (other than a limited one) is held liable for the debts of his firm. Under all systems of law, except those of Belgium and some of the U.S. states, all shares must have a nominal value expressed in money terms, such as $10, £1, DM. 50, or Fr. 100, the latter two being the minimum permissible under West German and French law. A company may issue shares for a price greater than this nominal value (the excess being known as a share premium), but it generally cannot issue them for less. Any part of that nominal value and the share premium that has not so far been paid is the measure of the shareholder's maximum liability to contribute if the company becomes insolvent. If shares are issued without a nominal value (no par value shares), the subscription price is fixed by the directors and is the measure of the shareholder's maximum liability to contribute. Usually the subscription price of shares is paid to the company fairly soon after they are issued. The period for payment of all the installments is rarely more than a year in common-law countries, and it is not uncommon for the whole subscription price to be payable when the shares are issued. The actual subscription price is influenced by market considerations, such as the company's profit record and prospects, and by the market value of the company's existing shares. Although directors have a duty to obtain the best subscription price possible, they can offer new shares to existing shareholders at favourable prices, and those shareholders can benefit either by subscribing for the new shares or by selling their subscription rights to other persons. Under European legislation directors are bound to offer new shares to existing shareholders in the first place unless they explicitly forgo their preemptive rights. In most U.S. states (but not in the United Kingdom) such preemptive rights are implied if the new shares belong to the same class as existing shares, but the rights may be negated by the company's constitution.

Dividend declaration

Dividends. The third difference between share holding and partnerships is that a partner is automatically entitled to his share of profits of the firm as soon as they are ascertained, but a shareholder is only entitled to a dividend out of the company's profits when it has been declared. Under English law, dividends are usually declared at annual general meetings of shareholders, though the company's constitution usually provides that the shareholders cannot declare higher dividends than the directors recommend. Under American law dividends are usually declared by the directors, and if shareholders consider, in view of the company's profits, that too small a dividend has been paid, they may apply to the court to direct payment of a reasonable dividend. West German law similarly protects shareholders of public companies against niggardly dividends by giving the annual general meeting power to dispose as it wishes of at least half the profit shown by the company's annual accounts before making transfers to reserve. For the same object Swedish law empowers the holders of 10 percent of a company's shares to require at least one-fifth of its accumulated profits and reserves to be distributed as a dividend, provided that the total distribution does not exceed one-half of the profits of its last financial year. Thus, most national law recognizes potential conflict of interest between directors and shareholders.

Classes of shares. Companies may issue shares of different classes, the commonest classes being ordinary and preference, or in U.S. terminology, common and preferred shares. Preference shares are so called because they are entitled by the terms on which they are issued to payment of a dividend of a fixed amount (usually expressed as a percentage of their nominal value) before any dividend is paid to the ordinary shareholders. In the case of cumulative preference shares, any unpaid part of a year's dividend is carried forward and added to the next year's dividend, and so on until the arrears of preference dividend are paid off. The accumulation of arrears of preference dividend depreciates the value of the ordinary shares, whose holders cannot be paid a dividend until the arrears of preference dividend have been paid. Consequently, it has been common in the United States (but not in the United Kingdom) for companies to issue noncumulative preference shares, giving their holders the right to a fixed preferential dividend each year if the company's profits are sufficient to pay it, but limiting the dividend to the amount of the profits of the year if they are insufficient to pay the preference dividend in full. Preference shares are not common in Europe, but under West German and Italian law they have the distinction of being the only kind of shares that can be issued without voting rights in general meetings, all other shares carrying voting rights proportionate to their nominal value by law.

History of the limited-liability company. The limited-liability company, or corporation, is a relatively recent innovation. Only since the mid-19th century have incorporated businesses risen to ascendancy over other modes of ownership. Thus, any attempt to trace the forerunners of the modern corporation should be distinguished from a general history of business or a chronicle of associated activity. Men have embarked on enterprises for profit and have joined together for collective purposes since the dawn of recorded history, but these early enterprises were forerunners of the contemporary corporation in terms of their functions and activities, not in terms of their mode of incorporation. When a group of Athenian or Phoenician merchants pooled their savings to build or charter a trading vessel, their organization was not a corporation but a partnership; ancient societies did not have laws of incorporation that delimited the scope and standards of business activity.

Corporations in the Middle Ages

The corporate form itself developed in the early Middle Ages with the growth and codification of civil and canon law. Several centuries, however, passed before business ownership was subsumed under this arrangement. The first corporations were towns, universities, and ecclesiastical orders. These differed from partnerships in that the corporation existed independently of any particular membership. Unlike modern business corporations, they were not the "property" of their participants. The holdings of a monastery, for example, belonged to the order itself; no individual owned shares in its assets. The same was true of the medieval guilds, which dominated many trades and occupations. As corporate bodies, they were chartered by government, and their business practices were regulated by public statutes; each guild member, however, was an individual proprietor who ran his own establishment, and, while many guilds had substantial properties, these were the historic accruals of the associations themselves. By the 15th century, the courts of England had agreed on the principle of "limited liability": *Si quid universitati debetur, singulis non debetur, nec quod debet universitas, singuli debent* ("If something is owed to the group, it is not owed to the individuals nor do the individuals owe what the group owes"). Originally applied to guilds and municipalities, this principle set limits on how much an alderman of the Liverpool Corporation, for example, might be called upon to pay if the city ran into debt or bankruptcy. Applied later to stockholders in business corporations, it served to encourage investment because the most an individual could lose in the event of the firm's failure would be the actual amount he had originally paid for his shares.

Incorporation of business enterprises began in England during the Elizabethan era. This was a period when businessmen were beginning to accumulate substantial surpluses, and overseas exploration and trade presented expanded investment opportunities. This was an age that gave overriding regulatory powers to the state, which sought to ensure that business activity was consonant with current mercantilist conceptions of national prosperity. Thus, the first joint-stock companies, while financed with private capital, were created by public charters setting down in detail the activities in which the enterprises might operate. In 1600, Queen Elizabeth I granted to a group of investors headed by the Earl of Cumberland the right to be "one body corporate," known as the Governor and Company of Merchants of London, trading into the East Indies. The East India Company was bestowed a trading

The East India Company

monopoly in its territories and also was given authority to make and enforce laws in the areas it entered. The East India Company, the Royal African Company, the Hudson's Bay Company, and similar incorporated firms were semipublic enterprises acting both as arms of the state and as vehicles for private profit. The same principle held with the colonial charters on the American continent. In 1606 the crown vested in a syndicate of "loving and well-disposed Subjects" the right to develop Virginia as a royal domain, including the power to coin money and to maintain a military force. The same was done, in subsequent decades, for the "Governor and Company of the Massachusetts Bay in New England," and for William Penn's "Free Society of Traders" in Pennsylvania.

Much of North America's settlement was initially underwritten as a business venture. But, while British investors accepted the regulations inhering in their charters, American entrepreneurs came to regard such rules as repressive and unrealistic. The U.S. War of Independence can be interpreted as a movement against the tenets of this mercantile system, raising serious questions about a direct tie between business enterprise and public policy. One result of that war, therefore, was to establish the premise that a corporation need not show that its activities advance a specific public purpose. Alexander Hamilton, the first secretary of the treasury and an admirer of Adam Smith, took the view that businessmen should be encouraged to explore their own avenues of enterprise. "To cherish and stimulate the activity of the human mind, by multiplying the objects of enterprise, is not among the least considerable of the expedients by which the wealth of a nation may be promoted," he wrote in 1791.

19th-century statutes

The growth of independent corporations did not occur overnight. For a long time, both in Europe and in the United States, the corporate form was regarded as a creature of government, providing a form of monopoly. In the United States the new state legislatures granted charters principally to public-service companies intending to build or operate docks, bridges, turnpikes, canals, and waterworks, as well as to banks and insurance companies. Of the 335 companies receiving charters prior to 1800, only 13 were firms engaging in commerce or manufacturing. By 1811, however, New York had adopted a general act of incorporation, setting the precedent that businessmen had only to provide a summary description of their intentions for permission to launch an enterprise. By the 1840s and 1850s, the rest of the states had followed suit. In Great Britain after 1825, the statutes were gradually liberalized so that the former privilege of incorporating joint-stock companies became the right of any group complying with certain minimum conditions, and the principle of limited liability was extended to them. A similar development occurred in France and parts of what are now Germany.

By the 20th century, in terms of size, influence, and visibility, the corporation has become the dominant business form in Western industrial societies. While corporations may be large or small, ranging from firms having hundreds of thousands of employees to neighbourhood businesses of very modest proportions, public attention has increasingly focused on the several hundred giant companies that play a preponderant economic role in the United States, Japan, Korea, the nations of western Europe, Canada, Australia, New Zealand, South Africa, and several other countries. These firms not only occupy important positions in the economy, but they have great social, political, and cultural influence as well. Both at home and abroad they affect the operations of national and local governments, give shape to local communities, and influence the values of ordinary individuals. Therefore, while in fact and in law corporate businesses are private enterprises, their activities have consequences that are public in character and as pervasive as those of many governments.

OTHER FORMS OF BUSINESS ASSOCIATION

Besides the partnership and the company or corporation there are a number of other forms of business association, of which some are developments or adaptations of the partnership or company, some are based on contract between the members or on a trust created for their benefit, and others are statutory creations. The first of these classes includes the cooperative society; the building society or home loan association and its West German equivalent, the *Bausparkasse;* the trustee savings bank or people's or cooperative bank; the friendly society or mutual insurance association; and the American mutual fund investment company. The essential features of these associations are that they provide for the small or medium investor; and, although they originated as contractual associations, they are now governed in most countries by special legislation and not by the law applicable to companies or corporations.

Contractual associations

The establishment and management of cooperatives is treated in most countries under laws distinct from those governing other business associations. The cooperative is a legal entity but typically owned and controlled by those who use it or work in it, though there may be various degrees of participation and profit sharing. The essential point is that the directors and managers are accountable ultimately to the enterprise members, not to the outside owners of capital. This form is rooted in a strong sense of social purpose; it was devised more than a century ago as an idealistic alternative to the conventional capitalist business association. It has been particularly associated with credit, retailing, agricultural marketing, and crafts.

The second class comprises the English unit trust and the European *fonds d'investissements* or*Investmentfonds,* which fulfill the same functions as the U.S. mutual funds; the Massachusetts business trust (now little used but providing a means of limiting the liability of participants in a business activity like the limited partnership); the foundation (*fondation, Stiftung*), a European organization that has social or charitable objects and often carries on a business whose profits are devoted to those objects; and, finally, the cartel or trade association, which regulates the business activities of its individual members and is itself extensively regulated by antitrust and antimonopoly legislation.

The third class of associations, those wholly created by statute, comprise corporations formed to carry on nationalized business undertakings (such as the Bank of England and the German Federal Railways) or to coexist with other businesses in the same field (such as the Italian Istituto per la Ricostruzione Industriale) or to fulfill a particular governmental function (such as the Tennessee Valley Authority). Such statutory associations usually have no share capital, though they may raise loans from the public. They are regarded in European law as being creatures of public law, like departments and agencies of the government. In recent years, however, a hybrid between the state corporation and the privately owned corporation or company has appeared in the form of the mixed company or corporation (*société mixte*). In this kind of organization part of the association's share capital is held by the state or a state agency and part by private persons, this situation often resulting from a partial acquisition of the association's shares by the state. In only France and Italy are there special rules governing such associations; in the United Kingdom and West Germany they are subject to the ordinary rules of company law.

Management and control of companies

The structure of management

The simplest form of management is the partnership. In Anglo-American common-law and European civil-law countries, every partner is entitled to take part in the management of the firm's business, unless he is a limited partner; however, a partnership agreement may provide that an ordinary partner shall not participate in management, in which case he is a dormant partner but is still personally liable for the debts and obligations incurred by the other managing partners.

The management structure of companies or corporations is more complex. The simplest is that envisaged by English, Belgian, Italian, and Scandinavian law, by which the shareholders of the company periodically elect a board of directors who collectively manage the company's affairs and reach decisions by a majority vote but also have the right to delegate any of their powers, or even the whole management of the company's business, to one or more of their number. Under this regime it is common for a managing director (*directeur général, direttore generale*) to be appointed, often with one or more assistant managing directors, and for the board of directors to authorize them to enter into all transactions needed for carrying on the company's business, subject only to the general supervision of the board and to its approval of particularly important measures, such as issuing shares or bonds or borrowing. The U.S. system is a development of this basic pattern. By the laws of most states it is obligatory for the board of directors elected periodically by the shareholders to appoint certain executive officers, such as the president, vice president, treasurer, and secretary. The latter two have no management powers and fulfill the administrative functions that in an English company are the concern of its secretary; but the president and in his absence the vice president have by law or by delegation from the board of directors the same full powers of day-to-day management as are exercised in practice by an English managing director.

The most complex management structures are those provided for public companies under West German and French law. The management of private companies under these systems is confided to one or more managers (*gérants, Geschäftsführer*) who have the same powers as managing directors. In the case of public companies, however, West German law imposes a two-tier structure, the lower tier consisting of a supervisory committee (*Aufsichtsrat*) whose members are elected periodically by the shareholders and the employees of the company in the proportion of two-thirds shareholder representatives and one-third employee representatives (except in the case of mining and steel companies where shareholders and employees are equally represented), and the upper tier consisting of a management board (*Vorstand*) comprising one or more persons appointed by the supervisory committee but not from its own number. The affairs of the company are managed by the management board, subject to the supervision of the supervisory committee, to which it must report periodically and which can at any time require information or explanations. The supervisory committee is forbidden to undertake the management of the company itself, but the company's constitution may require its approval for particular transactions, such as borrowing or the establishment of branches overseas, and by law it is the supervisory committee that fixes the remuneration of the managers and has power to dismiss them.

The German two-tiered public company

The French management structure for public companies offers two alternatives. Unless the company's constitution otherwise provides, the shareholders periodically elect a board of directors (*conseil d'administration*), which "is vested with the widest powers to act on behalf of the company" but which is also required to elect a president from its members who "undertakes on his own responsibility the general management of the company," so that in fact the board of directors' functions are reduced to supervising him. The similarity to the West German pattern is obvious, and French legislation carries this further by openly permitting public companies to establish a supervisory committee (*conseil de surveillance*) and a management board (*directoire*) like the West German equivalents as an alternative to the board of directors–president structure.

Dutch and Italian public companies tend to follow the West German pattern of management, although it is not expressly sanctioned by the law of those countries. The Dutch *commissarissen* and the Italian *sindaci*, appointed by the shareholders, have taken over the task of supervising the directors and reporting on the wisdom and efficiency of their management to the shareholders.

SEPARATION OF OWNERSHIP AND CONTROL

Dispersion of ownership

The investing public is a major source of funds for new or expanding operations. As companies have grown, their need for funds has grown, with the consequence that legal ownership of companies has become widely dispersed. For example, in large U.S. corporations, shareholders may run into the hundreds of thousands and even more. Although large blocks of shares may be held by wealthy individuals or institutions, the total amount of stock in these companies is so large that even a very wealthy person is not likely to own more than a small fraction of it.

The chief effect of this stock dispersion has been to give effective control of the companies to their salaried managers. Although each company holds an annual meeting open to all stockholders, who may vote on company policy, these gatherings, in fact, tend to ratify ongoing policy. Even if sharp questions are asked, the presiding officers almost invariably hold enough proxies to override outside proposals. The only real recourse for a dissatisfied shareholder is to sell his stock and invest in a firm whose policies are more to his liking. (If enough shareholders do this, of course, the price of the stock will fall quite markedly, perhaps impelling changes in management personnel or company policy.) Occasionally, there are "proxy battles," when attempts are made to persuade a majority of shareholders to vote against a firm's managers (or to secure representation of a minority bloc on the board), but such struggles seldom involve the largest companies. It is in the managers' interest to keep the stockholders happy, for, if the company's shares are regarded as a good buy, then it is easy to raise additional capital through a new stock issue.

Thus, if a company is performing well in terms of sales and earnings, its executives will have a relatively free hand. If a company gets into trouble, its usual course is to agree to be merged into another incorporated company or to borrow money. In the latter case, the lending institution may insist on a new chief executive of its own choosing. If a company undergoes bankruptcy and receivership, the court may appoint someone to head the operation. But managerial autonomy is the rule. The salaried executives typically have the discretion and authority to decide what products and services they will put on the market, where they will locate plants and offices, how they will deal with employees, and whether and in what directions they will expand their spheres of operation.

EXECUTIVE MANAGEMENT

The markets that corporations serve reflect the great variety of humanity and human wants; accordingly, firms that serve different markets exhibit great differences in technology, structure, beliefs, and practice. The essence of competition and innovation lies in differentiation and change, so corporations are in general under degrees of competitive pressure to modify or change their existing offerings, to introduce new products or services. Similarly, as markets decline or become less profitable, they are under pressure to invent or discover new wants and markets. Resisting this pressure for change and variety are benefits derived from regulated manufacturing, from standardization of machines and tools, and from labour specialization. Every firm has to arrive at a mode of balancing change and stability, a conflict often expressed in distinctions drawn between capital and revenue and long- and short-term operations and strategy. Many corporations have achieved relatively stable product–market relationships, providing further opportunity for growth within particular markets and expansion into new areas. Such relative market control endows corporate executives and officers with considerable discretion over resources and, in turn, with considerable corporate powers. In theory these men and women are hired to manage someone else's property; in practice, however, many management officers have come increasingly to regard the stockholders as simply one of several constituencies to which they must report at periodic intervals through the year.

Management motivation

Managerial decision making. The guidelines governing management decisions cannot be reduced to a simple formula. Traditionally, economists have assumed that the goal of a business enterprise was to maximize its profits. There are, however, problems of interpretation with this simple assertion. First, over time the notion of "profit" is itself unclear in operational terms. Today's profits can be increased at the expense of profits years away, by cutting maintenance, deferring investment, and exploiting staff. Second, there are questions over whether expenditure on offices, cars, staff expenses, and other trappings of status reduces shareholders' wealth or whether these are part of necessary performance incentives for executives. Some proponents of such expenditures believe that they serve to enhance contacts, breed confidence, improve the flow of information, and stimulate business. Third, if management asserts primacy of profits, this may in itself provide negative signals to employees about systems of corporate values. Where long-term success requires goodwill, commitment, and cooperation, focus on short-term profit may alienate or drive away those very employees upon whom long-term success depends.

Generally speaking, most companies turn over only about half of their earnings to stockholders as dividends. They plow the rest of their profits back into the operation. A major motivation of executives is to expand their operations faster than those of their competitors. The important point, however, is that without profit over the long term no firm can survive. For growing firms in competitive markets a major indicator of executive competence is the ability to augment company earnings by increasing sales or productivity or by achieving savings in other ways. This principle distinguishes the field of business from other fields. A drug company makes pharmaceuticals and may be interested in improving health, but it exists, first and foremost, to make profits. If it found that it could make more money by manufacturing frozen orange juice, it might choose to do so.

The modern executive. Much has been written about business executives as "organization men." According to this view, typical company managers no longer display the individualism of earlier generations of entrepreneurs. They seek protection in committee-made decisions and tailor their personalities to please their superiors; they aim to be good "team" members, adopting the firm's values as their own. The view is commonly held that there are companies—and entire industries—that have discouraged innovative ideas. The real question now is whether or not companies will develop policies to encourage autonomy and adventuresomeness among managers.

Company cadets in Japan

In Japan, where the employees of large corporations tend to remain with the same employer throughout their working lives, the corporations recruit young men upon their graduation from universities and train them as company cadets. Those among the cadets who demonstrate ability and a personality compatible with the organization are later selected as managers. Because of the seniority system, many are well past middle age before they achieve high status. There are signs that the system is weakening, however, as efforts are more often made to lift promising young men out of low-echelon positions. Criticism of the traditional method has been stimulated by the example of some of the newer corporations and of those owned by foreign capital. The few men in the Japanese business world who have emerged as personalities are either founders of corporations, managers of family enterprises, or small businessmen. They share a strong inclination to make their own decisions and to minimize the role of directors and boards. (S.N.W./Ed.)

Business finance

The planning, analysis, and control operations are responsibilities of the financial manager, who is usually close to the top of the organizational structure of a firm. Typically the manager is a member of the first level of the company staff in a large organization. In very large firms major financial decisions are often made by a finance committee. In small firms, the owner-manager usually conducts the financial operations. Much of the day-to-day work of business finance is conducted by lower level staff; their work includes handling cash receipts and disbursements, borrowing from commercial banks on a regular and continuing basis, and formulating cash budgets.

Financial decisions affect both the profitability and the riskiness of a firm's operations. An increase in the cash position, for instance, reduces risk; but, because cash is not an earning asset, converting other types of assets to cash reduces the firm's profitability. Similarly, the use of additional debt raises the profitability of the firm, but more debt means more risk. Striking a balance—between risk and profitability—that will maintain the long-term value of the firm's securities is the task of finance.

SHORT-TERM FINANCIAL OPERATIONS

Financial planning and control. Short-term financial operations are closely involved with the financial planning and control activities of the firm. These include financial ratio analysis, profit planning, financial forecasting, and budgeting.

Analysis of the balance sheet

Financial ratio analysis. A firm's balance sheet contains many items that taken by themselves have no clear meaning. Financial ratio analysis is a way of appraising their relative importance. The ratio of current assets to current liabilities, for example, gives the analyst an idea of the extent to which the firm can meet its current obligations. This is known as a liquidity ratio. Financial leverage ratios (such as the debt–asset ratio and debt as a percentage of total capitalization) are used to make judgments about the advantages to be gained from raising funds by the issuance of bonds (debt) rather than stock. Activity ratios, relating to the turnover of such asset categories as inventories, accounts receivable, and fixed assets, show how intensively the firm is employing its assets. The firm's primary operating objective is to earn a good return on its invested capital, and various profit ratios (profits as a percentage of sales, of assets, or of net worth) show how successfully it is meeting this objective.

Ratio analysis is used to compare a firm's performance with that of other firms in the same industry or with the performance of industry in general. It is also used to study trends in the firm's performance over time and thus to anticipate problems before they develop.

Profit planning. Ratio analysis applies to the firm's current operating posture. But the firm must also plan for future growth. This requires decisions as to the expansion of existing operations and, in manufacturing, to the development of new product lines. The firm must choose between productive processes requiring various degrees of mechanization or automation—that is, various amounts of fixed capital in the form of machinery and equipment. This will increase fixed costs—that is, costs that are relatively constant and do not decrease when the firm is operating at levels below full capacity. The higher the proportion of fixed costs to total costs, the higher must be the level of operation before profits begin, and the more sensitive will profits be to changes in the level of operation.

Estimate of sales

Financial forecasting. The financial manager must also make overall forecasts of future capital requirements to assure that funds will be available to finance new investment programs. The first step in making such a forecast is to obtain an estimate of sales during each year of the planning period. This estimate is worked out jointly by the marketing, production, and finance departments: the marketing manager estimates demand; the production manager estimates capacity; and the financial manager estimates availability of funds to finance new accounts receivable, inventories, and fixed assets.

For the predicted level of sales, the financial manager estimates the funds that will be available from the company's operations and compares this amount with what will be needed to pay for the new fixed assets (machinery, equipment, etc.). If the growth rate exceeds 10 percent a year, asset requirements are likely to exceed internal sources of funds, so plans must be made to finance them by issuing securities. If, on the other hand, growth is slow, more funds will be generated than are required to support the estimated growth in sales. In this case, the financial manager will consider a number of alternatives, including increasing dividends to stockholders, retiring debt, using excess funds to acquire other firms, or, perhaps, increasing expenditures on research and development.

Control through budgeting. Once the firm's general goals for the planning period have been established, the next step is to set up a detailed plan of operation—the budget. A complete budget system encompasses all aspects of the firm's operations over the planning period. It may even allow for changes in plans as required by factors outside the firm's control.

Budgeting is a part of the total planning activity in the firm, so it must begin with a statement of the firm's long-range plan. The long-range plan includes a long-range sales forecast. This forecast requires a determination of the number and types of products that will be manufactured in the years encompassed by the long-range plan. Short-term budgets are formulated within the framework of the long-range plan. Normally, there is a budget for every individual product and for every significant activity of the firm.

Establishing budgetary controls requires a realistic understanding of the firm's activities. For example, a small firm purchases more parts and uses more labour and less machinery; a larger firm will buy raw materials and use machinery to manufacture end items. In consequence, the smaller firm should budget higher parts and labour cost ratios, while the larger firm should budget higher overhead cost ratios and larger investments in fixed assets. If standards are unrealistically high, frustrations and resentment will develop. If standards are unduly lax, costs will be out of control, profits will suffer, and morale will drop.

The cash budget and management of cash. One of the principal methods of forecasting the financial needs of a business is the cash budget. The cash budget forecasts the combined effects of planned operations on the firm's cash flow. A positive net cash flow means that the firm will have surplus funds to invest. But if the cash budget indicates that an increase in the volume of operations will lead to a negative cash flow, additional financing will be required. The cash budget thus indicates the amount of funds that will be needed or available month by month, or even week by week.

Disposition of excess cash

A firm may have excess cash for a number of reasons. There are likely to be seasonal or cyclical fluctuations in business. Resources may be deliberately accumulated as a protection against a number of contingencies. Since it is wasteful to allow large amounts of cash to remain idle, the financial manager will try to find short-term investments for sums that he will need later. Short-term government or business securities can be selected and balanced in such a way that he obtains the maturities and risks appropriate to the financial situation of his firm.

Managing accounts receivable. Accounts receivable are the credit a firm gives its customers. The volume and terms of such credit vary among businesses and among nations; for manufacturing firms in the United States, for example, the ratio of receivables to sales ranges between 8 and 12 percent, representing an average collection period of approximately one month. The basis of a firm's credit policy is the practice in its industry; generally, a firm must meet the terms offered by competitors. Much depends, of course, on the individual customer's credit standing.

To evaluate a customer as a credit risk, the credit manager considers what may be called the five C's of credit: character, capacity, capital, collateral, and conditions. Information on these items is obtained from the firm's previous experience with the customer, supplemented by information from various credit associations and credit-reporting agencies. In reviewing a credit program, the financial manager should regard losses from bad debts as part of the cost of doing business. Accounts receivable represent an investment in the expansion of sales. The return of this investment can be calculated as in any capital budgeting problem.

Managing inventories. Every company must carry stocks of goods and materials in inventory. The size of the investment in inventory depends on various factors, including the level of sales, the nature of the productive processes, and the speed with which goods perish or become obsolescent.

The problems involved in managing inventories are basically the same as those in managing other assets, including cash. A basic stock must be on hand at all times. Because the unexpected may occur, it is also wise to have safety stocks; these represent the little extra needed to avoid the costs of not having enough. Additional amounts—anticipation stocks—may be required to meet future growth needs. Finally, some inventory accumulation results from the economies of purchasing in large quantities: it is always cheaper to buy more than is immediately needed, whether of raw materials, money, or plant and equipment. There is a standard procedure for determining the most economical amounts to order, one that relates purchasing requirements to costs and carrying charges. While carrying charges rise as average inventory holdings increase, certain other costs (ordering costs and stock-out costs) fall as average inventory holdings rise. These two sets of costs comprise the total cost of ordering and carrying inventories, and it is fairly easy to calculate an optimal order size that will minimize total inventory costs.

Working capital

Short-term financing. The main sources of short-term financing are (1) trade credit, (2) loans from commercial banks, and (3) commercial paper.

Trade credit. A firm customarily buys its supplies and materials on credit from other firms, recording the debt as an account payable. This trade credit, as it is commonly called, is the largest single category of short-term credit. Credit terms are usually expressed with a discount for prompt payment. Thus the seller may state that if payment is made within 10 days of the invoice date, a 2 percent cash discount will be allowed. If the cash discount is not taken, payment is due 30 days after the date of invoice. The cost of not taking cash discounts is the price of the credit, an amount equal to an effective rate of interest of 36.7 percent annually.

Commercial banks. Commercial bank lending appears on the balance sheet as notes payable and is second in importance to trade credit as a source of short-term financing. Banks occupy a pivotal position in the short-term and intermediate-term money markets. As a firm's financing needs grow, banks are called upon to provide additional funds. A single loan obtained from a bank by a business firm is not different in principle from a loan obtained by an individual. The firm signs a conventional promissory note. Repayment is made in a lump sum at maturity or in installments throughout the life of the loan. A line of credit, as distinguished from a single loan, is a formal or informal understanding between the bank and the borrower as to the maximum loan balance the bank will allow at any one time.

In the United States the role of commercial banks in the financing of business is somewhat unusual. The Banking Act of 1933 required the separation of investment banking and commercial banking functions, whereas in most other countries commercial banks are a source of long-term as well as of short-term financing.

Commercial paper. Commercial paper, a third source of short-term credit, consists of well-established firms' promissory notes sold primarily to other business firms, insurance companies, pension funds, and banks. Commercial paper is issued for periods varying from two to six months. The rates on prime commercial paper vary, but they are generally slightly below those on prime business loans.

A basic limitation of the commercial paper market is that its resources are limited to the excess liquidity that corporations, the main suppliers of funds, may have at any particular time. Another disadvantage is the impersonality of the dealings; a bank is much more likely to help a good customer weather a storm than is a commercial paper dealer.

Use of security in short-term financing. Most short-term business loans are unsecured. It is ordinarily better to borrow on an unsecured basis, but frequently a borrower's credit rating is not strong enough to justify an unsecured loan. The most common types of collateral used for short-term credit are inventories and accounts receivable.

Financing through accounts receivable can be done either by pledging the receivables or by selling them outright, a process called factoring in the United States. When a receivable is pledged, the borrower retains the risk that the person or firm who owes the receivable will not pay; this risk is typically passed on to the lender when factoring is involved.

When loans are secured by inventory, the lender takes title to them. He may or may not take physical possession of them. Under a field warehousing arrangement, the inventory is under the physical control of a warehouse company, which releases the inventory only on order from the lending institution. Canned goods, lumber, steel, coal, and other standardized products are the types of goods usually covered in field warehouse arrangements.

Financing equipment

Intermediate-term financing. Whereas short-term loans are repaid in a period of weeks or months, intermediate-term loans are scheduled for repayment in one to 15 years. Obligations due in 15 or more years are thought of as long-term debt. The major forms of intermediate-term financing include (1) term loans, (2) conditional sales contracts, and (3) lease financing.

Term loans. A term loan is a business credit with a maturity of more than one year but less than 15 years. Usually the term loan is retired by systematic repayments (amortization payments) over its life. It may be secured by a chattel mortgage on equipment, but the larger, stronger companies are able to borrow on an unsecured basis. Commercial banks and life insurance companies are the principal suppliers of term loans. The interest cost of term loans varies with the size of the loan and the strength of the borrower.

Term loans involve more risk to the lender than do short-term loans. The lender's funds are tied up for a long period, and during this time the borrower's situation can change markedly. To protect themselves, lenders often include in the loan agreement stipulations that the borrower will maintain his current liquidity ratio at a specified level, limit his acquisitions of fixed assets, keep his debt ratio below a stated amount, and in general follow policies that are acceptable to the lender.

Conditional sales contracts. Conditional sales contracts are a common method of obtaining equipment byagreeing to pay forit in installments over a period of up to five years. Until payment is completed, the seller of the equipment continues to hold title to the equipment.

Leasing. It is not necessary to purchase assets in order to use them. Railroad companies in the United States, for instance, have acquired much of their equipment by leasing it. Whether or not leasing is advantageous depends—aside from tax advantages—on the firm's access to funds; leasing provides an alternative method of financing. A lease contract, however, being a fixed obligation, is similar to debt and uses some of the firm's debt-carrying ability. It will generally be advantageous to a firm to own its land and buildings, because their value is likely to increase, but this consideration does not apply to equipment.

The statement is frequently made that leasing involves higher interest rates than other forms of financing, but this need not always be true. Much depends on the firm's standing as a credit risk. Moreover, it is difficult to separate the money costs of leasing from the other services that may be embodied in a leasing contract. If the leasing company can perform nonfinancial services, such as maintenance of the equipment, at a lower cost than the lessee or someone else could perform them, the effective cost of leasing may be lower than for funds obtained from borrowing or other sources.

Although leasing involves fixed charges, it enables a firm to present lower debt-to-asset ratios in its financial statements. Many lenders, in examining financial statements, give less weight to a lease obligation than to a loan obligation.

LONG-TERM FINANCIAL OPERATIONS

Managing the capital structure

Use of bonds. Long-term capital may be raised either through borrowing or by the issuance of stock. Long-term borrowing is done by selling bonds, which are promissory notes that obligate the firm to pay interest at specific times. Secured bondholders have prior claim on the firm's assets. If the company goes out of business, the bondholders are entitled to be paid the face value of their holdings plus interest. Stockholders, on the other hand, have no more than a residual claim on the company: they are entitled to a share of the profits, if there are any, but it is the prerogative of the board of directors to decide whether a dividend will be paid and how large it will be.

Long-term financing involves the choice between debt (bonds) and equity (stocks). Each firm will choose its own capital structure, seeking the combination of debt and equity that will minimize the costs of raising capital. As conditions in the capital market vary (for instance, changes in interest rates, the availability of funds, and the relative costs of alternative methods of financing), the firm's desired capital structure will change correspondingly.

The larger the proportion of debt in the capital structure (leverage), the higher will be the returns to equity. This is because bondholders do not share in the profits. The difficulty with this, of course, is that a high proportion of debt increases the firm's fixed costs and increases the degree of fluctuation in the returns to equity for any given degree of fluctuation in the level of sales. If used successfully, leverage increases the returns to owners but decreases the returns to owners when it is used unsuccessfully. Indeed, if leverage is unsuccessful, the result may be the bankruptcy of the firm.

Forms of long-term debt. There are various forms of long-term debt. A mortgage bond is one secured by a lien on fixed assets such as plant and equipment. A debenture is a bond not secured by specific assets but accepted by investors because the firm has a high credit standing or obligates itself to follow policies that assure a high rate of earnings. A still more junior lien is the subordinated debenture, which is secondary to all other debentures and specifically to short-term bank loans.

The use of long-term debt will be encouraged when sales and earnings are relatively stable, profit margins are large enough to make more leverage advantageous to the stockholders, an increase is expected in profits or the general price level, the existing debt ratio is relatively low, the price–earnings ratios on common stock are low in relation to the levels of interest rates, management is concerned with maintaining voting control over the company, cash-flow requirements under the bond agreement are not burdensome, and the restrictions on management written into the bond indenture are not onerous.

Stock. Equity financing is done with common and preferred stock. Preferred stock usually has priority over common stock with respect to earnings and claims on assets in liquidation. Preferred stock is usually cumulative—that is, the omission of dividends in one or more years creates an accumulated claim. The dividends on preferred stock are usually fixed at a specific percentage of face value. A company issuing preferred stock gains the advantages of limited dividends and no maturity—that is, the advantages of selling bonds but without the restrictions of bonds. Companies sell preferred stock when they seek more leverage but wish to avoid the fixed charges of debt. The advantages of preferred stock will be reinforced if a company's debt ratio is already high and if common stock financing is relatively expensive.

If a bond or preferred stock issue was sold when interest rates were higher than they are at present, it may be profitable to call the old issue and refund it with a new, lower cost issue. This depends on how the immediate costs and premiums that must be paid compare with the annual savings that can be obtained.

Earnings and dividend policies. The size and frequency of dividend payments are critical issues in company policy. Dividend policy affects the financial structure, the flow of funds, corporate liquidity, stock prices, and the morale of stockholders. If earnings are paid out as dividends, they cannot be used for company expansion. Some stockholders are interested in receiving maximum current returns on their investment, while others prefer reinvestment of earnings so that the company's capital will increase.

Companies tend to reinvest their earnings to a higher degree when there are chances for profitable expansion. Thus, at times when profits are high, the amounts reinvested are greater and dividends are smaller. For similar reasons, reinvestment is likely to decrease when profits decline, and dividends are likely to increase.

High-dividend policy

Companies having relatively stable earnings over a period of years tend to pay high dividends. Well-established large firms are likely to pay higher than average dividends because they have better access to capital markets and are not as dependent as other firms on internal financing. In the same way, if a firm has a strong cash or liquidity position, it is likely to pay higher dividends than if it has not. A firm with heavy indebtedness has implicitly committed itself to paying relatively low dividends and retaining earnings to service the debt. It may decide, however, to continue with high dividends in order to facilitate a stock issue or a refunding of its debt. If the directors of a company are concerned with maintaining control of it, they may retain earnings so that they can finance expansion without having to issue stock. Some companies favour a stable dividend policy rather than allow dividends to fluctuate with earnings; the dividend rate will then be lower when profits are high and higher when profits are temporarily in decline. Companies whose stock is closely held by a few high-income stockholders are likely to pay lower dividends in order to permit the stockholders to avoid an increase in personal income taxes.

In Europe, until recently, company financing tended to rely heavily on internal sources. This was because many companies were owned by families and, also, because a highly developed capital market was lacking. In the less developed countries today, firms rely heavily on internal financing; they also tend to make more use of short-term bank loans and other forms of short-term financing than is typical in other countries.

Convertible bonds and stock warrants. Companies sometimes issue bonds or preferred stock that give holders the option of converting them into common stock or of purchasing stock at favourable prices. Convertible bonds carry the option of conversion into common stock at a specified price during a particular period. Stock purchase warrants are given with bonds or preferred stock as an inducement to the investor; they permit him to buy common stock in the company at a stated price whenever he chooses. Such option privileges make it easier for small companies to sell bonds or preferred stock. They help large companies to float new issues on more favourable terms than they could otherwise obtain. When bondholders exercise conversion rights, the company's debt ratio is reduced because bonds are replaced by stock. The exercise of stock warrants, on the other hand, brings additional funds into the company but leaves the existing debt or preferred stock on the books. Option privileges also permit a company to sell new stock at more favourable prices than those prevailing at the time of issue, since the prices stated on the options are higher. They are most popular, therefore, at times when stock prices are expected to have an upward trend.

GROWTH AND DECLINE

Growth by combination

Mergers and consolidations. Companies often grow by combining with other companies. One company may purchase all or part of another; two companies may merge by exchanging shares; or a wholly new company may be formed through consolidation of the old companies. From the financial manager's viewpoint, this kind of expansion is like any other investment decision: the acquisition should be made if it increases the acquiring firm's net present value as reflected in the price of its stock.

The most important term that must be negotiated in a combination is the price the acquiring firm will pay for the assets it takes over. Present earnings, expected future earnings, and the effects of the merger on the rate of earnings growth of the surviving firm are perhaps the most important determinants of the price that will be paid. Current market prices are the second most important determinant of prices in mergers: depending on whether or not asset values are indicative of the earning power of the acquired firm, book values may exert an important influence on the terms of the merger. Other, nonmeasurable, factors are sometimes the overriding determinant in bringing companies together: synergistic effects (wherein the net result is greater than the combined value of the individual components) may be present to a sufficient extent to warrant paying more for the firm to be acquired than earnings and asset values would indicate.

A merger may be treated as either a purchase or a pooling of interests. In a purchase, a larger firm generally takes over a smaller one and assumes all management control. The amount actually paid for the smaller firm is reflected in the acquiring firm's balance sheet; if more was paid for the acquired firm than the book value of its assets, the difference is reflected in the acquiring firm's financial statements as goodwill. In a pooling of interests, the merged firms are usually about the same size; both managements carry on important functions after the merger; and common stock, rather than cash or bonds, is used in payment. The total assets of the surviving firm in a pooling are equal to the sum of the assets of the two independent companies, and no surplus remains to be written off as a charge against earnings.

Basis of a successful merger

The basic requirements for the success of a merger are that it fit into a soundly conceived long-range plan and that the resulting firm have performance characteristics superior to those attainable by the previous companies independently. In the heady environment of a rising stock market, mergers have often been motivated by superficial financial aims. Companies with stock selling at a high price relative to earnings have found it advantageous to merge with companies having a lower price–earnings ratio; this enables them to increase their earnings per share, thus appealing to investors who purchase stock on the basis of earnings.

Efficiencies in general management

Some mergers, particularly those of "conglomerates," which bring together firms in unrelated fields, owe their success to economies of management. In the 1950s certain large-scale changes in managerial technology occurred. The role of the general management functions (planning, control, organizing, information) and other functions centralized at top management levels (research, finance, legal services) increased in importance. The costs of managing large, diversified firms were substantially reduced. This explains generally the spread of conglomerate mergers in the United States.

In mergers, one firm disappears. An alternative is for one firm to buy all or a majority of the voting stock of another and to run it as an operating subsidiary. The acquiring firm is then called a holding company. There are several advantages in the holding company: it can control the acquired firm with a smaller investment than would be required in a merger; each firm remains a separate legal entity, and the obligations of one are separate from those of the other; and stockholder approval is not necessary, as it is in the case of a merger. There are also disadvantages to holding companies, including the possibility of multiple taxation and the danger that the high rate of leverage will amplify the earnings fluctuations of the operating companies.

Reorganization. When a firm cannot operate profitably the owners may seek to reorganize it. The first question to be answered is whether the firm might not be better off by ceasing to do business. If the decision is made that the firm is to survive, it must be put through the process of reorganization. Legal procedures are always costly, especially in the case of business failure; both the debtor and the creditors are better off if matters can be handled on an informal basis rather than through the courts. The informal procedures used in reorganization are (1) extension, which postpones the settlement of outstanding debt, and (2) composition, which reduces the amount owed.

If voluntary settlement through extension or composition is not possible, the matter must be taken to court. If the court decides on reorganization rather than liquidation, it appoints a trustee to control the firm and to prepare a formal plan of reorganization. The plan must meet standards of fairness and feasibility: the concept of fairness involves the appropriate distribution of proceeds to each claimant; the test of feasibility relates to the ability of the new enterprise to carry the fixed charges resulting from the reorganization plan. (J.F.W.)

Modern trends

Multinational and conglomerate companies

The sheer size of the largest limited-liability companies, or corporations—especially "multinationals," with holdings across the world—has been a subject of discussion and public concern since the end of the 19th century. For with this rise has come market and political power. While some large firms have declined, been taken over, or gone out of business, others have grown to replace them. The giant firms continue to increase their sales and assets, by expanding their markets, by diversifying, and by absorbing smaller companies. Diversification carried to the extreme has brought into being the conglomerate company, which acquires and operates subsidiaries that are often in unrelated fields. The holding company, with the conglomerate, acts as a kind of internal stock market, allocating funds to its subsidiaries on the basis of financial performance. The decline or failure of many conglomerates, however, has cast doubt upon the competence of any one group of executives to manage a diversity of unrelated operations. Empirical evidence from the United States suggests that conglomerates have been less successful financially than companies that have had a clear product-market focus based on organizational strengths and competencies.

The causes of such vast corporate growth have found varying explanations. One school of thought, most prominently represented by the U.S. economist John Kenneth Galbraith, sees growth as stemming from the imperatives of modern technology. Only a large firm can employ the range of talent needed for research and development in areas such as aerospace and nuclear energy. And only companies of this stature have the capacity for innovating industrial processes and entering international markets. Just as government has had to grow in order to meet new responsibilities, so have corporations found that producing for the contemporary economy calls for the intricate interaction of executives, experts, and extensive staffs of employees. While there is certainly room for small firms, the kinds of goods and services that the public seems to want increasingly require the resources that only a large company can master.

Others hold that the optimum size of the efficient firm is substantially smaller than many people believe. For instance George Romney, a former president of the U.S. company American Motors Corporation, contended that an automobile company could prosper and be profitable while producing only 200,000 cars a year. By this reasoning, most of the divisions of the huge U.S. General Motors Corporation could be established as separate companies. Some research has shown that profit rates in industries having a large number of smaller firms are just as high as in those in which a few big companies dominate a market. In this view, corporate expansion stems not from technological necessity but rather from an impulse to acquire or establish new subsidiaries or to branch out into new fields. The structures of most large corporations are really the equivalent of a congeries of semi-independent companies. In some cases these divisions compete against one another as if they were separately owned. The picture has been further complicated by growth across national boundaries, producing multinational companies, principally firms from western Europe and North America. Their enormous size and extent raise questions about their accountability and political and economic influence and power.

THE IMPACT OF THE LARGE COMPANY

Power and influence of giant corporations

While it is generally agreed that the power of large companies extends beyond the economic sphere, this influence is difficult to measure in any objective way. The processes of business entail at least some effort to ensure the sympathetic enactment and enforcement of legislation, since costs and earnings are affected by tax rates and government regulations. Companies and business groups send agents to local and national capitals and use such vehicles as advertising to enlist support for policies that they favour. Although, in many countries, companies may not legally contribute directly to candidates running for public office, their executives and stockholders may do so as individuals. Companies may, however, make payments to influence peddlers and contribute to committees working to pass or defeat legislative proposals. In practical terms, many lawmakers look upon companies as part of their constituency, although, if their districts depend on local plants, these lawmakers may be concerned more with preserving jobs than with protecting company profits. In any case, limited-liability companies are central institutions in society; it would be unrealistic to expect them to remain aloof from the political process that affects their operations, performance, and principles.

The decisions made by company managements have ramifications throughout society. In effect, companies can decide which parts of the country or even which parts of the world will prosper and which will decline by choosing where to locate their plants and other installations. The giant companies not only decide what to produce but also help to instill in their customers a desire for the amenities that the companies make available. To the extent that large firms provide employment, their personnel requirements determine the curricula of schools and universities. For these reasons, individuals' aspirations and dissatisfactions are likely to be influenced by large companies. This does not mean that large business firms can influence the public in any way they choose; it is simply that they are the only institutions available to perform certain functions. Automobiles, typewriters, frozen food, and electric toasters must come from company auspices if they are to be provided at all. Understanding this dependence as a given, companies tend to create an environment congenial to the conduct of their business.

THE SOCIAL ROLE OF THE LARGE COMPANY

Some company executives believe that their companies should act as "responsible" public institutions, holding power in trust for the community. Most companies engage in at least some public-service projects and make contributions to charities. A certain percentage of these donations can be deducted from a corporation's taxable income. Most of the donated money goes to private health, education, and welfare agencies, ranging from local hospital and charity funds to civil-rights groups and cultural institutions.

At the other extreme, it is generally agreed that companies should reject the notion that they have public duties, that society as a whole will be better off if companies maximize their profits, for this will expand employment, improve technology, raise living standards, and also provide individuals with more money to donate to causes of their own choosing. A cornerstone of this argument is that management has no right to withhold dividends. If stockholders wish to give gifts themselves, they should do so from their personal funds. On the other hand, some critics complain that large companies have been much too conservative in defining their responsibilities. Not only have most firms avoided public controversy, but also they have sought to reap public-relations benefits from every sum that they donate. Very few, say the critics, have made more than a token effort to promote minority hiring, provide day-care centres, or take on school dropouts and former convicts. Companies have also been charged with abandoning the central cities, profiting from military contracts, misrepresenting their merchandise, and investing in foreign countries governed by repressive regimes. A perennial indictment has been that profits, prices, and executive compensation are too high, while the wages and taxes paid by corporations are too low.

Consumer and environmental criticism

In the late 20th century a new school of critics emerged who stressed the social costs of the large company. They charged that automobiles, pharmaceuticals, and other products were badly designed and dangerous to their users. The new consumer movement, led by such figures as the U.S. lawyer Ralph Nader, was joined by environmental critics who pointed to the quantities of waste products released into streams and into the air. Local and national laws were passed in an effort to set higher standards of safety and to force companies to install antipollution devices. Not all of the critics understand that the costs of these measures are passed on to the consumer. If a nuclear power plant must have cooling towers so that it does not discharge heated water into an adjacent lake, for example, the extra equipment results in higher electricity bills. Most companies are hesitant to take such steps on their own initiative, fearing that they will need to raise prices without thereby increasing profits. Society, however, is already paying for the costs of traffic congestion, trash removal, and nutritional deficiencies. The prices charged by companies are far from reflecting the total impact that the manufacture and consumption of their products have upon human life.

BIBLIOGRAPHY

U.S. corporations: JOHN P. DAVIS, *Corporations: A Study of the Origin and Development of Great Business Combinations and Their Relation to the Authority of the State,* 2 vol. (1905, reprinted 1971), remains the definitive historical account of the corporate form in the medieval and mercantile periods; while EPHRAIM LIPSON, *The Economic History of England,* vol. 1, 12th ed., and vol. 2–3, 6th ed. (1960–64), provides a full exposition of the joint-stock companies and the chartered companies. LOUIS M. HACKER, *American Capitalism, Its Promise and Accomplishment* (1957, reprinted 1979), traces the rise of corporations in the United States in the 19th century. The divorce of ownership and management is analyzed in ADOLPH A. BERLE and GARDINER C. MEANS, *The Modern Corporation and Private Property,* rev. ed. (1968); and the implications of this development are treated in JOHN KENNETH GALBRAITH, *The New Industrial State,* 3rd ed. rev. (1978). Analysis of the competitive powers of the free market is continued in NICHOLAS WOLFSON, *The Modern Corporation: Free Markets Versus Regulation* (1984). WILBERT E. MOORE, *The Conduct of the Corporation* (1962, reprinted 1975), focuses on internal operations; while RICHARD J. BARBER, *The American Corporation: Its Power, Its Money, Its Politics* (1970), concentrates on external aspects. OSBORN ELLIOTT, *Men at the Top* (1959), examines the backgrounds and behaviour of company executives. JOSEPH LIVINGSTON, *The American Stockholder,* new rev. ed. (1963), evaluates the individuals and institutions that own corporate shares. MILTON FRIEDMAN, *Capitalism and Freedom* (1962, reprinted 1982), is a plea for noninterference by public agencies; while ESTES KEFAUVER, *In a Few Hands: Monopoly Power in America* (1965), supports further regulation and antitrust action by government. EDWARD S. MASON (ed.), *The Corporation in Modern Society* (1960, reprinted 1980); and ANDREW HACKER (ed.), *The Corporation Take-Over* (1964, reprinted 1970), contain theoretical analyses and research findings. Managerial styles of the modern corporation are examined in BRUCE HENDERSON, *The Logic of Business Strategy* (1984); A.L. MINKES and C.S. NUTTALL, *Business Behavior and Management Structure* (1985); JOHANNES M. PENNINGS (ed.), *Organizational Strategy and Change* (1985); and EDGAR H. SCHEIN, *Organizational Culture and Leadership* (1985).

European limited-liability companies: The growth of corporations in Europe is discussed in MICHAEL M. POSTAN, *An Economic History of Western Europe, 1945–1964* (1967). See also P. SARGANT FLORENCE, *Ownership, Control and Success of Large Companies: An Analysis of English Industrial Structure and Policy, 1936–1951* (1961); and JOHN SHEAHAN, *Promotion and Control of Industry in Postwar France* (1963).

Japanese companies: For the historical development of the Japanese economy, see WILLIAM W. LOCKWOOD, *The Economic Development of Japan,* expanded ed. (1968, reprinted 1970); and HENRY ROSOVSKY, *Capital Formation in Japan, 1868–1940* (1961), which cover the period from the Meiji Restoration to World War II; and RYUTARO KOMIYA (ed.), *Postwar Economic Growth in Japan* (1966; originally published in Japanese, 1963), for the postwar period. For a statistical analysis of Japan's economic growth since the 1860s, LAWRENCE KLEIN and KAZUSHI OHKAWA (eds.), *Economic Growth: The Japanese Experience Since the Meiji Era* (1968), is useful. The characteristics of entrepreneurs in the early Meiji period, when modern capitalism rose in Japan, are given in JOHANNES HIRSHMEIER, *The Origins of Entrepreneurship in Meiji Japan* (1964). KAZUO NODA, "The Postwar Japanese Executive," in RYUTARO KOMIYA (ed.), *op. cit.,* explains the role of business executives in the post-World War II period. Some aspects of Japanese industrial labour are described in EZRA F. VOGEL, *Japan's New Middle Class,* 2nd ed. (1971); and in a comparative study by ARTHUR M. WHITEHILL, JR., and SHIN-ICHI TAKEZAWA, *The Other Worker: A Comparative Study of Industrial Relations in the United States and Japan* (1968). Regarding the Japanese industrial structure, JOE S. BAIN, *International Differences in Industrial Structure: Eight Nations in the 1950's* (1966, reprinted 1980), is recommended, though rather outdated now. Japan's bureaucratic establishment is described in MARSHALL E. DIMOCK, *The Japanese Technocracy* (1968). For a view of Japan's management system, see MICHAEL Y. YOSHINO, *Japan's Managerial System* (1968, reprinted 1971); THOMAS F.M. ADAMS and NORITAKE KOBAYASHI, *The World of Japanese Business* (1969); and ROBERT J. BALLON (ed.), *Doing Business in Japan,* 2nd ed. rev. (1968). In addition, JAMES C. ABEGGLEN, *The Japanese Factory* (1958, reprinted 1979); and SOLOMON B. LEVINE, *Industrial Relations in Postwar Japan* (1958), are considered semiclassics in the management field. See also JAMES C. ABEGGLEN, *The Strategy of Japanese Business* (1984).

Cooperatives: INTERNATIONAL LABOUR OFFICE, *Co-operative Management and Administration* (1960, reprinted with rev. bibliog., 1978), is a comprehensive introduction and guide. ROBERT OAKESHOTT, *The Case for Workers' Co-ops* (1978), discusses the principles and reviews the experience; while JAROSLAV VANEK (ed.), *Self-Management: Economic Liberation of Man* (1975), provides a collection of readings.

Multinational development: Growth of multinationals and the political implications of the phenomenon are reviewed in CHRISTOPHER TUGENDHAT, *The Multinationals* (1971, reissued 1984); IAN M. CLARKE, *The Spatial Organization of Multinational Corporations* (1985); and THOMAS A. POYNTER, *Multinational Enterprises and Government Intervention* (1984).

Business law: L.C.B. GOWER, *Gower's Principles of Modern Company Law,* 4th ed. (1979); ROBERT R. PENNINGTON, *Company Law,* 4th ed. (1979); and ROBERT R. PENNINGTON and FRANK WOOLDRIDGE, *Company Law in the European Communities,* 3rd ed. (1982), are textbooks written primarily for students but may also be used by practitioners. ROBERT R. PENNINGTON, *The Investor and the Law* (1968), is primarily a comparative study of the laws of the United States and the western European countries on investment law, with consideration given to questions relevant to business associations. M.A. WEINBERG, M.V. BLANK, and A.L. GREYSTOKE, *Weinberg and Blank on Take-Overs and Mergers,* 4th ed. (1979), is a practitioner's textbook on English law. Two works intended for the general reader are A. RUBNER, *The Ensnared Shareholder* (1965); and G. GOYDER, *The Responsible Company* (1961). HENRY WINTHROP BALLANTINE, *Ballantine on Corporations,* rev. ed. (1946); GEORGE D. HORNSTEIN, *Corporation Law and Practice* (1959); and RICHARD W. JENNINGS and RICHARD M. BUXBAUM, *Corporations, Cases and Materials,* 5th ed. (1979), are standard student textbooks. EDWARD ROSS ARANOW and HERBERT A. EINHORN, *Proxy Contests for Corporate Control,* 2nd ed. (1968); and EDWARD ROSS ARANOW, HERBERT A. EINHORN, and GEORGE BERLSTEIN, *Developments in Tender Offers for Corporate Control* (1977), are detailed practitioner's books that the experienced reader will find interesting. WOLFGANG G. FRIEDMANN and RICHARD C. PUGH (eds.), *Legal Aspects of Foreign Investment* (1959); ROBERT R. PENNINGTON, *Companies in the Common Market,* 2nd ed. (1970); and EDGAR M. CHURCH, *Business Associations Under French Law* (1960), are suitable works for the reader who has no knowledge of the company law of overseas countries. G. RIPERT and R. ROBLOT (eds.), *Traité élémentaire de droit commercial,* 11th ed., vol. 1 (1983); A. HUECK, *Gesellschaftsrecht,* 17th ed. (1975); and ALESSANDRO GRAZIANI, *Diritto delle società,* 5th ed. (1963), are standard students' textbooks on French, German, and Italian company law.

Business finance: Comprehensive introductions to the theory of business finance include J. FRED WESTON and EUGENE F. BRIGHAM, *Essentials of Managerial Finance,* 7th ed. (1985), and *Managerial Finance,* 7th ed. (1981); JAMES C. VAN HORNE, *Financial Management and Policy,* 6th ed. (1983); ROBERT WILLARD JOHNSON, *Financial Management,* 5th ed. (1982); J.R. FRANKS and J.E. BROYLES, *Modern Managerial Finance* (1979); and J.M. SAMUELS and F.M. WILKES, *Management of Company Finance,* 3rd ed. (1980). A practical guide to balance sheet analysis and finance for the layman is R. VAUSE and N. WOODWARD, *Finance for Managers,* 2nd ed. (1981). (S.N.W./Ed.)

The History of the Byzantine Empire

The very name Byzantine illustrates the misconceptions to which the empire's history has often been subject, for its inhabitants would hardly have considered the term appropriate to themselves or to their state. Theirs was, in their view, none other than the Roman Empire, founded shortly before the beginning of the Christian Era by God's grace to unify his people in preparation for the coming of his Son. Proud of that Christian and Roman heritage, convinced that their earthly empire so nearly resembled the heavenly pattern that it could never change, they called themselves Romaioi, or Romans. Modern historians agree with them only in part. The term East Rome accurately described the political unit embracing the Eastern provinces of the old Roman Empire until 476, while there were yet two emperors. The same term may even be used until the last half of the 6th century, as long as men continued to act and think according to patterns not unlike those prevailing in an earlier Roman Empire. During these same centuries, nonetheless, there were changes so profound in their cumulative effect that after the 7th century state and society in the East differed markedly from their earlier forms. In an effort to recognize that distinction, historians traditionally have described the medieval empire as "Byzantine."

The latter term is derived from the name Byzantium, borne by a colony of ancient Greek foundation on the European side of the Bosporus, midway between the Mediterranean and the Black Sea; the city was, by virtue of its location, a natural transit point between Europe and Asia Minor (Anatolia). Refounded as the "new Rome" by the emperor Constantine in 330, it was endowed by him with the name Constantinople, the city of Constantine. The derivation from Byzantium is suggestive in that it emphasizes a central aspect of Byzantine civilization: the degree to which the empire's administrative and intellectual life found a focus at Constantinople from 330 to 1453, the year of the city's last and unsuccessful defense under the 11th (or 12th) Constantine. The circumstances of the last defense are suggestive, too, for in 1453 the ancient, medieval, and modern worlds seemed briefly to meet. The last Constantine fell in defense of the new Rome built by the first Constantine. Walls that had held firm in the early Middle Ages against German, Hun, Avar, Slav, and Arab were breached finally by modern artillery, in the mysteries of which European technicians had instructed the most successful of the Central Asian invaders: the Ottoman Turks.

The fortunes of the empire thus were intimately entwined with those of peoples whose achievements and failures constitute the medieval history of both Europe and Asia. Nor did hostility always characterize the relations between Byzantines and those whom they considered "barbarian." Even though the Byzantine intellectual firmly believed that civilization ended with the boundaries of his world, he opened it to the barbarian, provided that the latter (with his kin) would accept Baptism and render loyalty to the emperor. Thanks to the settlements that resulted from such policies, many a name, seemingly Greek, disguises another of different origin: Slavic, perhaps, or Turkish. Barbarian illiteracy, in consequence, obscures the early generations of more than one family destined to rise to prominence in the empire's military or civil service. Byzantium was a melting-pot society, characterized during its earlier centuries by a degree of social mobility that belies the stereotype, often applied to it, of an immobile, caste-ridden society.

A source of strength in the early Middle Ages, Byzantium's central geographical position served it ill after the 10th century. The conquests of that age presented new problems of organization and assimilation, and these the emperors had to confront at precisely the time when older questions of economic and social policy pressed for answers in a new and acute form. Satisfactory solutions were never found. Bitter ethnic and religious hostility marked the history of the empire's later centuries, weakening Byzantium in the face of new enemies descending upon it from east and west. The empire finally collapsed when its administrative structures could no longer support the burden of leadership thrust upon it by military conquests.

This article is divided into the following sections:

The empire to 867

THE ROMAN AND CHRISTIAN BACKGROUND

Unity and diversity in the late Roman Empire. The Roman Empire, the ancestor of the Byzantine, remarkably blended unity and diversity, the former being by far the better known since its constituents were the predominant features of Roman civilization. The common Latin language, the coinage, the "international" army of the Roman legions, the urban network, the law, and the Greco-

Roman heritage of civic culture loomed largest among those bonds that Augustus and his successors hoped would bring unity and peace to a Mediterranean world exhausted by centuries of civil war. To strengthen these sinews of imperial civilization, the emperors hoped that a lively and spontaneous trade might develop among the several provinces. At the pinnacle of this world stood the emperor himself, the man of wisdom who would shelter the state from whatever mishaps fortune had darkly hidden. The emperor alone could provide this protection since, as the embodiment of all the virtues, he possessed in perfection those qualities displayed only imperfectly by his individual subjects.

The Roman formula of combating fortune with reason and therewith assuring unity throughout the Mediterranean world worked surprisingly well in view of the pressures for disunity that time was to multiply. Conquest had brought regions of diverse background under Roman rule. The Eastern provinces were ancient and populous centres of that urban life that for millennia had defined the character of Mediterranean civilization. The Western provinces had only lately entered upon their own course of urban development under the not always tender ministrations of their Roman masters.

Each of the aspects of unity enumerated above had its other side. Not everyone understood or spoke Latin. Paralleling and sometimes influencing Roman law were local customs and practices, understandably tenacious by reason of their antiquity. Pagan temples, Jewish synagogues, and Christian baptisteries attest to the range of organized religions with which the official forms of the Roman state, including those of emperor worship, could not always peacefully coexist. And far from unifying the Roman world, economic growth often created self-sufficient units in the several regions, provinces, or great estates.

Greco-Roman civic tradition

Given the obstacles against which the masters of the Roman state struggled, it is altogether remarkable that Roman patriotism was ever more than an empty formula, that cultivated gentlemen from the Pillars of Hercules to the Black Sea were aware that they had "something" in common. This "something" might be defined as the Greco-Roman civic tradition in the widest sense of its institutional, intellectual, and emotional implications. Grateful for the conditions of peace that fostered it, men of wealth and culture dedicated their time and resources to glorifying that tradition through adornment of the cities that exemplified it and through education of the young who they hoped might perpetuate it.

Upon this world the barbarians descended after about AD 150. To protect the frontier against them, warrior emperors devoted whatever energies they could spare from the constant struggle to reassert control over provinces where local regimes emerged. In view of the ensuing warfare, the widespread incidence of disease, and the rapid turnover among the occupants of the imperial throne, it would be easy to assume that little was left of either the traditional fabric of Greco-Roman society or the bureaucratic structure designed to support it.

Neither assumption is accurate. Devastation was haphazard, and some regions suffered while others did not. In fact, the economy and society of the empire as a whole during that period was more diverse than it had ever been. Impelled by necessity or lured by profit, people moved from province to province. Social disorder opened avenues to eminence and wealth that the more stable order of an earlier age had closed to the talented and the ambitious. For personal and dynastic reasons, emperors favoured certain towns and provinces at the expense of others, and the erratic course of succession to the throne, coupled with a resulting constant change among the top administrative officials, largely deprived economic and social policies of recognizable consistency.

The reforms of Diocletian and Constantine. The definition of consistent policy in imperial affairs was the achievement of two great soldier-emperors, Diocletian (ruled 284–305) and Constantine I (sole emperor 324–337), who together ended a century of anarchy and refounded the Roman state. There are many similarities between them, not the least being the range of problems to which they addressed themselves: both had learned from the 3rd-century anarchy that one man alone and unaided could not hope to control the multiform Roman world and protect its frontiers; as soldiers, both considered reform of the army a prime necessity in an age that demanded the utmost mobility in striking power; both found the old Rome and Italy an unsatisfactory military base for the bulk of the imperial forces. Deeply influenced by the soldier's penchant for hierarchy, system, and order, a taste that they shared with many of their contemporaries as well as the emperors who preceded them, they were appalled by the lack of system and the disorder characteristic of the economy and the society in which they lived. Both, in consequence, were eager to refine and regularize certain desperate expedients that had been adopted by their rough military predecessors to conduct the affairs of the Roman state. Whatever their personal religious convictions, both, finally, believed that imperial affairs would not prosper unless the emperor's subjects worshiped the right gods in the right way.

Rule of succession

The means they adopted to achieve these ends differ so profoundly that one, Diocletian, looks to the past and ends the history of Rome; the other, Constantine, looks to the future and founds the history of Byzantium. Thus, in the matter of succession to the imperial office, Diocletian adopted precedents he could have found in the practices of the 2nd century AD. He associated with himself a coemperor, or Augustus. Each Augustus then adopted a young colleague, or Caesar, to share in the rule and eventually to succeed the senior partner. This rule of four, or tetrarchy, failed of its purpose, and Constantine replaced it with the dynastic principle of hereditary succession, a procedure generally followed in subsequent centuries. To divide administrative responsibilities, Constantine replaced the single praetorian prefect, who had traditionally exercised both military and civil functions in close proximity to the emperor, with regional prefects established in the provinces and enjoying civil authority alone. In the course of the 4th century, four great "regional prefectures" emerged from these Constantinian beginnings, and the practice of separating civil from military authority persisted until the 7th century.

Contrasts in other areas of imperial policy are equally striking. Diocletian persecuted Christians and sought to revive the ancestral religion. Constantine, a convert to the new faith, raised it to the status of a "permitted religion." Diocletian established his headquarters at Nicomedia, a city that never rose above the status of a provincial centre during the Middle Ages, while Constantinople, the city of Constantine's foundation, flourished mightily. Diocletian sought to bring order into the economy by controlling wages and prices and by initiating a currency reform based upon a new gold piece, the aureus, struck at the rate of 60 to the pound of gold. The controls failed and the aureus vanished, to be succeeded by Constantine's gold solidus. The latter piece, struck at the lighter weight of 72 to the gold pound, remained the standard for centuries. For whatever reason, in summary, Constantine's policies proved extraordinarily fruitful. Some of them—notably hereditary succession, the recognition of Christianity, the currency reform, and the foundation of the capital—determined in a lasting way the several aspects of Byzantine civilization with which they are associated.

Yet it would be a mistake to consider Constantine a revolutionary or to overlook those areas in which, rather than innovating, he followed precedent. Earlier emperors had sought to constrain groups of men to perform certain tasks that were deemed vital to the survival of the state but that proved unremunerative or repellent to those forced to assume the burden. Such tasks included the tillage of the soil, which was the work of the peasant, or *colonus;* the transport of cheap bulky goods to the metropolitan centres of Rome or Constantinople, which was the work of the shipmaster, or *navicularius;* and services rendered by the *curiales,* members of the municipal senate charged with the assessment and collection of local taxes. Constantine's laws in many instances extended or even rendered hereditary these enforced responsibilities, thus laying the foundations for the system of *collegia,* or hereditary state guilds, that was to be so noteworthy a feature of late-Roman social life. Of particular importance, he required the *colonus* (peasant) to remain in the locality to which the tax lists ascribed him.

THE 5TH CENTURY: PERSISTENCE OF GRECO-ROMAN CIVILIZATION IN THE EAST

Whether innovative or traditional, Constantine's measures determined the thrust and direction of imperial policy throughout the 4th century and into the 5th. The state of the empire in 395 may, in fact, be described in terms of the outcome of Constantine's work. The dynastic principle was established so firmly that the emperor who died in that year, Theodosius I, could bequeath the imperial office jointly to his sons, both of whom were young and incompetent: Arcadius in the East and Honorius in the West. Never again would one man rule over the full extent of the empire in both its halves. Constantinople had probably grown to a population of between 200,000 and 500,000; in the 5th century the emperors sought to restrain rather than promote its growth. After 391 Christianity was far more than one among many religions: from that year onward, imperial decree prohibited all forms of pagan cult, and the temples were closed. Imperial pressure was often manifest at the church councils of the 4th century, with the emperor assuming a role he was destined to fill again during the 5th century in defining and suppressing heresy.

Economic prosperity

Economic and social policies. The empire's economy had prospered in a spotty fashion. Certain provinces, or parts of provinces such as northern Italy, flourished commercially as well as agriculturally. Constantinople, in particular, influenced urban growth and the exploitation of agricultural frontiers. Balkan towns along the roads leading to the great city prospered, while others not so favoured languished and even disappeared. Untilled land in the hilly regions of northern Syria fell under the plow to supply foodstuffs for the masses of Constantinople. As the 4th century progressed, not only did Constantine's solidus remain indeed solid gold, but evidence drawn from a wide range of sources suggests that gold in any form was far more abundant than it had been for at least two centuries. It may be that new sources of supply for the precious metal had been discovered: these perhaps were in spoils plundered from pagan temples; or perhaps were from mines newly exploited in western Africa and newly available to the lands of the empire, thanks to the appearance of camel-driving nomads who transported the gold across the Sahara to the Mediterranean coastline of North Africa.

The extreme social mobility noted in the late 3rd and early 4th centuries seems less characteristic of the second half of the latter century. Certainly the emperors continued their efforts to bind men collectively to their socially necessary tasks, but the repetition of laws tying the *colonus* to his estate, the *navicularius* to his ship, and the *curialis* to his municipal senate suggests that these edicts had little effect. Indeed, it would be a mistake to conclude from such legislation that Roman society was universally and uniformly organized in castes determined in response to imperial orders. There was always a distinction between what an emperor wanted and what he could obtain, and, as the foregoing survey has suggested, there were distinctions among the provinces as well.

Even before the end of the first quarter of the 5th century, these provincial differences were visible; and, in no small degree, they help to explain the survival of imperial government and Greco-Roman civilization in the East while both eventually perished in the West. Throughout the Eastern provinces, population levels seem to have remained higher, and the emperors in Constantinople never had to search (at least until the 6th century) for men to fill the ranks of their armies. As might be expected in those eastern lands in which urban civilization was several centuries old, cities persisted and, with them, a merchant class and a monetary economy. Eastern merchants, known in the sources as Syrians, assumed the carrying trade between East and West, often establishing colonies in the beleaguered cities of the latter region.

Most important, the emperor in the East never lost access to, or control over, his sources of manpower and money. An older and probably more wealthy senatorial class, or aristocracy, in the West consolidated its great estates and assumed a form of protection or patronage over the labouring rural classes, depriving the state of desperately needed military and financial services. The senatorial class in the East seems to have been of more recent origin, its beginnings to be found among those favourites or parvenus who had followed Constantine to his new capital. By the early 5th century, their wealth seems to have been, individually, much less than the resources at the disposal of their Western counterparts; their estates were far more scattered and their rural dependents less numerous. They were thus less able to challenge the imperial will and less able to interpose themselves between the state, on the one hand, and its potential soldiers or taxpayers, on the other.

Battle of Adrianople

Relations with the barbarians. These differences between Eastern and Western social structures, together with certain geographical features, account for the different reception found by the Germanic invaders of the 4th and 5th centuries in East and West. Although the Germanic people had eddied about the Danube and Rhine frontiers of the empire since the 2nd century, their major inroads were made only in the latter half of the 4th century, when the ferocious Huns drove the Ostrogoths and Visigoths to seek refuge within the Danubian frontier of the empire. The initial interaction between Roman and barbarian was far from amicable; the Romans seemed to have exploited their unwelcome guests, and the Goths rose in anger, defeating an East Roman army at Adrianople in 378 and killing the Eastern emperor in command. Emperor Theodosius (ruled 384–395) adopted a different policy, granting the Goths lands and according them the legal status of allies, or *foederati,* who fought within the ranks of the Roman armies as autonomous units under their own leaders.

Neither in West nor East did Theodosius' policy of accommodation and alliance prove popular. The Goths, like most Germanic peoples with the exception of the Franks and the Lombards, had been converted to Arian Christianity, which the Catholic, or Orthodox, Romans considered a dangerous heresy. The warlike ways of the Germans found little favour with a senatorial aristocracy essentially pacifist in its outlook, and the early 5th century is marked in both halves of the empire by reactions against Germanic leaders in high office. At Constantinople in 400, for example, the citizens rose against the senior officer of the imperial guard (*magister militum*), Gainas, slaughtering him together with his Gothic followers. Although this particular revolt was, in many respects, less productive of immediate results than similar episodes in the West, and the Germanic leaders later reappeared in roles of command throughout the East, the latter acted thenceforth as individuals without the support of those nearly autonomous groups of soldiers that western barbarian commanders continued to enjoy.

Furthermore, the East made good use of its resources in gold, in native manpower, and in diplomacy, while quickly learning how best to play off one enemy against another. In the reign of Theodosius II (408–450), the Huns under their chieftain Attila received subsidies of gold that both kept them in a state of uneasy peace with the Eastern Empire and may have proved profitable to those merchants of Constantinople who traded with the barbarians. When Marcian (ruled 450–457) refused to continue the subsidies, Attila was diverted from revenge by the prospect of conquests in the West. He never returned to challenge the Eastern Empire, and, with his death in 453, his Hunnic empire fell apart. Both Marcian and his successor, Leo I (ruled 457–474), had ruled under the tutelage of Flavius Ardaburius, Aspar; but Leo resolved to challenge Aspar's pre-eminence and the influence of the Goths elsewhere in the empire by favouring the warlike Isaurians and their chieftain, Tarasicodissa, whom he married to the imperial princess, Ariadne. The Isaurian followers of Tarasicodissa, who was to survive a stormy reign as the Emperor Zeno (474–491), were rough mountain folk from southern Anatolia and culturally probably even more barbarous than the Goths or the other Germans. Yet, in that they were the subjects of the Roman emperor in the East, they were

Dissolution of the Western Empire

undoubtedly Romans and proved an effective instrument to counter the Gothic challenge at Constantinople. In the prefecture of Illyricum, Zeno ended the menace of Theodoric the Amal by persuading him (488) to venture with his Ostrogoths into Italy. The latter province lay in the hands of the German chieftain Odoacer, who in 476 had deposed Romulus Augustulus, the last Roman emperor in the West. Thus, by suggesting that Theodoric conquer Italy as his Ostrogothic kingdom, Zeno maintained at least a nominal supremacy in that western land while ridding the Eastern Empire of an unruly subordinate.

With Zeno's death and the accession of the Roman civil servant Anastasius I (ruled 491–518), Isaurian occupation of the imperial office ended, but it was not until 498 that the forces of the new emperor effectively took the measure of Isaurian resistance. After the victory of that year, the loyal subject of the Eastern Roman emperor could breathe easily: Isaurians had been used to beat Germans, but the wild mountain folk had, in their turn, failed to take permanent possession of the imperial office. Imperial authority had maintained its integrity in the East while the Western Empire had dissolved into a number of successor states: the Angles and Saxons had invaded Britain as early as 410; the Visigoths had possessed portions of Spain since 417, and the Vandals had entered Africa in 429; the Franks, under Clovis I, had begun their conquest of central and southern Gaul in 481; and Theodoric was destined to rule in Italy until 526.

The Monophysite heresy

Religious controversy. If ethnic hostility within the empire was less a menace around the year 500 than it had often been in the past, dissensions stemming from religious controversy seriously threatened imperial unity, and the political history of the next century cannot be understood without some examination of the so-called Monophysite heresy. It was the second great heresy in the Eastern Empire, the first having been the dispute occasioned by the teachings of the Alexandrian presbyter Arius, who, in an effort to maintain the uniqueness and majesty of God the Father, had taught that he alone had existed from eternity, while God the Son had been created in time. Thanks in part to imperial support, the Arian heresy had persisted throughout the 4th century and was definitively condemned only in 381 with promulgation of the doctrine that Father and Son were of one substance and thus coexistent.

If the Fathers of the 4th century quarreled over the relations between God the Father and God the Son, those of the 5th century faced the problem of defining the relationship of the two natures—the human and the divine—within God the Son, Christ Jesus. The theologians of Alexandria generally held that the divine and human natures were united indistinguishably, whereas those of Antioch taught that two natures coexisted separately in Christ, the latter being "the chosen vessel of the Godhead . . . the man born of Mary." In the course of the 5th century, these two contrasting theological positions became the subject of a struggle for supremacy among the rival sees of Constantinople, Alexandria, and Rome. Nestorius, patriarch of Constantinople in 428, adopted the Antiochene formula, which, in his hands, came to stress the human nature of Christ to the neglect of the divine. His opponents (first the Alexandrian patriarch, Cyril, and later Cyril's followers, Dioscorus and Eutyches) in reaction emphasized the single divine nature of Christ, the result of the Incarnation. Their belief in Monophysitism, or the one nature of Christ as God the Son, became extraordinarily popular throughout the provinces of Egypt and Syria. Rome, in the person of Pope Leo I, declared in contrast for Dyophysitism, a creed teaching that two natures, perfect and perfectly distinct, existed in the single person of Christ. At the Council of Chalcedon (451), the latter view triumphed thanks to the support of Constantinople, which changed its position and condemned both Nestorianism, or the emphasis on the human nature of Christ, and Monophysitism, or the belief in the single divine nature.

More important for the purposes of military and political history than the theological details of the conflict was the impact Monophysitism produced on the several regions of the Mediterranean world. Partly because it provided a formula to express resistance to Constantinople's imperial rule, Monophysitism persisted in Egypt and Syria. Until these two provinces were lost to Islām in the 7th century, each Eastern emperor had somehow to cope with their separatist tendencies as expressed in the heresy. He had either to take arms against Monophysitism and attempt to extirpate it by force, to formulate a creed that would somehow blend it with Dyophysitism, or frankly to adopt the heresy as his own belief. None of these three alternatives proved successful, and religious hostility was not the least of the disaffections that led Egypt and Syria to yield, rather readily, to the Arab conqueror. If ever the East Roman emperor was to reassert his authority in the West, he necessarily had to discover a formula that would satisfy Western orthodoxy while not alienating Eastern Monophysitism.

Anastasius I

The empire at the end of the 5th century. In the reign of Anastasius I (491–518), all these tendencies of the 5th century found their focus: the sense of Romanitas, which demanded a Roman rather than an Isaurian or a German emperor, the conflict between Orthodoxy and Monophysitism, and the persisting economic prosperity of the Eastern Roman Empire. Acclaimed and elected as the Roman and Orthodox emperor who would end both the hated hegemony of the Isaurians and the detested activity of the Monophysite heretics, Anastasius succeeded in the first of these objectives while failing in the second. While he defeated the Isaurians and transported many of them from their Anatolian homeland into Thrace, he gradually came to support the Monophysite heresy despite the professions of Orthodoxy he had made upon the occasion of his coronation. If his policies won him followers in Egypt and Syria, they alienated his Orthodox subjects and led, finally, to constant unrest and civil war.

Anastasius' economic policies were far more successful; if they did not provide the basis for the noteworthy achievements of the 6th century in military affairs and the gentler arts of civilization, they at least explain why the Eastern Empire prospered in those respects during the period in question. An inflation of the copper currency, prevailing since the age of Constantine, finally ended with welcome results for those members of the lower classes who conducted their operations in the base metal. Responsibility for the collection of municipal taxes was taken from the members of the local senate and assigned to agents of the praetorian prefect. Trade and industry were probably stimulated by the termination of the *chrysargyron,* a tax in gold paid by the urban classes. If, by way of compensating for the resulting loss to the state, the rural classes had then to pay the land tax in money rather than kind, the mere fact that gold could be presumed to be available in the countryside is a striking index of rural prosperity. In the East, the economic resurgence of the 4th century had persisted, and it is not surprising that Anastasius enriched the treasury to the extent of 320,000 pounds of gold during the course of his reign.

With such financial resources at their disposal, the Emperor's successors could reasonably hope to reassert Roman authority among the western Germanic successor states, provided they could accomplish two objectives: first, they must heal the religious discord among their subjects; second, they must protect the eastern frontier against the threat of Sāsānian Persia. Since there was, in fact, to be concurrent warfare on both fronts during the 6th century, some knowledge of the age-old rivalry between Rome and Persia is essential to an understanding of the problems confronted by the greatest among Anastasius' successors, Justinian I (ruled 527–565), as he undertook the conquest of the West.

The rise of Sāsānian Persia

In 224 the ancient Persian Empire had passed into the hands of a new dynasty, the Sāsānians, whose regime brought new life to the enfeebled state. Having assured firm control over the vast lands already subject to them, the Sāsānians took up anew the old struggle with Rome for northern Mesopotamia and its fortress cities of Edessa and Nisibis, lying between the Tigris and the Euphrates. In the course of the 4th century, new sources of hostility emerged as East Rome became a Christian empire. Partly by reaction, Sāsānian Persia strengthened the ecclesiastical organization that served its Zoroastrian religion; intolerance and persecution became the order of the day within Persia, and strife between the empires assumed something of the character of religious warfare. Hostilities were exacerbated when Armenia, lying to the north between the two realms, converted to Christianity and thus seemed to menace the religious integrity of Persia. If small-scale warfare during the 4th and 5th centuries rarely erupted into major expeditions, the threat to Rome nonetheless remained constant, demanding vigilance and the construction of satisfactory fortifications. By 518, the balance might be said to have tipped in the favour of Persia as it won away the cities of Theodosiopolis, Amida, and Nisibis.

THE 6TH CENTURY: FROM EAST ROME TO BYZANTIUM

The accession of Justinian I

The 6th century opened, in effect, with the death of Anastasius and the accession of the Balkan soldier who replaced him, Justin I (ruled 518–527). During most of Justin's reign, actual power lay in the hands of his nephew and successor, Justinian I. The following account of these more than 40 years of Justinian's effective rule is based upon the works of Justinian's contemporary, the historian Procopius. The latter wrote a laudatory account of the Emperor's military achievements in his *Polemon* (*Wars*) and coupled it in his *Anecdota* (*Secret History*) with a venomous threefold attack upon the Emperor's personal life, the character of the empress Theodora, and the conduct of the empire's internal administration. Justinian's reign may be divided into three periods: (1) an initial age of conquest and cultural achievement extending until the decade of the 540s; (2) 10 years of crisis and near disaster during the 540s; and (3) the last decade of the reign, in which mood, temper, and social realities more nearly resembled those to be found under Justinian's successors than those prevailing throughout the first years of his own reign.

After 550, it is possible to begin to speak of a medieval Byzantine, rather than an ancient East Roman, empire. Of the four traumas that eventually transformed the one into the other—namely, pestilence, warfare, social upheaval, and the Arab Muslim assault of the 630s—the first two were features of Justinian's reign.

The years of achievement to 540. Justinian is but one example of the civilizing magic that Constantinople often worked upon the heirs of those who ventured within its walls. Justin, the uncle, was a rude and illiterate soldier; Justinian, the nephew, was a cultivated gentleman, adept at theology, a mighty builder of churches, and a sponsor of the codification of Roman law. All these accomplishments are, in the deepest sense of the word, civilian, and it is easy to forget that Justinian's empire was almost constantly at war during his reign. The history of East Rome during that period illustrates, in classical fashion, how the impact of war can transform ideas and institutions alike.

The reign opened with external warfare and internal strife. From Lazica to the Arabian Desert, the Persian frontier blazed with action in a series of campaigns in which many of the generals later destined for fame in the West first demonstrated their capacities. The strength of the East Roman armies is revealed in the fact that, while containing Persian might, Justinian could nonetheless dispatch troops to attack the Huns in the Crimea and to maintain the Danubian frontier against a host of enemies. In 532 Justinian decided to abandon military operations in favour of diplomacy. He negotiated, at the cost of considerable tribute, an "Endless Peace" with the Persian king, Khosrow, which freed the Roman's hands for operations in another quarter of the globe. Thus Justinian succeeded in attaining the first of the objectives needed for reconquest in the West: peace in the East.

Even before his accession, Justinian had aided in the attainment of the second. Shortly after his proclamation as emperor, Justin had summoned a council of bishops at Constantinople. The council reversed the policies of Anastasius, accepted the orthodox formula of Chalcedon, and called for negotiations with the pope. Justinian had personally participated in the ensuing discussions, which restored communion between Rome and all the Eastern churches save Egypt. No longer could a barbarian king hope to maintain the loyalties of his Catholic subjects by persuading them that a Monophysite emperor ruled in the East.

The Nika revolt

In the same year of 532, Justinian survived a revolt in Constantinople, stemming from the Nika riot, which initially threatened his life no less than his throne but, in the event, only strengthened his position. To understand the course of events, it is essential to remember that Constantinople, like other great East Roman cities, had often to depend upon its urban militia, or demes, to defend its walls. Coinciding with divisions within the demes were factions organized to support rival charioteers competing in the horse races: the Blues and the Greens. It was originally thought that these two factions were divided by differing political and religious views and that these views were aired to the Emperor during the races. More recent scholarship has shown that the factions were seldom motivated by anything higher than partisan fanaticism for their respective charioteers. The Nika riot—"*Nika!*" ("Conquer!" or "Win!") being the slogan shouted during the races—of 532, however, was one of the rare occasions when the factions voiced political opposition to the imperial government. Angered at the severity with which the urban prefect had suppressed a riot, the Blues and Greens first united and freed their leaders from prison; they insisted then that Justinian dismiss from the office two of his most unpopular officials: John of Cappadocia and Tribonian. Even though the Emperor yielded to their demands, the crowd was not appeased, converted its riot into a revolt, and proclaimed a nephew of Anastasius as emperor. Justinian was saved only because the empress, Theodora, refused to yield. Justinian's able general, Belisarius, sequestered the rebels in the Hippodrome and slaughtered them to the number of 30,000. The leaders were executed, and their estates passed, at least temporarily, into the Emperor's hands.

After 532 Justinian ruled more firmly than ever before. With the subsequent proclamation of the "Endless Peace," he could hope to use his earlier won reputation as a champion of Chalcedonian orthodoxy and appeal to those Western Romans who preferred the rule of a Catholic Roman emperor to that of an Arian German kinglet. In these early years of the 530s, Justinian could indeed pose as the pattern of a Roman and Christian emperor. Latin was his language, and his knowledge of Roman history and antiquities was profound.

Code of Justinian

In 529 his officials had completed a major collection of the emperors' laws and decrees promulgated since the reign of Hadrian. Called the Codex Constitutionum and partly founded upon the 5th-century Theodosian Code, it comprised the first of four works compiled between 529 and 565 called the Corpus Juris Civilis (Body of Civil Law), commonly known as the Code of Justinian. This first collection of imperial edicts, however, pales before the Digesta completed under Tribonian's direction in 533. In the latter work, order and system were found in (or forced upon) the contradictory rulings of the great Roman jurists; to facilitate instruction in the schools of law, a textbook, the Institutiones (533), was designed to accompany the Digesta. The fourth book, the Novellae Constitutiones Post Codicem (commonly called the Novels), consists of collections of Justinian's edicts promulgated between 534 and 565.

Meanwhile, architects and builders worked apace to complete the new Church of the Holy Wisdom, Hagia Sophia, designed to replace an older church destroyed in the course of the Nika revolt. In five years they had constructed the edifice, and it stands today as one of the major monuments of architectural history.

In 533 the moment had clearly come to reassert Christian Roman authority in the West, and Vandal North Africa seemed the most promising theatre of operations. Although a major expedition mounted under Leo I had failed to win back the province, political conditions in the Vandal monarchy had altered to the Eastern emperor's favour. When King Hilderich was deposed and replaced, Justinian could rightfully protest this action taken against a monarch who had ceased persecution of North African Catholics and had allied himself with Constantinople. The Eastern merchants favoured military action in the West, but Justinian's generals were reluctant; possibly for that reason, only a small force was dispatched under Belisarius. Success came with surprising ease after two engagements, and in 534 Justinian set about organizing this new addition to the provinces of the Roman Empire.

These were, in fact, years of major provincial reorganization, and not in North Africa alone. A series of edicts dated in 535 and 536, clearly conceived as part of a master plan by the prefect John of Cappadocia, altered administrative, judicial, and military structures in Thrace and Asia Minor. In general, John sought to provide a simplified and economical administrative structure in which overlapping jurisdictions were abolished, civil and military functions were sometimes combined in violation of Constantinian principles, and a reduced number of officials were provided with greater salaries to secure better personnel and to end the lure of bribery.

In the prefaces to his edicts, Justinian boasted of his reconstituted authority in North Africa, hinted at greater conquests to come, and—in return for the benefits his decrees were to provide—urged his subjects to pay their taxes promptly so that there might be "one harmony between ruler and ruled." Quite clearly the Emperor was organizing the state for the most strenuous military effort, and, later (possibly in 539), reforms were extended to Egypt, whence the export of grain was absolutely essential for the support of expeditionary armies and Constantinople.

Campaigns in Italy

Developments during 534 and 535 in Ostrogothic Italy made it the most likely victim after the fall of Vandal North Africa. When Theodoric died in 526, he was succeeded by a minor grandson for whom Theodoric's daughter, Amalasuntha, acted as regent. Upon the boy's death, Amalasuntha attempted to seize power in her own right and connived at the assassination of three of her chief enemies. Her diplomatic relations with the Eastern emperor had always been marked by cordiality and even dependency; thus, when Amalasuntha, in turn, met her death in a blood feud mounted by the slain men's families, Justinian seized the opportunity to protest the murder.

In 535, as in 533, a small, tentative expedition sent to the West—in this instance, to Sicily—met with easy success. At first the Goths negotiated; then they stiffened their resistance, deposed their king, Theodahad, in favour of a stronger man, Witigis, and attempted to block Belisarius' armies as they entered the Italian peninsula. There the progress of East Roman arms proved slower, and victory did not come until 540 when Belisarius captured Ravenna, the last major stronghold in the north, and, with it, King Witigis, a number of Gothic nobles, and the royal treasure.

All were dispatched to Constantinople, where Justinian was presumably thankful for the termination of hostilities in the West. Throughout the 530s, Justinian's generals almost constantly had to fight to preserve imperial authority in the new province of North Africa and in the Balkans as well. In 539 a Gothic embassy reached Persia, and the information it provided caused the king, Khosrow, to grow restive under the constraints of the "Endless Peace." During the next year (the same year [540] that a Bulgar force raided Macedonia and reached the long walls of Constantinople), Khosrow's armies reached even Antioch in the pursuit of booty and blackmail. They returned unhurt, and 541 witnessed the Persian capture of a fortress in Lazica. In Italy, meanwhile, the Goths chose a new king, Totila, under whose able leadership the military situation in that land was soon to be transformed.

Outbreak of bubonic plague

The crisis of midcentury. At last the menace of simultaneous war on two fronts threatened Justinian's plans. During the 550s, his armies were to prove equal to the challenge, but a major disaster prevented them from so doing between 541 and about 548. The disaster was the bubonic plague of 541–543, the first of those shocks, or traumas, mentioned earlier, that would eventually transform East Rome into the medieval Byzantine Empire. The plague was first noted in Egypt, and from there it passed through Syria and Asia Minor to Constantinople. By 543 it had reached Italy and Africa, and it may also have attacked the Persian armies on campaign in that year. In East Asia the disease has persisted into the 20th century, providing medical science with an opportunity to view its causes and course. Transmitted to humans by fleas from infected rodents, the plague attacks the glands and early manifests itself by swellings (buboes) in armpit and groin, whence the name bubonic. To judge from Procopius' description of its symptoms at Constantinople in 542, the disease then appeared in its more virulent pneumonic form, wherein the bacilli settle in the lungs of the victims. The appearance of the pneumonic form was particularly ominous because it may be transmitted directly from person to person, spreading the infection all the more readily and producing exceptionally high mortality rates. Comparative studies, based upon statistics derived from incidence of the same disease in late-medieval Europe, suggest that between one-third and one-half the population of Constantinople may well have died, while the lesser cities of the empire and the countryside by no means remained immune.

The short-term impact of the plague may be seen in several forms of human activity during the 540s. Justinian's legislation of those years is understandably preoccupied with wills and intestate succession. Labour was scarce, and workers demanded wages so high that Justinian sought to control them by edict, as the monarchs of France and England were to do during the plague of the 14th century. In military affairs, above all, the record of those years is one of defeat, stagnation, and missed opportunities. Rather than effective Roman opposition, it was Khosrow's own weariness of an unprofitable war that led him to sign a treaty of peace in 545, accepting tribute from Justinian and preserving Persian conquests in Lazica. Huns, Sclaveni, Antae, and Bulgars ravaged Thrace and Illyricum, meeting only slight opposition from Roman armies. In Africa a garrison diminished by plague nervously faced the threat of Moorish invasion. In Italy, Totila took the offensive, capturing southern Italy and Naples and even forcing his way into Rome (546) despite Belisarius' efforts to relieve the siege. Desperately, Justinian's great general called for reinforcements from the East; if ever they came, they were slow in arriving and proved numerically less than adequate to the task confronting them.

The last years of Justinian I. After about 548, Roman fortunes improved, and, by the mid-550s, Justinian had won victories in most theatres of operation, with the notable and ominous exception of the Balkans. A tour of the frontiers might begin with the East. In 551 the fortress of Petra was recovered from the Persians, but fighting continued in Lazica until a 50 years' peace, signed in 561, defined relations between the two great empires. On balance, the advantage lay with Justinian. Although Justinian agreed to continue payment of tribute in the amount of 30,000 solidi a year, Khosrow, in return, abandoned his claims to Lazica and undertook not to persecute his Christian subjects.

The silk trade

The treaty also regulated trade between Rome and Persia, since rivalry between the two great powers had always had its economic aspects, focused primarily upon the silk trade. Raw silk reached Constantinople through Persian intermediaries, either by a land route leading from China through Persia or by the agency of Persian merchants in the Indian Ocean. The need to break this Persian monopoly had led Justinian to search for new routes and new peoples to serve as intermediaries: in the south, the Ethiopian merchants of the kingdom of Aksum; in the north, the peoples around the Crimea and in the Caucasian kingdom of Lazica, as well as the Turks of the steppes beyond the Black Sea. Other valuable commodities were exchanged in the Black Sea region, including textiles, jewelry, and wine from East Rome for the furs, leather, and slaves offered by the barbarians; yet, silk remained the commodity of prime interest. It was fortunate, then, that before 561, East Roman agents had smuggled silkworms from China into Constantinople, establishing a silk industry that would liberate the empire from dependence on Persia and become one of medieval Byzantium's most important economic operations.

In the West, Justinian's successes were even more spectacular. By 550 the Moorish threat had ended in North Africa. In 552 the armies of Justinian had intervened in a quarrel among the Visigothic rulers of Spain, and the

East Roman troops overstayed the invitation extended them, seizing the opportunity to occupy on a more permanent basis certain towns in the southeastern corner of the Iberian Peninsula. Most important of all, Italy was recovered. Early in the 550s, Justinian assembled a vast army composed not only of Romans but also of barbarians, including Lombards, Heruli, and Gepids, as well as Persian deserters. Command of this host eventually was given to an unlikely but, as events were to prove, able commander: the eunuch and chamberlain Narses. In two decisive battles (Busta Gallorum and Mons Lactarius), the East Roman general defeated first Totila and then his successor, Teias. The Goths agreed to leave Italy. Despite the continued resistance of certain Gothic garrisons, coupled with the intervention of Franks and Alamanni, after 554 the land was essentially a province of the East Roman Empire.

Balkan affairs

In view of the wide mixture of peoples that descended upon it, the Balkans present a far more complex situation, and the Romans used a wider variety of tactics to contain the barbarians. After the Kutrigur Bulgar attack of 540, Justinian worked to extend a system of fortifications that ran in three zones through the Balkans and as far south as the Pass of Thermopylae. Fortresses, strongholds, and watchtowers were not, however, enough. The Slavs plundered Thrace in 545 and returned in 548 to menace Dyrrhachium; in 550 the Sclaveni, a Slavic people, reached a point about 40 miles (65 kilometres) from Constantinople. The major invasion came in 559, when the Kutrigur Bulgars, accompanied by Sclaveni, crossed the Danube and divided their force into three columns. One column reached Thermopylae; the second gained a foothold on the Gallipoli Peninsula near Constantinople; and the third advanced as far as the suburbs of Constantinople itself, which the aged Belisarius had to defend with an unlikely force of civilians, demesmen, and a few veterans. Worried by Roman naval action on the Danube, which seemed to menace the escape route home, the Kutrigurs broke off the attack, returned north, and found themselves under attack from the Utigurs, a people whose support Justinian's agents had earlier connived at and won by suitable bribes. The two peoples weakened each other in warfare, of which the episode of 559 was not the first instance, and this was precisely the result at which Byzantine diplomacy was aimed.

As long as the financial resources remained adequate, diplomacy proved the most satisfactory weapon in an age when military manpower was a scarce and precious commodity. Justinian's subordinates were to perfect it in their relationships with Balkan and south Russian peoples. For, if the Central Asian lands constituted a great reservoir of people, whence a new menace constantly emerged, the very proliferation of enemies meant that one might be used against another through skillful combination of bribery, treaty, and perfidy. East Roman relations in the late 6th century with the Avars, a Mongol people seeking refuge from the Turks, provide an excellent example of this "defensive imperialism." The Avar ambassadors reached Constantinople in 557, and, although they did not receive the lands they demanded, they were loaded with precious gifts and allied by treaty with the empire. The Avars moved westward from south Russia, subjugating Utigurs, Kutrigurs, and Slavic peoples to the profit of the empire. At the end of Justinian's reign, they stood on the Danube, a nomadic people hungry for lands and additional subsidies and by no means unskilled themselves in a sort of perfidious diplomacy that would help them pursue their objectives.

Impact of the bubonic plague

No summary of the quiet, but ominous, last years of Justinian's reign would be complete without some notice of the continuing attacks of bubonic plague and the impact they were to continue to produce until the 8th century. As have other societies subjected to devastation from warfare or disease, East Roman society might have compensated for its losses of the 540s had the survivors married early and produced more children in the succeeding generations. Two developments prevented recovery. Monasticism, with its demands for celibacy, grew apace in the 6th century, and the plague returned sporadically to attack those infants who might have replaced fallen members of the older generations.

The resulting shortage of manpower affected several aspects of a state and society that perceptibly were losing their Roman character and assuming their Byzantine. The construction of new churches, so noteworthy a feature of the earlier years, ceased as men did little more than rebuild or add to existing structures. An increasing need for taxes, together with a decreasing number of taxpayers, evoked stringent laws that forced members of a village tax group to assume collective responsibility for vacant or unproductive lands. This, contemporary sources avow, was a burden difficult to assume, in view of the shortage

The Byzantine Empire at the death of Justinian in AD 565.

of agricultural workers after the plague. Finally, the armies that won the victories described above in east and west were largely victorious only because Justinian manned them as never before with barbarians: Goths, Armenians, Heruli, Gepids, Saracens, and Persians—to name only the most prominent. It was far from easy to maintain discipline among so motley an army; yet, once the unruly barbarian accepted the quieter life of the garrison soldier, he tended to lose his fighting capacity and prove, once the test came, of little value against the still warlike barbarian facing him beyond the frontier. The army, in short, was a creation of war and kept its quality only by participating in battlefield action, but further expansive warfare could hardly be undertaken by a society chronically short of men and money.

Problems of the late 6th century

In summary, the East Roman (or better, the Byzantine) state of the late 6th century seemed to confront many of the same threats that had destroyed the Western Empire in the 5th century. Barbarians pressed upon it from beyond the Balkan frontier, and peoples of barbarian origin manned the armies defending it. Wealth accumulated during the 5th century had been expended; and, to satisfy the basic economic and military needs of state and society, there were too few native Romans. If the Byzantine Empire avoided the fate of West Rome, it did so only because it was to combine valour and good luck with certain advantages of institutions, emotions, and attitudes that the older empire had failed to enjoy. One advantage already described, diplomatic skill, blends institutional and attitudinal change, for diplomacy would never have succeeded had not the Byzantine statesmen been far more curious and knowing than Justinian's 5th-century predecessor about the habits, customs, and movements of the barbarian peoples. The Byzantine's attitude had changed in yet another way. He was willing to accept the barbarian within his society provided that the latter, in his turn, accept orthodox Christianity and the emperor's authority. Christianity was often, to be sure, a veneer that cracked in moments of crisis, permitting a very old paganism to emerge, while loyalty to the emperor could be forsworn and often was. Despite these shortcomings, the Christian faith and the ecclesiastical institutions defined in the 6th century proved better instruments by far to unite men and stimulate their morale than the pagan literary culture of the Greco-Roman world.

Christian culture of the Byzantine Empire. Justinian's legislation dealt with almost every aspect of the Christian life: entrance into it by conversion and Baptism; administration of the sacraments that marked its several stages; proper conduct of the laity to avoid the wrath God would surely visit upon a sinful people; finally, the standards to be followed by those who lived the particularly holy life of the secular or monastic clergy. Pagans were ordered to attend church and accept Baptism, while a purge thinned their ranks in Constantinople, and masses of them were converted by missionaries in Asia Minor. Only the orthodox wife might enjoy the privileges of her dowry; Jews and Samaritans were denied, in addition to other civil disabilities, the privilege of testamentary inheritance unless they converted. A woman who worked as an actress might better serve God were she to forswear any oath she had taken, even though before God, to remain in that immoral profession. Blasphemy and sacrilege were forbidden, lest famine, earthquake, and pestilence punish the Christian society. Surely God would take vengeance upon Constantinople, as he had upon Sodom and Gomorrah, should the homosexual persist in his "unnatural" ways.

Byzantine morality

Justinian regulated the size of churches and monasteries, forbade them to profit from the sale of property, and complained of those priests and bishops who were unlearned in the forms of the liturgy. His efforts to improve the quality of the secular clergy, or those who conducted the affairs of the church in the world, were most opportune. The best possible men were needed, for, in most East Roman cities during the 6th century, imperial and civic officials gradually resigned many of their functions to the bishop, or patriarch. The latter collected taxes, dispensed justice, provided charity, organized commerce, negotiated with barbarians, and even mustered the soldiers. By the early 7th century, the typical Byzantine city, viewed from without, actually or potentially resembled a fortress; viewed from within, it was essentially a religious community under ecclesiastical leadership. Nor did Justinian neglect the monastic clergy, or those who had removed themselves from the world. Drawing upon the regulations to be found in the writings of the 4th-century Church Father St. Basil of Caesarea, as well as the acts of 4th- and 5th-century church councils, he ordered the cenobitic (or collective) form of monastic life in a fashion so minute that later codes, including the rule of St. Theodore the Studite in the 9th century, only develop the Justinianic foundation.

Probably the least successful of Justinian's ecclesiastical policies were those adopted in an attempt to reconcile Monophysites and orthodox Chalcedonians. After the success of negotiations that had done so much to conciliate the West during the reign of Justin I, Justinian attempted to win over the moderate Monophysites, separating them from the extremists. Of the complicated series of events that ensued, only the results need be noted. In developing a creed acceptable to the moderate Monophysites of the East, Justinian alienated the Chalcedonians of the West and thus sacrificed his earlier gains in that quarter. The extreme Monophysites refused to yield. Reacting against Justinian's persecutions, they strengthened their own ecclesiastical organization, with the result that many of the fortress cities noted above, especially those of Egypt and Syria, owed allegiance to Monophysite ecclesiastical leadership. To his successors, then, Justinian bequeathed the same religious problem he had inherited from Anastasius.

If, in contrast, his regulation of the Christian life proved successful, it was largely because his subjects themselves were ready to accept it. Traditional Greco-Roman culture was, to be sure, surprisingly tenacious and even productive during the 6th century and was always to remain the treasured possession of an intellectual elite in Byzantium; but the same century witnessed the growth of a Christian culture to rival it. Magnificent hymns written by St. Romanos Melodos mark the striking development of the liturgy during Justinian's reign, a development that was not without its social implications. Whereas traditional pagan culture was literary and its pursuit or enjoyment thereby limited to the leisured and wealthy, the Christian liturgical celebration and its musical component were available to all, regardless of place or position. Biography, too, became both markedly Christian and markedly popular. Throughout the countryside and the city, holy men appeared in legend or in fact, exorcising demons, healing the sick, feeding the hungry, and warding off the invader. Following the pattern used in the 4th century by Athanasius to write the life of St. Anthony, hagiographers recorded the deeds of these extraordinary men, creating in the saint's life a form of literature that began to flower in the 6th and 7th centuries.

The rise of popular Christian culture

The vitality and pervasiveness of popular Christian culture manifested themselves most strongly in the veneration increasingly accorded the icon, an abstract and simplified image of Christ, the Virgin, or the saints. Notable for the timeless quality that its setting suggested and for the power expressed in the eyes of its subject, the icon seemingly violated the Second Commandment's explicit injunction against the veneration of any religious images. Since many in the early centuries of the church so believed, and in the 8th century the image breakers, or iconoclasts, were to adopt similar views, hostility toward images was nearly as tenacious an aspect of Christianity as it had been of Judaism before it.

The contrasting view—a willingness to accept images as a normal feature of Christian practice—would not have prevailed had it not satisfied certain powerful needs as Christianity spread among Gentiles long accustomed to representations of the divinity and among Hellenized Jews who had themselves earlier broken with the Mosaic commandment. The convert all the more readily accepted use of the image if he had brought into his Christianity, as many did, a heritage of Neoplatonism. The latter school taught that, through contemplation of that which could be seen (*i.e.*, the image of Christ), the mind might rise to contemplation of that which could not be seen (*i.e.,* the essence of Christ). From a belief that the seen suggests the unseen, it is but a short step to a belief that the seen contains the unseen and that the image deserves veneration because divine power somehow resides in it.

Men of the 4th century were encouraged to take such a step, influenced as they were by the analogous veneration that the Romans had long accorded the image of the emperor. Although the first Christians rejected this practice of their pagan contemporaries and refused to adore the image of a pagan emperor, their successors of the 4th century were less hesitant to render such honour to the images of the Christian emperors following Constantine. Since the emperor was God's vicegerent on Earth and his empire reflected the heavenly realm, the Christian must venerate, to an equal or greater degree, Christ and his saints. Thus the Second Commandment finally lost much of its force. Icons appeared in both private and public use during the last half of the 6th century: as a channel of divinity for the individual and as a talisman to guarantee success in battle. During the dark years following the end of Justinian I's reign, no other element of popular Christian belief better stimulated that high morale without which the Byzantine Empire would not have survived.

Justin II

The successors of Justinian: 565–610. Until Heraclius arrived to save the empire in 610, inconsistency and contradiction marked the policies adopted by the emperors, a reflection of their inability to solve the problems Justinian had bequeathed his successors. Justin II (565–578) haughtily refused to continue the payment of tribute to Avar or Persian; he thereby preserved the resources of the treasury, which he further increased by levying new taxes. Praiseworthy as his refusal to submit to blackmail may seem, Justin's intransigence only increased the menace to the empire. His successor, Tiberius II (578–582), removed the taxes and, choosing between his enemies, awarded subsidies to the Avars while taking military action against the Persians. Although Tiberius' general, Maurice, led an effective campaign on the eastern frontier, subsidies failed to restrain the Avars. They captured the Balkan fortress of Sirmium in 582, while the Slavs began inroads across the Danube that would take them, within 50 years, into Macedonia, Thrace, and Greece.

The accession of Maurice in 582 inaugurated a reign of 20 years marked by success against Persia, a reorganization of Byzantine government in the West, and the practice of economies during his Balkan campaigns that, however unavoidable, would destroy him in 602. Byzantine efforts against Sāsānian Persia were rewarded in 591 by a fortunate accident. The lawful claimant to the Persian throne, Khosrow II, appealed to Maurice for aid against the rebels who had challenged his succession. In gratitude for this support, Khosrow abandoned the frontier cities and the claims to Armenia, the two major sources of contention between Byzantium and Persia. The terms of the treaty gave Byzantium access, in Armenia, to a land rich in the soldiers it desperately needed and, equally important, an opportunity to concentrate on other frontiers where the situation had worsened.

The exarchate of Carthage and Ravenna

Confronted by a Visigothic resurgence in Spain and by the results of a Lombard invasion of Italy (568), which was steadily confining Byzantine power to Ravenna, Venice, and Calabria-Sicily in the south, Maurice developed a form of military government throughout the relatively secure province of North Africa and in whatever regions were left in Italy. He abandoned the old principle of separating civil from military powers, placing both in the hands of the generals, or exarchs, located, respectively, at Carthage and Ravenna. Their provinces, or exarchates, were subdivided into duchies composed of garrison centres that were manned not by professional soldiers but by conscript local landholders. The exarchate system of military government seems to have worked well: North Africa was generally quiet despite Moorish threats; and in 597 the ailing Maurice had intended to install his second son as emperor throughout those western possessions in which he had clearly not lost interest.

But the major thrust of his efforts during the last years of his reign was to be found in the Balkans, where, by dint of constant campaigning, his armies had forced the Avars back across the Danube by 602. In the course of these military operations, Maurice made two mistakes: the first weakened him; the second destroyed him together with his dynasty. Rather than constantly accompanying his armies in the field, as his 7th- and 8th-century successors were to do, Maurice remained for the most part in Constantinople, losing an opportunity to engage the personal loyalty of his troops. He could not count on their obedience when he issued unwelcome commands from afar that decreased their pay in 588, ordered them to accept uniforms and weapons in kind rather than in cash equivalents, and, in 602, required the soldiers to establish winter quarters in enemy lands across the Danube, lest their requirements prove too great a strain on the agricultural and financial resources of the empire's provinces south of the river. Exasperated by this last demand, the soldiers rose in revolt, put a junior officer named Phocas at their head, and marched on Constantinople. Again becoming politically active, the Blues and Greens united against Maurice, and the aged emperor watched as his five sons were slaughtered before he himself met a barbarous death.

The ensuing reign of Phocas (602–610) may be described as a disaster. Khosrow seized the opportunity offered him by the murder of his benefactor, Maurice, to initiate a war of revenge that led Persian armies into the Anatolian heartland. Subsidies again failed to restrain the barbarians north of the Danube; after 602 the frontier crumbled, not to be restored save at the cost of centuries of warfare. Lacking a legitimate title, holding his crown only by right of conquest, Phocas found himself confronted by constant revolt and rebellion. To contemporaries, the coincidence of pestilence, endemic warfare, and social upheaval seemed to herald the coming of the Antichrist, the resurrection of the dead, and the end of the world.

But it was a human saviour who appeared, albeit under divine auspices. Heraclius, son of the Exarch of Africa, set sail from the western extremes of the empire, placing his fleet under the protection of an icon of the Virgin against Phocas, stigmatized in the sources as the "corrupter of virgins." In the course of his voyage along the northern shores of the Mediterranean, Heraclius added to his forces and arrived at Constantinople in October 610 to be hailed as a saviour. With the warm support of the Green faction, he quickly bested his enemy, decapitating Phocas and, with him, those Phocas had advanced to high civil and military office. There were, in consequence, few experienced counselors to aid Heraclius, for, among the men of prominence under Phocas—and earlier under Maurice—few survived to greet the new emperor.

THE 7TH CENTURY: THE HERACLIANS AND THE CHALLENGE OF ISLĀM

Heraclius and the origin of the themes. The most threatening problem Heraclius faced was the external menace of the Avars and the Persians, and neither people abated its pressure during the first years of the new reign. The Avars almost captured the Emperor in 617 during a conference outside the long walls protecting the capital. The Persians penetrated Asia Minor and then turned to the south, capturing Jerusalem and Alexandria (in Egypt). The great days of the Persian Achaemenid Empire seemed to have come again, and there was little in the recent history of the Byzantine emperors that would encourage Heraclius to place much faith in the future. He clearly could not hope to survive unless he kept under arms the troops he had brought with him; yet, the fate of Maurice demonstrated that this would be no easy task, given the empire's lack of financial and agricultural resources.

Three sources of Heraclius' strength

Three sources of strength enabled Heraclius to turn defeat into victory. The first was the pattern of military government as he and the nucleus of his army would have known it in the exarchates of North Africa or Ravenna. As it had been in the West, so it now was in the East. Civil problems were inseparable from the military: Heraclius could not hope to dispense justice, collect taxes, protect the church, and assure the future to his dynasty unless military power reinforced his orders. A system of military government, the exarchate, had accomplished these objectives so well in the West that, in a moment of despair, Heraclius sought to return to the land of his origins. In all likelihood, he applied similar principles of military rule to his possessions throughout Asia Minor, granting his generals (*stratēgoi*) both civil and military authority over those lands that they occupied with their "themes," as the army groups, or corps, were called in the first years of the 7th century.

Second, during the social upheaval of the previous decade, the imperial treasury had doubtless seized the estates of prominent individuals who had been executed either during Phocas' reign of terror or after his death. In consequence, though the treasury lacked money, it nonetheless possessed land in abundance, and Heraclius could easily have supported with grants of land those cavalry soldiers whose expenses in horses and armament he could not hope to meet with cash. If this hypothesis is correct, then, even before 622, themes, or army groups—including the guards (Opsikioi), the Armenians (Armeniakoi), and the Easterners (Anatolikoi)—were given lands and settled throughout Asia Minor in so permanent a fashion that, before the century was out, the lands occupied by these themes were identified by the names of those who occupied them. The Opsikioi were to be found in the Opsikion theme, the Armeniakoi in the Armeniakon, and the Anatolikoi in the Anatolikon. The term theme ceased thereafter to identify an army group and described instead the medieval Byzantine unit of local administration, the theme under the authority of the themal commander, the general (*stratēgos*).

When Heraclius "went out into the lands of the themes" in 622, thereby undertaking a struggle of seven years' duration against the Persians, he utilized the third of his sources of strength: religion. The warfare that ensued was nothing less than a holy war: it was partly financed by the treasure placed by the church at the disposal of the state; the Emperor's soldiers called upon God to aid them as they charged into battle; and they took comfort in the miraculous image of Christ that preceded them in their line of march. A brief summary of the campaign unfortunately gives no idea of the difficulties Heraclius encountered as he liberated Asia Minor (622); fought in Armenia with allies found among the Christian Caucasian peoples, the Lazi, the Abasgi, and the Iberians (624); and struggled in far-distant Lazica while Constantinople withstood a combined siege of Avars and Persians (626). An alliance with the Khazars, a Turkic people from north of the Caucasus, proved of material assistance in those years and of lasting import in Byzantine diplomacy. Heraclius finally destroyed the main Persian host at Nineveh in 627 and, after occupying Dastagird in 628, savoured the full flavour of triumph when his enemy, Khosrow, was deposed and murdered. The Byzantine emperor might well have believed that, if the earlier success of the Persians signalized the resurrection of the Achaemenid Empire, his own successes had realized the dreams of Caesar, Augustus, and Trajan.

Defeat of the Persians

Yet this was a war fought by medieval Byzantium and not by ancient Rome. Its spirit was manifest in 630, when Heraclius triumphantly restored the True Cross to Jerusalem, whence the Persians had stolen it, and—even more—when Constantinople resisted the Avar–Persian assault of 626. During the attack, the patriarch Sergius maintained the morale of the valiant garrison by proceeding about the walls, bearing the image of Christ to ward off fire, and by painting upon the gates of the western walls images of the Virgin and child to ward off attacks launched by the Avars—the "breed of darkness." The Avars withdrew when Byzantine ships defeated the canoes manned by Slavs, upon whom the nomad Avars depended for their naval strength. The latter never recovered from their defeat. As their empire crumbled, new peoples from the Black Sea to the Balkans emerged to seize power: the Bulgars of Kuvrat, the Slavs under Samo, and the Serbs and Croats whom Heraclius permitted to settle in the northwest Balkans once they had accepted Christianity.

As for the Byzantine defenders of Constantinople, they celebrated their victory by singing Romanos' great hymn "Akathistos," with choir and crowd alternating in the chant of the "Alleluia." The hymn, still sung in a Lenten service, commemorates those days when Constantinople survived as a fortress under ecclesiastical leadership, its defenders protected by the icons and united by their liturgy. This they sang in Greek, as befitted a people whose culture was now Greek and no longer Latin.

The successors of Heraclius: Islām and the Bulgars. In the same year that Heraclius went out into the themes, Muḥammad made his withdrawal (*hijrah*) from Mecca to Medina, where he established the *ummah,* or Muslim community. Upon the Prophet's death in 632, the caliphs, or successors, channeled the energies of the Arab Bedouin by launching them upon a purposive and organized plan of conquest. The results were spectacular: a Byzantine army was defeated at the Battle of the Yarmūk River (636), thereby opening Palestine and Syria to Arab Muslim control. Alexandria capitulated in 642, removing forever the province of Egypt from Byzantine authority. The Arabs had, meanwhile, advanced into Mesopotamia, capturing the royal city of Ctesiphon and, eventually, defeating an army under command of the Persian king himself. So ended the long history of Persia under Achaemenids, Parthians, and Sāsānians; further conquests were shortly to initiate that region's Islāmic phase (see further IRAN: *History;* ISLĀMIC WORLD, THE).

The rise of Islām

At least three aspects of the contemporary situation of Byzantium and Persia account for the phenomenal ease with which the Arabs overcame their enemies: first, both empires, exhausted by wars, had demobilized before 632; second, both had ceased to support those client states on the frontiers of the Arabian Peninsula that had restrained the Bedouin of the desert for a century past; third, and particularly in reference to Byzantium, religious controversy had weakened the loyalties that Syrians and Egyptians rendered to Constantinople. Heraclius had sought in 638 to placate Monophysite sentiment in these two provinces by promulgating the doctrine of Monothelitism, holding that Christ, although of two natures, had but one will. Neither in the East nor in the West did this compromise prove successful. The victorious Muslims granted religious freedom to the Christian community in Alexandria, for example, and the Alexandrians quickly recalled their exiled Monophysite patriarch to rule over them, subject only to the ultimate political authority of the conquerors. In such a fashion the city persisted as a religious community under an Arab Muslim domination more welcome and more tolerant than that of Byzantium.

The aging Heraclius was unequal to the task of containing this new menace, and it was left to his successors—Constantine III (ruled February to May 641), Constans II (641–668), Constantine IV (668–685), and Justinian II (685–695, 705–711)—to do so. This bare list of emperors obscures the family conflicts that often imperiled the succession, but gradually the principle was established that, even if brothers ruled as coemperors, the senior's authority would prevail. Although strife between Blues and Greens persisted throughout the century, internal revolt failed to imperil the dynasty until the reign of Justinian II. The latter was deposed and mutilated in 695. With the aid of the Bulgars, he returned in 705 to reassume rule and wreak a vengeance so terrible that his second deposition, and death, in 711 is surprising only in its delay of six years. From 711 until 717 the fortunes of the empire foundered; in that year, Leo, *stratēgos* of the Anatolikon theme, arrived as a second Heraclius to found a dynasty that would rescue the empire from its new enemies, the Arab Muslims and the Bulgars.

Three features distinguish the military history of the years 641–717: first, an increasing use of sea power on the part of the Arabs; second, a renewed threat in the Balkans occasioned by the appearance of the Onogur Huns, known in contemporary sources as the Bulgars; third, a persisting interest among the emperors in their western possessions, despite the gradual attrition of Byzantine authority in the exarchates of Carthage and Ravenna. Thanks to the control that the Arabs gradually asserted over the sea routes to Constantinople, they climaxed their earlier assaults on Armenia and Asia Minor with a four years' siege of the great city itself (674–678). Defeated in this last attempt by the use of Greek fire, a flammable liquid of uncertain composition, the Arabs signed a 30 years' truce, according to which they agreed to pay tribute in money, men, and horses. Lured by the unsettled conditions following Justinian's second deposition, they renewed their assaults by land and sea, and in 717 the Arabs were again besieging Constantinople.

The Bulgar menace

On the Balkan frontier, meanwhile, the Bulgars assumed the role abdicated by the Avars after 626. A pagan people whom the Khazars had forced toward the Danube Delta in the latter part of the 7th century, they eluded Constantine IV's attempts to defeat them in 681. By virtue of a treaty signed in that year, as well as others dating from 705 and 716, the Bulgars were recognized as an independent kingdom, occupying (to the humiliation of Byzantium) lands south of the Danube into the Thracian plain. While the Bulgars had thus deprived the empire of control in the north and central Balkans, the Byzantines could take comfort in the expeditions of 658 and 688/689 launched, respectively, by Constans II and Justinian II into Macedonia and in the formation of the themes of Thrace (687) and Hellas (695); these moves were evidence that Byzantine authority was beginning to prevail along the peninsular coastline and in certain parts of Greece where Slavs had penetrated.

In the West, the situation was less reassuring. Monothelitism had evoked a hostile reception among the churches of North Africa and Italy, and the resulting disaffection had encouraged the exarchs of both Carthage (646) and Ravenna (652) to revolt. By the end of the century, Africa had been largely lost to Muslim conquerors who would, in 711, seize the last outpost at Septem. For the moment Sicily and the scattered Italian possessions remained secure. Constans undertook operations against the Lombards, and he apparently intended to move his capital to Sicily, before his assassination ended the career of the last Eastern emperor to venture into the West. In summary, Leo III in 717 ruled over an empire humiliated by the presence of pagan barbarians upon Balkan soil rightfully considered "Roman," threatened by an attack upon its Anatolian heartland and its capital, and reduced, finally, in the West to Sicily and the remnants of the Ravenna exarchate.

Economics and institutions

However dismal the military record, institutional and economic developments had permitted the empire to survive and were to provide foundations for greater success in the centuries to come. The themal system had taken root and, with it, probably the institution of soldiers' properties. Military service was a hereditary occupation: the eldest son assumed the burden of service, supported primarily by revenues from other members of the family who worked the land in the villages. This last was a task easier to accomplish at the end of the 7th century thanks to the colonies of Slavs and other peoples brought into the empire and settled in the rural areas by Heraclius, Constantine IV, and Justinian II. In the 8th and 9th centuries, other emperors, including Leo III, Constantine V, and Nicephorus I, were to continue the practice, thus ending the population decline that had long eroded the ranks of Byzantine society. There are unmistakable signs of agricultural expansion even before 800; and, at about that time, urban life, which had never vanished in Asia Minor, began to flourish and expand in the Balkans. To judge from the evidence of the Farmer's Law, dated in the 7th century, the technological base of Byzantine society was more advanced than that of contemporary western Europe: iron tools could be found in the villages; water mills dotted the landscape; and field-sown beans provided a diet rich in protein. None of these advances was to characterize western European agriculture until the 10th century. Byzantine agriculture enjoyed the further advantage of a highly developed tradition of careful farming that persisted even in the darkest days, enabling the peasant to make the most of the soil upon which he worked. The invasions had even provided a form of stimulus to development: having lost first its Egyptian granary and, later, its North African and Sicilian resources, the empire had to live essentially, although not totally, from whatever it could produce in the lands remaining to it. The invasions had also, in all probability, broken up many a large estate, and the small peasant holding seems to have been the "normal" form of rural organization in this period. Although collective village organization persisted in the form of the rural commune and, with it, certain collective agricultural practices, the state seems to have made little or no attempt to bind the peasant to the soil upon which the tax registers had inscribed him. While Byzantium remained a slave-owning society, the *colonus* of the later Roman Empire had vanished, and a greater degree of freedom and mobility characterized agricultural relationships during the 7th and 8th centuries.

So it was, too, in trade and commerce. After the loss of Egypt and North Africa, the grain fleets manned by hereditary shipmasters disappeared; in their place there emerged the independent merchant, of sufficient importance to call forth a code of customary law, the Rhodian Sea Law, to regulate his practices. Military and religious hostilities failed to check him as he traded with the Bulgars in Thrace and, through Cyprus, with the Arabs. Despite constant warfare, this was, in short, a healthier society than the late Roman, and its chances of survival were further increased when the sixth general council (680–681) condemned Monothelitism and anathematized its adherents. With Egypt and Syria under Muslim rule, it was no longer necessary to placate Eastern Monophysitism, and it seemed that doctrinal discord would no longer separate Constantinople from the West. Events were to prove otherwise.

THE AGE OF ICONOCLASM: 717–867

The veneration of icons

For more than a century after the accession of Leo III (717–741), a persisting theme in Byzantine history may be found in the attempts made by the emperors, often with wide popular support, to eliminate the veneration of icons, a practice that had earlier played a major part in creating the morale essential to survival. The sentiment had grown in intensity during the 7th century; the Quinisext Council (Council in Trullo) of 692 had decreed that Christ should be represented in human form rather than, symbolically, as the lamb. The reigning emperor, Justinian II, had taken the unprecedented step of placing the image of Christ on his coinage while proclaiming himself the "slave of God." Evidence of a reaction against such iconodule (or image venerating) doctrines and practices may be found early in the 8th century, but full-fledged Iconoclasm (or destruction of the images) emerged as an imperial policy only when Leo III issued his decrees of 730. Under his son, Constantine V (ruled 741–775), the iconoclastic movement intensified, taking the form of violent persecution of the monastic clergy, the foremost defenders of the iconodule position. The Council of Nicaea in 787 restored iconodule doctrine at the instigation of the empress Irene, but military reversals led Leo V to resurrect in 815 the iconoclastic policies associated with Constantine V, one of Byzantium's most successful generals. Not until 843 were the icons definitively restored to their places of worship and icon veneration solemnly proclaimed as Orthodox belief. Even this brief summary suggests that the Emperor's fortunes on the battlefield were of no small moment in determining his attitude toward the icons, those channels whence superhuman power descended to man. An account of the age of Iconoclasm opens appropriately, then, with its military history.

The reigns of Leo III (the Isaurian) and Constantine V. Almost immediately upon Leo's accession, the empire's fortunes improved markedly. With the aid of the Bulgars, he turned back the Muslim assault in 718 and, in the intervals of warfare during the next 20 years, addressed himself to the task of reorganizing and consolidating the themes in Asia Minor. Thanks to the assistance of the traditional allies, the Khazars, Leo's reign concluded with a major victory, won again at the expense of the Arabs, at Acroenos (740). His successor, Constantine, had first to fight his way to the throne, suppressing a revolt of the Opsikion and Armeniakon themes launched by his brother-in-law Artavasdos. During the next few years, internal disorder in the Muslim world played into Constantine's hands as the ʿAbbāsid house fought to seize the caliphate from the Umayyads. With his enemy thus weakened, Constantine won noteworthy victories in northern Syria, transferring the prisoners he had captured there to Thrace in preparation for the wars against the Bulgars that were to occupy him from 756 to 775. In no fewer than nine campaigns, he undermined Bulgar strength so thoroughly that the northern enemy seemed permanently weakened, if not crushed. Even the venom used by the iconodule chroniclers of Constantine's reign cannot disguise the enormous popularity his victories won him.

In later centuries, the folk of Constantinople would stand by his tomb, seeking his aid against whatever enemy imperiled the city's defenses.

The empress Irene

Constantine's weak successors. His successors all but let slip the gains won by the great iconoclast. Constantine's son Leo IV died prematurely in 780, leaving to succeed him his 10-year-old son, Constantine VI, under the regency of the empress Irene. Not much can be said for Constantine, and Irene's policies as regent and (after the deposition and blinding of her son at her orders) as sole ruler from 797 to 802 were all but disastrous. Her iconodule policies alienated many among the themal troops, who were still loyal to the memory of the great warrior emperor, Constantine V. In an effort to maintain her popularity among the monkish defenders of the icons and with the population of Constantinople, she rebated taxes to which these groups were subject; she also reduced the customs duties levied outside the port of Constantinople, at Abydos and Hieros. The consequent loss to the treasury weighed all the more severely since victories won by the Arabs in Asia Minor (781) and by the Bulgars (792) led both peoples to demand and receive tribute as the price of peace. A revolt of the higher palace officials led to Irene's deposition in 802, and the so-called Isaurian dynasty of Leo III ended with her death, in exile, on the isle of Lesbos.

In the face of the Bulgar menace, none of the following three emperors succeeded in founding a dynasty. Nicephorus I (ruled 802–811), the able finance minister who succeeded Irene, reimposed the taxes that the Empress had remitted and instituted other reforms that provide some insight into the financial administration of the empire during the early 9th century. In the tradition of Constantine V, Nicephorus strengthened the fortifications of Thrace by settling, in that theme, colonists from Asia Minor.

Taking arms himself, he led his troops against the new and vigorous Bulgar khan, Krum, only to meet defeat and death at the latter's hands. His successor, Michael I Rhangabe (811–813), fared little better; internal dissensions broke up his army as it faced Krum near Adrianople, and the resulting defeat cost Michael his throne. In only one respect does he occupy an important place in the annals of the Byzantine Empire. The first emperor to bear a family name, Michael's use of the patronymic, Rhangabe, bears witness to the emergence of the great families, whose accumulation of landed properties would soon threaten the integrity of those smallholders upon whom the empire depended for its taxes and its military service. The name Rhangabe seems to be a Hellenized form of a Slav original (*rokavu*), and, if so, Michael's ethnic origin and that of his successor, Leo V the Armenian (ruled 813–820), provide evidence enough of the degree to which Byzantium in the 9th century had become not only a melting-pot society but, further, a society in which even the highest office lay open to the man with the wits and stamina to seize it. Leo fell victim to assassination, but before his death events beyond his control had improved the empire's situation. Krum died suddenly in 814 as he was preparing an attack upon Constantinople, and his son, Omortag, arranged a peace with the Byzantine Empire in order to protect the western frontiers of his Bulgar empire against the pressures exerted by Frankish expansion under Charlemagne and his successors. Since the death of the fifth caliph, Hārūn ar-Rashīd, had resulted in civil war in the Muslim world, hostilities from that quarter ceased. Leo used the breathing space to reconstruct those Thracian cities that the Bulgars had earlier destroyed. His work indicates the degree of gradual Byzantine penetration into the coastal fringes of the Balkan Peninsula, as does the number of themes organized in that same region during the early 9th century: those of Macedonia, Thessalonica, Dyrrhachium, Dalmatia, and the Strymon.

Michael II and Thomas the Slavonian

The new emperor, Michael II, was indeed able to establish a dynasty—the Amorian, or Phrygian—his son Theophilus (829–842) and his grandson Michael III (842–867) each occupying the throne in turn, but none would have forecast so happy a future during Michael II's first years. Thomas the Slavonian, Michael's former comrade in arms, gave himself out to be the unfortunate Constantine VI and secured his coronation at the hands of the Patriarch of Antioch; this was accomplished with the willing permission of the Muslim caliph under whose jurisdiction Antioch lay. Thomas thereupon marched to Constantinople at the head of a motley force of Caucasian peoples whose sole bonds were to be found in their devotion to iconodule doctrine and their hatred of Michael's Iconoclasm. Assisted by Omortag and relying upon the defenses of Constantinople, Michael defeated his enemy, but the episode suggests the tensions beneath the surface of Byzantine society: the social malaise, the ethnic hostility, and the persisting discord created by Iconoclasm. All these may explain the weakness displayed throughout Theophilus' reign, when a Muslim army defeated the Emperor himself (838) as a prelude to the capture of the fortress of Amorium in Asia Minor. It may also explain the concurrent decline of Byzantine strength in the Mediterranean, manifest in the capture of Crete by the Arabs (826 or 827) and in the initiation of attacks upon Sicily that finally secured the island for the world of Islām. Iconoclasm certainly played its part in the further alienation of East from West, and a closer examination of its doctrines will suggest why this may have been.

The Iconoclastic Controversy. Iconoclasts and iconodules agreed on one fundamental point: a Christian people could not prosper unless it assumed the right attitude toward the holy images, or icons. They disagreed, of course, on what that attitude should be. Each could discover supporting arguments in the writings of the early church, and it is essential to remember that the debate over images is as old as Christian art. The fundamentals of Iconoclasm were by no means an 8th-century discovery. The ablest defender of the iconodule position was, however, the 8th-century theologian St. John of Damascus. Drawing upon Neoplatonic doctrine, John suggested that the image was but a symbol; the creation of the icon was justified since, by virtue of the Incarnation, God had himself become man.

The iconoclasts responded by pointing to the express wording of the Second Commandment. The condemnation therein of idolatry seems to have weighed heavily with Leo III, who may have been influenced by Islām, a religion that strictly prohibited the use of religious images. The latter point is debatable, as is the contention that Iconoclasm was particularly an expression of sentiment to be found in the eastern themes of the empire. There is little doubt, however, that Monophysitism influenced the ideas of Constantine V and, through him, the course of debate during the last half of the 8th century. In the eyes of the Monophysite, who believed in the single, indistinguishable, divine nature of Christ, the iconodule was guilty of sacrilege. Either he was a Nestorian, reducing the divine nature to human terms in the image, or he was a Chalcedonian Dyophysite, radically distinguishing that which man could not distinguish. Still another consideration favouring Iconoclasm may be found in the intimate connection of iconoclastic doctrine with the emperor's conception of his role as God's vicegerent on Earth. During the late 6th and 7th centuries, iconodule emperors had viewed themselves in a pietistic fashion, emphasizing their devotion and subservience to God. Constantine V, on the other hand, pridefully replaced the icons with imperial portraits and with representations of his own victories. Viewed in this light, Iconoclasm signaled a rebirth of imperial confidence; so deservedly great was Constantine's reputation, and so dismal were the accomplishments of his successors, that a Leo V, for one, could easily believe that God favoured the iconoclastic battalions.

Under Constantine V, the struggle against the icons became a struggle against their chief defenders, the monastic community. The immediate destruction wrought by Constantine and his zealous subordinates is, however, of less moment than the lasting effect of the persecution on the Orthodox clergy. Briefly put, the church became an institution rent by factions, wherein popular discontent found a means of expression. Intransigent iconodules looked for their leaders among the monks of Studion, the monastery founded by Studius, and they found one in the person of the monastery's abbot, St. Theodore Studites (759–826). In the patriarch Ignatius (847–858; 867–877) they discovered a spokesman after their own hearts: one drawn from the monastic ranks and contemptuous of all the allurements that the world of secular learning seemed to offer. More significant than the men to be found on the other extreme, iconoclast patriarchs, including Anastasius and John Grammaticus, were the representatives of the moderate party, composed of the patriarchs Tarasius, Nicephorus, Methodius, and Photius. Although iconodule in sympathy, the group enjoyed little rapport with the monastic zealots. Unlike the average monk, they were often educated laymen, trained in the imperial service and ready to compromise with imperial authority.

Byzantine relations with Catholic Europe

Not only was Iconoclasm a major episode in the history of the Byzantine, or Orthodox, Church, but it also permanently affected relations between the empire and Roman Catholic Europe. The Lombard advance, it may be remembered, had restricted Byzantine authority in Italy to the Exarchate of Ravenna, and to that quarter the popes of the 7th century, themselves ordinarily of Greek or Syrian origin, turned for protection against the common enemy. During the 8th century, two issues alienated Rome from Constantinople: Iconoclasm and quarrels stemming from the question of who should enjoy ecclesiastical jurisdiction over Illyricum and over Calabria in southern Italy. Pope Gregory II refused to accept the iconoclastic doctrines of Leo III; and his successor, Gregory III, had openly to condemn them at a council. Once Ravenna fell to the Lombards, and the exarchate ceased to exist in 751, the papacy had to seek a new protector. This was found in the person of the Frankish leader Pepin III, who sought some form of sanction to legitimize his seizure of the crown from the feeble hands of the last representative of the Merovingian dynasty. Thus Pope Stephen II (or III) anointed Pepin as king of the Franks in 754, and the latter entered Italy to take arms against the Lombard king. Even the restoration of icon veneration in 787 failed to bridge the differences between Orthodox Byzantium and Catholic Europe, for the advisers of Pepin's son and successor, Charlemagne, condemned the iconodule position as heartily as an earlier generation had rejected the iconoclast decrees of Leo III. Nor could the men of Charlemagne's time admit that a woman—the empress Irene—might properly assume the dignity of emperor of the Romans. For all these reasons, Charlemagne, king of the Franks and Lombards by right of conquest, assented to his coronation as emperor of the Romans on Christmas Day, 800, by Pope Leo III. No longer a barbarian king, Charlemagne became, by virtue of the symbolism of the age, a new Constantine. This the Byzantine chancery could not accept, for, if there were one God, one faith, and one truth, then there could be but one empire and one emperor; surely that emperor ruled in Constantinople, not in Charlemagne's Aachen. Subsequent disputes between Rome and Constantinople seemed often to centre upon matters of ecclesiastical discipline; underlying these differences were two more powerful considerations, neither of which could be ignored. According to theory there could be but one empire; clearly, there were two. And between Rome and Constantinople there stood two groups of peoples open to conversion: the Slavs of central Europe and the Bulgars in the Balkans. From which of the two jurisdictions would these people accept their Christian discipline? To which, in consequence, would they owe their spiritual allegiance?

The reign of Michael III

The reign of Michael III (ruled 842–867) draws together these and other threads from the past. Veneration of the icons was definitely rehabilitated in 843; and it was done in so diplomatic a fashion that the restoration, in itself, produced no new rifts, although old factionalisms persisted with the appointment of a monk, Ignatius, as patriarch. The latter's intransigent zealotry found little favour with Caesar Bardas, Michael's uncle, who had seized power from the Empress Regent in 856. Two years later Ignatius was deposed and replaced by a moderate: the scholar and layman Photius. No single person better exemplified the new age, nor, indeed, did any other play a larger part in the cultural rebirth and missionary activity among the Slavs, Bulgars, and Russians, which mark the middle of the 9th century. The same aggressive and enterprising spirit is manifest in the military successes won on the Asia Minor frontier, culminating in Petronas' victory at Poson (863) over the Muslim emir of Melitene.

In Sicily, and throughout the Mediterranean, Byzantine arms were less successful, but, thanks to Photius' diplomatic skill, the see of Constantinople maintained its position against Rome during the so-called Photian Schism. When Pope Nicholas I challenged Photius' elevation to the patriarchate, deploring as uncanonical the six days' speed with which he had been advanced through the successive ranks of the hierarchy, the Byzantine patriarch refused to bow. He skillfully persuaded Nicholas' delegates to a council summoned at Constantinople to investigate the matter that he was the lawful patriarch despite the persisting claims of the rival Ignatian faction. Nicholas, alleging that his men had been bribed, excommunicated Photius; a council at Constantinople responded (867) by excommunicating Nicholas in turn. The immediate issues between the two sees were matters of ecclesiastical supremacy, the liturgy, and clerical discipline; behind these sources of division lay the question of jurisdiction over the converts in Bulgaria. And behind that question may be found centuries of growing separation between the minds and institutions of the eastern and the western Mediterranean worlds, symbolized in the roles assumed by two among the major protagonists in the Photian Schism. It was the supreme spiritual authority, the pope, who hurled anathemas from the West, but it was God's vicegerent on Earth, the emperor Michael III, who presided at the council of 867.

Michael did not long survive this moment of triumph. Later that year, he was murdered by his favourite, Basil, who, on his bloody path to the throne, had earlier disposed of Caesar Bardas. As had Heraclius and Leo III before him, Basil came to found a dynasty, in this instance the Macedonian house. Unlike his predecessors, he came not as a saviour but as a peasant adventurer to seize an already sound empire whose next centuries were to be its greatest (see also EASTERN ORTHODOXY: *History*).

From 867 to the Ottoman conquest

THE MACEDONIAN ERA: 867–1025

Under the Macedonians, at least until the death of Basil II in 1025, the empire enjoyed a golden age. Its armies regained the initiative against the Arabs in the East, and its missionaries evangelized the Slavs, extending Byzantine influence in Russia and the Balkans. And, despite the rough military character of many of the emperors, there was a renaissance in Byzantine letters and important developments in law and administration. At the same time there were signs of decay: resources were squandered at an alarming rate; there was growing estrangement from the West; and a social revolution in Anatolia was to undermine the economic and military strength of the empire.

Founding of the dynasty

The empire was in theory an elective monarchy with no law of succession. But the desire to found and perpetuate a dynasty was strong, and it was often encouraged by popular sentiment. This was especially true in relation to the Macedonian dynasty, the founder, Basil I, having murdered his way to the throne in 867. Probably of Armenian descent, though they had settled in Macedonia, Basil's family was far from distinguished and can hardly have expected to produce a line of emperors that lasted through six generations and 189 years. But, having acquired the imperial crown, Basil tried to make sure that his family would not lose it and nominated three of his sons as coemperors. Though he was his least favourite,

The Macedonian Emperors, 867–1025

name	reign dates
Basil I	867–886
Leo VI	886–912
Constantine VII	913–959
Romanus I*	919–944
Romanus II	959–963
Nicephorus II	963–969
John I	969–976
Basil II	976–1025

*Ruled in Constantine's name.

through the scholarly Leo VI, who succeeded him in 886, the succession was at least secure. Even the three soldier-emperors who usurped the throne during the Macedonian era were conscious, in varying degrees, that they were protecting the rights of a legitimate heir during a minority: Romanus I Lecapenus for Constantine VII, the son of Leo VI; and Nicephorus Phocas and John Tzimisces for Basil II, the grandson of Constantine VII.

Military revival. A reassertion of Byzantine military and naval power in the East began with victories over the Arabs by Michael III's general Petronas in 856. From 863 the initiative lay with the Byzantines. The struggle with the Arabs, which had long been a struggle for survival, became a mounting offensive that reached its brilliant climax in the 10th century. By 867 a well-defined boundary existed between the Byzantine Empire and the territory of the ʿAbbāsid caliphate. Its weakest point was in the Taurus Mountains above Syria and Antioch. Basil I directed his operations against this point, recovered Cyprus for a while, and campaigned against the Paulicians, a heretical Christian sect whose anti-imperial propaganda was effective in Anatolia. But the conflict with Islām was one that concerned the whole empire, in the West as well as in the East, and by sea as well as by land. In 902 the Arabs completed the conquest of Sicily, but they were kept out of the Byzantine province of South Italy, for whose defense Basil I had even made some effort to cooperate with the Western emperor Louis II. The worst damage, however, was done by Arab pirates who had taken over the island of Crete. In 904 they plundered Thessalonica, carrying off quantities of loot and prisoners. Leo VI sent a naval expedition to Crete in 911, but the Muslims drove it off and humiliated the Byzantine navy off Chios in 912.

Success of eastern offensive

On the eastern frontier, the Byzantine offensive was sustained with great success during the reign of Romanus I Lecapenus by an Armenian general John Curcuas (Gurgen), who captured Melitene (934) and then Edessa (943), advancing across the Euphrates into the caliph's territory. It was Curcuas who paved the way for the campaigns of the two soldier-emperors of the next generation. In 961 Nicephorus Phocas, then domestic (commander) of the armies in the West, reconquered Crete and destroyed the Arab fleet that had terrorized the Aegean for 150 years; he thereby restored Byzantine naval supremacy in the eastern Mediterranean. In 962 his strategy achieved unexpected triumphs all along the eastern frontier and culminated in the capture of Aleppo in Syria. When he was proclaimed emperor in March 963, Nicephorus appointed another Armenian general, John Tzimisces, as domestic of the East, though he retained personal command of operations against the Arabs. By 965 he had driven them out of Cyprus and was poised for the reconquest of Syria. The revived morale and confidence of Byzantium in the East showed itself in the crusading zeal of Nicephorus Phocas and John Tzimisces for the reconquest of Syria and the Holy Land. The ground lost to Islām in the 7th century was thus fast being regained; and, although Jerusalem was never reached, the important Christian city of Antioch, seat of one of the patriarchs, was recaptured in 969. These victories were achieved largely by the new cavalry force built up by Nicephorus Phocas. In the areas recovered from the Arabs, land was distributed in military holdings with the interests of the cavalry in mind. But the victories were achieved at the expense of the western provinces, and an attempt to recover Sicily ended in failure in 965.

The campaigns of John Tzimisces, who usurped the throne in 969, were directed against the Emir of Mosul on the Tigris and against the new Fāṭimid caliph of Egypt, who had designs on Syria. By 975 almost all of Syria and Palestine, from Caesarea to Antioch, as well as a large part of Mesopotamia far to the east of the Euphrates, was in Byzantine control. The way seemed open for Tzimisces to advance to the ʿAbbāsid capital of Baghdad on the one hand and to Jerusalem and Egypt on the other. But he died in 976 and his successor, Basil II, the legitimate heir of the Macedonian house, concentrated most of his resources on overcoming the Bulgars in Europe, though he did not abandon the idea of further reconquest in the East. The Kingdom of Georgia (Iberia) was incorporated into the empire by treaty. Part of Armenia was annexed, with the rest of it to pass to Byzantium on the death of its king. Basil II personally led two punitive expeditions against the Fāṭimids in Syria, but otherwise his eastern policy was to hold and to consolidate what had already been gained. The gains can be measured by the number of new themes (provinces) created by the early 11th century in the area between Vaspurakan in the Caucasus and Antioch in Syria. The annexation of Armenia, the homeland of many of the great Byzantine emperors and soldiers, helped to solidify the eastern wall of the Byzantine Empire for nearly a century.

Relations with the Slavs and Bulgars. Although imperial territory in the East could be reclaimed only by military conquest, in the Balkans and in Greece the work of reclamation could be assisted by the diplomatic weapon of evangelization. The Slavs and the Bulgars could be brought within the Byzantine orbit by conversion to Christianity. The conversion of the Slavs was instigated by the patriarch Photius and carried out by the monks Cyril and Methodius from Thessalonica. Their invention of the Slavonic alphabet (Cyrillic and Glagolitic) made possible the translation of the Bible and the Greek liturgy and brought literacy as well as the Christian faith to the Slavic peoples. The work began in the Slavic Kingdom of Moravia and spread to Serbia and Bulgaria. Latin missionaries resented what they considered to be Byzantine interference among the northern Slavs, and there were repeated clashes of interest that further damaged relations between the sees of Rome and Constantinople. The conversion of the Bulgars became a competition between the two churches and was ably exploited by the Bulgar king Boris until, in 870, he opted for Orthodox Christianity on condition of having an archbishop of his own.

Conversion of the Slavs

Bulgarian wars. The trade with Constantinople that followed the missionaries whetted the appetites of the Slavs and Bulgars for a larger share in the material wealth of Byzantium. Simeon (Symeon) I of Bulgaria, who succeeded his father Boris in 893 and who had been educated at Constantinople, proved to be an even more dangerous enemy than the Arabs. His efforts to become emperor dominated Byzantine history for some 15 years. In 913 he brought his army to the walls of Constantinople, demanding the imperial title. The patriarch, Nicholas Mysticus, appeased Simeon for a time, but it was Romanus Lecapenus who, by patience and diplomacy, undermined the power of the Bulgars and thwarted Simeon's ambitions. Simeon died in 927, and his son Peter I came to terms with Byzantium and married a granddaughter of Romanus.

Relations with Russia. The Russians lay far outside the Roman jurisdiction. Their warships, sailing down the Dnepr from Kiev to the Black Sea, first attacked Constantinople in 860. They were beaten off, and almost at once Byzantine missionaries were sent into Russia. The Russians were granted trading rights in Constantinople in 911, but in 941 and 944, led by Prince Igor, they returned to the attack. Both assaults were repelled, and Romanus I set about breaking down the hostility and isolationism of the Russians by diplomatic and commercial contacts. In 957 Igor's widow, Olga, was baptized and paid a state visit to Constantinople during the reign of Constantine VII; her influence enabled Byzantine missionaries to work with greater security in Russia, thus spreading Christianity and Byzantine culture. Olga's son Svyatoslav was pleased to serve the empire as an ally against the Bulgars from

968 to 969, though his ambition to occupy Bulgaria led to war with Byzantium in which he was defeated and killed. In 971 John Tzimisces accomplished the double feat of humiliating the Russians and reducing Bulgaria to the status of a client kingdom. Byzantine influence over Russia reached its climax when Vladimir of Kiev, who had helped Basil II to gain his throne, received as his reward the hand of the Emperor's sister in marriage and was baptized in 989. The mass conversion of the Russian people followed, with the establishment of an official Russian Church subordinate to the patriarch of Constantinople.

Bulgar revolt. The Bulgars, however, were not content to be vassals of Byzantium and rebelled under Samuel, youngest of the four sons of a provincial governor in Macedonia. Samuel made his capital at Ochrida and created a Bulgarian empire stretching from the Adriatic to the Black Sea and even, for a while, into Greece, though Thessalonica remained Byzantine. The final settlement of the Bulgar problem was worked out by Basil II in a ruthless and methodical military campaign lasting for some 20 years, until, by 1018, the last resistance was crushed. Samuel's dominions became an integral part of the Byzantine Empire and were divided into three new themes. At the same time the Slav principalities of Serbia (Rascia and Dioclea) and Croatia became vassal states of Byzantium, and the Adriatic port of Dyrrhachium came under Byzantine control. Not since the days of Justinian had the empire covered so much European territory. But the annexation of Bulgaria meant that the Danube was now the only line of defense against the more northerly tribes, such as the Pechenegs, Cumans, and Magyars.

Bulgars crushed by Basil II

Estrangement from the West. The extension of Byzantine interests to the Adriatic, furthermore, had raised again the question of Byzantine claims to South Italy and, indeed, to the whole western part of the old Roman Empire. The physical separation of that empire into East and West had been emphasized by the settlement of the Slavs in the Balkan Peninsula and in Greece, and since the 7th century the two worlds had developed in their different ways. Their differences had been manifested in ecclesiastical conflicts, such as the Photian Schism. The conversion of the Slavs had produced bitterness between the agents of the rival jurisdictions. But the reestablishment of Byzantine authority in Greece and eastern Europe, added to the gains against the Muslim powers in Asia, reinforced the Byzantine belief in the universality of the empire, to which Italy and the West must surely be reunited in time. Until that time came, the fiction was maintained that the rulers of western Europe, like those of the Slavs, held their authority by virtue of their special relationship with the one true emperor in Constantinople.

It was sometimes suggested that a marriage alliance might bring together the Eastern and Western parts of the empire and so provide for a united defense against the common enemy in Sicily—the Arabs. In 944 Romanus II, son of Constantine VII, married a daughter of Hugh of Provence, the Carolingian claimant to Italy. Constantine VII also kept up diplomatic contact with Otto I, the Saxon king of Germany. But the case was dramatically altered when Otto was crowned emperor of the Romans in 962, for this was a direct affront to the unique position of the Byzantine emperor. Otto tried, and failed, to establish his claim, either by force in the Byzantine province in Italy or by negotiation in Constantinople. His ambassador Liudprand of Cremona wrote an account of his mission to Nicephorus Phocas in 968 and of the Emperor's scornful rejection of a proposed marriage between Otto's son and a Byzantine princess. The incident vividly demonstrates the superior attitude of the Byzantines toward the West in the 10th century. John Tzimisces relented to the extent of arranging for one of his own relatives to marry Otto II in 972, though the arrangement implied no recognition of a Western claim to the empire. Basil II agreed that Otto III also should marry a Byzantine princess. But this union was never achieved; and subsequently Basil reorganized the administration of Byzantine Italy and was preparing another campaign against the Arabs in Sicily at the time of his death in 1025. The myth of the universal Roman Empire died hard.

Holy Roman Empire founded in the West

Culture and administration. The Iconoclastic Controversy had aggravated the estrangement of the Byzantine Church and Empire from the West. But it helped to define the tenets of Orthodoxy; and it had an effect on the character of Byzantine society for the future. On the one hand, the church acquired a new unity and vitality: its missionaries spread the Orthodox faith in new quarters of the world, its monasteries proliferated, and its spiritual tradition was carried forward by the sermons and writings of the patriarch Photius in the 9th century and of Symeon the New Theologian in the 10th and 11th centuries. On the other hand, the empire became more aware of its Greco-Roman heritage. Interest in classical Greek scholarship revived following the reorganization of the University of Constantinople under Michael III. The revival was fostered and patronized particularly by the scholar-emperor Constantine VII Porphyrogenitus, who saw to the compilation of three great works on the administration, the court ceremonies, and the provinces of his empire. He also commissioned a history of the age to which he contributed a biography of his grandfather Basil I. The age produced little original research, but lexicons (such as the 10th-century *Suda*), anthologies, encyclopaedias, and commentaries (such as the *Lexicon* and *Bibliotheca* of Photius) were produced in great number. The soldier-emperors of the 10th century were less interested in intellectual pursuits, but scholarship received a new impetus in the 11th century with Michael Psellus.

The founder of the dynasty, Basil I, and his son Leo VI, made plain their intention to inaugurate a new era by a restatement of the imperial law. Basil hoped to make a complete revision of the legal code, but only a preliminary textbook (Procheiron) with an introduction (Epanagoge) appeared during his reign. Leo VI, however, accomplished the work with the publication of the 60 books of the Basilica, which Hellenized the legal code of Justinian and made it more intelligible and accessible to lawyers. Additions and corrections to meet the needs of the time were incorporated in Leo's 113 novels (decrees), which represent the last substantial reform of the civil law in Byzantium. Enshrined in this legislation was the principle of the absolute autocracy of the emperor as being himself the law. The Senate, the last vestige of Roman republican institutions, was abolished. Only in the matter of the spiritual welfare of his subjects did the emperor recognize any limits to his authority. The ideal relationship of a dyarchy between emperor and patriarch, the body and the soul of the empire, was written into the Epanagoge of Basil I, in a section probably composed by Photius.

Growth of bureaucracy

The administration in this period was ever more closely centralized in Constantinople, with an increasingly complex and numerous bureaucracy of officials who received their appointments and their salaries from the emperor. The emperor also controlled the elaborate machinery of the foreign and diplomatic service. Some of his civil servants, however, were powerful enough to play the part of kingmakers, notably Basil, the chamberlain who engineered the ascent to the throne of Nicephorus Phocas and John Tzimisces. Order and the regulation of trade, commerce, and industry in the capital were in the hands of the prefect of the city, whose functions are outlined in the 9th-century *Book of the Eparch.* He was responsible for organizing and controlling the guilds or colleges of craftsmen and retailers, whose legal rights and duties to the state were strictly circumscribed and supervised. The provinces in Europe and Asia were administered according to their territorial division into themes, which, by the 10th century, numbered more than 30. The themes, though subdivided and reduced in size, retained their military character. Their governors, or *stratēgoi,* combined military and civil authority and were directly answerable to the emperor, who appointed them. The army and the navy were, for the most part, recruited from the ranks of soldier-farmers who held hereditary grants of land within the territory of each theme. The border districts were protected by contingents of frontier troops, led by their own officers or lords of the marches. Their exploits and adventures were romanticized in the 10th-century folk-epic of Digenis Akritas. But warfare was studied and perfected as a science, and it was the subject of treatises such as the *Tactica* of Leo VI, derived from the *Strategicon* of the emperor Maurice.

Growth of landholding aristocracy

Social and economic change. The wars of reconquest on the eastern frontier in this period and the general military orientation of imperial policy brought to the fore a new class of aristocracy, whose wealth and power were based on land ownership and who held most of the higher military posts. Trade and industry in the cities were so rigidly controlled by the government that almost the only profitable form of investment for private enterprise was the acquisition of landed property. The military aristocracy, therefore, took to buying up the farms of free peasants and soldiers and reducing their owners to varying forms of dependence. As the empire grew stronger, the rich became richer. Given the system of agriculture prevailing in Anatolia and the Balkans, every failure of crops, every famine, drought, or plague produced a quota of destitute peasant-soldiers willing to turn themselves and their land over to the protection of a prosperous and ambitious landlord. The first emperor to see the danger in this development was Romanus I Lecapenus, who, in 922 and 934, passed laws to defend the small landowners against the acquisitive instincts of the "powerful"; for he realized that the economic as well as the military strength of the empire depended on the maintenance within the theme system of the institution of free, yet tax-paying, soldier-farmers and peasants in village communities. (Only freemen owed military service.)

Successive emperors after Romanus I enforced and extended his agrarian legislation. But the cost of the campaigns of reconquest from the Arabs had to be met by higher taxation, which drove many of the poorer peasants to sell their lands and to seek security as tenant farmers. Nicephorus Phocas, who belonged to one of the aristocratic landowning families of Anatolia, was naturally reluctant to act against members of his own class, though he adhered to the principle that the rights of the poor should be safeguarded. His laws about land tenure were particularly directed toward the creation of a more mobile force of heavy-armed cavalry recruited from those who could afford the equipment, which inevitably brought changes in the social structure of the peasant militia. On the other hand, Nicephorus took a firm line to prevent the accumulation of further land by the church, and he forbade any addition to the number of monasteries, whose estates, already extensive, were unproductive to the economy.

Basil II's land reforms

The last emperor to attempt to deal with the problem of land ownership seriously was Basil II, whose rise to the throne had involved the empire in a bitter and costly war against the aristocratic Sclerus and Phocas families. In 996 Basil promulgated comprehensive punitive legislation against the landed families, ordering the restitution of land acquired from the peasantry since 922 and requiring proof of title to other land going back in some cases as far as 1,000 years. Further, the system of collective responsibility for the payment of outstanding taxes known as the *allelengyon* now devolved not on the rest of the village community but on the nearest large landowner, whether lay or ecclesiastical. Basil's conquest of Bulgaria somewhat altered the social and economic pattern of the empire, for new themes were created there in which there was no long tradition of a landed aristocracy as in Anatolia. After his death in 1025 the powerful hit back, and the government in Constantinople was no longer able to check the absorption of small freeholders by the great landowners and the consequent feudalization of the empire.

This process was particularly disastrous for the military establishment. The success and prestige of the Byzantine Empire in the Macedonian era to a large extent depended on the unrivaled efficiency of its army in Anatolia. A professional force, yet mainly native to the soil and so directly concerned with the defense of that soil, it had no equal in the Western or the Arab world at the time. And yet it was in this institution that the seeds of decay and disintegration took root; for most of the army's commanders were drawn from the great landowners of Anatolia, who had acquired their riches and their status by undermining the social and economic structure on which its recruitment depended. Basil II had restrained them with such an iron hand that a reaction was inevitable after his death. Indeed, it is doubtful if Byzantine society could have tolerated another Basil II, despite all his triumphs. Soured by long years of civil war at the start of his reign, ascetic and uncultured by nature, Basil embodied the least attractive features of Byzantine autocracy. Some have called him the greatest of all the emperors. But the virtue of philanthropy, which the Byzantines prized and commended in their rulers, was not a part of his greatness; and the qualities that lent refinement to the Byzantine character, among them a love of learning and the arts, were not fostered during his reign. Yet, while Basil was busily earning his title of Bulgaroctonus ("Bulgar Slayer"), St. Symeon the New Theologian was exploring the love of God for man in some of the most poetic homilies in all mystical literature.

BYZANTINE DECLINE AND SUBJECTION TO WESTERN INFLUENCES: 1025–1260

Basil II never married. But after his death his relatives remained in possession of the throne until 1056, less because of their efficiency than because of a general feeling

The Byzantine Empire in 1025.

The later Macedonians

among the Byzantine people that the prosperity of the empire was connected with the continuity of the Macedonian dynasty. When Basil's brother Constantine VIII died in 1028, the line was continued in his two daughters, Zoe and Theodora. Zoe was married three times: to Romanus III Argyrus (ruled 1028–34), to Michael IV (1034–41), and to Constantine IX Monomachus (1042–55), who outlived her. When Constantine IX died in 1055, Zoe's sister, Theodora, reigned alone as empress until her death a year later.

The great emperors of the golden age, not all of them members of the Macedonian family, molded the history of that age. The successors of Basil II were rather the creatures of circumstances, because they did not make and seldom molded. In the 56 years from 1025 to 1081, there were 13 emperors. An attempt made by Constantine X Ducas to found a new dynasty was disastrously unsuccessful. Not until the rise of Alexius I Comnenus to power, in 1081, was stability restored by an ensured succession in the Comnenus family, who ruled for more than 100 years (1081–1185).

11th-century weakness. The state of the Byzantine Empire in the 11th century may be compared to that of the Roman Empire in the 3rd century, when, after a long period of secure prosperity, new pressures from beyond the frontiers aggravated the latent tensions in society. The brief reigns of Basil II's heirs reflected, and were often the product of, a division in the Byzantine ruling class, a conflict between the military aristocracy of the provinces and the civilian aristocracy, or bureaucracy, of Constantinople. Each faction put up rival emperors. The sophisticated urban aristocracy favoured rulers who would reverse the militaristic trend of the empire and who would expand the civil service and supply them and their families with lucrative offices and decorative titles. The military families, whose wealth lay not in the capital but in the provinces and who had been penalized by Basil II's legislation, favoured emperors who were soldiers and not civil servants. In this they were more realistic, for in the latter part of the 11th century it became ever clearer that the empire's military strength was no longer sufficient to hold back its enemies. The landowners in the provinces appreciated the dangers more readily than the government in Constantinople, and they made those dangers an excuse to enlarge their estates in defiance of all the laws passed in the 10th century. The theme system in Anatolia, which had been the basis of the empire's defensive and offensive power, was rapidly breaking down at the very moment when its new enemies were gathering their strength.

On the other hand, the urban aristocracy of Constantinople, reacting against the brutalization of war, strove to make the city a centre of culture and sophistication. The university was endowed with a new charter by Constantine IX in 1045, partly to ensure a steady flow of educated civil servants for the bureaucracy. The law school was revived under the jurist John Xiphilinus; the school of philosophy was chaired by Michael Psellus, whose researches into every field of knowledge earned him a reputation for omniscience and a great following of brilliant pupils. Psellus—courtier, statesman, philosopher, and historian—is in himself an advertisement for the liveliness of Byzantine society in the 11th century. What he and others like him failed to take into account was that their empire was more and more expending the resources and living on the reputation built up by the Macedonian emperors.

Arrival of new enemies. The new enemies that emerged in the 11th century, unlike the Arabs or the Bulgars, had no cause to respect that reputation. They appeared almost simultaneously on the northern, the eastern, and the western frontiers. It was nothing new for the Byzantines to have to fight on two fronts at once. But the task required a soldier on the throne. The Pechenegs, a Turkic tribe, had long been known as the northern neighbours of the Bulgars. Constantine VII had thought them to be valuable allies against the Bulgars, Magyars, and Russians. But after the conquest of Bulgaria, the Pechenegs began to raid across the Danube into what was then Byzantine territory. Constantine IX allowed them to settle south of the river, where their numbers and their ambitions increased. By the mid-11th century they were a constant menace to the peace in Thrace and Macedonia, and they encouraged the spirit of revolt among the Bogomil heretics in Bulgaria. It was left to Alexius I to avert a crisis by defeating the Pechenegs in battle in 1091.

Seljuq Turks in the East

The new arrivals on the eastern frontier were the Seljuq Turks, whose conquests were to change the whole shape of the Muslim and Byzantine worlds. In 1055, having conquered Persia, they entered Baghdad, and their prince assumed the title of sultan and protector of the ʿAbbāsid caliphate. Before long they asserted their authority to the borders of Fāṭimid Egypt and Byzantine Anatolia. They made their first explorations across the Byzantine frontier into Armenia in 1065 and, in 1067, as far west as Caesarea in central Anatolia. The raiders were inspired by the Muslim idea of holy war, and there was at first nothing systematic about their invasion. They found it surprisingly easy, however, to plunder the countryside and isolate the cities, owing to the long neglect of the eastern frontier defenses by the emperors in Constantinople. The emergency lent weight to the military aristocracy in Anatolia who, in 1068, finally secured the election of one of their own number, Romanus IV Diogenes, as emperor. Romanus assembled an army to deal with what he saw as a large-scale military operation. It was a sign of the times that his army was mainly composed of foreign mercenaries. In August 1071 it was defeated at Manzikert, near Lake Van in Armenia. Romanus was taken prisoner by the Seljuq sultan, Alp-Arslan. He was allowed to buy his freedom after signing a treaty, but the opposition in Constantinople refused to have him back as emperor and installed their own candidate, Michael VII. Romanus was treacherously blinded. The Seljuqs were thus justified in continuing their raids and were even encouraged to do so. Michael VII invited Alp-Arslan to help him against his rivals, Nicephorus Bryennius and Nicephorus Botaneiates, each of whom proclaimed himself emperor at Adrianople in 1077 and at Nicaea in 1078. In the four years of ensuing civil war there were no troops to defend the eastern frontier. By 1081 the Turks had reached Nicaea. The heart of the empire's military and economic strength, which the Arabs had never mastered, was now under Turkish rule.

Battle of Manzikert

The new enemies in the West were the Normans, who began their conquest of South Italy early in the 11th century. Basil II's project of recovering Sicily from the Arabs had been almost realized in 1042 by the one great general of the post-Macedonian era, George Maniaces, who was recalled by Constantine IX and killed as a pretender to the throne. The Normans thereafter made steady progress in Italy. Led by Robert Guiscard, they carried all before them; in April 1071, Bari, the last remaining Byzantine stronghold, fell after a three-year siege. Byzantine rule in Italy and the hope of a reconquest of Sicily were at an end.

The disasters at Manzikert and at Bari, in the same year 1071, at opposite extremes of the empire, graphically illustrate the decline of Byzantine power. The final loss of Italy seemed to underline the fact of the permanent division between the Greek East and the Latin West, which was now not only geographical and political but also increasingly cultural and ecclesiastical. In 1054 a state of schism had been declared between the churches of Rome and Constantinople. The political context of the event was the Norman invasion of Italy, which at the time was a matter of as much concern to the papacy as it was to Byzantium. But the event itself, the excommunication of the patriarch Michael Cerularius by Cardinal Humbert in Constantinople, symbolized an irreconcilable difference in ideology. The reform movement in the Roman Church had emphasized an ideal of the universal role of the papacy that was wholly incompatible with Byzantine tradition. Both sides also deliberately aggravated their differences by reviving all the disputed points of theology and ritual that had become battle cries during the Photian Schism in the 9th century. The schism of 1054 passed unnoticed by contemporary Byzantine historians; its significance as a turning point in East–West relations was fully realized only later.

Schism between churches

Alexius I and the First Crusade. But even the events of 1071 had not made the decline of Byzantium irretrievable. The shrinking of its boundaries reduced the empire from its status as a dominating world power to that of a small Greek state fighting for survival. That survival now depended on the new political, commercial, and ecclesiastical forces in the West, for it could no longer draw on its former military and economic resources in Anatolia. The civil aristocracy of Constantinople yielded with bad grace. After four years of civil war, the military lords triumphed with the accession of Alexius I Comnenus, the greatest soldier and statesman to hold the throne since Basil II. The history of his reign was written in elegant Greek by his daughter Anna Comnena; and, as she remarks, it began with an empire beset by enemies on all sides. The Normans captured Dyrrhachium (modern Durrës, Alb.) in 1082 and planned to advance overland to Thessalonica. Alexius called on the Venetians to help him, but Robert Guiscard's death in 1085 temporarily eased the Norman problem. The following year the Seljuq sultan died, and the sultanate was split by internal rivalries. Fortune thus played into Alexius's hands by ridding him of two of his besetting enemies. By his own efforts, however, he defeated the Pechenegs in 1091.

The Venetians had been pleased to help drive the Normans out of the Adriatic Sea but demanded a heavy price. In 1082 Alexius granted them trading privileges in Constantinople and elsewhere on terms calculated to outbid Byzantine merchants. This charter was the cornerstone of the commercial empire of Venice in the eastern Mediterranean. But it fed the flames of Byzantine resentment against the Latins; and it provoked the rich, who might have been encouraged to invest their capital in shipbuilding and trade, to rely on the more familiar security of landed property.

Involvement in the First Crusade

The terms that Alexius made with his enemies in the first 10 years of his reign were not meant to be permanent. He fully expected to win back Anatolia from the Seljuqs; his plans, however, were not given time to mature, for matters were precipitated by the arrival in the East of the first crusaders from western Europe (1096). Alexius had undoubtedly solicited the help of mercenary troops from the West but not for the liberation of the Holy Land from the infidel. The urgent need was the protection of Constantinople and the recovery of Anatolia. The Byzantines were more realistic about their Muslim neighbours than the distant popes and princes of the West. Jerusalem had finally been taken by the Seljuqs in 1071, but the most immediate threat to Byzantium came from the Pechenegs and the Normans. Alexius was tactful in his dealings with the pope and ready to discuss the differences between the churches. But neither party foresaw the consequences of Pope Urban II's appeal in 1095 for recruits to fight a Holy War. The response in western Europe was overwhelming. The motives of those who took the cross as crusaders ranged from religious enthusiasm to a mere spirit of adventure or a hope of gain; and it was no comfort to Alexius to learn that four of the eight leaders of the First Crusade were Normans, among them Bohemond, the son of Robert Guiscard. Since the crusade had to pass through Constantinople, however, the Emperor had some control over it. He required its leaders to swear to restore to the empire any towns or territories they might conquer from the Turks on their way to the Holy Land. In return, he gave them guides and a military escort. Still, the cost was enormous, for the crusaders had to be supplied with food or live off the land as they went.

Nicaea fell to them in 1097 and was duly handed over to the Emperor in accord with the agreement. In 1098 they reached, and captured, Antioch. There the trouble started. Bohemond refused to turn over the city and instead set up his own principality of Antioch. His example was imitated in the establishment of the Latin Kingdom of Jerusalem (1100), which had fallen to the crusaders the year before, and of the counties of Edessa and Tripoli. The crusaders settled down to colonize and defend the coast of Palestine and Syria and to quarrel among themselves. While they did so, Alexius was able to establish a new and more secure boundary between Byzantium and Islām through the middle of Anatolia. Full advantage was taken of the prevailing rivalry between the Seljuq sultans at Konya and the rival dynasty of the Dānishmend emirs at Melitene (near modern Malatya, Tur.); and a limit was set to the westward expansion of the Turks.

The *pronoia* system

The First Crusade thus brought some benefits to Byzantium. But nothing could reconcile the emperor to Bohemond of Antioch. In 1107 Bohemond mounted a new invasion of the empire from Italy. Alexius was ready and defeated him at Dyrrhachium in 1108. Byzantine prestige was higher than it had been for many years, but the empire could barely afford to sustain the part of a great power. Alexius reconstituted the army and re-created the fleet, but only by means of stabilizing the gold coinage at one-third of its original value and by imposing a number of supplementary taxes. It became normal practice for taxes to be farmed out, which meant that the collectors recouped their outlay on their own terms. People in the provinces had the added burden of providing materials and labour for defense, communications, and provisions for the army, which now included very large numbers of foreigners. The supply of native soldiers had virtually ceased with the disappearance or absorption of their military holdings. Alexius promoted an alternative source of native manpower by extending the system of granting estates in *pronoia* (by favour of the emperor) and tying the grant to the military obligation. The recipient of a *pronoia* was entitled to all the revenues of his estate and to the taxes payable by his tenants (*paroikoi*), on condition of equipping himself as a mounted cavalryman with a varying number of troops. He was in absolute possession of his property until it reverted to the crown upon his death. Similarly, Alexius tried to promote more profitable development of the estates of the church by granting them to the management of laymen as *charistikia* or benefices. As an expedient, the *pronoia* system had advantages both for the state and for the military aristocracy who were its main beneficiaries. But in the long term it hastened the fragmentation of the empire among the landed families and the breakdown of centralized government that the 10th-century emperors had laboured to avert.

Later Comneni. The policies of Alexius I were continued by his son John II Comnenus (reigned 1118–43) and his grandson Manuel I Comnenus (reigned 1143–80). In the 12th century there was a growing involvement of the Western powers in the affairs of the East, as well as an increasingly complex political situation in Europe. In Asia, too, matters were complicated by the conflict between the Seljuqs and the Dānishmends, by the emergence of the kingdom of Lesser Armenia in Cilicia, and by the activities of the crusader states. Foreign relations and skillful diplomacy became of paramount importance for the Byzantines. John II tried and failed to break what was becoming the Venetian monopoly of Byzantine trade, and he sought to come to terms with the new kingdom of Hungary, to whose ruler he was related by marriage. Alexius I had seen the importance of Hungary, lying between the Western and Byzantine empires, a neighbour of the Venetians and the Serbs. More ominous still was the establishment of the Norman Kingdom of Sicily under Roger II in 1130. But John II astutely allied himself with the Western emperor against it.

Appeasement of the West

Manuel I realized even more clearly that Byzantium could not presume to ignore or offend the new powers in the West, and he went out of his way to understand and to appease them. Certain aspects of the Western way of life appealed to Manuel. His first and second wives were both Westerners, and Latins were welcomed at his court and even granted estates and official appointments. This policy was distasteful to most of his subjects; and it was unfortunate for his intentions that the Second Crusade occurred early in his reign (1147), for it aggravated the bitterness between Greeks and Latins and brought Byzantium deeper than ever into the tangled politics of western Europe. Its leaders were Louis VII of France and the emperor Conrad III, and its failure was blamed on Byzantine treachery. The French king discussed with Roger of Sicily the prospect of attacking Constantinople, and in 1147 Roger invaded Greece. But Manuel retained the personal friendship and the alliance of Conrad III against the Normans and even planned a joint Byzantine-German campaign against them in Italy.

No such cooperation was possible with Conrad's successor, Frederick I Barbarossa, after 1152. To Frederick, the alliance between the Holy Roman Empire and what he called "the kingdom of the Greeks" was not one between equals. Manuel launched a vain invasion of the Norman kingdom on his own account in 1154, but it was too late for a revival of Byzantine imperialism in the West. It was hard for the Byzantines to accept the fact that their empire might soon become simply one among a number of Christian principalities.

In the Balkans and in the Latin East Manuel was more successful. His armies won back much of the northwest Balkans and almost conquered Hungary, reducing it to a client kingdom of Byzantium. The Serbs, too, under their leader Stephen Nemanja, were kept under control, while Manuel's dramatic recovery of Antioch in 1159 caused the crusaders to treat the Emperor with a new respect. But in Anatolia he overreached himself. To forestall the formation of a single Turkish sultanate, Manuel invaded the Seljuq territory of Rūm in 1176. His army was surrounded and annihilated at Myriocephalon. The battle marked the end of the Byzantine counteroffensive against the Turks begun by Alexius I. Its outcome delighted the Western emperor, Frederick I Barbarossa, who had supported the Seljuq sultan of Rūm against Manuel and who now openly threatened to take over the Byzantine Empire by force.

Manuel's personal relationships with the crusaders and with other Westerners remained cordial to the end. But his policies had antagonized the Holy Roman Empire, the papacy, the Normans, and, not least, the Venetians. His effort to revive Byzantine prestige in Italy and the Balkans, and his treaties with Genoa (1169) and Pisa (1170), roused the suspicions of Venice; and in 1171, following an anti-Latin demonstration in Constantinople, all Venetians in the empire were arrested and their property was confiscated. The Venetians did not forget this episode. They, too, began to think in terms of putting Constantinople under Western control as the only means of securing their interest in Byzantine trade.

Manuel's policies antagonized many of his own people as well. His favouritism to the Latins was unpopular, as was his lavish granting of estates in *pronoia.* A reaction set in shortly after his death in 1180, originated by his cousin Andronicus I Comnenus, who ascended to the throne after another anti-Latin riot in Constantinople. Andronicus murdered Manuel's widow and son Alexius II. He posed as the champion of Byzantine patriotism and of the oppressed peasantry. But to enforce his reforms he behaved like a tyrant. By undermining the power of the aristocracy he weakened the empire's defenses and undid much of Manuel's work. The King of Hungary broke his treaty, and Stephen Nemanja of Serbia declared his independence from Byzantium and founded a new Serbian kingdom. Within the empire, too, disintegration proceeded. In 1185 Isaac Comnenus, governor of Cyprus, set himself up as independent ruler of the island. In the same year the Normans again invaded Greece and captured Thessalonica. The news prompted a counterrevolution in Constantinople, and Andronicus was murdered.

He was the last of the Comnenian family to wear the crown. His successor, Isaac II Angelus, was brought to power by the aristocracy. His reign, and, still more, that of his brother Alexius III, saw the collapse of what remained of the centralized machinery of Byzantine government and defense. Isaac tried at least to keep his foreign enemies in check. The Normans were driven out of Greece in 1185. But in 1186 the Bulgars began a rebellion that was to lead to the formation of the Second Bulgarian Empire. Matters were not made easier by the arrival of the Third Crusade, provoked by the loss of Jerusalem to the Muslim leader Saladin in 1187. One of its leaders was Frederick I Barbarossa, whose avowed intention was to conquer Constantinople. He died on his way to Syria. But Richard I the Lion-Heart of England appropriated Cyprus from Isaac Comnenus, and the island never again reverted to Byzantine rule.

The Fourth Crusade and the establishment of the Latin Empire. In 1195 Isaac II was deposed and blinded by his brother Alexius III. The Westerners, who had again blamed the failure of their crusade on the Byzantines, saw ways of exploiting the situation. The emperor Henry VI had united the Norman Kingdom of Sicily with the Holy Roman Empire. He inherited the ambitions of both to master Constantinople, and his brother, Philip of Swabia, was married to a daughter of the dethroned Isaac II. Alexius bought off the danger by paying tribute to Henry, but Henry died in 1197. The idea had now gained ground in the West that the conquest of Constantinople would solve a number of problems and would be of benefit not only to trade but also to the future of the crusade and the church. In 1198 Innocent III was elected pope. The new rulers of Hungary, Serbia, and Bulgaria all turned to him for the recognition of the sovereignty that Byzantium would not give them.

Conquest and colonization by the West

It was under Innocent's inspiration that the Fourth Crusade was launched, and it was by the diversion of that crusade from its purpose and objective that the conquest and colonization of the Byzantine Empire by the West was realized. A multiplicity of causes and coincidences led up to the event, but the ambition of Venice, which supplied the ships, must rank high among them. A plausible excuse was offered by the cause of restoring Isaac II, whose son Alexius IV had escaped to the West to seek help, and who made lavish promises of reward to his benefactors. But when, in 1203, the crusaders drove Alexius III out of Constantinople, Isaac II and his son proved incapable either of fulfilling the promises or of stifling the anti-Latin prejudice of their people, who proclaimed an emperor of their own in the person of Alexius V. The Venetians and crusaders therefore felt justified in taking their own reward by conquering and dividing Constantinople and the Byzantine provinces among themselves. The city fell to them in April 1204. They worked off their resentment against the inhabitants in an unparalleled orgy of looting and destruction, which did irreparable damage to the city and immeasurable harm to East–West understanding.

The Venetians, led by their doge, Enrico Dandolo, gained most from the enterprise by appropriating the principal harbours and islands on the trade routes. The crusaders set about the conquest of the European and Asiatic provinces. The first Latin emperor, Baldwin I, was the suzerain of the feudal principalities that they established in Thrace, Thessalonica, Athens, and the Morea (Peloponnese). He soon came into conflict with the ruler of Bulgaria. Still more serious was the opposition offered by the three provincial centres of Byzantine resistance. At Trebizond (Trabzon) on the Black Sea, two brothers of the Comnenian family laid claim to the imperial title. In Epirus in northwestern Greece Michael Angelus Ducas, a relative of Alexius III, made his capital at Arta and harassed the crusader states in Thessaly. The third centre of resistance was based on the city of Nicaea in Anatolia, where Theodore I Lascaris, another relative of Alexius III, was crowned as emperor in 1208 by a patriarch of his own making. Of the three, Nicaea lay nearest to Constantinople, between the Latin Empire and the Seljuq sultanate of Rūm; and its emperors proved worthy of the Byzantine traditions of fighting on two fronts at once and of skillful diplomacy. Theodore Lascaris and his son-in-law John III Vatatzes built up at Nicaea a microcosm of the Byzantine Empire and church in exile. The Latins were thus never able to gain a permanent foothold in Anatolia; and even in Europe their position was constantly threatened by the Byzantine rulers of northern Greece, though in the centre and south of the country their conquests were more lasting.

The most successful of the Latin emperors was Baldwin's brother, Henry of Flanders, after whose death in 1216 the Latin Empire lost the initiative and the recovery of Constantinople became a foreseeable goal for the Byzantines in exile. The Latin regime was prolonged less by its own vitality than by the inability of the successor states of Epirus and Nicaea to cooperate. In 1224 Theodore Ducas of Epirus, who had extended his territories across the north of Greece and far into Bulgaria, wrested Thessalonica from the Latins and was crowned emperor there in defiance of the Emperor in Nicaea. In 1230, however, he was defeated in battle against the Bulgars before reaching Constantinople; and his defeat gave John III Ducas Vatatzes the chance to extend his own empire into Europe, to ally with the Bulgars, and so to encircle Constantinople. Theodore's successor was made to renounce his imperial title, and Thessalonica surrendered to the empire of Nicaea in 1246. The Mongol invasion of Anatolia, which had meanwhile thrown the East into confusion, was of great benefit to Nicaea, for it weakened the Seljuq sultanate and isolated the rival empire of Trebizond.

The accession of Michael Palaeologus

John Vatatzes might well have crowned his achievements by taking Constantinople had he not died in 1254. When his son Theodore II Lascaris (1254–58) died in 1258, leaving an infant son, John IV, the regency and then the throne in Nicaea were taken over by Michael VIII Palaeologus (reigned 1259–82). Michael came from one of the aristocratic families of Nicaea whom Theodore II had mistrusted. But it was he who carried the work of the Lascarid emperors to its logical conclusion. The Byzantine state in Epirus had revived under Michael II Ducas, who set his sights on Thessalonica. Despite several efforts to reach a diplomatic settlement, the issue between the rival contenders had finally to be resolved in battle at Pelagonia in Macedonia in 1259. Michael II was supported by William of Villehardouin, the French prince of the Morea, and by Manfred, the Hohenstaufen king of Sicily. The victory went to the army of Nicaea. Two years later a general of that army entered Constantinople. The last of the Latin emperors, Baldwin II, fled to Italy; and the Venetians were dispossessed of their lucrative commercial centre. In August 1261 Michael VIII was crowned as emperor in Constantinople; the boy heir to the throne of Nicaea, John IV Lascaris, was blinded and imprisoned. In this way, the dynasty of Palaeologus, the last to reign in Constantinople, was inaugurated.

THE EMPIRE UNDER THE PALAEOLOGI: 1261–1453

The empire in exile at Nicaea had become a manageable and almost self-sufficient unit, with a thriving economy based on agriculture and, latterly, on trade with the Seljuqs. It had no navy but the land frontiers in Anatolia, policed by well-paid troops, were stronger than they had been since the 12th century. By stretching the frontiers into Europe the empire had not dissipated its strength; for the possession of Thessalonica balanced that of Nicaea. When the seat of government was moved from Nicaea to Constantinople, that balance was upset, the economy was re-oriented, and the defense system in Anatolia began to break down. Constantinople was still the New Jerusalem for the Byzantines. To leave it in foreign hands was unthinkable. But after the dismemberment of the empire by the Fourth Crusade, the city was no longer the focal point of an integrated structure. It was more like an immense city-state in the midst of a number of more or less independent provinces. Much of Greece and the islands remained in French or Italian hands. The Byzantine rulers of Epirus and Thessaly, like the emperors in Trebizond, refused to recognize Michael VIII as emperor. His treatment of the Lascarid heir of Nicaea, for which the patriarch Arsenius excommunicated him, appalled many of his own subjects and provoked what was known as the Arsenite schism in the Byzantine Church. Many in Anatolia, loyal to the memory of the Lascarid emperors who had enriched and protected them, condemned Michael VIII as a usurper.

Michael VIII. The new dynasty was thus founded in an atmosphere of dissension, but its founder was determined that it should succeed. He took measures for the rehabilitation, repopulation, and defense of Constantinople. He stimulated a revival of trade by granting privileges to Italian merchants. The Genoese, who had agreed to lend him ships for the recovery of the city from their Venetian rivals, were especially favoured; and soon they had built their own commercial colony at Galata opposite Constantinople, and cornered most of what had long been a Venetian monopoly. Inevitably, this led to a conflict between Genoa and Venice, of which the Byzantines were the main victims. Some territory was taken back from the Latins, notably in the Morea and the Greek islands. But little was added to the imperial revenue; and Michael VIII's campaigns there and against Epirus and Thessaly ate up the resources that had been accumulated by the emperors at Nicaea.

Threat of reconquest by the West

The dominating influence on Byzantine policy for most of Michael's reign was the threat of reconquest by the Western powers. Charles of Anjou, the brother of the French king Louis IX, displaced Manfred of Sicily and inherited his title in 1266; he then organized a coalition of all parties interested in re-establishing the Latin empire, posing as the pope's champion to lead a crusade against the schismatic Greeks. Michael VIII countered this threat by offering to submit the Church of Constantinople to the see of Rome, thereby inviting the pope's protection

and removing the only moral pretext for a repetition of the Fourth Crusade. The offer to reunite the churches had been made as a diplomatic ploy to previous popes by previous emperors, but never in such compelling circumstances. Pope Gregory X accepted it at its face value, and at the second Council of Lyon in 1274 a Byzantine delegation professed obedience to the Holy See in the name of their emperor. Michael's policy, sincere or not, was violently opposed by most of his people, and he had to persecute and imprison large numbers of them in order to persuade the papacy that the union of the churches was being implemented. Later popes were not convinced by the pretense. In 1281 Charles I (Charles of Anjou) invaded the empire. His army was beaten back in Albania, but he at once prepared a new invasion by sea, supported by Venice, Serbia, Bulgaria, and the separatist rulers of northern Greece. His plans, however, were wrecked in 1282 by a rebellion in Sicily called the Sicilian Vespers and by the intervention of Peter III of Aragon, which the Byzantines encouraged. Michael VIII died at the end of the same year. He had saved his empire from its most persistent enemy, but he died condemned by his church and people as a heretic and a traitor.

Neglect of eastern defenses

Whatever sins he may have committed in the eyes of the Orthodox Church, it is true that Michael VIII, by concentrating on the danger from the West, neglected, if he did not betray, the eastern provinces where he had come to power. Frontier defense troops in Anatolia were withdrawn to Europe or neglected, and bands of Turkish raiders, driven westward by the upheaval of the Mongol invasion, began to penetrate into Byzantine territory. Like the Seljuqs in the 11th century, the new arrivals found little organized opposition. Some of the local Byzantines even collaborated with them out of their own antipathy to the Emperor in Constantinople. By about 1280 the Turks were plundering the fertile valleys of western Anatolia, cutting communications between the Greek cities, and their emirs were beginning to carve out small principalities. Michael VIII's network of diplomacy covered the Mongols of Iran and the Golden Horde in Russia, as well as the Mamlūks of Egypt. But diplomacy was ineffective against Muslim Ghazis (warriors inspired by the ideal of holy war); by the time the threat from Italy was removed in 1282, it was almost too late to save Byzantine Anatolia.

Nor was it possible to raise armies to fight in Europe and Asia simultaneously. The native recruitment fostered by the Comnenian emperors had fallen off since 1261. Estates held in *pronoia* had become hereditary possessions of their landlords, who ignored or were relieved of the obligation to render military service to the government. The knights of the Fourth Crusade had found many familiar elements of feudalism in the social structure of the Byzantine provinces. By the end of the 13th century the development had gone much further. The officers of the Byzantine army were still mostly drawn from the native aristocracy. But the troops were hired, and the cost of maintaining a large army in Europe, added to the lavish subsidies that Michael VIII paid to his friends and allies, crippled the economy.

Andronicus II. Michael's son Andronicus II (reigned 1282–1328) unwisely attempted to economize by cutting down the size of the army and disbanding the navy. Unemployed Byzantine sailors sold their services to the new Turkish emirs, who were already raiding the Aegean islands. The Genoese became the suppliers and defenders of Constantinople by sea, which excited the jealousy of the Venetians to the pitch of war and led to the first of a series of naval battles off Constantinople in 1296. In reaction against his father's policy, Andronicus II pursued a line of almost total isolation from the papacy and the West. The union of Lyon was solemnly repudiated and Orthodoxy restored, to the deep satisfaction of most Byzantines. But there were still divisive conflicts in society. The Arsenite schism in the church was not healed until 1310; the rulers of Epirus and Thessaly remained defiant and kept contact with the successors of Charles I in Italy; and the people of Anatolia aired their grievances in rebellion. As the Turks encroached on their land, refugees in growing numbers fled to the coast or to Constantinople, bringing new problems for the government. In 1302 a band of Turkish warriors defeated the Byzantine army near Nicomedia in northwestern Anatolia. Its leader, Osman I, was the founder of the Osmanli, or Ottoman, people, who were soon to overrun the Byzantine Empire in Europe.

Appearance of Ottoman Turks

In 1303 Andronicus hired a professional army of mercenaries, the Grand Catalan Company. The Catalans made one successful counterattack against the Turks in Anatolia. But they were unruly and unpopular, and when their leader was murdered they turned against their employers. For some years they used the Gallipoli Peninsula as a base from which to ravage Thrace, inviting thousands of Turks to come over and help them. The Catalans finally moved west; in 1311 they conquered Athens from the French and established the Catalan Duchy of Athens and Thebes. The Turks whom they left behind were not ejected from Gallipoli until 1312. The cost of hiring the Catalans, and then of repairing the damage that they had done, had to be met by desperate measures. The face value of the Byzantine gold coin, the *hyperpyron,* was lowered when its gold content was reduced to a mere 50 percent; and the people had to bear still greater burdens of taxation—some payable in kind by farmers. Inflation and rising prices led to near famine in Constantinople, the population of which was swollen by vast numbers of refugees.

Cultural revival. Materially, the empire seemed almost beyond hope of recovery in the early 14th century, but spiritually and culturally it showed a remarkable vitality. The church, no longer troubled over the question of union with Rome, grew in prestige and authority. The patriarchs of Constantinople commanded the respect of all the Orthodox churches, even beyond the imperial boundaries; and Andronicus II, himself a pious theologian, yielded to the patriarch the ancient right of imperial jurisdiction over the monastic settlement on Mt. Athos. There was a new flowering of the Byzantine mystical tradition in a movement known as Hesychasm, whose chief spokesman was Gregory Palamas, a monk from Athos. The theology of the Hesychasts was thought to be heterodox by some theologians, and a controversy arose in the second quarter of the 14th century that had political undertones and was as disruptive to the church and state as the Iconoclastic dispute had been in an earlier age. It was not resolved until 1351.

Mysticism and scholarship

The revival of mystical speculation and the monastic life may have been in part a reaction against the contemporary revival of secular literature and learning. Scholarship of all kinds was patronized by Andronicus II. As in the 11th century, interest was mainly centred on a rediscovery of ancient Greek learning. The scholar Maximus Planudes compiled a famous anthology and translated a number of Latin works into Greek, though knowledge of Latin was rare and most of the Byzantine scholars prided themselves on having in their Hellenic heritage an exclusive possession that set them apart from the Latins. A notable exception was Demetrius Cydones who, like Michael Psellus, managed affairs of state for a number of emperors for close to 50 years. Cydones translated the works of Thomas Aquinas into Greek; he was the forerunner of a minority of Byzantine intellectuals who joined the Roman Church and looked to the West to save their empire from ruin. More typical of his class was Theodore Metochites, the Grand Logothete, or chancellor, of Andronicus II, whose encyclopaedic learning rivaled that of Psellus. His pupil Nicephorus Gregoras, in addition to his researches in philosophy, theology, mathematics, and astronomy, wrote a history of his age. The tradition of Byzantine historiography, maintained by George Acropolites, the historian of the Empire of Nicaea, was continued in the 14th century by George Pachymeres, by Gregoras, and finally by the emperor John VI Cantacuzenus, who wrote his memoirs after his abdication in 1354.

Andronicus III and John Cantacuzenus. The histories they wrote tell more of politics and personalities than of the underlying social and economic tensions in their society that were to find expression in a series of civil wars. Trouble broke out in 1320 when Andronicus II, purely for family reasons, disinherited his grandson Andronicus III. The cause of the young emperor was taken up by his friends, and there was periodic warfare from 1321 to 1328, when the older Andronicus had to yield the throne. It was in some ways a victory for the younger generation of the aristocracy, of whom the leading light was John Cantacuzenus. It was he who guided the empire's policies during the reign of Andronicus III (1328–41). They were men of greater drive and determination, but the years of fighting had made recovery still more difficult and had given new chances to their enemies. In 1329 they fought and lost a battle at Pelekanon (near Nicomedia) against Osman's son, Orhan, whose Turkish warriors went on to capture Nicaea in 1331 and Nicomedia in 1337. Northwestern Anatolia, once the heart of the empire, was now lost. There seemed no alternative but to accept the fact and to come to terms with the Ottomans and the other Turkish emirs. By so doing, Andronicus III and Cantacuzenus were able to call on the services of almost limitless numbers of Turkish soldiers to fight for them against their other enemies: the Italians in the Aegean islands and the Serbs and the Bulgars in Macedonia and Thrace.

The power of Serbia, which Andronicus II had managed to control by diplomatic means, grew alarmingly after the accession of Stefan Dušan to the Serbian throne in 1331. Dušan exploited to the full the numerous embarrassments of the Byzantines and in 1346 announced his ambitions by having himself crowned as emperor of the Serbs and Greeks. The greatest practical achievement of Andronicus III was the restoration to Byzantine rule of the long-separated provinces of Epirus and Thessaly. But only a few years later, in 1348, the whole of northern Greece was swallowed up in the Serbian Empire of Stefan Dušan.

Outbreak of civil war

When Andronicus III died in 1341, civil war broke out for a second time. The contestants on that occasion were John Cantacuzenus, who had expected to act as regent for the boy-heir John V, and his political rivals led by his former partisan Alexius Apocaucus, the patriarch John Calecas, and the empress mother Anne of Savoy, who held power in Constantinople. Cantacuzenus, befriended and then rejected by Dušan of Serbia, was crowned as Emperor John VI in Thrace in 1346; and, with the help of Turkish troops, he fought his way to victory in the following year. Like Romanus Lecapenus, he protested that he was no more than the protector of the legitimate heir to the throne, John V Palaeologus. His brief reign, from 1347 to 1354, might have turned the tide of Byzantine misfortunes had not the second civil war provoked unprecedented social and political consequences. In the cities of Thrace and Macedonia the people vented their dissatisfaction with the ruling aristocracy by revolution. It was directed mainly against Cantacuzenus and the class that he represented. The movement was most memorable and lasting in Thessalonica, where a faction known as the Zealots seized power in a coup d'état and governed the city as an almost independent commune until 1350.

The second civil war was consequently even more destructive of property and ruinous to the economy than the first. At the same time, in 1347, the Black Death decimated the population of Constantinople and other parts of the empire. John VI Cantacuzenus, nevertheless, did what he could to restore the economy and stability of the empire. To coordinate the scattered fragments of its territory he assigned them as appanages to individual members of the imperial family. His son Manuel took over the province of the Morea in 1349 with the rank of despot and governed it with growing success until his death in 1380; his eldest son, Matthew, was given a principality in Thrace; while the junior emperor John V, who had married a daughter of Cantacuzenus, ruled in Thessalonica after 1351.

Cantacuzenus also tried but failed to weaken the economic stranglehold of the Genoese by rebuilding a Byzantine war fleet and merchant navy. The effort involved him in warfare, first on his own and then as an unwilling partner of the Venetians against the Genoese, from which Byzantium emerged as the loser. The revenue of the Genoese colony at Galata, derived from custom dues, was now far greater than that of Constantinople. The empire's poverty was reflected in dilapidated buildings and falling standards of luxury. The crown jewels had been pawned to Venice during the civil war, and the Byzantine gold coin, hopelessly devalued, had given place in international trade to the Venetian ducat. More and more, Byzantium was at the mercy of its foreign competitors and enemies, who promoted and exploited the political and family rivalries among the ruling class. John Cantacuzenus was never popular as an emperor, and feeling against him came to a head when some of his Ottoman mercenaries took the occasion of the destruction of Gallipoli by earthquake to occupy and fortify the city in March 1354. It was their first permanent establishment in Europe, at the key point of the crossing from Asia. In November of the same year John V

The Byzantine Empire in 1355.

Turkish occupation of Gallipoli

Palaeologus, encouraged by the Anti-Cantacuzenist Party, forced his way into Constantinople. In December Cantacuzenus abdicated and became a monk. Though his son Matthew, who had by then been crowned as coemperor, fought on for a few years, the dynasty of Cantacuzenus was not perpetuated.

Turkish expansion. John Cantacuzenus' relationship with the Turks had been based on personal friendship with their leaders, among them Orhan, to whom he gave his daughter in marriage. But once the Turks had set up a base on European soil and had seen the possibilities of further conquest, such relationships were no longer practicable. Stefan Dušan, who very nearly realized his ambition to found a new Serbo-Byzantine empire, was the only man who might have prevented the subsequent rapid expansion of the Turks into the Balkans, but he died in 1355 and his empire split up. The new emperor, John V, hoped that the Western world would sense the danger, and in 1355 he addressed an appeal for help to the Pope. The popes were concerned for the fate of the Christian East but guarded in their offers to Constantinople so long as the Byzantine Church remained in schism from Rome. In 1366 John V visited Hungary to beg for help, but in vain. In the same year his cousin Amadeo, count of Savoy, brought a small force to Constantinople and recaptured Gallipoli from the Turks, who had by then advanced far into Thrace. Amadeo persuaded the Emperor to go to Rome and make his personal submission to the Holy See in 1369. On his way home, John was detained at Venice as an insolvent debtor; during his absence the Turks scored their first victory over the successors of Stefan Dušan on the Marica River near Adrianople in 1371. The whole of Macedonia was open to them. The remaining Serbian princes and the ruler of Bulgaria became their vassals, and in 1373 the Emperor was forced to do the same.

Byzantium became a vassal state of the Turks, pledged to pay tribute and to provide military assistance to the Ottoman sultan. The possession of Constantinople thereafter was disputed by the Emperor's sons and grandsons in a series of revolutions, which were encouraged and sometimes instigated by the Turks, the Genoese, or the Venetians. John V's son Andronicus IV, aided by the Genoese and the sultan Murad I, mastered the city for three years (1376–79). He rewarded the Turks by giving back Gallipoli to them, and Murad made his first European capital at Adrianople. The Venetians helped John V to regain his throne in 1379, and the empire was once again divided into appanages under his sons. Only his second son, Manuel, showed any independence of action. For nearly five years, from 1382 to 1387, Manuel reigned as emperor at Thessalonica and laboured to make it a rallying point for resistance against the encroaching Turks. But the city fell to Murad's army in April 1387. When the Turks then drove deeper into Macedonia, the Serbs again organized a counteroffensive but were overwhelmed at Kossovo in 1389.

Manuel II and respite from the Turks. The loss of Thessalonica and the Battle of Kossovo sealed off Constantinople by land. The new sultan Bayezid I (1389–1402) intended to make it his capital; when Manuel II came to that throne at his father's death in 1391, the Sultan warned him that he was emperor only inside the city walls. The Turks already controlled the rest of Byzantine Europe, except for the south of Greece.

In 1393 Bayezid completed his conquest of Bulgaria, and soon afterward he laid siege to Constantinople. The blockade was to last for many years. Manuel II, like his father, pinned his hopes of rescue on the West. A great crusade against the Turks was organized by the King of Hungary, but it was defeated at Nicopolis on the Danube in 1396. In 1399 the French marshal Boucicaut, who had been at Nicopolis and had returned to the relief of Constantinople with a small army, persuaded Manuel to travel to western Europe to put the Byzantine case in person. From the end of 1399 to June 1403 the Emperor visited in Italy, France, and England, leaving his nephew John VII in charge of Constantinople. Manuel's journey did something to stimulate Western interest in Greek learning. His friend and ambassador in the West, Manuel Chrysoloras, a pupil of Demetrius Cydones, was appointed to teach Greek at Florence. The Pope instituted a defense fund for Constantinople. Interest and sympathy were forthcoming but little in the way of practical help. During Manuel's absence, however, the Ottomans were defeated at Ankara by the Mongol leader Timur (Tamerlane) in July 1402. Bayezid was captured and his empire in Asia was shattered. His four sons contended with each other to secure possession of the European provinces, which had been little affected by the Mongol invasion, and to reunite the Ottoman dominions. In these wholly unexpected circumstances the Byzantines found themselves the favoured allies first of one Turkish contender, then of another. The blockade of Constantinople was lifted. Thessalonica—with Mt. Athos and other places—was restored to Byzantine rule, and the payment of tribute to the sultan was annulled. In 1413 Mehmed I, helped and promoted by the emperor Manuel, triumphed over his rivals and became sultan of the reintegrated Ottoman Empire.

Appeals of Manuel II in western Europe

During his reign, from 1413 to 1421, the Byzantines enjoyed their last respite. Manuel II, aware that it could not last, made the most of it by strengthening the defenses and administration of the fragments of his empire. The most flourishing province in the last years was the Despotate of Morea. Its prosperity had been built up first by the sons of John Cantacuzenus (who died there in 1383) and then by the son and grandson of John V—Theodore I and Theodore II Palaeologus. Its capital city of Mistra became a haven for Byzantine scholars and artists and a centre of the last revival of Byzantine culture, packed with churches, monasteries, and palaces. Among its scholars was George Gemistus Plethon, a Platonist who dreamed of a rebirth of Hellenism on Hellenic soil.

Final Turkish assault. When Murad II became sultan, in 1421, the days of Constantinople and of Hellenism were numbered. In 1422 Murad revoked all the privileges accorded to the Byzantines by his father and laid siege to Constantinople. His armies invaded Greece and blockaded Thessalonica. The city was then a possession of Manuel II's son Andronicus, who in 1423 handed it over to the Venetians. For seven years Thessalonica was a Venetian colony, until, in March 1430, the Sultan assaulted and captured it. Meanwhile, Manuel II had died in 1425, leaving his son John VIII as emperor. John, who had already traveled to Venice and Hungary in search of help, was prepared to reopen negotiations for the union of the churches as a means of stirring the conscience of Western Christendom. His father had been skeptical about the benefits of such a policy, knowing that it would antagonize most of his own people and arouse the suspicion of the Turks. The proposal was made, however, at the Council of Florence in 1439, attended by the emperor John VIII, his patriarch, and many Orthodox bishops and dignitaries. After protracted and difficult discussions, they agreed to submit to the authority of Rome. The union of Florence was badly received by the citizens of Constantinople and by most of the Orthodox world. But it had its notable adherents, such as the bishops Bessarion of Nicaea and Isidore of Kiev, both of whom retired to Italy as cardinals of the Roman Church. Bessarion's learning and library helped to encourage further Western interest in Greek scholarship. The union of Florence also helped to stimulate a crusade against the Turks. Once again it was led by the king of Hungary, Władysław III of Poland, supported by George Branković of Serbia and by János Hunyadi of Transylvania. But there were disagreements among its leaders, and the Christian army was annihilated at Varna in 1444.

Fall of Thessalonica

The Byzantine collapse and the Ottoman triumph followed swiftly thereafter. In 1448 Constantine XI (or XII), the last emperor, left Mistra for Constantinople when his brother John VIII died without issue. His two other brothers, Thomas and Demetrius, continued to govern the Morea, the last surviving Byzantine province. In 1449 Mehmed II (sultan 1444–46 and 1451–81) began to prepare for the final assault on Constantinople. No further substantial help came from the West, and the formal celebration of the union of the churches in Hagia Sophia in 1452 was greeted with a storm of protest. Even in their extremity, the Byzantines would not buy their freedom at the expense of their Orthodox faith. They found the prospect of being ruled by the Turks less odious than that of being indebted to the Latins. When the crisis came, however, the Venetians in Constantinople, and a Genoese contingent commanded by Giovanni Giustiniani, wholeheartedly cooperated in the defense of the city. Mehmed II laid siege to the walls in April 1453. His ships were obstructed by a chain that the Byzantines had thrown across the mouth of the Golden Horn. The ships were therefore dragged overland to the harbour from the seaward side, bypassing the defenses. The Sultan's heavy artillery continually bombarded the land walls until, on May 29, some of his soldiers forced their way in. Giustiniani was mortally wounded. The emperor Constantine was last seen fighting on foot at one of the gates.

The Sultan allowed his victorious troops three days and nights of plunder before he took possession of his new capital. The Ottoman Empire had now superseded the Byzantine Empire; and some Greeks, like the contemporary historian Critobulus of Imbros, recognized the logic of the change by bestowing on the Sultan all the attributes of the emperor. The material structure of the empire, which had long been crumbling, was now under the management of the sultan-basileus. But the Orthodox faith was less susceptible to change. The Sultan acknowledged the fact that the church had proved to be the most enduring element in the Byzantine world, and he gave the Patriarch of Constantinople an unprecedented measure of temporal authority by making him answerable for all Christians living under Ottoman rule.

The last scattered pockets of Byzantine resistance were eliminated within a decade after 1453. Athens fell to the Turks in 1456–58, and in 1460 the two despots of Morea surrendered. Thomas fled to Italy, Demetrius to the Sultan's court. In 1461 Trebizond, capital of the last remnant of Greek empire, which had maintained its precarious independence by paying court to Turks and Mongols alike, finally succumbed; the transformation of the Byzantine world into the Ottoman world was at last complete.

BIBLIOGRAPHY. The following surveys and analyses provide brief introductions to Byzantine history and civilization: NORMAN H. BAYNES and H. ST. L.B. MOSS (eds.), *Byzantium: An Introduction to East Roman Civilization* (1948, reissued 1969); J.M. HUSSEY, *The Byzantine World,* 4th ed. (1970); and PHILIP WHITTING (ed.), *Byzantium: An Introduction,* 2nd rev. ed. (1981). Deeper study of Byzantine history should begin with GEORGE OSTROGORSKY, *History of the Byzantine State,* 2nd ed. (1968, reissued 1969; originally published in German, 3rd ed., 1963); and *The Cambridge Medieval History:* vol. 4, *The Byzantine Empire,* 2nd ed. (1966–67), which contains extensive bibliographies. Various aspects of Byzantine history and civilization are discussed in NORMAN H. BAYNES, *Byzantine Studies and Other Essays* (1955, reprinted 1974); ROBERT BROWNING, *The Byzantine Empire* (1980); FRANZ DÖLGER, *Byzanz und die europäische Staatenwelt* (1953, reprinted 1976); H.W. HAUSSIG, *A History of Byzantine Civilization* (1971; originally published in German, 1959); ALEXANDER KAZHDAN and GILES CONSTABLE, *People and Power in Byzantium: An Introduction to Modern Byzantine Studies* (1982); CYRIL MANGO, *Byzantium, the Empire of New Rome* (1980); and STEVEN RUNCIMAN, *Byzantine Civilisation* (1933, reissued 1970), and *The Byzantine Theocracy* (1977). A.A. VASILIEV, *History of the Byzantine Empire, 324–1453,* 2nd ed. rev. (1952, reprinted 1971; originally published in Russian in different eds., 1917–25), is now somewhat out-of-date. The geography of the Byzantine Empire is treated in ALFRED PHILIPPSON, *Das byzantinische Reich als geographische Erscheinung* (1939); and its church and theology in HANS-GEORG BECK, *Kirche und theologische Literatur im byzantinischen Reich,* 2nd ed. (1977); and in JOHN MEYENDORFF, *Byzantine Theology* (1974, reprinted 1983). Current research is contained in periodicals: *Byzantinische Zeitschrift* (semiannual), published in Munich; *Byzantion* (semiannual), published in Brussels; *Byzantinoslavica* (semiannual), published in Prague; *Dumbarton Oaks Papers* (annual), published in Washington, D.C.; *Jahrbuch der österreichischen Byzantinistik* (annual), published in Vienna; *Revue des Études Byzantines* (annual), published in Paris; *Travaux et Mémoires* (irregular), published in Paris by the Centre de Recherche d'Histoire et Civilisation Byzantines; and *Византийский Временник* (annual), published in Moscow and Leningrad.

The Roman and Christian background: The first two chapters in *The Cambridge Medieval History,* vol. 4, part 1, introduce the reader to the problems discussed in this section: H. ST. L.B. MOSS, "The Formation of the East Roman Empire, 330–717," pp. 1–41; and G. MATHEW, "The Christian Background," pp. 42–60. Further reading might include A.H.M. JONES, *The Later Roman Empire, 284–602: A Social, Economic, and Administrative Survey,* 3 vol. (1964, reprinted in 2 vol., 1973); NORMAN H. BAYNES, *Constantine the Great and the Christian Church* (1930, reprinted 1975); GILBERT DAGRON, *Naissance d'une capitale: Constantinople et ses institutions de 330 à 451* (1974); and the survey by PETER BROWN, *The World of Late Antiquity, AD 150–750* (1971; U.K. title, *The World of Late Antiquity: From Marcus Aurelius to Muhammad*).

The 5th and 6th centuries: J.B. BURY, *History of the Later Roman Empire from the Death of Theodosius I. to the Death of Justinian (A.D. 395 to A.D. 565),* 2nd ed., 2 vol. (1923, reprinted 1963); and ERNEST STEIN, *Histoire du Bas-Empire,* 2 vol., ed. by JEAN-REMY PALANQUE (1949–59; vol. 1 originally published in German, 1928), give extensive and well-documented coverage of the whole period. Other works on Justinian and his age are: BERTHOLD RUBIN, *Das Zeitalter Iustinians,* vol. 1 (1960); JOHN W. BARKER, *Justinian and the Later Roman Empire* (1966, reprinted 1977); and ROBERT BROWNING, *Justinian and Theodora* (1971). The role of the demes and factions is analyzed by ALAN CAMERON, *Circus Factions: Blues and Greens at Rome and Byzantium* (1976).

The 7th century and the Heraclian reforms: A readable survey of this and the following three centuries is ROMILLY JENKINS, *Byzantium: The Imperial Centuries, A. D. 610–1071* (1966, reissued 1969). A general overview of the 7th century is found in the essays collected in *Dumbarton Oaks Papers,* vol. 13 (1959, reprinted 1967). On the foundation of the themes and on agrarian problems, see JOHANNES KARAYANNOPULOS, *Die Entstehung der byzantinischen Themenordnung* (1959); and PAUL LEMERLE, *The Agrarian History of Byzantium from the Origins to the Twelfth Century,* translated from the French (1979). Byzantium's relations with Eastern Europe are discussed in DIMITRI OBOLENSKY, "The Empire and Its Northern Neighbours, 565–1018," *The Cambridge Medieval History,* vol. 4, part 1, pp. 473–518, and in his *Byzantine Commonwealth* (1971, reissued 1982). A good history of Iconoclasm is EDWARD JAMES MARTIN, *A History of the Iconoclastic Controversy* (1930, reprinted 1978); and various aspects of the matter are treated in ANTHONY BRYER and JUDITH HERRIN (eds.), *Iconoclasm* (1977).

The 9th century: The standard survey remains J.B. BURY, *A History of the Eastern Roman Empire from the Fall of Irene to the Accession of Basil I, A.D. 802–867* (1912, reprinted 1965). Of particular importance are the works of F. DVORNIK: *Les Légendes de Constantin et de Méthode vues de Byzance,* 2nd ed. (1969), *Les Slaves, Byzance et Rome au IX^{e} siècle* (1926, reprinted 1970), *The Photian Schism: History and Legend* (1948, reprinted 1970), and *Byzantine Missions Among the Slavs* (1970). See also H. GRÉGOIRE, "The Amorians and Macedonians, 842–1025," *The Cambridge Medieval History,* vol. 4, pp. 105–192. Relations between Byzantium and the Arabs are discussed in A.A. VASILIEV, *Византия и арабы:* vol. 1, *Политические отношения Византии и арабов за время Аморийской династии* (1900), available also in French translation.

The Macedonian dynasty (867–1025): ROBERT BROWNING, *Byzantium and Bulgaria* (1975); J.B. BURY, *The Imperial Administrative System in the Ninth Century* (1911, reprinted 1958); J.M. HUSSEY, *Church and Learning in the Byzantine Empire, 867–1185* (1937, reprinted 1963); STEVEN RUNCIMAN, *A History of the First Bulgarian Empire* (1930), *The Eastern Schism* (1955, reprinted 1983), and *The Emperor Romanus Lecapenus and His Reign* (1929, reprinted 1969); GUSTAVE SCHLUMBERGER, *L'Epopée byzantine à la fin du X^{e} siècle,* 3 vol. (1896–1905, reprinted 1969); A.A. VASILIEV, *Византия и арабы:* vol. 2, *Политические отношения Византии и арабов за время Македонской династии* (1902), available also in French translation; ALBERT VOGT, *Basile I^{er}, empereur de Byzance (867–886) et la civilisation byzantine à la fin du IX^{e} siècle* (1908, reprinted 1973); and ARNOLD TOYNBEE, *Constantine Porphyrogenitus and His World* (1973).

Byzantine decline and renewal (1025–1180): MICHAEL ANGOLD, *The Byzantine Empire 1025–1204* (1984); FERDINAND CHALANDON, *Essai sur le règne d'Alexis I^{er} Comnène (1081–1118)* (1900, reissued 1971), and *Jean II Comnène, 1118–1143, et Manuel I Comnène, 1143–1180* (1912, reissued 1971); and DEMETRIOS I. Caesar

A Roman general, dictator, and statesman, Gaius Julius Caesar changed the course of the history of the Greco-Roman world decisively and irreversibly. The Greco-Roman society has been extinct for so long that most of the names of its great men mean little to the average, educated modern man. But Caesar's name, like Alexander's, is still on people's lips throughout the Christian and Islāmic worlds. Even people who know nothing of Caesar as a historic personality are familiar with his family name as a title signifying a ruler who is in some sense uniquely supreme or paramount—the meaning of *Kaiser* in German, *tsar* in the Slavonic languages, and *qayṣar* in the languages of the Islāmic world.

Caesar's gens (clan) name, Julius (Iulius), is also familiar in the Christian world; for in Caesar's lifetime the Roman month Quintilis, in which he was born, was renamed "July" in his honour. This name has survived, as has Caesar's reform of the calendar. The old Roman calendar was inaccurate and manipulated for political purposes. Caesar's calendar, the Julian calendar, is still partially in force in the Eastern Orthodox Christian countries; and the Gregorian calendar, now in use in the West, is the Julian, slightly corrected by Pope Gregory XIII.

Caesar, marble bust. In the Capitoline Museum, Rome.

FAMILY BACKGROUND AND CAREER

Caesar's gens, the Julii, were patricians; *i.e.,* members of Rome's original aristocracy, which had coalesced in the 4th century BC with a number of leading plebeian (commoner) families to form the nobility that had been the governing class in Rome since then. By Caesar's time, the number of surviving patrician gentes was small; and in the gens Julia the Caesares seem to have been the only surviving family. Though some of the most powerful noble families were patrician, patrician blood was no longer a political advantage; it was actually a handicap, since a patrician was debarred from holding the paraconstitutional but powerful office of tribune of the plebs. The Julii Caesares traced their lineage back to the goddess Venus, but the family was not snobbish or conservative-minded. It was also not rich or influential or even distinguished.

A Roman noble won distinction for himself and his family by securing election to a series of public offices, which culminated in the consulship, with the censorship possibly to follow. This was a difficult task for even the ablest and most gifted noble unless he was backed by substantial family wealth and influence. Rome's victory over Carthage in the Second Punic War (218–201 BC) had made Rome the paramount power in the Mediterranean basin; an influential Roman noble family's clients (that is, protégés who, in return, gave their patrons their political support) might include kings and even whole nations, besides numerous private individuals. The requirements and the costs of a Roman political career in Caesar's day were high, and the competition was severe; but the potential profits were of enormous magnitude. One of the perquisites of the praetorship and the consulship was the government of a province, which gave ample opportunity for plunder. The whole Mediterranean world was, in fact, at the mercy of the Roman nobility and of a new class of Roman businessmen, the equites ("knights"), which had grown rich on military contracts and on tax farming.

Military manpower was supplied by the Roman peasantry. This class had been partly dispossessed by an economic revolution following on the devastation caused by the Second Punic War. The Roman governing class had consequently come to be hated and discredited at home and abroad. From 133 onward there had been a series of alternate revolutionary and counter-revolutionary paroxysms. It was evident that the misgovernment of the Roman state and the Greco-Roman world by the Roman nobility could not continue indefinitely and it was fairly clear that the most probable alternative was some form of military dictatorship backed by dispossessed Italian peasants who had turned to long-term military service.

The Julii Caesares

The traditional competition among members of the Roman nobility for office and the spoils of office was thus threatening to turn into a desperate race for seizing autocratic power. The Julii Caesares did not seem to be in the running. It was true that Sextus Caesar, who was perhaps the dictator's uncle, had been one of the consuls for 91; and Lucius Caesar, one of the consuls for 90, was a distant cousin, whose son and namesake was consul for 64. In 90, Rome's Italian allies had seceded from Rome because of the Roman government's obstinate refusal to grant them Roman citizenship, and, as consul, Lucius Caesar had introduced emergency legislation for granting citizenship to the citizens of all Italian ally states that had not taken up arms or that had returned to their allegiance.

Whoever had been consul in this critical year would have had to initiate such legislation, whatever his personal political predilections. There is evidence, however, that the Julii Caesares, though patricians, had already committed themselves to the antinobility party. An aunt of the future dictator had married Gaius Marius, a self-made man (*novus homo*) who had forced his way up to the summit by his military ability and had made the momentous innovation of recruiting his armies from the dispossessed peasants.

The date of Caesar the dictator's birth has long been disputed. The day was July 12 or 13; the traditional (and perhaps most probable) year is 100; but if this date is correct, Caesar must have held each of his offices two years in advance of the legal minimum age. His father, Gaius Caesar, died when Caesar was but 16; his mother, Aurelia, was a notable woman, and it seems certain that he owed much to her.

In spite of the inadequacy of his resources, Caesar seems to have chosen a political career as a matter of course. From the beginning, he probably privately aimed at winning office, not just for the sake of the honours but in order to achieve the power to put the misgoverned Roman state and Greco-Roman world into better order in accordance with ideas of his own. It is improbable that Caesar deliberately sought monarchical power until after he had crossed the Rubicon in 49, though sufficient power to impose his will, as he was determined to do, proved to mean monarchical power.

In 84 Caesar committed himself publicly to the radical side by marrying Cornelia, a daughter of Lucius Cornelius

Sulla

Cinna, a noble who was Marius' associate in revolution. In 83 Lucius Cornelius Sulla returned to Italy from the East and led the successful counter-revolution of 83–82; Sulla then ordered Caesar to divorce Cornelia. Caesar refused and came close to losing not only his property (such as it was) but his life as well. He found it advisable to remove himself from Italy and to do military service, first in the province of Asia and then in Cilicia.

In 78, after Sulla's death, he returned to Rome and started on his political career in the conventional way, by acting as a prosecuting advocate—of course, in his case, against prominent Sullan counter-revolutionaries. His first target, Gnaeus Cornelius Dolabella, was defended by Quintus Hortensius, the leading advocate of the day, and was acquitted by the extortion-court jury, composed exclusively of senators.

Caesar then went to Rhodes to study oratory under a famous professor, Molon. En route he was captured by pirates (one of the symptoms of the anarchy into which the Roman nobility had allowed the Mediterranean world to fall). Caesar raised his ransom, raised a naval force, captured his captors, and had them crucified—all this as a private individual holding no public office. In 74, when Mithradates VI Eupator, king of Pontus, renewed war on the Romans, Caesar raised a private army to combat him.

In his absence from Rome, Caesar was made a member of the politico-ecclesiastical college of pontifices; and on his return he gained one of the elective military tribuneships. Caesar now worked to undo the Sullan constitution in cooperation with Pompey (Gnaeus Pompeius), who had started his career as a lieutenant of Sulla but had changed sides since Sulla's death. In 69 or 68 Caesar was elected quaestor (the first rung on the Roman political ladder). In the same year his wife, Cornelia, and his aunt Julia, Marius' widow, died; in public funeral orations in their honour, Caesar found opportunities for praising Cinna and Marius. Caesar afterward married Pompeia, a distant relative of Pompey. Caesar served his quaestorship in the province of Farther Spain (modern Andalusia and Portugal).

Caesar as political figure

Caesar was elected one of the curule aediles for 65, and he celebrated his tenure of this office by unusually lavish expenditure with borrowed money. He was elected pontifex maximus in 63 by a political dodge. By now he had become a controversial political figure. After the suppression of Catiline's conspiracy in 63, Caesar, as well as the millionaire Marcus Licinius Crassus, was accused of complicity. It seems unlikely that either of them had committed himself to Catiline; but Caesar proposed in the Senate a more merciful alternative to the death penalty, which the consul Cicero was asking for the arrested conspirators. In the uproar in the Senate, Caesar's motion was defeated.

Caesar was elected a praetor for 62. Toward the end of the year of his praetorship, a scandal was caused by Publius Clodius in Caesar's house at the celebration there of the rites, for women only, of Bona Dea (a Roman deity of fruitfulness, both in the Earth and in women). Caesar consequently divorced Pompeia. He obtained the governorship of Farther Spain for 61–60. His creditors did not let him leave Rome until Crassus had gone bail for a quarter of his debts; but a military expedition beyond the northwest frontier of his province enabled Caesar to win loot for himself as well as for his soldiers, with a balance left over for the treasury. This partial financial recovery enabled him, after his return to Rome in 60, to stand for the consulship for 59.

The first triumvirate and the conquest of Gaul. The value of the consulship lay in the lucrative provincial governorship to which it would normally lead. On the eve of the consular elections for 59, the Senate sought to allot to the two future consuls for 59, as their proconsular provinces, the unprofitable supervision of forests and cattle trails in Italy. The Senate also secured by massive bribery the election of an anti-Caesarean, Marcus Calpurnius Bibulus. But they failed to prevent Caesar's election as the other consul.

Caesar now succeeded in organizing an irresistible coalition of political bosses. Pompey had carried out his mission to put the East in order with notable success, but after his return to Italy and his disbandment of his army in 62, the Senate had thwarted him—particularly by preventing him from securing land allotments for his veterans. Caesar, who had assiduously cultivated Pompey's friendship, now entered into a secret pact with him. Caesar's master stroke was to persuade Crassus to join the partnership, the so-called first triumvirate. Crassus—like Pompey, a former lieutenant of Sulla—had been one of the most active of Pompey's obstructors so far. Only Caesar, on good terms with both, was in a position to reconcile them. Early in 59, Pompey sealed his alliance with Caesar by marrying Caesar's only child, Julia. Caesar married Calpurnia, daughter of Lucius Piso, who became consul in 58.

As consul, Caesar introduced a bill for the allotment of Roman public lands in Italy, on which the first charge was to be a provision for Pompey's soldiers. The bill was vetoed by three tribunes of the plebs, and Caesar's colleague Bibulus announced his intention of preventing the transaction of public business by watching the skies for portents whenever the public assembly was convened. Caesar then cowed the opposition by employing some of Pompey's veterans to make a riot, and the distribution was carried out. Pompey's settlement of the East was ratified *en bloc* by an act negotiated by an agent of Caesar, the tribune of the plebs Publius Vatinius. Caesar himself initiated a noncontroversial and much-needed act for punishing misconduct by governors of provinces.

Another act negotiated by Vatinius gave Caesar Cisalpine Gaul (between the Alps, the Apennines, and the Adriatic) and Illyricum. His tenure was to last until February 28, 54. When the governor-designate of Transalpine Gaul suddenly died, this province, also, was assigned to Caesar at Pompey's instance. Cisalpine Gaul gave Caesar a military recruiting ground; Transalpine Gaul gave him a springboard for conquests beyond Rome's northwest frontier.

Caesar's Roman strategy

Between 58 and 50, Caesar conquered the rest of Gaul up to the left bank of the Rhine and subjugated it so effectively that it remained passive under Roman rule throughout the Roman civil wars between 49 and 31. This achievement was all the more amazing in light of the fact that the Romans did not possess any great superiority in military equipment over the north European barbarians. Indeed, the Gallic cavalry was probably superior to the Roman, horseman for horseman. Rome's military superiority lay in its mastery of strategy, tactics, discipline, and military engineering. In Gaul, Rome also had the advantage of being able to deal separately with dozens of relatively small, independent, and uncooperative states. Caesar conquered these piecemeal, and the concerted attempt made by a number of them in 52 to shake off the Roman yoke came too late.

Great though this achievement was, its relative importance in Caesar's career and in Roman history has been overestimated in Western tradition (as have his brief raids on Britain). In Caesar's mind his conquest of Gaul was probably carried out only as a means to his ultimate end. He was acquiring the military manpower, the plunder, and the prestige that he needed to secure a free hand for the prosecution of the task of reorganizing the Roman state and the rest of the Greco-Roman world. This final achievement of Caesar's looms much larger than his conquest of Gaul, when it is viewed in the wider setting of world history and not just in the narrower setting of the Greco-Roman civilization's present daughter civilization in the West.

In 58 Rome's northwestern frontier, established in 125, ran from the Alps down the left bank of the upper Rhône River to the Pyrenees, skirting the southeastern foot of the Cévennes and including the upper basin of the Garonne River without reaching the Gallic shore of the Atlantic. In 58 Caesar intervened beyond this line, first to drive back the Helvetii, who had been migrating westward from their home in what is now central Switzerland. He then crushed Ariovistus, a German soldier of fortune from beyond the Rhine. In 57 Caesar subdued the distant and warlike Belgic group of Gallic peoples in the north, while his lieutenant Publius Licinius Crassus subdued what are now the regions of Normandy and Brittany.

In 56 the Veneti, in what is now southern Brittany, started a revolt in the northwest that was supported by the still unconquered Morini on the Gallic coast of the Straits of Dover and the Menapii along the south bank of the lower Rhine. Caesar reconquered the Veneti with some difficulty and treated them barbarously. He could not finish off the conquest of the Morini and Menapii before the end of the campaigning season of 56; and in the winter of 56–55 the Menapii were temporarily expelled from their home by two immigrant German peoples, the Usipetes and Tencteri. These peoples were exterminated by Caesar in 55. In the same year he bridged the Rhine just below Koblenz to raid Germany on the other side of the river, and then crossed the Channel to raid Britain. In 54 he raided Britain again and subdued a serious revolt in northeastern Gaul. In 53 he subdued further revolts in Gaul and bridged the Rhine again for a second raid.

Vercingetorix

The crisis of Caesar's Gallic war came in 52. The peoples of central Gaul found a national leader in the Arvernian Vercingetorix. They planned to cut off the Roman forces from Caesar, who had been wintering on the other side of the Alps. They even attempted to invade the western end of the old Roman province of Gallia Transalpina. Vercingetorix wanted to avoid pitched battles and sieges and to defeat the Romans by cutting off their supplies—partly by cavalry operations and partly by "scorched earth"—but he could not persuade his countrymen to adopt this painful policy wholeheartedly.

The Bituriges insisted on standing siege in their town Avaricum (Bourges), and Vercingetorix was unable to save it from being taken by storm within one month. Caesar then besieged Vercingetorix in Gergovia near modern Clermont-Ferrand. A Roman attempt to storm Gergovia was repulsed and resulted in heavy Roman losses—the first outright defeat that Caesar had suffered in Gaul. Caesar then defeated an attack on the Roman army on the march and was thus able to besiege Vercingetorix in Alesia, to the northwest of Dijon. Alesia, like Gergovia, was a position of great natural strength, and a large Gallic army came to relieve it; but this army was repulsed and dispersed by Caesar, and Vercingetorix then capitulated.

During the winter of 52–51 and the campaigning season of 51, Caesar crushed a number of sporadic further revolts. The most determined of these rebels were the Bellovaci, between the Rivers Seine and Somme, around Beauvais. Another rebel force stood siege in the south in the natural fortress of Uxellodunum (perhaps the Puy d'Issolu on the Dordogne) until its water supply gave out. Caesar had the survivors' hands cut off. He spent the year 50 in organizing the newly conquered territory. After that, he was ready to settle his accounts with his opponents at home.

Antecedents and outcome of the civil war of 49–45. During his conquest of Gaul, Caesar had been equally busy in preserving and improving his position at home. He used part of his growing wealth from Gallic loot to hire political agents in Rome.

Dissolution of the triumvirate

Meanwhile the cohesion of the triumvirate had been placed under strain. Pompey had soon become restive toward his alarmingly successful ally Caesar, as had Crassus toward his old enemy Pompey. The alliance was patched up in April 56 at a conference at Luca (Lucca), just inside Caesar's province of Cisalpine Gaul. It was arranged that Pompey and Crassus were to be the consuls for 55 and were to get laws promulgated prolonging Caesar's provincial commands for another five years and giving Crassus a five-year term in Syria and Pompey a five-year term in Spain. These laws were duly passed. Crassus was then eliminated by an annihilating defeat at the Parthians' hands in 53. The marriage link between Pompey and Caesar had been broken by Julia's death in 54. After this, Pompey irresolutely veered further and further away from Caesar, until, when the breach finally came, Pompey found himself committed to the nobility's side, though he and the nobility never trusted each other.

The issue was whether there should or should not be an interval between the date at which Caesar was to resign his provincial governorships and, therewith, the command over his armies and the date at which he would enter his proposed second consulship. If there were to be an interval, Caesar would be a private person during that time, vulnerable to attack by his enemies; if prosecuted and convicted, he would be ruined politically and might possibly lose his life. Caesar had to make sure that, until his entry on his second consulship, he should continue to hold at least one province with the military force to guarantee his security.

This issue had already been the object of a series of political manoeuvres and countermanoeuvres at Rome. The dates on which the issue turned are all in doubt. As had been agreed at Luca in 56, Caesar's commands had been prolonged for five years, apparently until February 28, 49, but this is not certain. In 52, a year in which Pompey was elected sole consul and given a five-year provincial command in Spain, Caesar was allowed by a law sponsored by all 10 tribunes to stand for the consulship *in absentia*. If he were to stand in 49 for the consulship for 48, he would be out of office, and therefore in danger, during the last 10 months of 49. As a safeguard for Caesar against this, there seems to have been an understanding—possibly a private one at Luca in 56 between him and Pompey—that the question of a successor to Caesar in his commands should not be raised in the Senate before March 1, 50. This manoeuvre would have ensured that Caesar would retain his commands until the end of 49. However, the question of replacing Caesar was actually raised in the Senate a number of times from 51 onward; each time Caesar had the dangerous proposals vetoed by tribunes of the plebs who were his agents—particularly Gaius Scribonius Curio in 50 and Mark Antony in 49.

The issue was brought to a head by one of the consuls for 50, Gaius Claudius Marcellus. He obtained resolutions from the Senate that Caesar should lay down his command (presumably at its terminal date) but that Pompey should not lay down his command simultaneously. Curio then obtained on December 1, 50, a resolution (by 370 votes to 22) that both men should lay down their commands simultaneously. Next day Marcellus (without authorization from the Senate) offered the command over all troops in Italy to Pompey, together with the power to raise more; and Pompey accepted. On January 1, 49, the Senate received from Caesar a proposal that he and Pompey should lay down their commands simultaneously. Caesar's message was peremptory, and the Senate resolved that Caesar should be treated as a public enemy if he did not lay down his command "by a date to be fixed."

Caesar crosses the Rubicon

On January 10–11, 49, Caesar led his troops across the little river Rubicon, the boundary between his province of Cisalpine Gaul and Italy proper. He thus committed the first act of war. This was not, however, the heart of the matter. The actual question of substance was whether the misgovernment of the Greco-Roman world by the Roman nobility should be allowed to continue or whether it should be replaced by an autocratic regime. Either alternative would result in a disastrous civil war. The subsequent partial recuperation of the Greco-Roman world under the principate suggests, however, that Caesarism was the lesser evil.

The civil war was a tragedy, for war was not wanted either by Caesar or by Pompey or even by a considerable part of the nobility, while the bulk of the Roman citizen body ardently hoped for the preservation of peace. By this time, however, the three parties that counted politically were all entrapped. Caesar's success in building up his political power had made the champions of the old regime so implacably hostile to him that he was now faced with a choice between putting himself at his enemies' mercy or seizing the monopoly of power at which he was accused of aiming. He found that he could not extricate himself from this dilemma by reducing his demands, as he eventually did, to the absolute minimum required for his security. As for Pompey, his growing jealousy of Caesar had led him so far toward the nobility that he could not come to terms with Caesar again without loss of face.

The first bout of the civil war moved swiftly. In 49 Caesar drove his opponents out of Italy to the eastern side of the Straits of Otranto. He then crushed Pompey's army in Spain. Toward the end of 49, he followed Pompey across the Adriatic and retrieved a reverse at Dyrrachium by winning a decisive victory at Pharsalus on August 9, 48. Caesar pursued Pompey from Thessaly to Egypt, where Pompey was murdered by an officer of King Ptolemy. Caesar wintered in Alexandria, fighting with the populace and dallying with Queen Cleopatra. In 47 he fought a brief local war in northeastern Anatolia with Pharnaces, king of the Cimmerian Bosporus, who was trying to regain his father Mithradates' kingdom of Pontus. Caesar's famous words, *Veni, vidi, vici* ("I came, I saw, I conquered"), are his own account of this campaign.

Caesar then returned to Rome, but a few months later, now with the title of dictator, he left for Africa, where his opponents had rallied. In 46 he crushed their army at Thapsus and returned to Rome, only to leave in November for Farther Spain to deal with a fresh outbreak of resistance, which he crushed on March 17, 45, at Munda. He then returned to Rome to start putting the Greco-Roman world in order. He had less than a year's grace for this huge task of reconstruction before his assassination in the Senate House at Rome on March 15, 44 (the Ides of March).

Caesar's death

Caesar's death was partly due to his clemency and impatience, which, in combination, were dangerous for his personal security. Caesar had not hesitated to commit atrocities against "barbarians" when it had suited him, but he was almost consistently magnanimous in his treatment of his defeated Roman opponents. Thus clemency was probably not just a matter of policy. Caesar's earliest experience in his political career had been Sulla's implacable persecution of his defeated domestic opponents. Caesar amnestied his opponents wholesale and gave a number of them responsible positions in his new regime. Gaius Cassius Longinus, who was the moving spirit in the plot to murder him, and Marcus Junius Brutus, the symbolic embodiment of Roman republicanism, were both former enemies. "*Et tu, Brute*" ("You too, Brutus") was Caesar's expression of his particular anguish at being stabbed by a man whom he had forgiven, trusted, and loved.

There were, however, also a number of ex-Caesareans among the 60 conspirators. They had been goaded into this volte-face by the increasingly monarchical trend of Caesar's regime and, perhaps at least as much, by the aristocratic disdain that inhibited Caesar from taking any trouble to sugar the bitter pill. Some stood to lose, rather than to gain, personally by the removal of the autocrat who had made their political fortunes. But even if they were acting on principle, they were blind to the truth that the reign of the Roman nobility was broken beyond recall and that even Caesar might not have been able to overthrow the *ancien régime* if its destruction had not been long overdue. They also failed to recognize that by making Caesar a martyr they were creating his posthumous political fortune.

If Caesar had not been murdered in 44, he might have lived on for 15 or 20 years. His physical constitution was unusually tough, though in his last years he had several epileptic seizures. What would he have done with this time? The answer can only be guessed from what he did do in the few months available. He found time in the year 46 to reform the Roman calendar. In 45 he enacted a law laying down a standard pattern for the constitutions of the *municipia,* which were by this time the units of local self-government in most of the territory inhabited by Roman citizens. In 59 Caesar had already resurrected the city of Capua, which the republican Roman regime more than 150 years earlier had deprived of its juridical corporate personality; he now resurrected the other two great cities, Carthage and Corinth, that his predecessors had destroyed. This was only a part of what he did to resettle his discharged soldiers and the urban proletariat of Rome. He was also generous in granting Roman citizenship to aliens. (He had given it to all of Cisalpine Gaul, north of the Po, in 49.) He increased the size of the Senate and made its personnel more representative of the whole Roman citizenry.

At his death, Caesar was on the point of starting out on a new military campaign to avenge and retrieve Crassus' disastrous defeat in 53 by the Parthians. Would Caesar have succeeded in recapturing for the Greco-Roman world the extinct Seleucid monarchy's lost dominions east of the Euphrates, particularly Babylonia? The fate of Crassus' army had shown that the terrain in northern Mesopotamia favoured Parthian cavalry against Roman infantry. Would Caesar's military genius have outweighed this handicap? And would Rome's hitherto inexhaustible reservoir of military manpower have sufficed for this additional call upon it? Only guesses are possible, for Caesar's assassination condemned the Romans to another 13 years of civil war, and Rome would never again possess sufficient manpower to conquer and hold Babylonia.

PERSONALITY AND REPUTATION

Caesar was not and is not lovable. His generosity to defeated opponents, magnanimous though it was, did not win their affection. He won his soldiers' devotion by the victories that his intellectual ability, applied to warfare, brought them. Yet, though not lovable, Caesar was and is attractive, indeed fascinating. His political achievement required ability, in effect amounting to genius, in several different fields, including administration and generalship besides the minor arts of wire pulling and propaganda.

In all these, Caesar was a supreme virtuoso. But if he had not also been something more than this he would not have been the supremely great man that he undoubtedly was.

Caesar was great beyond—and even in conflict with—the requirements of his political ambition. He showed a human spiritual greatness in his generosity to defeated opponents, which was partly responsible for his assassination. (The merciless Sulla abdicated and died in his bed.)

Speeches and writings

Another field in which Caesar's genius went far beyond the requirements of his political ambition was his writings. Of these, his speeches, letters, and pamphlets are lost. Only his accounts (both incomplete and supplemented by other hands) of the Gallic War and the civil war survive. Caesar ranked as a masterly public speaker in an age in which he was in competition first with Hortensius and then with Cicero.

All Caesar's speeches and writings, lost and extant, apparently served political purposes. He turned his funeral orations for his wife and for his aunt to account, for political propaganda. His accounts of his wars are subtly contrived to make the unsuspecting reader see Caesar's acts in the light that Caesar chooses. The accounts are written in the form of terse, dry, factual reports that look impersonal and objective, yet every recorded fact has been carefully selected and presented. As for the lost *Anticato,* a reply to Cicero's eulogy of Caesar's dead opponent Marcus Porcius Cato, it is a testimony to Caesar's political insight that he made the time to write it, in spite of the overwhelming military, administrative, and legislative demands on him. He realized that Cato, in giving his life for his cause (46), had made himself posthumously into a much more potent political force than he had ever been in his lifetime. Caesar was right, from his point of view, to try to put salt on Cato's tail. He did not succeed, however. For the next 150 years, Cato the martyr continued to be a nuisance, sometimes a menace, to Caesar's successors.

The mark of Caesar's genius in his writings is that though they were written for propaganda they are nevertheless of outstanding literary merit. A reader who has seen through their prosaic purpose can ignore it and appreciate them as splendid works of art.

Caesar's most amazing characteristic is his energy, intellectual and physical. He prepared his seven books on the Gallic War for publication in 51 when he still had serious revolts in Gaul on his hands, and he wrote his books on the civil war and his *Anticato* in the hectic years between 49 and 44. His physical energy was of the same order. For instance, in the winter of 57–56 he found time to visit his third province, Illyria, as well as Cisalpine Gaul; and in the interval between his campaigns of 55 and 54 he transacted public business in Cisalpine Gaul and went to Illyria to settle accounts with the Pirustae, a turbulent tribe in what is now Albania. In 49 he marched, within a single campaigning season, from the Rubicon to Brundisium and from Brundisium to Spain. At Alexandria, probably aged 53, he saved himself from sudden death by his prowess as a swimmer.

Caesar's physical vitality perhaps partly accounts for his sexual promiscuity, which was out of the ordinary, even by contemporary Greek and Roman standards. It was rumoured that during his first visit to the East he had had homosexual relations with King Nicomedes of Bithynia. The rumour is credible, though not proved, and was repeated throughout Caesar's life. There is no doubt of Caesar's heterosexual affairs, many of them with married women. Probably Caesar looked upon these as trivial recreations. Yet he involved himself at least twice in escapades that might have wrecked his career. If he did in fact have an affair with Pompey's wife, Mucia, he was risking his entente with Pompey. A more notorious, though not quite so hazardous, affair was his liaison with Cleopatra. By dallying with her at Alexandria, he risked losing what he had just won at Pharsalus. By allowing her to visit him in Rome in 46, he flouted public feeling and added to the list of tactless acts that, cumulatively, goaded old comrades and amnestied enemies into assassinating him.

Caesar's achievement

This cool-headed man of genius with an erratic vein of sexual exuberance undoubtedly changed the course of history at the western end of the Old World. By liquidating the scandalous and bankrupt rule of the Roman nobility, he gave the Roman state—and with it the Greco-Roman civilization—a reprieve that lasted for more than 600 years in the East and for more than 400 years in the relatively backward West. Caesar substituted for the Roman oligarchy an autocracy that could never afterward be abolished. If he had not done this when he did it, Rome and the Greco-Roman world might have succumbed, before the beginning of the Christian era, to barbarian invaders in the West and to the Parthian Empire in the East. The prolongation of the life of the Greco-Roman civilization had important historical effects. Under the Roman Empire the Near East was impregnated with Hellenism for six or seven more centuries. But for this the Hellenic element might not have been present in sufficient strength to make its decisive impact on Christianity and Islām. Gaul, too, would have sunk deeper into barbarism when the Franks overran it, if it had not been associated with the civilized Mediterranean world for more than 500 years as a result of Caesar's conquest.

Caesar's political achievement was limited. Its effects were confined to the western end of the Old World and were comparatively short-lived by Chinese or ancient Egyptian standards. The Chinese state founded by Shih Huang Ti in the 3rd century BC still stands, and its future may be still greater than its past. Yet, even if Caesar were to prove to have been of lesser stature than this Chinese colossus, he would still remain a giant by comparison with the common run of human beings (see also GRECO-ROMAN CIVILIZATION: *Ancient Rome*).

MAJOR WORKS

Military commentaries: in seven books, *Commentarii de bello Gallico,* covering the years 58–52 BC, written in 52–51 BC (*The Gallic War,* 1917); in three books, *Commentarii de bello civili,* covering the year 49–48 BC, written probably in 45 BC (*The Civil Wars,* 1914; *Caesar's War Commentaries,* 1953).

De bello Alexandrino (*The Alexandrian War,* 1955); *De bello Africo* (*The African War,* 1955); and *De bello Hispaniensi* (*The Spanish War,* 1955), though ascribed by the manuscripts of Caesar, are generally regarded as of uncertain authorship. Caesar's speeches, letters, and pamphlets are all lost.

A translation of Caesar's works is available in the Loeb series (1914–55) and in the Penguin Classics series (1951 and 1967).

BIBLIOGRAPHY

Ancient works: CAESAR, *De bello Gallico,* books i–vii (Book viii, covering events of 51 BC, was written after Caesar's death by AULUS HIRTIUS), ed. by T. RICE HOLMES (1914, reprinted 1979), and *De bello civili,* books i–iii. The *Bellum Alexandrinium* (the wars of 47 BC), *De bello Africo,* and *De bello Hispaniensi* are all anonymous but contemporary with Caesar and are included with his works; CICERO, letters and speeches; SALLUST, *Epistulae ad Caesarem* (the authenticity of these two memoranda addresses to Caesar has been questioned); APPIAN, *Civil Wars,* book ii; DIO CASSIUS, books xxxvii–xliv; PLUTARCH, *Lives of Caesar, Pompey, and Crassus;* SUETONIUS, *Divus Julius;* and VELLEIUS PATERCULUS, book ii, 41–56.

Modern works: THEODOR MOMMSEN, *The History of Rome,* vol. 4–5, rev. ed. (1895; originally published in German, 1854–56); GUGLIELMO FERRERO, *The Greatness and Decline of Rome,* vol. 1–2 (1907–09, reprinted 1971; originally published in Italian, 1902–07); T.R.E. HOLMES, *Caesar's Conquest of Gaul,* 2nd ed. (1911, reprinted 1971), and *Ancient Britain and the Invasions of Julius Caesar,* esp. ch. 6–8 (1907, reissued 1936); EDUARD MEYER, *Caesars Monarchie und das Principat des Pompejus,* 3rd ed. (1922); M. CARY *et al.,* in *Cambridge Ancient History,* vol. 9, ch. 11–13 and 15–18 (1932); JÉRÔME CARCOPINO, *César,* vol. 2 of *La République romaine de 133 à 44 avant J.-C.,* by GUSTAVE BLOCH (1940); RONALD SYME, *The Roman Revolution* (1939, reissued 1966); LILY R. TAYLOR, *Party Politics in the Age of Caesar* (1949, reissued 1975); MATTHIAS GELZER, *Caesar: Politician and Statesman* (1968; originally published in German, 1921, 6th ed., 1960), a scholarly biography; ALEXANDER H. MCDONALD, *Republican Rome* (1966); STEFAN WEINSTOCK, *Divus Julius* (1971), a study of Caesar as a religious reformer and creator of the ruler cult; MICHAEL GRANT, *Caesar* (1975), a popular biography, with maps and illustrations; and PETER B. ELLIS, *Caesar's Invasion of Britain* (1978), a popularly written account of the invasion.

(A.J.T./Ed.)

Cairo

Cairo, the capital of Egypt, is the largest city in Africa. Its Arabic name, al-Qāhirah, means "Victorious." The city has stood for more than 1,000 years on the same site on the banks of the Nile, primarily on the eastern shore, some 500 miles (800 kilometres) downstream from the Aswān High Dam. Cairo is the gateway to the Nile Delta, which begins about 10 miles to the north where the lower Nile separates into the Rosetta and Damietta branches, and it has served for centuries as the stronghold from which to defend all of Egypt to the south.

Cairo is a place of vivid contrasts. Along the well-irrigated shoreline, lush tropical vegetation, tall palms, flowering flame trees, and skyscrapers are profiled against a cloudless sky; in the older inland quarters to the east, beneath the foothills of the Arabian Desert (aṣ-Ṣaḥrā' ash-Sharqīyah; "Eastern Desert") and the rocky promontories of the Muqaṭṭam Hills and the Red Mountain (al-Jabal al-Aḥmar, with its petrified forest), browns and ochres are the dominant hues of land and buildings.

The city juxtaposes ancient and new, East and West. The Great Pyramids near Memphis stand at the southwestern edge of the metropolis, and an obelisk in the northeast marks the site of Heliopolis, where Plato once studied; modern landmarks include elegant Western-style high-rise hotels overlooking the Nile River. Between these extremes are other architectural monuments dating from Roman, Arab, and Turkish times. In addition to department stores, cinemas, hotels, and town houses, Cairo contains a large functioning bazaar and an extensive medieval city endowed with more than 400 registered historic monuments—mosques, mausoleums, crenellated walls, and massive gateways—dating from AD 130 to the early 19th century.

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

Climate. The typical desert climate contrasts daytime dry heat with cool nights freshened by Nile breezes. Cairo has only two seasons: approximately eight months of summer and four months of winter. In the hottest of the summer months, June, July, and August, the average daily maximum temperature is 95° F (35° C) and the average daily minimum is 70° F (21° C). The summer temperature has reached as high as 117° F (47° C). During winter, days are warmed by the strong Tropic of Cancer sun, but nights are cool and humid. The average daily maximum temperature in January–February is 67° F (19° C) and the average daily minimum is 47° F (9° C). A healthful climate has long made Cairo a renowned winter resort.

The city layout. *The old and new quarters.* Cairo is fan-shaped, narrowest in the south, where the river valley is wedged between desert escarpments, and widest in the north, where the valley blends into the Delta. Over the centuries the city expanded westward as a receding river channel left land flood-free. In response to heightened demand, however, the city also has been elongated to the north and south and has developed an expanding annex on the Nile's western shore.

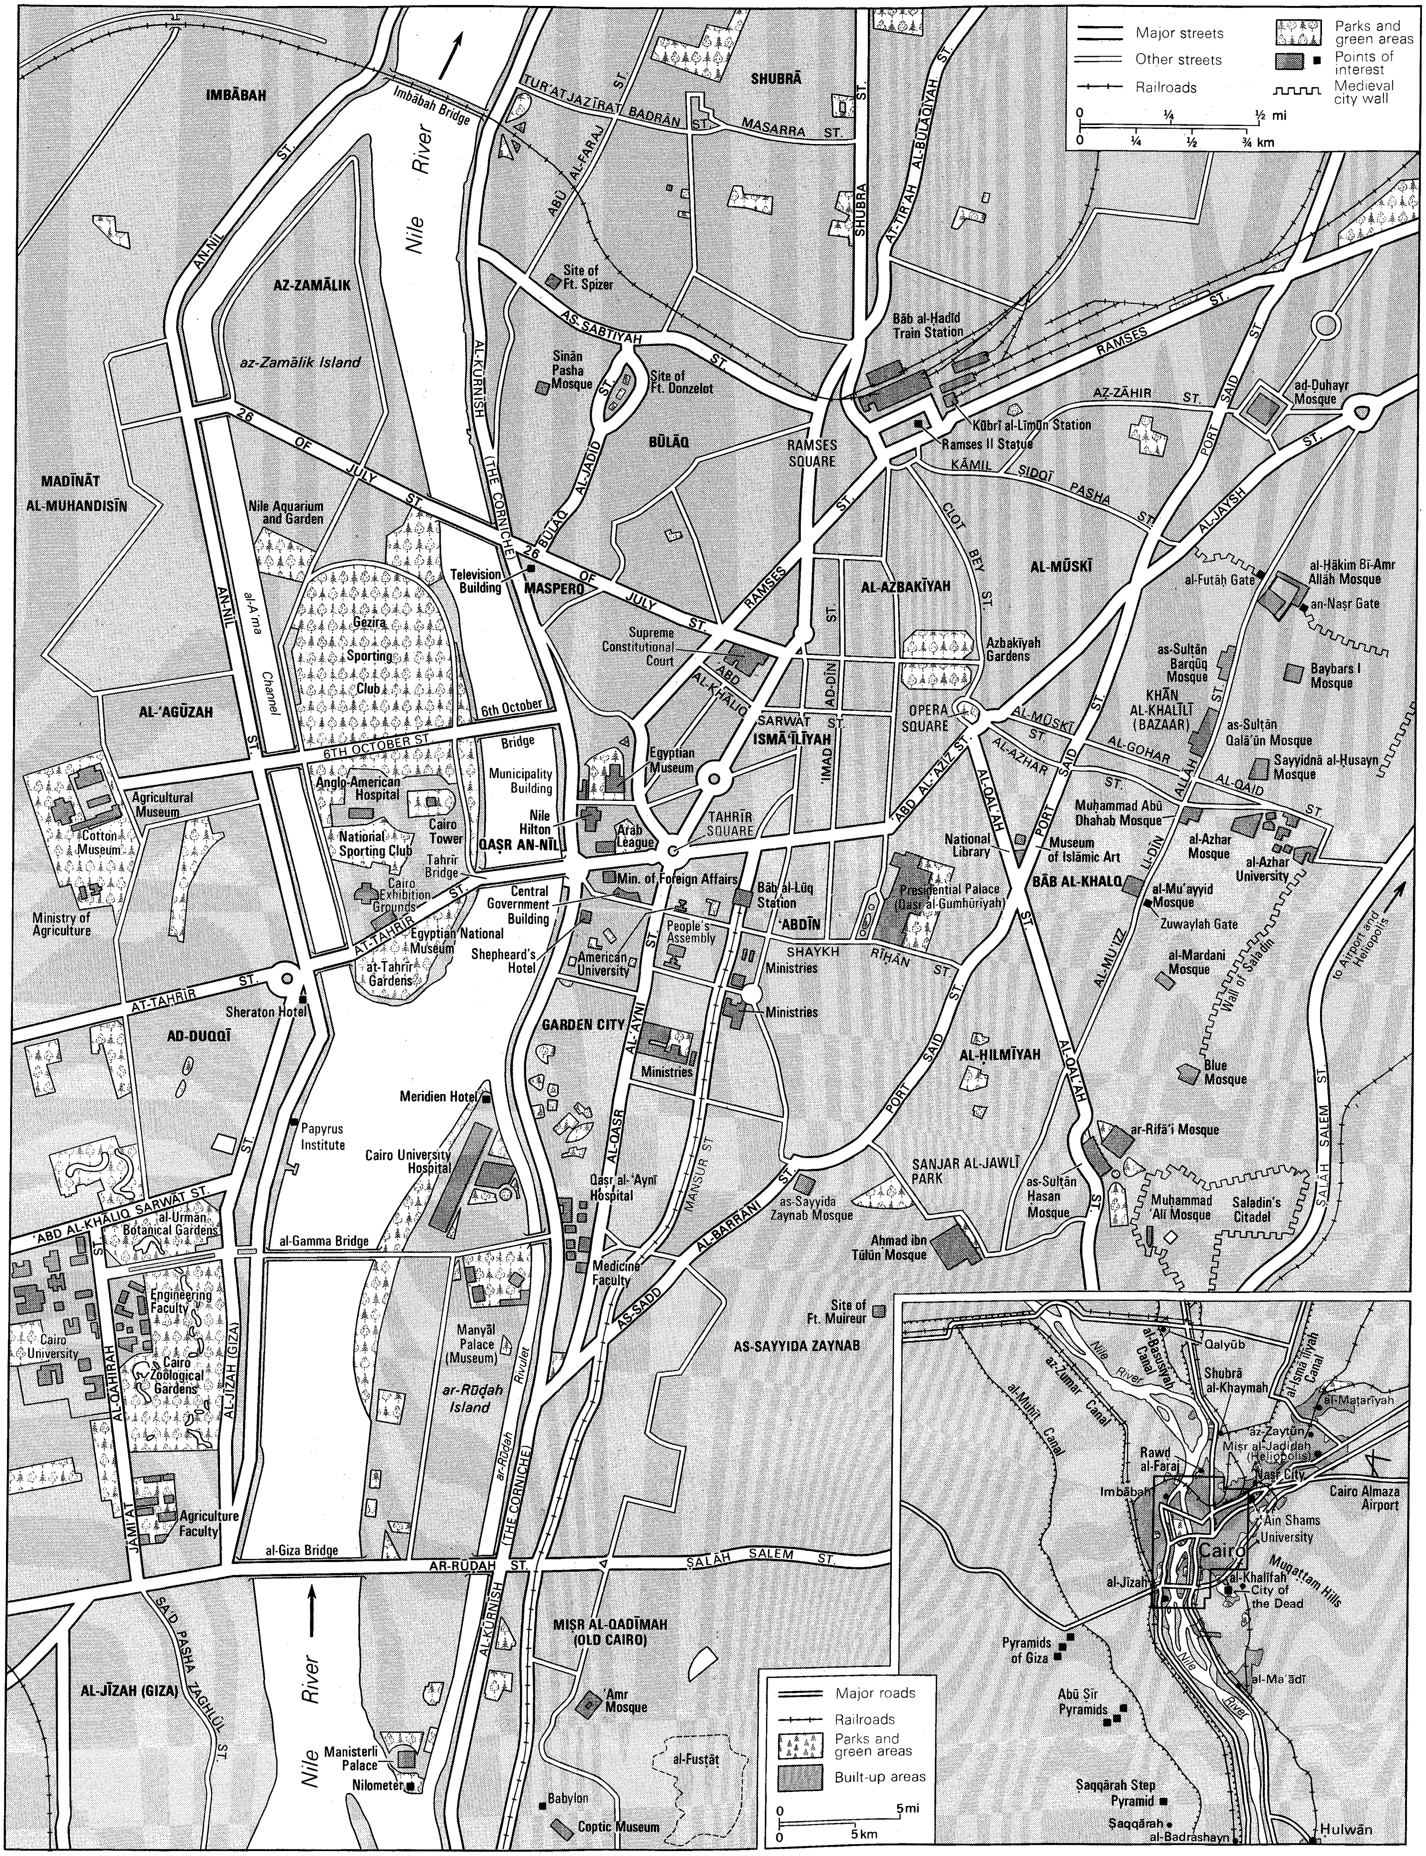
The *muḥāfaẓah* (governorate) of Cairo is one of the administrative districts into which Egypt is divided. The boundaries of the governorate encompass only half of the urbanized area; Ḥulwān, an industrial satellite in the extreme south, is included, but industrial satellites in the far north, such as Shubrā al-Khaymah, and the heavily developed quarters on the west bank belong to other *muḥāfaẓāt*.

Sectors of the city

The organization of the metropolitan complex is understandable only in the context of the city's history. The three oldest areas constitute densely populated slums that virtually surround the Westernized core. The largest of these is the city built under the Fāṭimid dynasty, with pre-19th-century extensions (al-Jamālīyah, ad-Darb al-Aḥmar, Bāb ash-Sha'rīyah, eastern as-Saiyīdah Zīnab, northern al-Khalīfah). In this densely settled zone containing the oldest buildings are most of Cairo's historic monuments, from the Mosque of Baybars I at the northern edge to Saladin's Citadel in the south. Among the major bazaars near al-Azhar Mosque in the central walled city are the Khān al-Khalīlī (1390) and the markets for gold articles, copper ware, textiles, rugs, amber, spices, and leather goods. Two major thoroughfares run north and south: Mu'izz li-Dīn Allāh, which bisects the old city and contains the major mosques and markets; and Port Said Street, which runs along the bed of an ancient canal that once marked the western border of Fāṭimid Cairo. Al-Gohar al-Qaid Street (which runs into al-Mūskī Street) and al-Azhar Street connect the old city with the central business district. A diagonal, al-Qal'ah Street, links the central business district with the Citadel. Most other streets are narrow, twisting, and often dead-end. Only major thoroughfares are open to motor vehicles.

The other two old quarters are Būlāq, to the northwest of the medieval city, and Miṣr al-Qadīmah (Old Cairo), to the south; they served as port suburbs of Cairo before the city expanded to encompass them. Būlāq, an island until 1340 and the main port by 1560, became an industrial quarter in the early 19th century. It contains small workshops, the National Press, textile factories, and trade schools. A poor population, including many village migrants, is housed there at extremely high densities. The mosques of Abū al-'Alā' and Sinān Pasha are among the few historic buildings remaining; many of the older structures have been razed to make room for commercial and office buildings. Miṣr al-Qadīmah is an even poorer quarter, although only a small section is ancient. The walled compound of Babylon, with its semi-submerged Roman bastion, its Coptic churches and museum, and its ancient synagogue and houses, is virtually intact, as is the reconstructed 'Amr Mosque nearby. The rich agricultural land between Cairo and Ḥulwān has been given over to apartments, and the residential suburb of al-Ma'ādī, built for single-family residences under the British, now hosts several skyscrapers.

Flanked by these older quarters are the central business district (al-Azbakīyah) and its residential quarters (Garden



Cairo and (inset) its metropolitan area.

City, Ismāʿīlīyah), which spread onto the Gezīrah, the island offshore. The major thoroughfare is al-Kūrnīsh (the Corniche), a highway paralleling the river, built since the overthrow of the monarchy in 1952. From north to south are the imposing Television Building, the Ramses Hilton Hotel, the Municipality Building, the Nile Hilton Hotel (with the Egyptian Museum behind it), and Shepheard's Hotel. Also in the vicinity are the intricately curved streets of Garden City, lined with tall apartment houses. The Gezīrah, across the Nile from al-Kūrnīsh, is the site of hotels, the Cairo Tower, museums, public gardens, a racetrack, and sporting and officers' clubs, as well as elegant housing.

Between the imposing Nile riverfront and the ancient inland quarters is a transitional zone (al-Mūskī, Bāb al-Lūq, eastern ʿAbdīn, an-Naṣrīyah, al-Ḥilmīyah) of working-class status. It was chiefly developed in the 19th century and contains the National Library, the Museum of Islāmic Art, and the Presidential Palace (Qaṣr al-Gumhūriyah) and archives.

The City
f the
ead"

Along the eastern and southern edges of the metropolis are extensive cemeteries—a zone called "the City of the Dead," which has no counterpart outside Egypt. In a vast, dusty, ochre-coloured zone unserved by municipal utilities are found exquisite shrine-mosques and mausoleums of early religious leaders (such as that of Imām ash-Shāfiʿī, an al-Fusṭāṭ resident and founder of Egypt's major legal tradition) and of Mamlūk sultans (among the most beautiful are the memorials of Qāʾit Bāy, Barqūq, and Qalāʾūn). More modest and modern structures are also found there. Particularly since the population increase that occurred during World War II, housing and shops have been added to the City of the Dead. Some 250,000 Cairenes live there, for the most part without government sanction.

The northern and western peripheries have grown dramatically. On the west bank and on the island of ar-Rūḍah are located developed residential quarters (ad-Duqqī and al-Jīzah, or Giza), the zoological and botanical gardens, an agricultural museum, and the campus of Cairo University. A large-scale housing project is Workers' City in Imbābah, while Engineers' City (Madīnāt al-Muhandisīn) is now the domain of Cairo's middle and upper middle classes. Expansion has also taken place to the north. Beginning about 1905 but expanding substantially in the 1920s, the northern quarters of Rawḍ al-Faraj, Shubrā, Sharabīyah, al-Qubbah, al-ʿAbbāsīyah, al-Maṭarīyah, az-Zaytūn, and Miṣr al-Jadīdah (Heliopolis) gained population. Since that time urban developments have increasingly encroached on agricultural land and have been extended into the desert periphery by elaborate irrigation schemes. Heliopolis, first conceived in 1905, and Naṣr City, a new town begun in 1958, are examples of such developments. A rural population still inhabits the northern fringe, but squatter settlements are also found there. The newest zones of Cairo's metropolitan area, however, are a series of satellite towns being built in desert areas beyond the city centre. Sites and services housing projects, in which the government designs the subdivision and puts in streets, sewers, electricity, and water lines, also occupy desert peripheries.

Architectural styles. Building styles in Cairo are related to the historic period during which each quarter developed. In the oldest sections, two- to four-storied structures prevail, most built of fired brick covered with plaster and sometimes shored with half-timbering. Wood, being scarce, is used frugally. Some of the oldest homes have windows covered with delicately turned wooden lattices (*mashrabīyah*) and massive wooden doors decorated with inlay, brass, or iron nailheads, indicating past elegance. The traditional dwellings (of which only a few remain intact) open onto fountained courtyards and have separate quarters for men and women; the traditional workshops and warehouse inns (of which more have survived) have galleries overlooking the interior court.

European
architectural
influences

Parts of Cairo built in the 19th century reveal exaggerated European influences—highly ornate stone exteriors, cupolas, and Romanesque doorways. While this ungainly and incongruous style, darkened with time, predominates in the transitional zone, perhaps the most outlandish examples are the later Palace of Sakākīnī (northeast of Baybars I Mosque) and the 20th-century palace of Baron Empain, founder of Heliopolis.

In the early modern Western quarters, built at the turn of the 20th century, the architectural style is Parisian; most of the moderately tall buildings are of stone or poured concrete. Closer to the Nile and on the islands, a contemporary Mediterranean style predominates. Tall reinforced concrete and glass structures with balconies are decorated with tile. In these less derivative forms, Egyptian architectural genius, so noticeable in the clean, almost stark lines of the ancient temples, seems to be reemerging.

The monuments of the eastern cemeteries are Mamlūk in design, each topped by a plain or fluted dome; the lesser tombs are simpler rectangles. Houses there and in the rural fringe areas typically are built of mud or of crudely fired brick, resembling traditional village housing in the hinterland.

Robert Frerck/Odyssey Productions

Al-Azhar Mosque (domed building on right), with adjoining buildings of al-Azhar University (founded in 970).

In the quarters on the west and north the more elegant districts have both handsome high-rise apartments and one- or two-storied "villas," with high walls enclosing colourful gardens. Lower middle- and working-class housing consists exclusively of concrete multiflat structures, gray or yellow-beige in colour, often with shops occupying the ground floor. The poorest zones contain three- to five-storied walk-ups, often of crudely fired redbrick.

All roofs are flat. In most quarters commercial buildings are scattered among the dwellings, and in the poorer quarters one also finds an occasional industrial workshop.

THE PEOPLE

Cairo's population previously was diverse, both ethnically and religiously, but the vast majority now is Muslim. The remainder are Egyptian Christians of the Coptic Orthodox faith. Members of the once-dominant foreign groups (English, French, Swiss, and Belgian) had mostly left by 1957; the more modest Italian and Greek communities remained and have been joined by Arab nationals (Syrians, Palestinians, and Sudanese) as well as by diplomatic and technical personnel from eastern Europe. Differences of status within the Egyptian population depend largely on place of origin (many residents of Cairo were born in rural Egypt), class, and degree of modernity. About half of the population lives in the city proper, and half lives in the suburbs.

THE ECONOMY

Industry. From its inception the economy of Cairo has been based on governmental functions, commerce, trade, and industrial production. Especially since the 1920s, the modern productive sector has expanded dramatically. Large-scale industrialization since the 1952 revolution has built upon previous developments in textiles (utilizing the long-staple cotton for which Egypt is famous) and food processing, which consists of canning and freezing the wide variety of fruits and vegetables grown in the fertile Delta, as well as processing the tobacco and sugarcane grown in Upper Egypt. In addition to the production of iron and steel, consumer goods, such as cars and refrigerators, are made. Especially since 1956, the output of a wide variety of smaller consumer goods has increased.

Cairo's significance within the nation

Cairo is the primary national centre for modern economic production and financial control. It contains most of Egypt's important banks, shipping companies, and airlines; about one-third of all sports, amusement, cafés, restaurants, and hotels in the country are also concentrated in Cairo.

Although about one-half of Cairo's predominantly male labour force works in the expanding modern sector of the economy, both on the assembly lines and in auxiliary commercial and financial institutions, a substantial traditional sector still survives, in which craftsmanship and personal relationships play an important role.

Labour. About one-third of all workers are engaged in service occupations, many of which are of only dubious productivity and viability. The government's development plans are directed toward mobilizing this labour force. Unemployment is relatively high in Cairo. In the mid-1980s as many as 3,200,000 Egyptian labourers were employed as guest workers, primarily in the oil-producing Persian Gulf states and Libya, but many were repatriated when oil prices fell and production slowed. Their return has helped to drive Cairo's unemployment even higher.

Transportation. Cairo is served by an international airport beyond Heliopolis and by train service to other major cities. Air-conditioned trains connect Alexandria with the Bāb al-Ḥadīd Train Station in Cairo, and there is overnight sleeper service to Luxor and Aswān. The city itself has mass-transit facilities. Construction began in 1981 on an extensive metropolitan rail system, and its first phase, which concentrated on the upgrading of the existing line between Cairo and Ḥulwān to the south, was completed in 1987. The hub of the metropolitan system is a 2.7-mile subway network under central Cairo, construction of which began in 1982. Streetcars and buses thread through all but the Fāṭimid quarters. Local assembly plants as well as imports have made an increasing number of automobiles available, and bypass highways and overpasses have been built to relieve the growing traffic congestion. In the old city, donkey-drawn carts are still seen, but they are rapidly disappearing.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Before 1949 Cairo was anomalously administered by a combination of national policymakers and local administrators. In 1949 the municipality (*baladīyah*) of Cairo was created, being inaugurated, together with a town council, in 1950. In 1960 the national Ministry for Local Administration was established, after which it promulgated a uniform system for local governments. Although the ministry was dissolved in 1971, some basic changes introduced have been retained, including the merger of the *baladīyah* with the *muḥāfaẓah* (governorate) of Cairo.

At the head of the governorate of Cairo is the governor, who is appointed by the president and assisted by the executive committee of the governorate. This committee includes under secretaries from the major national ministries, such as education, housing, health, social affairs, finance, and the interior. Several special administrations are also under the committee's direction. The Municipal Council of Cairo (Majlis Muḥāfazah al-Qāhirah), consisting of both elected representatives and members ex officio, was dissolved in 1971 and replaced by the Popular Assembly (al-Majlis al-Sha'abī), in which only elected representatives can vote. The central government still maintains financial control over local programs and budgets.

Public utilities. Gas and water systems have existed since the 1860s and electrical and sewerage systems since the early 20th century. The majority of the city's older dwellings are connected to the electrical grid, but fewer than one-half have water and sewer connections. The major challenge has been to extend utility lines of all types to new quarters and suburbs and to repair and maintain the older installations. Nile water is filtered and purified, and tap water is both safe and pleasant to drink. The sewerage system has been substantially renovated and its capacity enlarged. Telephone service was substantially renovated in 1985.

Health. Most of Egypt's health and medical facilities are concentrated in Cairo. There are several government hospitals, including the enormous general hospitals of Qaṣr al-ʿAynī and Dimardash and the mental hospital at ʿAbbāssīyah. The city is also served by numerous smaller private hospitals (such as Dār al-Shifāʾ, the Italian Hospital, and the Anglo-American Hospital). Special clinics and various public hospitals are devoted to prevalent eye diseases (chiefly trachoma).

Education. Primary education is compulsory, and the illiteracy rate has been greatly reduced. In addition to primary and secondary schools, the educational facilities include technical institutes, pre-university superior schools, and foreign schools. Both the number of schools and the number of pupils have risen markedly.

Higher education

Cairo is also Egypt's centre of higher education and attracts not only Egyptian students but also students from other Arab countries. The various faculties of Cairo University produce the country's largest number of college graduates and specialized professionals (doctors, lawyers, and engineers). ʿAin Shams University is also a notable institution, and al-Azhar University, which previously specialized in religious subjects and language and literature, now includes teaching in the sciences on its supplementary campus in Naṣr City. The privately run American University in Cairo offers instruction in English in various arts and sciences.

CULTURAL LIFE

Cairo is the cultural capital of the Middle East as well as the region's chief mass media centre. For many centuries the region's major religious and cultural institutions have been concentrated there. During the 19th century European cultural institutions, such as theatre and opera, were added. The Baroque Opera House, where music by Egyptian composers was sometimes heard, was home to the Cairo Symphony Orchestra and host to guest ballet and opera companies, including the indigenous Reḍā Folklore Ballet Troop. The opera house, on Opera Square in the downtown area, was destroyed by fire in 1971, and construction of a replacement on the southern tip of the Gezīrah was undertaken in 1986.

Egypt has long been known for its musical and dramatic talent, and there has been a renaissance of the legitimate Arabic theatre. The majority of Arabic films are produced by Egyptian companies in Cairo. The leading cinema stars, as well as the most popular musical entertainers of the Arab world, make Cairo their headquarters. Egyptian radio is broadcast throughout North Africa, into the Fertile Crescent, and south into Africa.

Cairo is rich in museums, such as the Egyptian Museum, on Taḥrīr Square, which displays the treasures of Tutankhamen; the Coptic Museum in Miṣr al-Qadīmah, specializing in pre-Islāmic icons, textiles, and stones; the beautifully renovated Museum of Islāmic Art in Bāb al-Khalq, with Mamlūk Qur'āns and objects of wood, brass, inlay, and glass; the War (Citadel) Museum; and the Turkish-style Manyāl Palace Museum (on ar-Rūḍah Island). The mosques of Cairo offer as rich a store as any museum.

The Cairo Zoological Gardens in al-Jīzah contain extensive collections of rare tropical animals in a garden setting. Entertainment facilities available include sailboat trips up the Nile, as well as innumerable riverfront cafés, restaurant boats, and nightclubs. In addition to the older sporting facilities on the Gezīrah (racetracks, swimming clubs, and gardens), there is a racetrack at Heliopolis. Naṣr City is the site of the Cairo Stadium and has numerous playing fields.

History

THE EARLY PERIOD

Although ruined Memphis, 14 miles southwest of Cairo, was a metropolis 5,000 years ago, and about 2,000 years ago the Romans occupied a town on the site of Cairo called Babylon (now the Miṣr al-Qadīmah quarter), the seed from which contemporary Cairo sprang was the town of al-Fusṭāṭ, founded as a military encampment in AD 641 by 'Amr ibn al-'Āṣ, commander of the Arabs who brought Islām to Egypt. Successor dynasties added royal suburbs (al-'Askar, founded in 750 by the Umayyads; al-Qaṭā'i', founded in 870 by Aḥmad ibn Ṭūlūn) to the increasingly prosperous commercial and industrial port city of al-Fusṭāṭ. Little remains of these early developments in the southern part of the city, except the tower of Trajan (AD 130), the mosques of 'Amr ibn al-'Āṣ (641) and Aḥmad ibn Ṭūlūn (878), and the partially excavated mounds covering the site of al-Fusṭāṭ.

In 969 adherents of a dissident Islāmic sect, the Fāṭimids, invaded Egypt from what is now Tunisia. The conquering general, Jawhar, established a new rectangular walled city northeast of existing settlements. Initially named al-Manṣūrīyah, the city was renamed al-Qāhirah in 973–974 when the Fāṭimid caliph al-Mu'izz arrived to make it the capital of a dynasty that lasted for 200 years. Al-Qāhirah and al-Fusṭāṭ coexisted until 1168, when unfortified al-Fusṭāṭ was set on fire to protect Cairo from the crusaders. The crusaders were driven off by a Sunnī (orthodox Islāmic) army from Syria, after which the victorious commander, Saladin, founded the Ayyūbid dynasty, which controlled a vast empire from Cairo.

The Mamlūk era

Even though al-Fusṭāṭ was partially rebuilt, Cairo itself became transformed from a royal enclave into an imperial metropolis. Saladin further extended the 11th-century walls built by a high official called Badr al-Jamālī (the northern and southern walls and three main gates, al-Futuḥ Gate, an-Naṣr Gate, and Zuwaylah Gate, are still extant) and constructed a citadel on the Muqaṭṭam spur (now dominated by the Muḥammad 'Alī Mosque). After 1260, when Baybars I became the first Mamlūk sultan of undisputed legitimacy, Cairo served as the capital of the Mamlūk empire, which governed Egypt and the Fertile Crescent until 1516.

Medieval Cairo reached its apogee during the Mamlūk era. By about 1340, almost 500,000 persons lived in an area five times greater than the original Fāṭimid walled city, and Cairo had become the greatest city of Africa, Europe, and Asia Minor. Its al-Azhar University was the principal seat of Islāmic learning. The city was a key link in the profitable East–West spice trade and the recipient of tribute from a wealthy empire. Most of Cairo's greatest architectural masterpieces were built during this epoch.

Decline set in thereafter—sporadically at first, and then precipitously. The population was decimated by plagues, including the Black Death in 1348. The spice trade monopoly was broken by Vasco da Gama's voyage from Portugal to India (1497–99). Finally, political autonomy was lost to the conquering Turks, who, after 1517, reduced Cairo to a provincial capital. In 1798, when Napoleon and his troops arrived in Cairo, fewer than 300,000 people were living in the city and its two port suburbs, Miṣr al-Qadīmah and Būlāq. The Turks returned after Napoleon's defeat in 1801. In 1805 Muḥammad 'Ali, commander of an Albanian contingent, was appointed pasha, thus founding the dynasty that ruled Egypt until his great-great-grandson, Farouk I, abdicated in 1952.

DEVELOPMENT OF THE CITY

Modern urban growth began in the 1830s, but only during Ismā'īl's reign (1863–79) was the city fundamentally transformed. Influenced by Baron Haussmann's renovation of Paris, Ismā'īl ordered the construction of a European-style city to the west of the medieval core. French city-planning methods dominated the design of the districts of al-Azbakīyah (with its large park), 'Abdīn, and Ismā'īlīyah—all now central zones of contemporary Cairo. By the end of the 19th century these districts were well developed, but with the rise of British hegemony from 1882 onward, they became transformed into a colonial enclave. Following the overthrow of the monarchy in 1952, however, the number and power of foreign residents declined.

The 20th century

During the 20th century, Cairo grew spectacularly in both population and area. Improvements in transportation fostered the growth of suburban Heliopolis and al-Ma'ādī; flood control permitted riverfront development; bridges encouraged settlement of islands (ar-Rūḍah and az-Zamālik) and of the west bank. By mid-century the city was primarily growing northward into the fertile Delta, a trend further encouraged by industrialization. Since 1952 the government has attempted to accommodate Cairo's rapidly increasing population by building planned suburbs (Naṣr City, Muqattam City, Engineers' City) and, more recently, distant satellite towns, such as May 15th, October 6th, and Tenth of Ramaḍān towns.

BIBLIOGRAPHY. Descriptive and pictorial works include DEBORAH COWLEY and ALEYA SEROUR (eds.), *Cairo: A Practical Guide,* 5th ed. rev. by MARIANNE PEARSON (1986), a concise compilation of useful information; G.S.P. FREEMAN-GRENVILLE, *The Beauty of Cairo: A Historical Guide to the Chief Islamic and Coptic Monuments* (1981); MALISE RUTHVEN, *Cairo* (1980), with excellent photographs; and *Cairo: A Life Story of 1000 Years, 969–1969* (1969), mostly illustrations and photographs, published by the Cairo Ministry of Culture. Socioeconomic conditions in the city are dealt with in MARCEL CLERGET, *Le Caire: étude de géographie urbaine et d'histoire économique,* 2 vol. (1934), a scholarly work on the city from its origins to 1927. Historical overviews are provided by CARL F. PETRY, *The Civilian Elite of Cairo in the Later Middle Ages* (1981), a discussion of the relationship between Islāmic religious scholars and the ruling class of Cairo in the 15th century; JANET L. ABU-LUGHOD, *Cairo: 1001 Years of the City Victorious* (1971), a scholarly historical and sociological study; STANLEY LANE-POOLE, *The Story of Cairo* (1902, reprinted 1971), heavily architectural; JAMES ALDRIDGE, *Cairo* (1969), general and anecdotal; and DESMOND STEWART, *Cairo: 5500 Years* (1968; U.K. title, *Great Cairo: Mother of the World,* 1969), a beautifully written, brief history with contemporary vignettes.

Calcutta

Calcutta (Bengali Kalikātā), from 1772 to 1912 the capital of British India and since 1947 the capital of West Bengal, is India's largest city and one of its major ports. The city is located on the east bank of the Hooghly River, once the main channel of the Ganges River, about 96 miles (154 kilometres) upstream from the head of the Bay of Bengal; there the port city developed as a point of transshipment from water to land and from river to sea.

The city proper has an area of about 40 square miles (104 square kilometres); however, the metropolitan area (Calcutta Urban Agglomeration) is much larger, consisting of about 533 square miles. A city of commerce, transport, and manufacture, Calcutta is the dominant urban centre of eastern India.

The city's name is an Anglicized version of Kalikātā. According to some, Kalikātā is derived from the Bengali word Kālīkshetra, meaning "Ground of (the goddess) Kālī." Some say the city's name derives from the location of its original settlement on the bank of a canal (*khāl*). A third opinion traces it to the Bengali words for lime (*kali*) and burnt shell (*kata*), since the area was noted for the manufacture of shell-lime. Still another opinion is that the name is derived from the Bengali term *kilkilā* (meaning, "flat area"), which is mentioned in the old literature.

This article is divided into the following sections:

Physical and human geography

THE CHARACTER OF THE CITY

Fashioned by the colonial British in the manner of a grand European capital—yet now set in one of the poorest and most overpopulated regions of India—Calcutta has grown into a city of sharp contrasts and contradictions. Calcutta has had to assimilate strong European influences and overcome the limitations of its colonial legacy in order to find its own unique identity. In the process it created an amalgam of East and West that found its expression in the life and works of the 19th-century Bengali elite and its most noteworthy figure, the poet and mystic Rabindranath Tagore.

This largest and most vibrant of Indian cities thrives amidst seemingly insurmountable economic, social, and political problems. Its citizens exhibit a great joie de vivre that is demonstrated in a penchant for art and culture and a level of intellectual vitality and political awareness unsurpassed in the rest of the country. No other Indian city can draw the kinds of crowds that throng to Calcutta's book fairs, art exhibitions, and concerts. There is a lively trading of polemics on walls, which has led to Calcutta being dubbed the "city of posters."

Yet for all of Calcutta's vitality, many of the city's residents live in some of the worst conditions, far removed from the cultural milieu. The city's energy, however, penetrates even to the meanest of slums, as a large number of Calcuttans sincerely support the efforts of those who minister to the poor and suffering. In short, Calcutta remains an enigma to many Indians as well as to foreigners. It continues to puzzle newcomers and to arouse an abiding nostalgia in the minds of those who have lived there.

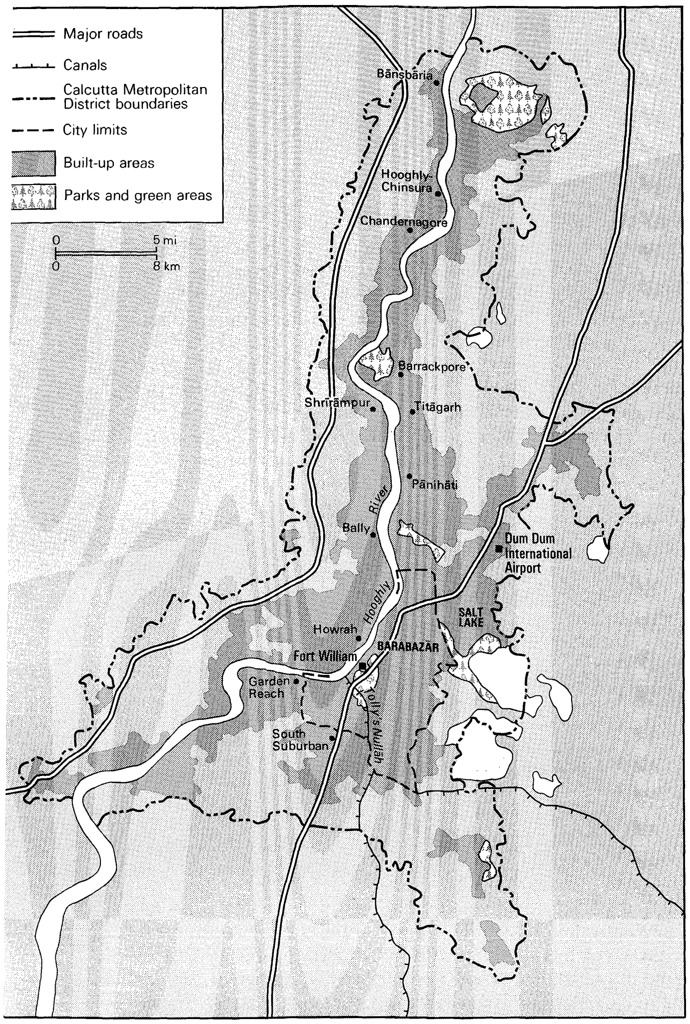
THE LANDSCAPE

The city site. The location of the city appears to have been originally selected partly because of its easily defensible position and partly because of its favourable trading location. The low, swampy, hot, and humid riverbank otherwise has little to recommend it. Its maximum elevation is about 30 feet (nine metres) above sea level. Eastward from the river the land slopes away to marshes and swamplands. Similar topography on the west bank of the river has confined the metropolitan area to a strip three to five miles wide on either bank of the river. Reclamation of the Salt Lake area on the northeastern fringe of the city demonstrated that the spatial expansion of the city is feasible, and further reclamation projects have been undertaken to the east, south, and west of the central area.

The principal suburbs of Calcutta are Howrah (on the west bank), Baranagar to the north, South Dum Dum to the northeast, the South Suburban Municipality (Behāla) to the south, and Garden Reach in the southwest. The whole urban complex is held together by close socioeconomic ties.

Climate. Calcutta has a subtropical climate with a seasonal regime of monsoons (rain-bearing winds). The maximum temperature reaches about 108° F (42° C) and the minimum temperature about 44° F (7° C). The average annual rainfall is about 64 inches (1,625 millimetres). Most of this falls from June to September, the period of the monsoon. These months are very humid and sometimes sultry. During October and November the rainfall dwindles. The winter months, from about the end of November to the end of February, are pleasant and rainless; fogs and mists occasionally reduce visibility in the early morning hours at this season, as also do thick blankets of smog in the evenings. The atmospheric pollution has greatly increased since the early 1950s. Factories, motor vehicles, and thermal-generating stations, which burn coal, are primary causes of this pollution, but monsoon winds act as cleansing agents by bringing in fresh air masses and also hastening the removal of water pollution.

The city layout. The most striking aspect of the layout of Calcutta is its rectangular, north–south orientation. With the exception of the central areas where Europeans formerly lived, the city has grown haphazardly. This haphazard development is most noticeable in the fringe areas around the central core formed by the city of Calcutta and the suburb of Howrah. The bulk of the city's administrative and commercial activity is concentrated in the Barabazār district, a small area north of the Maidān



Calcutta and surrounding area.

(the park containing Fort William and many of the city's cultural and recreational facilities). This has encouraged the development of a pattern of daily commuting that has overburdened Calcutta's transportation system, utilities, and other municipal facilities.

The street plan

Calcutta's system of streets and roads reflects the city's historical development. Local streets are narrow. There is only one express highway—Kāzi Nazrul Islām Avenue, which stretches from Calcutta to Dum Dum. The main roads form a grid pattern primarily in the old European sector, but elsewhere road planning has a haphazard character. Part of the reason for this has been the difficulty of providing enough river crossings; and it is for the same reason that most streets and highways run from north to south. Nullahs (watercourses) and canals that require bridging have also been important factors in influencing the road pattern.

The housing shortage

Housing. The city has an acute housing shortage. Of the persons living in institutional shelters in the Calcutta Metropolitan District, more than two-thirds live in the city itself. About three-fourths of the housing units in the city are used for dwelling purposes only. There are hundreds of bustees, or slums, where about one-third of the city's population lives. A bustee is officially defined as "a collection of huts standing on a plot of land of at least one-sixth of an acre." There also are bustees built on less than one-sixth of an acre (one-fifteenth of a hectare). The majority of huts are tiny, unventilated, single-story rooms, often dilapidated. They have few sanitary facilities, and there is very little open space. The government sponsors a bustee-improvement program.

Architecture. In contemporary Calcutta the skyline is broken in some areas by skyscrapers and tall multistory blocks. The cityscape has changed rapidly. The Chowringhee area in central Calcutta, once a row of palatial houses, has been given up to offices, hotels, and shops. In northern and central Calcutta, buildings are still mainly two or three stories high. In southern and south central Calcutta, multistoried apartment buildings have become more common.

Western architectural influences

Western influence is dominant in Calcutta's architectural monuments. The Rāj Bhavan (the state governor's residence) is an imitation of Kedleston Hall in Derbyshire; the High Court resembles the Cloth Hall at Ypres, Belg.; the Town Hall is in Grecian style with a Doric-Hellenic portico; St. Paul's Cathedral is of Indo-Gothic-style architecture; the Writers' Building is of Gothic-style architecture with statuary on top; the Indian Museum is in an Italian style; and the General Post Office, with its majestic dome, has Corinthian columns. The beautiful column of the Sahid Minār (Ochterlony Monument) is 165 feet high—its base is Egyptian, its column Syrian, and its cupola in the Turkish style. The Victoria Memorial represents an attempt to combine classical Western influence with Mughal architecture; the Nakhoda Mosque is modeled on Akbar's Tomb at Sikandra; the Birla Planetarium is based on the stupa (Buddhist reliquary) at Sānchī.

The West Bengal Legislative Council is a dignified building in the modern architectural style. The Ramakrishna Mission Institute of Culture, the most important example of postindependence construction, follows the style of ancient Hindu palace architecture in northwestern India.

THE PEOPLE

The density of population is extremely high, about 85,500 persons per square mile (33,000 per square kilometre). Overcrowding has reached virtually intolerable proportions in many sections of the city. Calcutta has experienced a high rate of population growth for more than a century, but events such as the partitioning of Bengal in 1947 and warfare in Bangladesh in the early 1970s precipitated massive population influxes. Large refugee colonies have also sprung up in the northern and southern suburbs. In addition, a large number of migrants from other states—mostly from neighbouring Bihār and Orissa and eastern Uttar Pradesh—have come to Calcutta in search of employment.

More than four-fifths of the population is Hindu. Muslims and Christians constitute the largest minorities, but there are some Sikhs, Jains, and Buddhists. The dominant language is Bengali, but Urdu, Oriya, Tamil, Punjabi, and other languages are also spoken. Calcutta is also a cosmopolitan city: other groups present include a variety of peoples from Asia (notably Bangladeshis and Chinese), Europeans, North Americans, and Australians. Calcutta was racially segregated under British rule, the Europeans living in the city centre and Indians living to the north and south. The pattern of segregation has continued in the modern city, although the distribution is now based on religious, linguistic, educational, and economic criteria. Slums and low-income residential areas, however, exist side-by-side with more affluent areas.

THE ECONOMY

Calcutta's position as one of India's preeminent economic centres is rooted in its industries, financial and trade activities, and role as a major port; it is also a major centre for printing, publishing, and newspaper circulation, as well as for recreation and entertainment. The products of Calcutta's hinterland include coal, iron, manganese, mica, petroleum, tea, and jute. Unemployment has been a continuing and growing problem since the 1950s. Unemployment in Calcutta is, to a large extent, a problem of the college-educated and of people trained for clerical and other white-collar jobs.

Manufactured products

Industry. Calcutta is the world's largest processor of jute. The jute industry was established in the 1870s, and mills now extend north and south of the city centre on both banks of the Hooghly River. Engineering constitutes the city's other major industry. In addition, city factories produce and distribute a variety of consumer goods—notably foodstuffs, beverages, tobacco, and textiles—other light manufactures, and chemicals. Calcutta's industries have been in a general decline since Indian independence in 1947. Major factors contributing to this decline have been the loss of the eastern part of Bengal at independence, an overall decline in Calcutta's industrial productivity, and the lack of industrial diversification in the city.

Finance and trade. The Calcutta stock exchange plays an important part in the organized financial market of the country. Foreign banks also have a significant business base in Calcutta although the city's importance as an international banking centre has declined. In addition, the controlling agency for coal mines is in Calcutta. Jute mills and large-scale engineering industries are also controlled from the city; and the Bengal Chamber of Commerce and Industry, the Bengal National Chamber of Commerce and Industry, and the Indian Chamber of Commerce are based there.

That the city's economy is primarily mercantile is reflected in the fact that about two-fifths of the workers are employed in trade and commerce. Other important occupations include public-sector service in government departments, financial institutions, and medical and educational institutions. Private-sector services include the stock exchange, medical and educational services, legal services, accountancy and credit firms, chambers of commerce, and various utility services.

Transportation. The condition of the surfaced roads in the city is poor, although the traffic load is heavy. The mass-transportation system mainly depends on trams and buses. Trams are under government management. Buses are run by the government and by private companies. In 1986 the first section of a subway system—the first in India—was opened in the city.

The connection between Calcutta and its hinterland to the west depends upon only a few bridges over the Hooghly—the Howrah Bridge and, farther north, the bridges at Bally and Naihāti. The Howrah Bridge, Calcutta's main link with the hinterland, carries eight lanes of vehicular traffic, has two tramway tracks in the centre, and is one of the most heavily used bridges in the world. A second bridge between Howrah and Calcutta has been under construction since the 1970s.

The Grand Trunk Road (National Highway No. 2) is one of the oldest road routes in India. It runs from Howrah to Kashmir and is the main route connecting the city with northern India. Other national highways connect Calcutta with the west coast of India, the northern part of West Bengal, and the frontier with Bangladesh.

Two railway terminals—Howrah on the west bank and Sealdah on the east—serve the railway networks running north and south as well as those running east and west. Calcutta's major air terminal, at Dum Dum, handles international and domestic flights.

The Calcutta port handles—in terms of volume—one-tenth of India's import cargoes and about one-twelfth of its export cargoes. Some decline in traffic has occurred, however, partly because of problems encountered in dredging silt from the river and partly because of labour problems. Transport, storage, wholesaling, and retailing requirements for exports and imports are concentrated in Calcutta and Howrah. The Calcutta port lost its position as India's preeminent cargo handler in the 1960s, but it and the port of Haldia (about 40 miles downstream) still account for a large portion of the country's foreign exchange.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Government in the city proper is the responsibility of the Calcutta Municipal Corporation; the corporation's council is composed of one elected representative from each of the city's 100 wards. The council members annually elect a mayor, a deputy mayor, and a number of committees to conduct the activities of the corporation. A commissioner, the executive head of the corporation, is responsible to its elected membership. The city is also a part of the Calcutta Metropolitan District, an entity created to oversee planning and development on a regional basis. This district includes a large rural hinterland around the urban centres.

Because Calcutta is the capital of West Bengal, the governor resides in the city in the historic Rāj Bhavan. The state Legislative Assembly is located in the city, as is the Secretariat, housed in the Writers' Building, with the state ministries in charge of various departments. The Calcutta High Court, exercising original jurisdiction over the city and appellate jurisdiction over West Bengal, is also located there. A number of national government institutions—including the National Library, the Indian Museum, and the Geological Survey of India—are also in the city.

Services. Filtered water is supplied from the main waterworks located outside the city at Palta, as well as from some 200 major wells and 3,000 smaller ones. The Farakka Barrage (dam) on the Ganges, 240 miles upriver from Calcutta, ensures a generally saline-free water supply for the city; but because existing water supplies are inadequate, salinity continues to be a problem during the dry months. In addition, unfiltered water, supplied daily for watering the city streets and for the fire brigade, is used by many residents for their daily needs. This circumstance was largely responsible for the former prevalence of cholera during the summer months, but chlorination of unfiltered water and cholera inoculation have reduced considerably the occurrence of the disease.

Water supplies

Municipal Calcutta has several hundred miles of sewers and surface drains, but much of the city remains unsupplied with sewers. Accumulation of silt has narrowed many sewer channels. Unsanitary methods of human-waste disposal persist in the unsewered areas of the city. The system of removing garbage and of garbage dumping is also unsatisfactory.

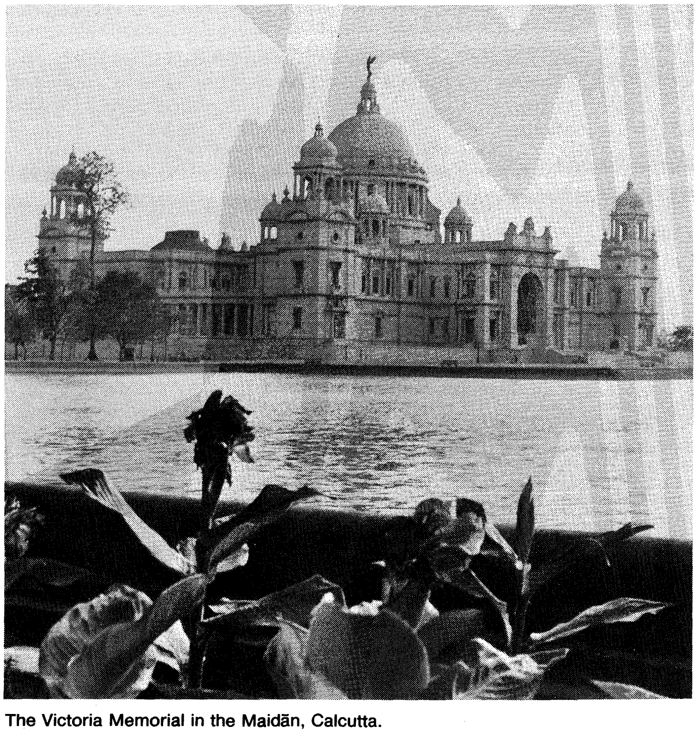
Calcutta is supplied with electricity by a variety of sources, including the Calcutta Electric Supply Corporation; West Bengal State Electricity Board; Durgapur Projects, Ltd.; Bandel Thermal Power Station; Santaldih Power Station; and Damodar Valley Corporation Grid. There is still a gap, however, between generating capacity and potential demand, and temporary power interruptions occur on occasion.

Security

Administration of the Calcutta police force is vested in the city's commissioner of police, as is direction of the suburban police force. The city is divided into four police divisions. The fire brigade has its headquarters in central Calcutta.

Health. Smallpox has been completely eradicated from the city, and death from malaria and enteric fever has been brought under control. The incidence of tuberculosis has also declined. Hundreds of hospitals, private clinics, free dispensaries run by the Calcutta Municipal Corpora-

G.R. Richardson—Taurus Photos



The Victoria Memorial in the Maidān, Calcutta.

tion and charitable trusts, and state-operated polyclinics serve the Calcutta region. The Order of the Missionaries of Charity, an organization founded (1948) by Mother Teresa (recipient of the Nobel Peace Prize of 1979), cares for the blind, the aged, the dying, and lepers in the poorest sections of the city. There are several medical colleges in addition to other medical research centres. The number of doctors per 1,000 persons is greater in Calcutta than in most parts of the country, but their distribution is uneven; and since the city is a medical centre for the northeastern region of India, its health-care facilities are always overcrowded.

Medical acilities

Education. Education has long been a mark of higher social status in Calcutta. The city has been a centre of learning since the resurgence in Indian education that began in Bengal in the early 19th century. The first English-style school, the Hindu College (later called Presidency College), was founded in 1817.

Primary education is supervised by the government of West Bengal and is free in schools run by the municipal corporation. A large number of children, however, attend recognized schools that are under private management. Most secondary schools are under the supervision of the state, but some are accredited through the national government and a few through the British educational system.

The universities

Calcutta has three major universities: the University of Calcutta, Jadavpur University, and Rabindra Bharati University. The University of Calcutta, founded in 1857, has more than 150 affiliated colleges. Besides these colleges, university colleges of arts (humanities), commerce, law, medicine, science, and technology specialize in postgraduate teaching and research. Jadavpur University has three faculties—arts (humanities), science, and engineering. Although the university has a small number of colleges affiliated with it, its main focus is on graduate and post-graduate instruction on a single campus. Rabindra Bharati University specializes in humanities and the fine arts (dance, drama, and music).

Research institutions include the Indian Statistical Institute, the Indian Association for the Cultivation of Science, the Bose Institute (natural science), and the All-India Institute of Hygiene and Public Health, which is a constituent college of the University of Calcutta.

CULTURAL LIFE

Calcutta is the most important cultural centre of India. The city is the birthplace of modern Indian literary and artistic thought and of Indian nationalism, and the efforts of its citizens to preserve Indian culture and civilization have no parallel in the rest of the country. The blending of Eastern and Western cultural influences over the centuries has stimulated the creation of numerous and diverse organizations that contribute to Calcutta's cultural life. In addition to the three universities, these include the Asiatic Society, the Bengal Literary Society (Bangiya Sahitya Parishad), the Ramakrishna Mission Institute of Culture, the Academy of Fine Arts, the Birla Academy of Art and Culture, and the Maha Bodhi Society.

Museums and libraries. Greater Calcutta has more than 30 museums, which cover a wide variety of fields. The Indian Museum, founded in 1814, is the oldest in India and is the largest museum of its kind in the country; the archaeology and numismatic sections contain the most valuable collections. The exhibits at Victoria Memorial trace Britain's relations with India. The Asutosh Museum of Indian Art in the University of Calcutta has exhibits of the folk art of Bengal among its collections. Valuable library collections are to be found in the Asiatic Society, Bengal Literary Society, and the University of Calcutta; the National Library is the largest in India and contains a fine collection of rare books and manuscripts.

The arts. Calcuttans have long been active in literary and artistic pursuits. The literary movement spawned there in the mid-19th century through exposure to Western forms sparked a cultural renaissance throughout India. The best exponent of this movement was Rabindranath Tagore, winner of the Nobel Prize for Literature of 1913, whose remarkable creativity in poetry, music, drama, and painting continues to enrich the cultural life of the city. Calcutta remains at the vanguard of artistic movements in the country, and several artists' societies present annual shows.

Calcutta is also a centre of traditional and contemporary music and dance. In 1937 Tagore inaugurated the first All-Bengal Music Conference in Calcutta. Since then, a number of classical Indian music conferences have been held every year. The home of many classical dancers, Calcutta was also the location of Uday Shankar's experiments at adapting Western theatrical techniques to traditional dance forms. The school of dance, music, and drama founded by him has been in the city since 1965.

Theatre and films

Professional drama got its start in Calcutta in the 1870s with the founding of the National Theatre. Modern dramatic forms were pioneered in the city by such playwrights as Girish Chandra Ghosh and Dirabandhu Mitra. Calcutta is still an important centre of professional and amateur theatre and of experimental drama. The city has also been a pioneering centre of motion-picture production in India. The avant-garde film directors Satyajit Ray and Mrinal Sen have achieved international acclaim. There are scores of cinemas in the city, which regularly show films in English, Bengali, and Hindi.

Recreation. More than 200 parks, squares, and open spaces are maintained by the Calcutta Municipal Corporation. There is, however, very little open space in the overcrowded parts of the city. The Maidān, about two miles in length and a mile in width, is the best-known open space; the major soccer, cricket, and hockey fields are located there. Adjacent to the Maidān is one of the oldest cricket fields in the world, Ranji Stadium, in the Eden Gardens; Netāji Stadium, for indoor events, is also in the vicinity. The Salt Lake Stadium, built to the east of the city, can seat 100,000 spectators. There are two racecourses and two golf courses within the city, and rowing at the Lake Club and the Bengal Rowing Club is popular. The Zoological Gardens are spread over an area of some 50 acres (20 hectares). The Indian Botanical Gardens is located on the west bank of the rivers; the herbarium there contains about 40,000 species of plants.

History

THE EARLY PERIOD

The name Kalikātā had been mentioned in the rent-roll of the Mughal emperor Akbar (reigned 1556–1605) and also in the *Manasā-maṅgal* of the Bengali poet Bipradās (1495). The history of Calcutta as a British settlement dates from the establishment of a trading post there by Job Charnock, an agent of the English East India Company, in 1690. Charnock had previously had disputes with officials of the Mughal Empire at the river port of Hooghly and had been obliged to leave, after which he attempted unsuccessfully to establish himself at other places down the river. When the Mughal officials, not wishing to lose what they had gained from the English company's commerce, permitted Charnock to return once more, he chose Calcutta as the seat of his operations. The site was apparently carefully selected, being protected by the Hooghly River on the west, a creek to the north, and by salt lakes about two and a half miles to the east. Rival Dutch, French, and other European settlements were higher up the river on the west bank, so that access from the sea was not threatened, as it was at the port of Hooghly. The river at this point was also wide and deep; the only disadvantage was that the marshes to the east and swamps within the area made the spot unhealthy. Moreover, before the coming of the English, three local villages—Sutānati, Kalikātā, and Gobindapore, which were later to become parts of Calcutta—had been chosen as places to settle by Indian merchants who had migrated from the silted-up port of Satgāon, farther upstream. The presence of these merchants may have been to some extent responsible for Charnock's choice of the site.

By 1696, when a rebellion broke out in the nearby district of Burdwān, the Mughal provincial administration had become friendly to the growing settlement. The servants of the company, who asked for permission to fortify their trading post, or factory, were given permission in general terms to defend themselves. The rebels were easily crushed by the Mughal government, but the settlers' defensive structure of brick and mud remained and, in 1700, came to be known as Fort William. In 1698 the English obtained letters patent that granted them the privilege of purchasing the zamindari right (the right of revenue collection; in effect, the ownership) of the three villages.

GROWTH OF THE CITY

In 1717 the Mughal emperor Farrukh-siyar granted the East India Company freedom of trade in return for a yearly payment of 3,000 rupees; this arrangement gave a great impetus to the growth of Calcutta. A large number of Indian merchants flocked to the city. The servants of the company, under the company's flag, carried on a duty-free private trade. When the Marāṭhās from the southwest began incursions against the Mughals in the western districts of Bengal in 1742, the English obtained permission from ʿAli Vardi Khan, the nawab (ruler) of Bengal, to dig an entrenchment in the northern and eastern part of the town to form a moat on the land side. This came to be known as the Marāṭhā Ditch. Although it was not completed to the southern end of the settlement, it marked the city's eastern boundary.

In 1756 the Nawab's successor, Sirāj-ud-Dawlah, captured the fort and sacked the town. Calcutta was recaptured in January 1757 by Robert Clive, one of the founders of British power in India, and by the British admiral Charles Watson. The Nawab was defeated shortly afterward at Plassey (June 1757), after which British rule in Bengal was assured. Gobindapore was cleared of its forests, and the new Fort William was built on its present site, overlooking the Hooghly at Calcutta, where it became the symbol of British military ascendancy.

The capital of British India

Calcutta did not become the capital of British India until 1772, when the first governor general, Warren Hastings, transferred all important offices to the city from Murshidābād, the provincial Mughal capital. In 1773 Bombay and Madras became subordinate to the government at Fort William. A supreme court administering English law began to exercise original jurisdiction over the city as far as the Marāṭhā Ditch (now Ācharya Prafulla Chandra and Jagadish Chandra Bose roads).

In 1706 the population of Calcutta had been about 10,000 to 12,000. By 1752 it had increased to nearly 120,000 and by 1821 to 180,000. The White (British) Town was built on ground that had been raised and drained. There were so many palaces in the British sector of the city that it was named the "city of palaces." Outside the British town were built the mansions of the newly rich, as well as clusters of huts. The names of different quarters of the city—such as Kumārtuli (the potters' district) and Sankaripara (the conch-shell workers' district)—still indicate the various occupational castes of the people who became residents of the growing metropolis. Two distinct areas—one British, one Indian—came to coexist in Calcutta.

Calcutta at this time was described as a pestilential town. There were few good roads. In 1814 a Lottery Committee was constituted to finance public improvement by means of lotteries, and between 1814 and 1836 it took some effective measures to improve conditions. The corporation was established in 1841. Cyclones in 1864, 1867, and 1870, however, devastated the poorer, low-lying areas.

Development of the port

By successive stages, as British power extended over the subcontinent, the whole of northern India became a hinterland for the port of Calcutta. The abolition of inland customs duties in 1835 created an open market, and the construction of railways (beginning in 1854) further quickened the development of business and industry. It was at this time that the Grand Trunk Road from Calcutta to Peshāwar (now in Pakistan) was completed. British mercantile, banking, and insurance interests flourished. The Indian sector of Calcutta also became a busy hub of commerce and was thronged with people from all parts of India and many other parts of Asia. Calcutta became the intellectual centre of the subcontinent.

CALCUTTA IN THE 20TH CENTURY

The 20th century marked the beginning of Calcutta's woes. Lord Curzon, viceroy of India, partitioned Bengal in 1905, making Dacca (now Dhākā) the capital of eastern Bengal and Assam. Insistent agitation led to the annulment of this partition, but in 1912 the capital of British India was removed from Calcutta to Delhi, where the government could enjoy relative calm. The partition of Bengal in 1947 was a final blow.

Modern social problems

As Calcutta's population grew larger, social problems also became more insistent, as did demands for home rule for India. Communal riots occurred in 1926, and, when Mahatma Gandhi called for noncompliance with unjust laws, riots occurred in 1930. In World War II, Japanese air raids upon the Calcutta docks caused damage and loss of life. The most serious communal riots of all took place in 1946, when the partition of British India became imminent and tensions between Muslims and Hindus reached their height.

In 1947 the partition of Bengal between India and Pakistan constituted a serious setback for Calcutta, which became the capital of West Bengal only, losing the trade of a part of its former hinterland. At the same time, millions of refugees from East Pakistan (now Bangladesh) flocked to Calcutta, aggravating social problems and increasing overcrowding, which had already assumed serious proportions. Economic stagnation in the mid-1960s further increased the instability of the city's social and political life and fueled a flight of capital from the city. The management of many companies was assumed by the state government. Particularly in the 1980s, large-scale public works programs and centralized regional planning contributed to the improvement of economic and social conditions in the city.

Calendar

A calendar is a means of grouping days in ways convenient for regulating civil life and religious observances and for historical and scientific purposes. The word is derived from the Latin *calendarium,* meaning interest register, or account book, itself a derivation from *calendae* (or *kalendae*), the first day of the Roman month, the day on which future market days, feasts, and other occasions were proclaimed.

The development of a calendar is vital for the study of chronology, since this is concerned with reckoning time by regular divisions, or periods, and using these to date events. It is essential, too, for any civilization that needs to measure periods for agricultural, business, domestic, or other reasons. The first practical calendar to evolve from these requirements was the Egyptian, and it was this that the Romans developed into the Julian calendar that served western Europe for more than 1,500 years. The Gregorian calendar was a further improvement and has been almost universally adopted because it satisfactorily draws into one system the dating of religious festivals based on the phases of the Moon and seasonal activities determined by the movement of the Sun. Such a calendar system is complex, since the periods of the Moon's phases and the Sun's motion are incompatible; but by adopting regular cycles of days and comparatively simple rules for their application, the calendar provides a year with an error of less than half a minute.

This article is divided into the following sections:

Measurement of time and types of calendars

STANDARD UNITS AND CYCLES

The basic unit of computation in a calendar is the day, and although days are now measured from midnight to midnight this has not always been so. Astronomers, for instance, from about the 2nd century AD until 1925 counted days from noon to noon. In earlier civilizations and among primitive peoples, where there was less communication between different settlements or groups, different methods of reckoning the day presented no difficulties. Most primitive tribes used a dawn-to-dawn reckoning, calling a succession of days so many dawns, or suns. Later, the Babylonians, Jews, and Greeks counted a day from sunset to sunset, whereas the day was said to begin at dawn for the Hindus and Egyptians and at midnight for the Romans. The Teutons counted nights, and from them the grouping of 14 days called a fortnight is derived.

Divisions of the day

There was also great variety in the ways in which the day was subdivided. In Babylonia, for example, the astronomical day was divided differently than the civil day, which, as in other ancient cultures, was composed of "watches." The length of the watches was not constant but varied with the season, the day watches being the longer in summer and the night watches in the winter. Such seasonal rariations in divisions of the day, now called seasonal or temporal hours, became customary in antiquity because they corresponded to the length of the Sun's time above the horizon, at maximum in summer and at minimum in winter. Only with the advent of mechanical clocks in western Europe at the end of the 13th century did seasonal (unequal) hours become inconvenient.

Most early Western civilizations used 24 seasonal hours in the day—12 hours of daylight and 12 of darkness. This was the practice of the Greeks, the Sumerians and Babylonians, the Egyptians, and the Romans, and of Western Christendom so far as civil reckoning was concerned. The church adopted its own canonical hours for reckoning daily worship: there were seven of these—matins, prime, terce, sext, none, vespers, and compline—but in secular affairs the system of 24 hours held sway. This number, 2 × 12, or 24, was derived in Babylonia from the Sumerian sexagesimal method of reckoning, based on gradations of 60 ($5 \times 12 = 60$) rather than on multiples of 10. In Babylonia, for most purposes, both daylight and night were divided into three equal watches, and each watch was subdivided into half- and quarter-watches. Babylonian astronomers, perhaps in preference to the variable civil system, divided every day into 12 equal units, called *bēru,* each of which was subdivided into 30 *gesh.* The oldest known astronomical texts are from the Old Babylonian period, but this dual system may be attributable to earlier Sumerian society.

Origins of the week

Once the day is divided into parts, the next task is to gather numbers of days into groups. Among primitive peoples, it was common to count moons (months) rather than days, but later a period shorter than the month was thought more convenient, and an interval between market days was adopted. In West Africa some tribes used a four-day interval; in central Asia five days was customary; the Assyrians adopted five days and the Egyptians, 10 days, whereas the Babylonians attached significance to the days of the lunation that were multiples of seven. In ancient Rome, markets were held at eight-day intervals; because of the Roman method of inclusive numeration, the market day was denoted *nundinae* ("ninth-day") and the eight-day week, an *inter nundium.*

The seven-day week may owe its origin partly to the four (approximately) seven-day phases of the Moon and partly to the Babylonian belief in the sacredness of the number seven, which was probably related to the seven planets. Moreover, by the 1st century BC the Jewish seven-day week seems to have been adopted throughout the Roman world, and this influenced Christendom. The names in English of the days of the week are derived from Latin or Anglo-Saxon names of gods.

The month is based on the lunation, that period in which the Moon completes a cycle of its phases. The period lasts approximately 29½ days, and it is easy to recognize and short enough for the days to be counted without using large numbers. In addition, it is very close to the average menstrual period of women and also to the duration of cyclic behaviour in some marine creatures. Thus, the month possessed great significance and was often the governing period for religious observances, of which the dating of Easter is a notable example. Most early calendars were, essentially, collections of months, the Babylonians using 29- and 30-day periods alternately, the Egyptians fixing the duration of all months at 30 days, with the Greeks copying them, and the Romans in the Julian calendar having a rather more complex system using one 28-day period with the others of either 30 or 31 days.

The seasons

The month is not suitable for determining the seasons, for these are a solar, not a lunar, phenomenon. Seasons vary in different parts of the world—in tropical countries there are just the rainy and dry periods, but elsewhere there are successions of wider changes. In Egypt the annual flooding of the Nile was followed by seeding and then harvest, and three seasons were recognized; but in Greece and other more northern countries there was a succession of four seasons of slightly different lengths. However many there seemed to be, it was everywhere recognized that seasons were related to the Sun and that they could be determined from solar observations. These might consist of noting the varying length of the midday shadow cast by a stick thrust vertically into the ground or follow the far more sophisticated procedure of deducing from nocturnal observations the Sun's position against the background of the stars. In either case the result was a year of 365 days, a period incompatible with the 29½-day lunation. To find some simple relationship between the two periods was the problem that faced all calendar makers from Babylonian times onward.

Nonastronomical cycles

A number of nonastronomical natural signs have also been used in determining the seasons. In the Mediterranean area, such indications change rapidly, and Hesiod (*c.* 800 BC) mentions a wide variety: the cry of migrating cranes, which indicated a time for plowing and sowing; the time when snails climb up plants, after which digging in vineyards should cease; and so on. An unwitting approximation to the tropical year may also be obtained by intercalation, using a simple lunar calendar and observations of animal behaviour. Such an unusual situation has grown up among the Yami fishermen of Botel-Tobago Island, near Taiwan. They use a calendar based on phases of the Moon, and some time about March (the precise date depends on the degree of error of their lunar calendar compared with the tropical year) they go out in boats with lighted flares. If flying fish appear, the fishing season is allowed to commence, but if the lunar calendar is too far out of step with the seasons, the flying fish will not rise. Fishing is then postponed for another lunation, which they insert in the lunar calendar, thus having a year of 13 instead of the usual 12 lunations.

TIME DETERMINATION BY STARS, SUN, AND MOON

Measurement of the day, the month, and the year

Celestial bodies provide the basic standards for determining the periods of a calendar. Their movement as they rise and set is now known to be a reflection of the Earth's rotation, which, although not precisely uniform, can conveniently be averaged out to provide a suitable calendar day. The day can be measured either by the stars or by the Sun. If the stars are used, then the interval is called the sidereal day and is defined by the period between two passages of a star (more precisely of the vernal equinox, a reference point on the celestial sphere) across the meridian: it is 23 hours 56 minutes 4.10 seconds of mean solar time (see below). The interval between two passages of the Sun across the meridian is a solar day. In practice, since the rate of the Sun's motion varies with the seasons, use is made of a fictitious Sun that always moves across the sky at an even rate. This period of constant length, far more convenient for civil purposes, is the mean solar day, which has a duration in sidereal time of 24 hours 3 minutes 56.55 seconds. It is longer than the sidereal day because the motion of the Earth in its orbit during the period between two transits of the Sun means that the Earth must complete more than a whole revolution to bring the Sun back to the meridian. The mean solar day is the period used in calendar computation.

The month is determined by the Moon's passage around the Earth, and, as in the case of the day, there are several ways in which it can be defined. In essence, these are of two kinds: first, the period taken by the Moon to complete an orbit of the Earth and, second, the time taken by the Moon to complete a cycle of phases. Among primitive societies, the month was determined from the phases; this interval, the synodic month, is now known to be 29.53059 days. The synodic month grew to be the basis of the calendar month.

The year is the period taken by the Earth to complete an orbit around the Sun and, again, there are a number of ways in which this can be measured. But for calculating a calendar that is to remain in step with the seasons, it is most convenient to use the tropical year, since this refers directly to the Sun's apparent annual motion. The tropical year is defined as the interval between successive passages of the Sun through the vernal equinox (*i.e.,* when it crosses the celestial equator late in March) and amounts to 365.242199 mean solar days.

The tropical year and the synodic month are incommensurable, 12 synodic months amounting to 354.36706 days, almost 11 days shorter than the tropical year. Moreover, neither is composed of a complete number of days, so that to compile any calendar that keeps in step with the Moon's phases or with the seasons it is necessary to insert days at appropriate intervals; such additions are known as intercalations.

Locating the Sun among the stars

In primitive lunar calendars, intercalation was often achieved by taking alternately months of 29 and 30 days. When, in order to keep dates in step with the seasons, a solar calendar was adopted, some greater difference between the months and the Moon's phases was bound to occur. And the solar calendar presented an even more fundamental problem—that of finding the precise length of the tropical year. Observations of cyclic changes in plant or animal life were far too inaccurate, and astronomical observations became necessary. Since the stars are not visible when the Sun is in the sky, some indirect way had to be found to determine its precise location among them. In tropical and subtropical countries it was possible to use the method of heliacal risings. Here the first task was to determine the constellations around the whole sky through which the Sun appears to move in the course of a year. Then, by observing the stars rising in the east just after sunset it was possible to know which were precisely opposite in the sky, where the Sun lay at that time. Such heliacal risings could, therefore, be used to determine the seasons and the tropical year. In temperate countries, the angle at which stars rise up from the horizon is not steep enough for this method to be adopted, so that there wood or stone structures were built to mark out points along the horizon to allow analogous observations to be made.

Stonehenge

The most famous of these is Stonehenge in Wiltshire, England, where the original structure appears to have been built about 2000 BC and additions made at intervals several centuries later. It is composed of a series of holes, stones, and archways arranged mostly in circles, the outermost ring of holes having 56 marked positions, the inner ones 30 and 29, respectively. In addition, there is a large stone—the heel stone—set to the northeast, as well as some smaller stone markers. Observations were made by lining up holes or stones with the heel stone or one of the other markers and watching for the appearance of the Sun or Moon against that point on the horizon that lay in the same straight line. The extreme north and south positions on the horizon of the Sun—the summer and winter solstices—were particularly noted, while the inner circles, with their 29 and 30 marked positions, allowed "hollow" and "full" (29- or 30-day) lunar months to be counted off. More than 600 contemporaneous structures of an analogous but simpler kind have been discovered in Britain, in Brittany, and elsewhere in Europe and the Americas. It appears, then, that astronomical observation for calendrical purposes was a widespread practice in some temperate countries three to four millennia ago.

Today a solar calendar is kept in step with the seasons by a fixed rule of intercalation. But although the Egyptians, who used the heliacal rising of Sirius to determine the annual inundation of the Nile, knew that the tropical year was about 365.25 days in length, they still used a 365-day year without intercalation. This meant that the calendar date of Sirius' rising became increasingly out of step with the original dates as the years progressed. In consequence, while the agricultural seasons were regulated by the heliacal rising of Sirius, the civil calendar ran its own separate course. It was not until well into Roman times that an intercalary day once every four years was instituted to retain coincidence.

COMPLEX CYCLES

The fact that neither months nor years occupied a whole number of days was recognized quite early in all the great civilizations. Some observers also realized that the difference between calendar dates and the celestial phenomena due to occur on them would first increase and then diminish until the two were once more in coincidence. The succession of differences and coincidences would be cyclic, recurring time and again as the years passed. An early recognition of this was the Egyptian Sothic cycle, based on the star Sirius (called Sothis by ancient Egyptians). The error with respect to the 365-day year and the heliacal risings of Sirius amounted to one day every four tropical years, or one whole Egyptian calendar year every 1,460 tropical years (4 × 365), which was equivalent to 1,461 Egyptian calendar years. After this period the heliacal rising and setting of Sothis would again coincide with the calendar dates (see below *The Egyptian calendar*).

The *octaëteris*

The main use of cycles was to try to find some commensurable basis for lunar and solar calendars, and the best known of all the early attempts was the *octaëteris*, usually attributed to Cleostratus of Tenedos (*c.* 500 BC) and Eudoxus of Cnidus (390–*c.* 340 BC). The cycle covered eight years, as its name implies, and so the *octaëteris* amounted to 8 × 365, or 2,920 days. This was very close to the total of 99 lunations (99 × 29.5 = 2,920.5 days), so this cycle gave a worthwhile link between lunar and solar calendars. When, in the 4th century BC, the accepted length of the year became 365.25 days, the total number of solar calendar days involved became 2,922, and it was then realized that the *octaëteris* was not as satisfactory a cycle as supposed.

The saros

Another early and important cycle was the saros, essentially an eclipse cycle. There has been some confusion over its precise nature because the name is derived from the Babylonian word *shār* or *shāru,* which could mean either "universe" or the number 3,600 (*i.e.,* 60 × 60). In the latter sense it was used by Berosus (*c.* 290 BC) and a few later authors to refer to a period of 3,600 years. What is now known as the saros and appears as such in astronomical textbooks (still usually credited to the Babylonians) is a period of 18 years $11\frac{1}{3}$ days (or with one day more or less, depending on how many leap years are involved), after which a series of eclipses is repeated.

The Metonic cycle

In Central America an independent system of cycles was established (see below *Ancient and religious calendar systems: The Americas*). The most significant of all the early attempts to provide some commensurability between a religious lunar calendar and the tropical year was the Metonic cycle. This was first devised about 432 BC by the astronomer Meton of Athens. Meton worked with another Athenian astronomer, Euctemon, and made a series of observations of the solstices, when the Sun's noonday shadow cast by a vertical pillar, or gnomon, reaches its annual maximum or minimum, to determine the length of the tropical year. Taking a synodic month to be 29.5 days, they then computed the difference between 12 of these lunations and their tropical year, which amounted to 11 days. It could be removed by intercalating a month of 33 days every third year. But Meton and Euctemon wanted a long-term rule that would be as accurate as they could make it, and they therefore settled on a 19-year cycle. This cycle consisted of 12 years of 12 lunar months each and seven years each of 13 lunar months, a total of 235 lunar months. If this total of 235 lunations is taken to contain 110 hollow months of 29 days and 125 full months of 30 days, the total comes to (110 × 29) + (125 × 30), or 6,940 days. The difference between this lunar calendar and a solar calendar of 365 days amounted to only five days in 19 years and, in addition, gave an average length for the tropical year of 365.25 days, a much-improved value that was, however, allowed to make no difference to daily reckoning in the civil calendar. But the greatest advantage of this cycle was that it laid down a lunar calendar that possessed a definite rule for inserting intercalary months and kept in step with a cycle of the tropical years. It also gave a more accurate average value for the tropical year and was so successful that it formed the basis of the calendar adopted in the Seleucid Empire (Mesopotamia) and was used in the Jewish calendar and the calendar of the Christian Church; it also influenced Indian astronomical teaching.

The Metonic cycle was improved by both Callippus and Hipparchus. Callippus of Cyzicus (*c.* 370–300 BC) was perhaps the foremost astronomer of his day. He formed what has been called the Callippic period, essentially a cycle of four Metonic periods. It was more accurate than the original Metonic cycle and made use of the fact that 365.25 days is a more precise value for the tropical year than 365 days. The Callippic period consisted of 4 × 235, or 940 lunar months, but its distribution of hollow and full months was different from Meton's. Instead of having totals of 440 hollow and 500 full months, Callippus adopted 441 hollow and 499 full, thus reducing the length of four Metonic cycles by one day. The total days involved therefore became (441 × 29) + (499 × 30), or 27,759, and 27,759 ÷ (19 × 4) gives 365.25 days exactly. Thus the Callippic cycle fitted 940 lunar months precisely to 76 tropical years of 365.25 days.

Precession of the equinoxes

Hipparchus, who flourished in Rhodes about 150 BC and was probably the greatest observational astronomer of antiquity, discovered from his own observations and those of others made over the previous 150 years that the equinoxes, where the ecliptic (the Sun's apparent path) crosses the celestial equator (the celestial equivalent of the terrestrial Equator), were not fixed in space but moved slowly in a westerly direction. The movement is small, amounting to no more than 2° in 150 years, and it is known now as the precession of the equinoxes. Calendrically, it was an important discovery because the tropical year is measured with reference to the equinoxes, and precession reduced the value accepted by Callippus. Hipparchus calculated the tropical year to have a length of 365.242 days, which was very close to the present calculation of 365.242199 days; he also computed the precise length of a lunation, using a "great year" of four Callippic cycles. He arrived at the value of 29.53058 days for a lunation, which, again, is comparable with the present-day figure, 29.53059 days.

The calendar dating of historical events and the determination of how many days have elapsed since some astronomical or other occurrence are difficult for a number of reasons. Leap years have to be inserted, but, not always regularly, months have changed their lengths and new ones have been added from time to time, years have commenced on varying dates and their lengths have been computed in various ways. Since historical dating must take all these factors into account, it occurred to the 16th-century French classicist and literary scholar Joseph Justus Scaliger (1540–1609) that a consecutive numbering system could be of inestimable help. This he thought should be arranged as a cyclic period of great length, and he worked out the system that is known as the Julian period, in honour of his father Julius Caesar Scaliger (1484–1558). He published his proposals in Paris in 1583 under the title *De Emendatione Temporum.*

The Julian period is a cycle of 7,980 years. It is based on the Metonic cycle of 19 years, a "solar cycle" of 28 years, and the Indiction cycle of 15 years. The so-called solar cycle was a period after which the days of the seven-day week repeated on the same dates. Since one year contains 52 weeks of seven days, plus one day, the days of the week would repeat every seven years were no leap year to intervene. A Julian calendar (see below) leap year cycle is four

Cycle of Indiction

years, therefore the days of the week repeat on the same dates every 4 × 7 = 28 years. The cycle of the Indiction was a fiscal, not an astronomical, period. It first appears in tax receipts for Egypt in AD 303, and probably took its origin in a periodic 15-year taxation census that followed Diocletian's reconquest of Egypt in AD 297. By multiplying the Metonic, solar, and Indiction cycles together, Scaliger obtained his cycle of 7,980 years (19 × 28 × 15 = 7,980), a period of sufficient length to cover most previous and future historical dates required at any one time.

Scaliger, tracing each of the three cycles back in time, found that all coincided in the year 4713 BC, on the Julian calendar reckoning. On the information available to him, he believed this to be a date considerably before any historical events. He therefore set the beginning of the first Julian period at January 1, 4713 BC. The years of the Julian period are not now used, but the day number is still used in astronomy and in preparing calendar tables, for it is the only record where days are free from combination into weeks and months.

(C.A.R.)

Ancient and religious calendar systems

THE NEAR EAST AND THE MIDDLE EAST

The lunisolar calendar, in which months are lunar but years are solar—that is, are brought into line with the course of the Sun—was used in the early civilizations of the whole Middle East, except Egypt, and in Greece. The formula was probably invented in Mesopotamia in the 3rd millennium BC. Study of cuneiform tablets found in this region facilitates tracing the development of time reckoning back to the 27th century BC, near the invention of writing. The evidence shows that the calendar is a contrivance for dividing the flow of time into units that suit society's current needs. Though calendar makers put to use time signs offered by nature—the Moon's phases, for example—they rearranged reality to make it fit society's constructions.

Babylonian calendars. In Mesopotamia the solar year was divided into two seasons, the "summer," which included the barley harvest in the second half of May or in the beginning of June, and the "winter," which roughly corresponded to today's fall–winter. Three seasons (Assyria) and four seasons (Anatolia) were counted in northerly countries, but in Mesopotamia the bipartition of the year seemed natural. As late as *c.* 1800 BC the prognoses for the welfare of the city of Mari, on the middle Euphrates, were taken for six months.

The months began at the first visibility of the New Moon, and in the 8th century BC court astronomers still reported this important observation to the Assyrian kings. The names of the months differed from city to city, and within the same Sumerian city of Babylonia a month could have several names, derived from festivals, from tasks (*e.g.,* sheepshearing) usually performed in the given month, and so on, according to local needs. On the other hand, as early as the 27th century BC, the Sumerians had used artificial time units in referring to the tenure of some high official—*e.g.,* on N-day of the turn of office of PN, governor. The Sumerian administration also needed a time unit comprising the whole agricultural cycle; for example, from the delivery of new barley and the settling of pertinent accounts to the next crop. This financial year began about two months after barley cutting. For other purposes, a year began before or with the harvest. This fluctuating and discontinuous year was not precise enough for the meticulous accounting of Sumerian scribes, who by 2400 BC already used the schematic year of 30 × 12 = 360 days.

The royal year

At about the same time, the idea of a royal year took precise shape, beginning probably at the time of barley harvest, when the king celebrated the new (agricultural) year by offering first fruits to gods in expectation of their blessings for the year. When, in the course of this year, some royal exploit (conquest, temple building, and so on) demonstrated that the fates had been fixed favourably by the celestial powers, the year was named accordingly; for example, as the year in which "the temple of Ningirsu was built." Until the naming, a year was described as that "following the year named (after such and such event)." The use of the date formulas was supplanted in Babylonia by the counting of regnal years in the 17th century BC.

The use of lunar reckoning began to prevail in the 21st century BC. The lunar year probably owed its success to economic progress. A barley loan could be measured out to the lender at the next year's threshing floor. The wider use of silver as the standard of value demanded more flexible payment terms. A man hiring a servant in the lunar month of Kislimu for a year knew that the engagement would end at the return of the same month, without counting days or periods of office between two dates. At the city of Mari in about 1800 BC, the allocations were already reckoned on the basis of 29- and 30-day lunar months. In the 18th century BC, the Babylonian Empire standardized the year by adopting the lunar calendar of the Sumerian sacred city of Nippur. The power and the cultural prestige of Babylon assured the success of the lunar year, which began on Nisanu 1, in the spring. When, in the 17th century BC, the dating by regnal years became usual, the period between the accession day and the next Nisanu 1 was described as "the beginning of the kingship of PN," and the regnal years were counted from this Nisanu 1.

It was necessary for the lunar year of about 354 days to be brought into line with the solar (agricultural) year of approximately 365 days. This was accomplished by the use of an intercalated month. Thus, in the 21st century BC, a special name for the intercalated month *iti dirig* appears in the sources. The intercalation was operated haphazardly, according to real or imagined needs, and each Sumerian city inserted months at will; *e.g.,* 11 months in 18 years or two months in the same year. Later, the empires centralized the intercalation, and as late as 541 BC it was proclaimed by royal fiat. Improvements in astronomical knowledge eventually made possible the regularization of intercalation; and, under the Persian kings (*c.* 380 BC), Babylonian calendar calculators succeeded in computing an almost perfect equivalence in a lunisolar cycle of 19 years and 235 months with intercalations in the years 3, 6, 8, 11, 14, 17, and 19 of the cycle. The new year's day (Nisanu 1) now oscillated around the spring equinox within a period of 27 days.

Babylonian months

The Babylonian month names were Nisanu, Ayaru, Simanu, Du'uzu, Abu, Ululu, Tashritu, Arakhsamna, Kislimu, Tebetu, Shabatu, Adaru. The month Adaru II was intercalated six times within the 19-year cycle but never in the year that was 17th of the cycle, when Ululu II was inserted. Thus, the Babylonian calendar until the end preserved a vestige of the original bipartition of the natural year into two seasons, just as the Babylonian months to the end remained truly lunar and began when the New Moon was first visible in the evening. The day began at sunset. Sundials and water clocks served to count hours.

The influence of the Babylonian calendar was seen in many continued customs and usages of its neighbour and vassal states long after the Babylonian Empire had been succeeded by others. In particular, the Jewish calendar in use at relatively late dates employed similar systems of intercalation of months, month names, and other details (see below *The Jewish calendar*). The Jewish adoption of Babylonian calendar customs dates from the period of the Babylonian Exile in the 6th century BC.

Other calendars used in the ancient Near East. *The Assyrians and the Hittites.* Of the calendars of other peoples of the ancient Near East, very little is known. Thus, though the names of all or of some months are known, their order is not. The months were probably everywhere lunar, but evidence for intercalation is often lacking; for instance, in Assyria. For accounting, the Assyrians also used a kind of week, of five days, as it seems, identified by the name of an eponymous official. Thus, a loan could be made and interest calculated for a number of weeks in advance and independently of the vagaries of the civil year. In the city of Ashur, the years bore the name of the official elected for the year; his eponym was known as the *limmu.* As late as about 1070 BC, his installation date was not fixed in the calendar. From about 1100 BC, however, Babylonian month names began to supplant Assyrian names, and, when Assyria became a world power, it used the Babylonian lunisolar calendar.

The calendar of the Hittite Empire is known even less well. As in Babylonia, the first Hittite month was that of first fruits, and, on its beginning, the gods determined the fates.

Iran. At about the time of the conquest of Babylonia in 539 BC, Persian kings made the Babylonian cyclic calendar standard throughout the Persian Empire, from the Indus to the Nile. Aramaic documents from Persian Egypt, for instance, bear Babylonian dates besides the Egyptian. Similarly, the royal years were reckoned in Babylonian style, from Nisanu 1. It is probable, however, that at the court itself the counting of regnal years began with the accession day. The Seleucids and, afterward, the Parthian rulers of Iran maintained the Babylonian calendar. The fiscal administration in northern Iran, from the 1st century BC, at least, used Zoroastrian month and day names in documents in Pahlavi (the Iranian language of Sāsānian Persia). The origin and history of the Zoroastrian calendar year of 12 months of 30 days, plus five days (that is, 365 days), remain unknown. It became official under the Sāsānian dynasty, from about AD 226 until the Arab conquest in 621. The Arabs introduced the Muslim lunar year, but the Persians continued to use the Sāsānian solar year, which in 1079 was made equal to the Julian year by the introduction of the leap year.

The Egyptian calendar. The ancient Egyptians originally employed a calendar based upon the Moon, and, like many peoples throughout the world, they regulated their lunar calendar by means of the guidance of a sidereal calendar. They used the seasonal appearance of the star Sirius (Sothis); this corresponded closely to the true solar year, being only 12 minutes shorter. Certain difficulties arose, however, because of the inherent incompatibility of lunar and solar years. To solve this problem the Egyptians invented a schematized civil year of 365 days divided into three seasons, each of which consisted of four months of 30 days each. To complete the year, five intercalary days were added at its end, so that the 12 months were equal to 360 days plus five extra days. This civil calendar was derived from the lunar calendar (using months) and the agricultural, or Nile, fluctuations (using seasons); it was, however, no longer directly connected to either and thus was not controlled by them. The civil calendar served government and administration, while the lunar calendar continued to regulate religious affairs and everyday life.

In time, the discrepancy between the civil calendar and the older lunar structure became obvious. Because the lunar calendar was controlled by the rising of Sirius, its months would correspond to the same season each year, while the civil calendar would move through the seasons because the civil year was about one-fourth day shorter than the solar year. Hence, every four years it would fall behind the solar year by one day, and after 1,460 years it would again agree with the lunisolar calendar. Such a period of time is called a Sothic cycle.

The Sothic
cycle

Because of the discrepancy between these two calendars, the Egyptians established a second lunar calendar based upon the civil year and not, as the older one had been, upon the sighting of Sirius. It was schematic and artificial, and its purpose was to determine religious celebrations and duties. In order to keep it in general agreement with the civil year, a month was intercalated every time the first day of the lunar year came before the first day of the civil year; later, a 25-year cycle of intercalation was introduced. The original lunar calendar, however, was not abandoned but was retained primarily for agriculture because of its agreement with the seasons. Thus, the ancient Egyptians operated with three calendars, each for a different purpose.

The only unit of time that was larger than a year was the reign of a king. The usual custom of dating by reign was: "year 1, 2, 3 . . . , etc., of King So-and-So," and with each new king the counting reverted back to year One. King lists recorded consecutive rulers and the total years of their respective reigns.

The civil year was divided into three seasons, commonly translated: Inundation, when the Nile overflowed the agricultural land; Going Forth, the time of planting when the Nile returned to its bed; and Deficiency, the time of low water and harvest.

The months of the civil calendar were numbered according to their respective seasons and were not listed by any particular name—*e.g.,* third month of Inundation—but for religious purposes the months had names. How early these names were employed in the later lunar calendar is obscure.

The days in the civil calendar were also indicated by number and listed according to their respective months. Thus a full civil date would be: "Regnal year 1, fourth month of Inundation, day 5, under the majesty of King So-and-So." In the lunar calendar, however, each day had a specific name, and from some of these names it can be seen that the four quarters or chief phases of the Moon were recognized, although the Egyptians did not use these quarters to divide the month into smaller segments, such as weeks. Unlike most people who used a lunar calendar, the Egyptians began their day with sunrise instead of sunset because they began their month, and consequently their day, by the disappearance of the old Moon just before dawn.

Designa-
tion of
days

As was customary in early civilizations, the hours were unequal, daylight being divided into 12 parts, and the night likewise; the duration of these parts varied with the seasons. Both water clocks and sundials were constructed with notations to indicate the hours for the different months and seasons of the year. The standard hour of constant length was never employed in ancient Egypt.

(J.D.Sc./C.A.R.)

Ancient Greek calendars in relation to the Middle East.
Earliest sources. The earliest sources (clay tablets of the 13th century BC, the writings of Homer and Hesiod) imply the use of lunar months; Hesiod also uses reckoning determined by the observation of constellations and star groups; *e.g.,* the harvest coincides with the visible rising of the star group known as the Pleiades before dawn. This simultaneous use of civil and natural calendars is characteristic of Greek as well as Egyptian time reckoning. In the classical age and later, the months, named after festivals of the city, began in principle with the New Moon. The lunar year of 12 months and about 354 days was to be matched with the solar year by inserting an extra month every other year. The Macedonians used this system as late as the 3rd century BC, although 25 lunar months amount to about 737 days, while two solar years count about 730 days. In fact, as the evidence from the second half of the 5th century BC shows, at this early time the calendar was already no longer tied in with the phases of the Moon. The cities, rather, intercalated months and added or omitted days at will to adjust the calendar to the course of the Sun and stars and also for the sake of convenience, as, for instance, to postpone or advance a festival without changing its traditional calendar date. The calendric New Moon could disagree by many days with the true New Moon, and in the 2nd century BC Athenian documents listed side by side both the calendar date and that according to the Moon. Thus, the lunar months that were in principle parallel might diverge widely in different cities. Astronomers such as Meton, who in 432 BC calculated a 19-year lunisolar cycle, were not heeded by the politicians, who clung to their calendar-making power.

The year. The civil year (*etos*) was similarly dissociated from the natural year (*eniautos*). It was the tenure term of an official or priest, roughly corresponding to the lunar year, or to six months; it gave his name to his time period. In Athens, for instance, the year began on Hecatombaion 1, roughly midsummer, when the new archon entered his office, and the year was designated by his name; *e.g.,* "when Callimedes was archon"—that is, 360–359 BC. There was no New Year's festival.

Civil and
natural
years
compared

As the archon's year was of indefinite and unpredictable length, the Athenian administration for accounting, for the dates of popular assemblies, etc., used turns of office of the sections (prytanies) of the Council (Boule), which each had fixed length within the year. The common citizen used, along with the civil months, the seasonal time reckoning based on the direct observation of the Moon's phases and on the appearance and setting of fixed stars. A device (called a *parapēgma*) with movable pegs indicated the approximate correspondence between, for example, the rising of the star Arcturus and the civil date.

After Alexander's conquest of the Persian Empire, the Macedonian calendar came to be widely used by the Greeks in the East, though in Egypt it was supplanted by the Egyptian year at the end of the 3rd century BC. The Seleucids, from the beginning, adapted the Macedonian year to the Babylonian 19-year cycle (see above *Babylonian calendars*). Yet, Greek cities clung to their arbitrary system of time reckoning even after the introduction of the Julian calendar throughout the Roman Empire. As late as *c.* AD 200, they used the antiquated *octaëteris* (see above *Complex cycles*).

Months, days, seasons. The Athenian months were called Hecatombaion (in midsummer), Metageitnion, Boedromion, Pyanopsion, Maimacterion, Poseideion, Gamelion, Anthesterion, Elaphebolion, Mounychion, Thargelion, and Scirophorion. The position of the intercalary month varied. Each month, in principle, consisted of 30 days, but in roughly six months the next to last day, the 29th, was omitted. The days were numbered within each of the three decades of the month. Thus, for example, Hecatombaion 16th was called "6th after the 10th of Hecatombaion." The Macedonian months were Dios (in fall), Apellaios, Audynaios, Peritios, Dystros, Xanthicos, Artemisios, Daisios, Panemos, Loos, Gorpiaios, and Hyperberetaios. In the Seleucid calendar, Dios was identified with the Babylonian Tashritu, Apellaios with Arakhsamna, and so on.

Similar to the Babylonian civil pattern, the daylight time and the night were divided into four "watches" and 12 (unequal) hours each. Thus, the length of an hour oscillated between approximately 45 and 75 present-day minutes, according to the season. Water clocks, gnomons, and, after *c.* 300 BC, sundials roughly indicated time. The season division was originally bipartite as in Babylonia—summer and winter—but four seasons were already attested by about 650 BC. (E.J.Bi.)

The early Roman calendar. This originated as a local calendar in the city of Rome, supposedly drawn up by Romulus some seven or eight centuries before the Christian Era. The year began in March and consisted of 10 months, six of 30 days and four of 31 days, making a total of 304 days: it ended in December, to be followed by what seems to have been an uncounted winter gap. Numa Pompilius, according to tradition the second king of Rome (715?–673? BC), is supposed to have added two extra months, January and February, to fill the gap and to have increased the total number of days by 50, making 354. To obtain sufficient days for his new months, he is then said to have deducted one day from the 30-day months, thus having 56 days to divide between January and February. But since the Romans had, or had developed, a superstitious dread of even numbers, January was given an extra day; February was still left with an even number of days, but as that month was given over to the infernal gods, this was considered appropriate. The system allowed the year of 12 months to have 355 days, an uneven number.

The so-called Roman republican calendar was supposedly introduced by the Etruscan Tarquinius Priscus (616–579 BC), according to tradition the fifth king of Rome. He wanted the year to begin in January since it contained the festival of the god of gates (later the god of all beginnings), but expulsion of the Etruscan dynasty in 510 BC led to this particular reform's being dropped. The Roman republican calendar still contained only 355 days, with February having 28 days; March, May, July, and October 31 days each; January, April, June, August, September, November, and December 29 days. It was basically a lunar calendar and short by 10¼ days of a 365¼-day tropical year. In order to prevent it from becoming too far out of step with the seasons, an intercalary month, Intercalans, or Mercedonius (from *merces,* meaning wages, since workers were paid at this time of year), was inserted between February 23 and 24. It consisted of 27 or 28 days, added once every two years, and in historical times at least, the remaining five days of February were omitted. The intercalation was therefore equivalent to an additional 22 or 23 days, so that in a four-year period the total days in the calendar amounted to (4 × 355) + 22 + 23, or 1,465: this gave an average of 366.25 days per year.

Intercalation was the duty of the Pontifices, a board that assisted the chief magistrate in his sacrificial functions. The reasons for their decisions were kept secret, but, because of some negligence and a measure of ignorance and corruption, the intercalations were irregular, and seasonal chaos resulted. In spite of this and the fact that it was over a day too long compared with the tropical year, much of the modified Roman republican calendar was carried over into the Gregorian calendar now in general use. (C.A.R.)

The Jewish calendar. *The calendar in Jewish history.* Present knowledge of the Jewish calendar in use before the period of the Babylonian Exile is both limited and uncertain. The Bible refers to calendar matters only incidentally, and the dating of components of Mosaic Law remains doubtful. The earliest datable source for the Hebrew calendar is the Gezer Calendar, written probably in the age of Solomon, in the late 10th century BC. The inscription indicates the length of main agricultural tasks within the cycle of 12 lunations. The calendar term here is *yereaḥ,* which in Hebrew denotes both "moon" and "month." The second Hebrew term for month, *ḥodesh,* properly means the "newness" of the lunar crescent. Thus, the Hebrew months were lunar. They are not named in pre-exilic sources except in the biblical report of the building of Solomon's Temple in I Kings, where the names of three months, two of them also attested in the Phoenician calendar, are given; the months are usually numbered rather than named. The "beginning of the months" was the month of the Passover (see JUDAISM: *The cycle of the religious year*). In some passages, the Passover month is that of *ḥodesh ha-aviv,* the lunation that coincides with the barley being in the ear. Thus, the Hebrew calendar is tied in with the course of the Sun, which determines ripening of the grain. It is not known how the lunar year of 354 days was adjusted to the solar year of 365 days. The Bible never mentions intercalation. The year *shana,* properly "change" (of seasons), was the agricultural and, thus, liturgical year. There is no reference to the New Year's day in the Bible.

After the conquest of Jerusalem (587 BC), the Babylonians introduced their cyclic calendar (see above *Babylonian calendars*) and the reckoning of their regnal years from Nisanu 1, about the spring equinox. The Jews now had a finite calendar year with a New Year's day, and they adopted the Babylonian month names, which they continue to use. From 587 BC until AD 70, the Jewish civil year was Babylonian, except for the period of Alexander the Great and the Ptolemies (332–200 BC), when the Macedonian calendar was used. The situation after the destruction of the Temple in Jerusalem in AD 70 remains unclear. It is not known whether the Romans introduced their Julian calendar or the calendar that the Jews of Palestine used after AD 70 for their business transactions. There is no calendar reference in the New Testament; the contemporary Aramaic documents from Judaea are rare and prove only that the Jews dated events according to the years of the Roman emperors. The abundant data in the Talmudic sources concern only the religious calendar.

Use of the New Moon

In the religious calendar, the commencement of the month was determined by the observation of the crescent New Moon, and the date of the Passover was tied in with the ripening of barley. The actual witnessing of the New Moon and observing of the stand of crops in Judaea were required for the functioning of the religious calendar. The Jews of the Diaspora, or Dispersion, who generally used the civil calendar of their respective countries, were informed by messengers from Palestine about the coming festivals. This practice is already attested for 143 BC. After the destruction of the Temple in AD 70, rabbinic leaders took over from the priests the fixing of the religious calendar. Visual observation of the New Moon was supplemented and toward AD 200, in fact, supplanted by secret astronomical calculation. But the people of the Diaspora were often reluctant to wait for the arbitrary decision of the calendar makers in the Holy Land. Thus, in Syrian Antioch in AD 328–342, the Passover was always celebrated in (Julian) March, the month of the spring equinox, without regard to the Palestinian rules and rulings. To preserve the unity of Israel, the patriarch Hillel II, in 358/359, published the "secret" of calendar making, which essentially consisted of the use of the Babylonian 19-year cycle with some modifications required by the Jewish ritual.

The application of these principles occasioned controversies as late as the 10th century AD. In the 8th century, the Karaites, following Muslim practice, returned to the actual observation of the crescent New Moon and of the stand of barley in Judaea. But some centuries later they also had to use a precalculated calendar. The Samaritans, likewise, used a computed calendar.

Because of the importance of the Sabbath as a time divider, the seven-day week served as a time unit in Jewish worship and life. As long as the length of a year and of every month remained unpredictable, it was convenient to count weeks. The origin of the biblical septenary, or seven-day, week remains unknown; its days were counted from the Sabbath (Saturday for the Jews and Sunday for Christians). A visionary, probably writing in the Persian or early Hellenistic age under the name of the prediluvian Enoch, suggested the religious calendar of 364 days, or 52 weeks, based on the week, in which all festivals always fall on the same weekday. His idea was later taken up by the Qumrān community.

(E.J.Bi.)

The structure of the calendar. The Jewish calendar in use today is lunisolar, the years being solar and the months lunar, but it also allows for a week of seven days. Because the year exceeds 12 lunar months by about 11 days, a 13th month of 30 days is intercalated in the third, sixth, eighth, 11th, 14th, 17th, and 19th years of a 19-year cycle. For practical purposes—*e.g.,* for reckoning the commencement of the Sabbath—the day begins at sunset; but the calendar day of 24 hours always begins at 6 PM. The hour is divided into 1,080 parts (*ḥalaqim;* this division is originally Babylonian), each part (*ḥeleq*) equalling $3\frac{1}{3}$ seconds. The *ḥeleq* is further divided into 76 *regaʿim.*

'Full" and 'defective" months

The synodic month is the average interval between two mean conjunctions of the Sun and Moon, when these bodies are as near as possible in the sky, which is reckoned at 29 days 12 hours 44 minutes $3\frac{1}{3}$ seconds; a conjunction is called a *molad.* This is also a Babylonian value. In the calendar month, however, only complete days are reckoned, the "full" month containing 30 days and the "defective" month 29 days. The months Nisan, Sivan (Siwan), Av, Tishri, Shevaṭ, and, in a leap year, First Adar are always full; Iyyar, Tammuz, Elul, Ṭevet, and Adar (known as Second Adar, or Adar Sheni, in a leap year) are always defective, while Ḥeshvan (Ḥeshwan) and Kislev (Kislew) vary. The calendar, thus, is schematic and independent of the true New Moon. The number of days in a year varies. The number of days in a synodic month multiplied by 12 in a common year and by 13 in a leap year would yield fractional figures. Hence, again reckoning complete days only, the common year has 353, 354, or 355 days and the leap year 383, 384, or 385 days. A year in which both Ḥeshvan and Kislev are full, called complete (*shelema*), has 355 or (if a leap year) 385 days; a normal (*sedura*) year, in which Ḥeshvan is defective and Kislev full, has 354 or 384 days; while a defective (*ḥasera*) year, in which both these months are defective, has 353 or 383 days. The character of a year (*qeviʿa,* literally "fixing") is described by three letters of the Hebrew alphabet, the first and third giving, respectively, the days of the weeks on which the New Year occurs and Passover begins, while the second is the initial of the Hebrew word for defective, normal, or complete. There are 14 types of *qeviʿot,* seven in common and seven in leap years. The New Year begins on Tishri 1, which may be the day of the *molad* of Tishri but is often delayed by one or two days for various reasons. Thus, in order to prevent the Day of Atonement (Tishri 10) from falling on a Friday or a Sunday and the seventh day of Tabernacles (Tishri 21) from falling on a Saturday, the New Year must avoid commencing on Sundays, Wednesdays, or Fridays. Again, if the *molad* of Tishri occurs at noon or later, the New Year is delayed by one or, if this would cause it to fall as above, two days. These delays (*deḥiyyot*) necessitate, by reason of the above-mentioned limits on the number of days in the year, two other delays.

The seasons in the Jewish calendar

The mean beginning of the four seasons is called *tequfa* (literally "orbit," or "course"); the *tequfa* of Nisan denotes the mean Sun at the vernal equinox, that of Tammuz at the summer solstice, that of Tishri at the autumnal equinox, and that of Ṭevet at the winter solstice. As 52 weeks are the equivalent to 364 days, and the length of the solar year is nearly $365\frac{1}{4}$ days, the *tequfot* move forward in the week by about $1\frac{1}{4}$ days each year. Accordingly, reckoning the length of the year at the approximate value of $365\frac{1}{4}$ days, they are held to revert after 28 years ($28 \times 1\frac{1}{4} = 35$ days) to the same hour on the same day of the week (Tuesday, 6 PM) as at the beginning. This cycle is called the great, or solar, cycle (*maḥzor gadol* or *ḥamma*). The present Jewish calendar is mainly based on the more accurate value, in excess of the true tropical year by about 6 minutes 40 seconds. Thus, it is advanced by one day in about 228 years with regard to the equinox.

To a far greater extent than the solar cycle of 28 years, the Jewish calendar employs, as mentioned above, a small, or lunar, cycle (*maḥzor qaṭan*) of 19 years, adjusting the lunar months to the solar years by intercalations. Passover, on Nisan 14, is not to begin before the spring *tequfa,* and so the intercalary month is added after Adar. The *maḥzor qaṭan* is akin to the Metonic cycle described above.

The Jewish Era in use today is that dated from the supposed year of the Creation (designated *anno mundi* or AM) with its epoch, or beginning, in 3761 BC. For example, the Jewish year 5745 AM, the 7th in the 303rd lunar cycle and the 5th in the 206th solar cycle, is a regular year of 12 months, or 354 days. The *qeviʿa* is, using the three respective letters of the Hebrew alphabet as two numerals and an initial in the manner indicated above, HKZ, which indicates that Rosh Hashana (New Year) begins on the fifth (H = 5) and Passover on the seventh (Z = 7) day of the week and that the year is regular (K = *ke-sidra*); *i.e.,* Ḥeshvan is defective—29 days, and Kislev full—30 days. The Jewish year 5745 AM corresponds with the Christian Era period that began September 27, 1984, and ended September 15, 1985. Neglecting the thousands, current Jewish years AM are converted into years of the current Christian Era by adding 239 or 240—239 from the Jewish New Year (about September) to December 31 and 240 from January 1 to the eve of the Jewish New Year. The adjustment differs slightly for the conversion of dates of now-antiquated versions of the Jewish Era of the Creation and the Christian Era, or both. Tables for the exact conversion of such dates are available.

Months and important days. The months of the Jewish year and the notable days are as follows:

Tishri: 1–2, Rosh Hashana (New Year); 3, Fast of Gedaliah; 10, Yom Kippur (Day of Atonement); 15–21, Sukkot (Tabernacles); 22, Shemini Atzeret (Eighth Day of Solemn Assembly); 23, Simḥat Torah (Rejoicing of the Law).
Ḥeshvan.
Kislev: 25, Ḥanukka (Festival of Lights) begins.
Tevet: 2 or 3, Ḥanukka ends; 10, Fast.
Shevaṭ: 15, New Year for Trees (Mishna).
Adar: 13, Fast of Esther; 14–15, Purim (Lots).
Second Adar (Adar Sheni) or ve-Adar (intercalated month); Adar holidays fall in ve-Adar during leap years.
Nisan: 15–22, Pesaḥ (Passover).
Iyyar: 5, Israel Independence Day.
Sivan: 6–7, Shavuot (Feast of Weeks [Pentecost]).
Tammuz: 17, Fast (Mishna).
Av: 9, Fast (Mishna).
Elul.

(E.J.Wi.)

The Muslim calendar. The Muslim Era is computed from the starting point of the year of the emigration (Hegira); that is, from the year in which Muḥammad, the prophet of Islām, emigrated from Mecca to Medina, AD 622. The second caliph, ʿUmar I, who reigned 634–644, set the first day of the month Muḥarram as the beginning of the year; that is, July 16, 622, which had already been fixed by the Qurʾan as the first day of the year.

The years of the Muslim calendar are lunar and always consist of 12 lunar months alternately 30 and 29 days long, beginning with the approximate New Moon. The year has 354 days, but the last month (Dhū al-Ḥijjah) sometimes has an intercalated day, bringing it up to 30 days and making a total of 355 days for that year. The months do not keep to the same seasons in relation to the Sun, because there are no intercalations of months. The months regress through all the seasons every 32½ years.

Ramaḍān

Ramaḍān, the ninth month, is observed throughout the Muslim world as a month of fasting. According to the Qur'an, Muslims must see the New Moon with the naked eye before they can begin their fast. The practice has arisen that two witnesses should testify to this before a *qaḍī* (judge), who, if satisfied, communicates the news to the *muftī* (the interpreter of Muslim law), who orders the beginning of the fast. It has become usual for Middle Eastern Arab countries to accept, with reservations, the verdict of Cairo. Should the New Moon prove to be invisible, then the month Shaʿbān, immediately preceding Ramaḍān, will be reckoned as 30 days in length, and the fast will begin on the day following the last day of this month. The end of the fast follows the same procedure.

The era of the Hegira is the official era in Saudi Arabia, Yemen, and the principalities of the Persian Gulf. Egypt, Syria, Jordan, and Morocco use both the Muslim and the Christian eras. In all Muslim countries, people use the Muslim Era in private, even though the Christian Era may be in official use.

Some Muslim countries have made a compromise on this matter. Turkey, as early as 1088 AH (AD 1677), took over the solar (Julian) year with its month names but kept the Muslim Era. March 1 was taken as the beginning of the year (commonly called *marti year,* after the Turkish word *mart,* for March). Late in the 19th century, the Gregorian calendar was adopted. In the 20th century, Pres. Mustafa Kemal Atatürk ordered a complete change to the Christian Era. Iran, under Reza Shah Pahlavi (reigned 1925–41), also adopted the solar year but with Persian names for the months and keeping the Muslim Era. March 21 is the beginning of the Iranian year. Thus, the Iranian year 1359 began on March 21, 1980. This era is still in use officially. (See also ISLĀM: *Sacred places and days.*)

(N.A.Z.)

THE FAR EAST

The Hindu calendar. While the Republic of India has adopted the Gregorian calendar for its secular life, its Hindu religious life continues to be governed by the traditional Hindu calendar. This calendar, based primarily on the lunar revolutions, is adapted to solar reckoning.

Early history. The oldest system, in many respects the basis of the classical one, is known from texts of about 1000 BC. It divides an approximate solar year of 360 days into 12 lunar months of 27 (according to the early Vedic text Taittirīya Saṃhitā 4.4.10.1–3) or 28 (according to the Atharvaveda, the fourth of the Vedas, 19.7.1.) days. The resulting discrepancy was resolved by the intercalation of a leap month every 60 months. Time was reckoned by the position marked off in constellations on the ecliptic in which the Moon rises daily in the course of one lunation (the period from New Moon to New Moon) and the Sun rises monthly in the course of one year. These constellations (*nakṣatra*) each measure an arc of 13° 20′ of the ecliptic circle. The positions of the Moon were directly observable, and those of the Sun inferred from the Moon's position at Full Moon, when the Sun is on the opposite side of the Moon. The position of the Sun at midnight was calculated from the *nakṣatra* that culminated on the meridian at that time, the Sun then being in opposition to that *nakṣatra.* The year was divided into three thirds of four months, each of which would be introduced by a special religious rite, the *cāturmāsya* (four-month rite). Each of these periods was further divided into two parts (seasons or *ṛtu*): spring (*vasanta*), from mid-March until mid-May; summer (*grīṣma*), from mid-May until mid-July; the rains (*varṣa*), from mid-July until mid-September; autumn (*śarad*), from mid-September until mid-November; winter (*hemanta*), from mid-November until mid-January; and the dews (*śiśira*), from mid-January until mid-March. The spring months in early times were Madhu and Mādhava, the summer months Śukra and Śuci, the rainy months Nabhas and Nabhasya, the autumn months Īṣa and Ūrja, the winter months Sahas and Sahasya, and the dewy months Tapas and Tapasya. The month, counted from Full Moon to Full Moon, was divided into two halves (*pakṣa,* "wing") of waning (*kṛṣṇa*) and waxing (*śukla*) Moon, and a special ritual (*darśapūrṇamāsa,* "new and full moon rites") was prescribed on the days of New Moon (*amāvasya*) and Full Moon (*pūrṇimās*). The month had theoretically 30 days (*tithi;* see below), and the day (*divasa*) 30 hours (*muhūrta*).

The *nakṣatra*

This picture is essentially confirmed by the first treatise on time reckoning, the *Jyotiṣa-vedāṅga* ("Vedic auxiliary [text] concerning the luminaries") of about 100 BC, which adds a larger unit of five years (*yuga*) to the divisions. A further old distinction is that of two year moieties, the *uttarāyaṇa* ("northern course"), when the Sun has passed the spring equinox and rises every morning farther north, and the *dakṣiṇāyana* ("southern course"), when it has passed the autumnal equinox and rises progressively farther south.

The classical calendar. In its classic form (*Sūrya-siddhānta,* 4th century AD) the calendar continues from the one above with some refinements. With the influence of Hellenism, Greek and Mesopotamian astronomy and astrology were introduced. Though astronomy and time reckoning previously were dictated by the requirements of rituals, the time of which had to be fixed correctly, and not for purposes of divination, the new astrology came into vogue for casting horoscopes and making predictions. Zodiacal time measurement was now used side by side with the older *nakṣatra* one. The *nakṣatra* section of the ecliptic (13° 20′) was divided into four parts of 3° 20′ each; thus, two full *nakṣatra*s and a quarter of one make up one zodiac period, or sign (30°). The year began with the entry of the Sun (*saṃkrānti*) in the sign of Aries. The names of the signs (*rāśi*) were taken over and mostly translated into Sanskrit: *meṣa* ("ram," Aries), *vṛṣabha* ("bull," Taurus), *mithuna* ("pair," Gemini), *karkaṭa* ("crab," Cancer), *siṃha* ("lion," Leo), *kanyā* ("maiden," Virgo), *tulā* ("scale," Libra), *vṛścika* ("scorpion," Scorpius), *dhanus* ("bow," Sagittarius), *makara* ("crocodile," Capricornus), *kumbha* ("water jar," Aquarius), *mīna* ("fish," Pisces).

The precession of the vernal equinox from the Sun's entry into Aries to some point in Pisces, with similar consequences for the summer solstice, autumnal equinox, and winter solstice, has led to two different methods of calculating the *saṃkrānti* (entry) of the Sun into a sign. The precession (*ayana*) is not accounted for in the *nirayana* system (without *ayana*), which thus dates the actual *saṃkrānti* correctly but identifies it wrongly with the equinox or solstice, and the *sāyana* system (with *ayana*), which thus dates the equinox and solstice correctly but identifies it wrongly with the *saṃkrānti.*

While the solar system has extreme importance for astrology, which, it is claimed, governs a person's life as an individual or part of a social system, the sacred time continues to be reckoned by the lunar *nakṣatra* system. The lunar day (*tithi*), a 30th part of the lunar month, remains the basic unit. Thus, as the lunar month is only about 29½ solar days, the *tithi* does not coincide with the natural day (*ahorātra*). The convention is that that *tithi* is in force for the natural day that happened to occur at the dawn of that day. Therefore, a *tithi* beginning after dawn one day and expiring before dawn the next day is eliminated, not being counted in that month, and there is a break in the day sequence.

The names of the *nakṣatra*s, to which correspond the *tithi*s in the monthly lunar cycle and segments of months in the annual solar cycle, are derived from the constellations on the horizon at that time and have remained the same. The names of the months have changed: Caitra (March-April), Vaiśākha (April-May), Jyaiṣṭha (May-June), Āṣāḍha (June-July), Śrāvaṇa (July-August), Bhādrapada (August-September), Āśvina (September-October), Kārttika (October-November), Mārgaśīrṣa (November-December), Pauṣa (December-January), Māgha (January-February), and Phālguna (February-March).

Month names

In this calendar the date of an event takes the following form: month, fortnight (either waning or waxing Moon), name (usually the number) of the *tithi* in that fortnight, and the year of that era which the writer follows. Identification, particularly of the *tithi,* is often quite complicated, since it requires knowledge of the time of sunrise on that day and which 30th of the lunar month was in force then.

Eventually, India also adopted the seven-day week (*saptāha*) from the West and named the days after the corresponding planets: Sunday after the Sun, *ravivāra;* Monday after the Moon, *somavāra;* Tuesday after Mars, *maṅgalavāra;* Wednesday after Mercury, *budhavāra;* Thursday after Jupiter, *bṛhaspativāra;* Friday after Venus, *śukravāra;* and Saturday after Saturn, *śanivāra.*

A further refinement of the calendar was the introduction into dating of the place of a year according to its position in relation to the orbital revolution of the planet Jupiter, called *bṛhaspati* in Sanskrit. Jupiter has a sidereal period (its movement with respect to the "fixed" stars) of 11 years, 314 days, and 839 minutes, so in nearly 12 years it is back into conjunction with those stars from which it began its orbit. Its synodic period brings it into conjunction with the Sun every 398 days and 88 minutes, a little more than a year. Thus, Jupiter in a period of almost 12 years passes about the same series of *nakṣatra*s that the Sun passes in one year and, in a year, about the same *nakṣatra*s as the Sun in a month. A year then can be dated as the month of a 12-year cycle of Jupiter, and the date is given as, for example, grand month of Caitra. This is extended to a unit of five cycles, or the 60-year cycle of Jupiter (*bṛhaspaticakra*), and a "century" of 60 years is formed. This system is known from the 6th century AD onward.

At the other end of the scale, more precision is brought to the day. Every *tithi* is divided into two halves, called *karaṇa*s. The natural day is divided into units ranging from a *vipala* (0.4 second) to a *ghaṭikā* (24 minutes) and an "hour" (*muhūrta*) of 48 minutes; the full natural day has 30 such hours. The day starts at dawn; the first six *ghaṭikā*s are early morning, the second set of six midmorning, the third midday, the fourth afternoon, the fifth evening. Night lasts through three units (*yāma*) of time: six *ghaṭikā*s after sundown, or early night; two of midnight; and four of dawn.

Solar holidays

The sacred calendar. There are a few secular state holidays (*e.g.,* Independence Day) and some solar holidays, such as the entry of the Sun into the sign of Aries (*meṣa-saṃkrānti*), marking the beginning of the new astrological year; the Sun's entry into the sign of Capricornus (*makara-saṃkrānti*), which marks the winter solstice but has coalesced with a hoary harvest festival, which in southern India is very widely celebrated as the Poṅgal festival; and the *mahāviṣuva* day, which is New Year's Eve. But all other important festivals are based on the lunar calendar. As a result of the high specialization of deities and events celebrated in different regions, there are hundreds of such festivals, most of which are observed in smaller areas, though some have followings throughout India. A highly selective list of the major ones, national and regional, follows.

Rāmanavamī ("ninth of Rāma"), on Caitra Ś. (= *śukla,* "waxing fortnight") 9, celebrates the birth of Rāma.

Rathayātrā ("pilgrimage of the chariot"), Āṣāḍha Ś. 2, is the famous Juggernaut (Jagannātha) festival of the temple complex at Puri, Orissa.

Janmāṣṭamī ("eighth day of the birth"), Śrāvaṇa K. (= *kṛṣṇa,* "waning fortnight") 8, is the birthday of the god Kṛṣṇa.

Gaṇeśacaturthī ("fourth of Gaṇeśa"), Bhādrapada Ś. 4, is observed in honour of the elephant-headed god Gaṇeśa, a particular favourite of Mahārāshtra.

Durgā-pūjā ("homage to Durgā"), Āśvina Ś. 7–10, is special to Bengal, in honour of the destructive and creative goddess Durgā.

Daśahrā ("ten days"), or Dussera, Āśvina 7–10, is parallel to Durgā-pūjā, celebrating Rāma's victory over Rāvaṇa, and traditionally the beginning of the warring season.

Lakṣmīpūjā ("homage to Lakṣmī"), Āśvina Ś. 15, is the date on which commercial books are closed, new annual records begun, and business paraphernalia honoured; for Lakṣmī is the goddess of good fortune.

Dīpāvalī, Dīwālī ("strings of lights"), Kārttika K. 15 and Ś. 1, is the festival of lights, when light is carried from the waning to the waxing fortnight and presents are exchanged.

Mahā-śivarātrī ("great night of Śiva"), Māgha K. 13, is when the dangerous but, if placated, benevolent god Śiva is honoured on the blackest night of the month.

Holī (name of a demoness), Phālguna S. 14, is a fertility and role-changing festival, scene of great fun-poking at superiors.

Dolāyātrā ("swing festival"), Phālguna S. 15, is the scene of the famous hook-swinging rites of Orissa.

Gurū Nānak Jayantī, Kārttika S. 15, is the birthday of Nānak, the founder of the sect of Sikhism.

The eras. Not before the first century BC is there any evidence that the years of events were recorded in well-defined eras, whether by cycles, as the Olympic Games in Greece and the tenures of consuls in Rome, or the Roman year dating from the foundation of the city. Perhaps under outside influence, the recording of eras was begun at various times, but these were without universal appeal, and few have remained influential. Among those are (1) the Vikrama era, begun 58 BC; (2) the Śaka era, begun AD 78 (these two are the most commonly used); (3) the Gupta era, begun AD 320; (4) the Harṣa era, begun AD 606. All these were dated from some significant historical event. Of more mythological interest is the Kali era (Kali being the latest and most decadent period in the system of the four *Yuga*s), which is thought to have started either at dawn on February 18, 3102 BC, or at midnight between February 17 and 18 in that year. (J.A.B.v.B.)

The Chinese calendar. Evidence from the Shang oracle bone inscriptions shows that at least by the 14th century BC the Shang Chinese had established the solar year at 365¼ days and lunation at 29½ days. In the calendar that the Shang used, the seasons of the year and the phases of the Moon were all supposedly accounted for. One of the two methods that they used to make this calendar was to add an extra month of 29 or 30 days, which they termed the 13th month, to the end of a regular 12-month year. There is also evidence that suggests that the Chinese developed the Metonic cycle (see above *Complex cycles*)—*i.e.,* 19 years with a total of 235 months—a century ahead of Meton's first calculation (no later than the Spring and Autumn period, 770–476 BC). During this cycle of 19 years there were seven intercalations of months. The other method, which was abandoned soon after the Shang started to adopt it, was to insert an extra month between any two months of a regular year. Possibly, a lack of astronomical and arithmetical knowledge allowed them to do this.

Names of the points

By the 3rd century BC, the first method of intercalation was gradually falling into disfavour, while the establishment of the meteorological cycle, the *erh-shih-ssu chieh-ch'i* (Pinyin *ershisi jieqi*), during this period officially revised the second method. This meteorological cycle contained 24 points, each beginning one of the periods named consecutively the Spring Begins, the Rain Water, the Excited Insects, the Vernal Equinox, the Clear and Bright, the Grain Rains, the Summer Begins, the Grain Fills, the Grain in Ear, the Summer Solstice, the Slight Heat, the Great Heat, the Autumn Begins, the Limit of Heat, the White Dew, the Autumn Equinox, the Cold Dew, the Hoar Frost Descends, the Winter Begins, the Little Snow, the Heavy Snow, the Winter Solstice, the Little Cold, and the Severe Cold. The establishment of this cycle required a fair amount of astronomical understanding of the Earth as a celestial body, and without elaborate equipment it is impossible to collect the necessary information. Modern scholars acknowledge the superiority of pre-Sung Chinese astronomy (at least until about the 13th century AD) over that of other, contemporary nations.

The 24 points within the meteorological cycle coincide with points 15° apart on the ecliptic (the plane of the Earth's yearly journey around the Sun or, if it is thought that the Sun turns around the Earth, the apparent journey of the Sun against the stars). It takes about 15.2 days for the Sun to travel from one of these points to another (because the ecliptic is a complete circle of 360°), and the Sun needs $365\frac{1}{4}$ days to finish its journey in this cycle. Supposedly, each of the 12 months of the year contains two points, but, because a lunar month has only $29\frac{1}{2}$ days and the two points share about 30.4 days, there is always the chance that a lunar month will fail to contain both points, though the distance between any two given points is only 15°. If such an occasion occurs, the intercalation of an extra month takes place. For instance, one may find a year with two "Julys" or with two "Augusts" in the Chinese calendar. In fact, the exact length of the month in the Chinese calendar is either 30 days or 29 days—a phenomenon which reflects its lunar origin. Also, the meteorological cycle means essentially a solar year. The Chinese thus consider their calendar as *yin-yang li,* or a "lunar–solar calendar."

The *yin-yang li*

Although the *yin-yang li* has been continuously employed by the Chinese, foreign calendars were introduced to the Chinese, the Hindu calendar, for instance, during the T'ang (Tang) dynasty (618–907), and were once used concurrently with the native calendar. This situation also held true for the Muslim calendar, which was introduced during the Yüan dynasty (1206–1368). The Gregorian calendar was taken to China by Jesuit missionaries in 1582, the very year that it was first used by Europeans. Not until 1912, after the general public adopted the Gregorian calendar, did the *yin-yang li* lose its primary importance.

One of the most distinguished characteristics of the Chinese calendar is its time-honoured day-count system. By combining the 10 celestial stems, *kan* (*gan*), and the 12 terrestrial branches, *chih* (*zhi*), into 60 units, the Shang Chinese counted the days with *kan-chih* (*gan-zhi*) combinations cyclically. For more than 3,000 years, no one has ever tried to discard the *kan-chih* day-count system. Out of this method there developed the idea of *hsün,* (*xun*), 10 days, which some scholars would render into English as "week." The *kan-chih* combinations probably were adopted for year count by Han emperors during the 2nd century AD.

The *yin-yang li* may have been preceded by a pure lunar calendar because there is one occurrence of the "14th month" and one occurrence of the "15th month" in the Shang oracle bone inscriptions. Unless there was a drastic change in the computation, it is quite inconceivable that an extra 90 days should have been added to a regular year. Julius Caesar had made 45 BC into a year of 445 days for the sake of the adoption of the Julian calendar in the next year. Presumably, the Shang king could have done the same for similar reasons. From the above discussion on the intercalation of months, it is clear that within the *yin-yang li* the details of the lunar calendar are more important than those of the solar calendar. In a solar calendar the 24 meteorological points would recur on the same days every year. Moreover, if a solar calendar were adopted first, then the problem of intercalation would be more related to the intercalation of days rather than intercalation of months.

Many traditional Chinese scholars tried to synchronize the discrepancy between the lunation and the solar year. Some even developed their own ways of computation embodying accounts of eclipses and of other astronomical phenomena. These writings constitute the bulk of the traditional almanacs. In the estimation of modern scholars, at least 102 kinds of almanacs were known, and some were used regularly. The validity or the popularity of each of these almanacs depends heavily on the author's proficiency in handling planetary cycles. In the past these authors competed with one another for the position of calendar master in the Imperial court, even though mistakes in their almanacs could bring them punishment, including death.

(Ch.L.)

THE AMERICAS

The Mayan calendar. The basic structure of the Mayan calendar is common to all calendars of Meso-America (*i.e.,* the civilized part of ancient Middle America). It consists of a ritual cycle of 260 named days and a year of 365 days. These cycles, running concurrently, form a longer cycle of 18,980 days, or 52 years of 365 days, called a "Calendar Round," at the end of which a designated day recurs in the same position in the year.

The "Calendar Round"

The native Mayan name for the 260-day cycle is unknown. Some authorities call it the Tzolkin (Count of Days); others refer to it as the Divinatory Calendar, the Ritual Calendar, or simply the day cycle. It is formed by the combination of numerals 1 through 13, meshing day by day with an ordered series of 20 names. The names of the days differ in the languages of Meso-America, but there is enough correspondence of meaning to permit the correlation of the known series, and there is reason to think that all day cycles were synchronous. The days were believed to have a fateful character, and the Tzolkin was used principally in divination. Certain passages in the *Dresden Codex,* one of the three Mayan manuscripts that survived the conquest, show various Tzolkins divided into four parts of 65 days each, or into five parts of 52 days. The parts are in turn subdivided into a series of irregular intervals, and each interval is accompanied by a group of hieroglyphs and by an illustration, usually depicting a deity performing some simple act. The hieroglyphs apparently give a prognostication, but just how the Maya determined the omens is not known.

The 365-day year was divided into 18 named months of 20 days each, with an additional five days of evil omen, named Uayeb. In late times, the Maya named the years after their first days. Since both the year and the number (20) of names of days are divisible by five, only four names combined with 13 numbers could begin the year. These were called Year Bearers and were assigned in order to the four quarters of the world with their four associated colours. Unlike day cycles, years were not synchronous in all regions. They began at different times and in different seasons, and even among Maya-speaking peoples there was imperfect concordance of the months. Some differences may be due to postconquest attempts to keep the native year in step with the Christian calendar; others no doubt have an earlier origin.

The manner of recording historical dates is peculiar to the ancient Mayan calendar. The Maya did not use the names of years for this purpose. To identify a date of the Calendar Round, they designated the day by its numeral and name, and added the name of the current month, indicating the number of its days that had elapsed by prefixing one of the numerals from 0 through 19. A date written in this way will occur once in every Calendar Round, at intervals of 52 years.

This was not good enough to link events over longer periods of time. Mayan interest in history, genealogy, and astrology required accurate records of events far in the past. To connect dates to one another, the Maya expressed distances between them by a count of days and their multiples. They used what was essentially a vigesimal place-value system of numeration, which is one based on a count of 20, but modified it by substituting 18 for 20 as the multiplier of units of the second order, so that each unit in the third place had the value of 360 days instead of 400. In monumental inscriptions, the digits are usually accompanied by the names of the periods their units represent, although in the manuscripts the period names are omitted and placement alone indicates the value of the units. The period names in ascending order are: *kin* (day); *uinal* (20 days); *tun* (18 *uinals* or 360 days); *katun* (20 *tuns* or 7,200 days); *baktun* or cycle—native name unknown—(20 *katuns* or 144,000 days); and so on up to higher periods. By introducing an odd multiplier to form the *tun,* the Maya made multiplication and division difficult, and there are in the *Dresden Codex* long tables of multiples of numbers that could be more simply manipulated by addition and subtraction.

Period names

To correlate all historical records and to anchor dates firmly in time, the Maya established the "Long Count," a continuous count of time from a base date, 4 Ahau 8 Cumku, which completed a round of 13 *baktuns* far in the past. There were several ways in which one could indicate the position of a Calendar Round dated in the Long Count. The most direct and unambiguous was to use an Initial-Series (IS) notation. The series begins with an outsized composition of signs called the Initial-Series-introducing glyph, which is followed by a count of periods written in descending order. On the earliest known monument, Stela 29 from Tikal in Guatemala, the Initial Series reads: 8 *baktuns,* 12 *katuns,* 14 *tuns,* 8 *uinals,* 15 *kins,* which is written: IS. 8.12.14.8.15. It shows that the Calendar Round date that follows falls 1,243,615 days (just under 3,405 years) after the 4 Ahau 8 Cumku on which the Long Count is based. Stela 29 is broken, and its Calendar Round date is missing, but from the information above, it can be calculated to have been 13 Men 3 Zip (the 195th day of the Tzolkin, the 44th of the year).

The Mayan calendar.
(Top) Month signs. (Bottom) Day-signs.

Normally, only the opening date of an inscription is written as an Initial Series. From this date, distance numbers, called Secondary Series (SS), lead back or forward to other dates in the record, which frequently ends with a Period-Ending (PE) date. This is a statement that a given date completes a whole number of *tuns* or *katuns* in the next higher period of the Long Count. Such a notation identifies the date unambiguously within the historic period. The latest Period Ending recorded on a given monument is also known as its Dedicatory Date (DD), for it was a common custom to set up monuments on the completion of *katuns* of the Long Count and sometimes also at the end of every five or 10 *tuns.* The Maya also celebrated *katun* and five-*tun* "anniversaries" of important dates and recorded them in much the same way as the period endings.

Period-Ending dates gradually took the place of Initial Series, and, in northern Yucatán, where Mayan sites of the latest period are located, a new method of notation dispensed with distance numbers altogether by noting after a Calendar Round date the number of the current *tun* in a Long Count *katun* named by its last day. Long Count *katuns* end with the name Ahau (Lord), combined with one of 13 numerals; and their names form a Katun Round of 13 *katuns.* This round is portrayed in Spanish colonial manuscripts as a ring of faces depicting the Lords. There are also recorded prophesies for *tuns* and *katuns,* which make many allusions to history, for the Maya seem to have conceived time, and even history itself, as a series of cyclical, recurring events.

The discontinuance of Initial-Series notations some centuries before the conquest of Mexico by Spain makes all attempted correlations of the Mayan count with the Christian calendar somewhat uncertain, for such correlations are all based on the assumption that the Katun Round of early colonial times was continuous with the ancient Long Count. The correlation most in favour now equates the 4 Ahau 8 Cumku that begins the Mayan count with the Julian day 584,283 (see above *Complex cycles*). According to this correlation, the *katun* 13 Ahau that is said to have ended shortly before the foundation of Mérida, Yucatán, ended on November 14, 1539, by the Gregorian calendar, and it was the Long Count *katun* 11.16.0.0.0. 13 Ahau 8 Xul. Some tests of archaeological material by the radiocarbon method corroborate this correlation; but results are not sufficiently uniform to resolve all doubts, and some archaeologists would prefer to place the foundation of Mérida in the neighbourhood of 12.9.0.0.0. in the Mayan count. Correlations based on astronomical data so far have been in conflict with historical evidence, and none has gained a significant degree of acceptance.

Lunar correlations

The basic elements of the Mayan calendar have little to do with astronomy. A lunar count was, however, included in a Supplementary Series appended to Initial-Series dates. The series is composed of hieroglyphs labelled Glyphs *G, F, E* or *D, C, B,* and *A,* and a varying number of others. Glyph *G* changes its form daily, making a round of nine days, possibly corresponding to the nine gods of the night hours or Mexican Lords of the Night. Glyph *F* is closely associated with Glyph *G* and does not vary. Glyphs *E* and *D* have numerical coefficients that give the age of the current Moon within an error of two or three days; Glyph *C* places it in a lunar half year; and Glyph *A* shows whether it is made up of 29 or 30 days. The meaning of Glyph *B* is unknown. There are discrepancies in the lunar records from different sites, but during a period of about 80 years, called the Period of Uniformity, a standard system of grouping six alternating 29- and 30-day moons was used everywhere.

Occasionally included with the Supplementary Series is a date marking the conclusion of an 819-day cycle shortly before the date of Initial Series. The number of days in this cycle is obtained by multiplying together 13, 9, and 7, all very significant numbers in Mayan mythology.

It has been suggested that certain other dates, called determinants, indicate with a remarkable degree of accuracy how far the 365-day year had diverged from the solar year since the beginning of the Long Count, but this hypothesis is questioned by some scholars. The identification of certain architectural assemblages as observatories of solstices and equinoxes is equally difficult to substantiate. So far, it has not been demonstrated how the Maya reckoned the seasons of their agricultural cycle or whether they observed the tropical or the sidereal year.

In colonial times, the star group known as the Pleiades was used to mark divisions of the night, and the constellation Gemini was also observed. A computation table in the *Dresden Codex* records intervals of possible eclipses of the Sun and Moon. Another correlates five revolutions of the planet Venus around the Sun with eight 365-day years and projects the count for 104 years, when it returns to the beginning Tzolkin date. Three sets of month positions associated with the cycle suggest its periodic correction. Other computations have not been adequately explained, among them some very long numbers that transcend the Long Count. Such numbers appear also on monuments and indicate a grandiose conception of the complexity and the almost infinite extent of time.

The Mexican (Aztec) calendar. The calendar of the Aztec was derived from earlier calendars in the Valley of Mexico and was basically similar to that of the Maya. The ritual day cycle was called Tonalpohualli and was formed, as was the Mayan Tzolkin, by the concurrence of a cycle of numerals 1 through 13 with a cycle of 20 day names, many of them similar to the day names of the Maya. The Tonalpohualli could be divided into four or five equal parts, each of four assigned to a world quarter and a colour and including the centre of the world if the parts were five. To the Aztec, the 13-day period defined by the day numerals was of prime importance, and each of 20 such periods was under the patronage of a specific deity. A similar list of 20 deities was associated with individual day names, and, in addition, there was a list of 13 deities designated as Lords of the Day, each accompanied by a flying creature, and a list of nine deities known as Lords of the Night. The lists of deities vary somewhat in different sources. They were probably used to determine the fate of the days by the Tonalpouhque, who were priests trained in calendrical divination. These priests were consulted as to lucky days whenever an important enterprise was undertaken or when a child was born. Children were often named after the day of their birth; and tribal gods, who were legendary heroes of the past, also bore calendar names.

The Aztec and Mayan systems compared

The Aztec year of 365 days was also similar to the year of the Maya, though probably not synchronous with it. It had 18 named months of 20 days each and an additional five days, called *nemontemi,* which were considered to be very unlucky. Though some colonial historians mention the use of intercalary days, in Aztec annals there is no indication of a correction in the length of the year. The years were named after days that fall at intervals of 365 days, and most scholars believe that these days held a fixed position in the year, though there appears to be some disagreement as to whether this position was the first day, the last day of the first month, or the last day of the last month, as was suggested by a distinguished Mexican scholar. Since 20 and 365 are both divisible by five, only four day names—Acatl (Reed), Tecpatl (Flint), Calli (House), and Tochtli (Rabbit)—figure in the names of the 52 years that form a cycle with the Tonalpohualli. The cycle begins with a year 2 Reed and ends with a year 1 Rabbit, which was regarded as a dangerous year of bad omen. At the end of such a cycle, all household utensils and idols were discarded and replaced by new ones, temples were renovated, and human sacrifice was offered to the Sun at midnight on a mountaintop as people awaited a new dawn.

The year served to fix the time of festivals, which took place at the end of each month. The new year was celebrated by the making of a new fire, and a more elaborate ceremony was held every four years, when the cycle had run through the four day names. Every eight years was celebrated the coincidence of the year with the 584-day period of the planet Venus, and two 52-year cycles formed "One Old Age," when the day cycle, the year, and the period of Venus all came together. All these periods were noted also by the Maya.

Where the Aztec differed most significantly from the Maya was in their more primitive number system and in their less precise way of recording dates. Normally, they noted only the day on which an event occurred and the name of the current year. This is ambiguous, since the same day, as designated in the way mentioned above, can occur twice in a year. Moreover, years of the same name recur at 52-year intervals, and Spanish colonial annals often disagree as to the length of time between two events. Other discrepancies in the records are only partially explained by the fact that different towns started their year with different months. The most widely accepted correlation of the calendar of Tenochtitlán with the Christian Julian calendar is based on the entrance of Cortés into that city on November 8, 1519, and on the surrender of Cuauhtémoc on August 13, 1521. According to this correlation, the first date was a day 8 Wind, the ninth day of the month Quecholli, in a year 1 Reed, the 13th year of a cycle.

Aztec "Calendar Stone." The calendar, discovered in 1790, is a basaltic monolith. It weighs approximately 25 tons and is about 3.7 metres in diameter. In the Museo Nacional de Antropología, Mexico City.

The Mexicans, as all other Meso-Americans, believed in the periodic destruction and re-creation of the world. The "Calendar Stone" in the Museo Nacional de Antropología (National Museum of Anthropology) in Mexico City depicts in its central panel the date 4 Ollin (movement), on which they anticipated that their current world would be destroyed by earthquake, and within it the dates of previous holocausts: 4 Tiger, 4 Wind, 4 Rain, and 4 Water.

Peru: the Inca calendar. So little is known about the calendar used by the Inca that one can hardly make a statement about it for which a contrary opinion cannot be found. Some workers in the field even assert that there was no formal calendar but only a simple count of lunations. Since no written language was used by the Inca, it is impossible to check contradictory statements made by early colonial chroniclers. It is widely believed that the quipus of the Inca contain calendrical notations, but no satisfactory demonstration of this is possible.

Most historians agree that the Inca had a calendar based on the observation of both the Sun and the Moon, and their relationship to the stars. Names of 12 lunar months are recorded, as well as their association with festivities of the agricultural cycle; but there is no suggestion of the widespread use of a numerical system for counting time, although a quinary decimal system, with names of numbers at least up to 10,000, was used for other purposes. The organization of work on the basis of six weeks of nine days suggests the further possibility of a count by triads that could result in a formal month of 30 days.

The Chibcha system

A count of this sort was described by Alexander von Humboldt for a Chibcha tribe living outside of the Inca Empire, in the mountainous region of Colombia. The description is based on an earlier manuscript by a village priest, and one authority has dismissed it as "wholly imaginary," but this is not necessarily the case. The smallest unit of this calendar was a numerical count of three days, which, interacting with a similar count of 10 days, formed a standard 30-day "month." Every third year was made up of 13 moons, the others having 12. This formed a cycle of 37 moons, and 20 of these cycles made up a period of 60 years, which was subdivided into four parts and could be multiplied by 100. A period of 20 months is also mentioned. Although the account of the Chibcha system cannot be accepted at face value, if there is any truth in it at all it is suggestive of devices that may have been used also by the Inca.

In one account, it is said that the Inca Viracocha established a year of 12 months, each beginning with the New Moon, and that his successor, Pachacuti, finding confusion in regard to the year, built the sun towers in order to keep a check on the calendar. Since Pachacuti reigned less than a century before the conquest, it may be that the contradictions and the meagreness of information on the Inca calendar are due to the fact that the system was still in the process of being revised when the Spaniards first arrived.

(T.P.)

Despite the uncertainties, further research has made it clear that at least at Cuzco, the capital city of the Inca, there was an official calendar of the sidereal–lunar type, based on the sidereal month of 27⅓ days. It consisted of 328 nights (12 × 27⅓) and began on June 8/9, coinciding with the heliacal rising (the rising just after sunset) of the Pleiades; it ended on the first Full Moon after the June solstice (the winter solstice for the Southern Hemisphere). This sidereal–lunar calendar fell short of the solar year by 37 days, which consequently were intercalated. This intercalation, and thus the place of the sidereal–lunar within the solar year, was fixed by following the cycle of the Sun as it "strengthened" to summer (December) solstice and "weakened" afterward, and by noting a similar cycle in the visibility of the Pleiades.

(T.P./C.A.R.)

North American Indian time counts. No North American Indian tribe had a true calendar—a single integrated system of denoting days and longer periods of time. Usually, intervals of time were counted independently of one another. The day was a basic unit recognized by all tribes, but there is no record of aboriginal names for days. A common device for keeping track of days was a bundle of sticks of known number, from which one was extracted for every day that passed, until the bundle was exhausted. Longer periods of time were usually counted by moons, which began with the New Moon, or conjunction of the Sun and Moon. Years were divided into four seasons, occasionally five, and when counted were usually designated by one of the seasons; *e.g.,* a North American Indian might say that a certain event had happened 10 winters ago. Among sedentary agricultural tribes, the cycle of the seasons was of great ritual importance, but the time of the beginning of the year varied. Some observed it about the time of the vernal equinox, others in the fall. The Hopi tribe of northern Arizona held a new-fire ceremony in November. The Creek ceremony, known as the "Busk," was held late in July or in August, but it is said that each Creek town or settlement set its own date for the celebration.

As years were determined by seasons and not by a fixed number of days, the correlation of moons and years was also approximate and not a function of a daily count. Most tribes reckoned 12 moons to a year. Some northern tribes, notably those of New England, and the Cree tribes, counted 13. The Indians of the northwest coast divided their years into two parts, counting six moons to each part, and the Kiowa split one of their 12 moons between two unequal seasons, beginning their year with a Full Moon.

The naming of moons

The naming of moons is perhaps the first step in transforming them into months. The Zuni Indians of New Mexico named the first six moons of the year, referring to the remainder by colour designations associated with the four cardinal (horizontal) directions, and the zenith and the nadir. Only a few Indian tribes attempted a more precise correlation of moons and years. The Creeks are said to have added a moon between each pair of years, and the Haida from time to time inserted a "between moon" in the division of their year into two parts. It is said that an unspecified tribe of the Sioux or the Ojibwa (Chippewa) made a practice of adding a "lost moon" when 30 moons had waned.

A tally of years following an important event was sometimes kept on a notched stick. The best known record commemorates the spectacular meteoric shower (the Leonids) of 1833. Some northern tribes recorded series of events by pictographs, and one such record, said to have been originally painted on a buffalo robe and known as the "Lone-dog Winter Count," covers a period of 71 years beginning with 1800.

Early explorers had little opportunity to learn about the calendrical devices of the Indians, which were probably held sacred and secret. Contact with Europeans and their Christian calendar doubtless altered many aboriginal practices. Thus, present knowledge of the systems used in the past may not reflect their true complexity.

(T.P.)

The Western calendar and calendar reforms

The calendar now in general worldwide use had its origin in the desire for a solar calendar that kept in step with the seasons and possessed fixed rules of intercalation. Because it developed in Western Christendom, it had also to provide a method for dating movable religious feasts, the timing of which had been based on a lunar reckoning. To reconcile the lunar and solar schemes, features of the Roman republican calendar and the Egyptian calendar were combined.

The Roman republican calendar was basically a lunar reckoning and became increasingly out of phase with the seasons as time passed. By about 50 BC the vernal equinox that should have fallen late in March fell on the Ides of May, some eight weeks later, and it was plain that this error would continue to increase. Moreover, the behaviour of the Pontifices (see above *The early Roman calendar*) made it necessary to seek a fixed rule of intercalation in order to put an end to arbitrariness in inserting months.

In addition to the problem of intercalation, it was clear that the average Roman republican year of 366.25 days would always show a continually increasing disparity with the seasons, amounting to one month every 30 years, or three months a century. But the great difficulty facing any reformer was that there seemed to be no way of effecting a change that would still allow the months to remain in step with the phases of the Moon and the year with the seasons. It was necessary to make a fundamental break with traditional reckoning to devise an efficient seasonal calendar.

THE JULIAN CALENDAR

In the mid-1st century BC Julius Caesar invited Sosigenes, an Alexandrian astronomer, to advise him about the reform of the calendar, and Sosigenes decided that the only practical step was to abandon the lunar calendar altogether. Months must be arranged on a seasonal basis, and a tropical (solar) year used, as in the Egyptian calendar, but with its length taken as 365¼ days.

To remove the immense discrepancy between calendar date and equinox, it was decided that the year known in modern times as 46 BC should have two intercalations. The first was the customary intercalation of the Roman republican calendar due that year, the insertion of 23 days following February 23. The second intercalation, to bring the calendar in step with the equinoxes, was achieved by inserting two additional months between the end of November and the beginning of December. This insertion amounted to an addition of 67 days, making a year of no less than 445 days and causing the beginning of March, 45 BC in the Roman republican calendar, to fall on what is still called January 1 of the Julian calendar.

Previous errors having been corrected, the next step was to prevent their recurrence. Here Sosigenes' suggestion about a tropical year was adopted and any pretense to

Leap year

a lunar calendar was rejected. The figure of 365.25 days was accepted for the tropical year, and, to achieve this by a simple civil reckoning, Caesar directed that a calendar year of 365 days be adopted and that an extra day be intercalated between February 23 and 24 every fourth year. Since February ordinarily had 28 days, February 23 was the sixth day before the Kalendae, or beginning of March, and was known as the *sexto-kalendae;* the intercalary day, when it appeared, came the day after and was therefore called the *bis-sexto-kalendae.* This practice led to the term bissextile being used to refer to such a leap year. The name leap year is a later connotation, probably derived from the Old Norse *hlaupa* ("to leap") and used because, in a bissextile year, any fixed festival after February leaps forward, falling on the second weekday from that on which it fell the previous year, not on the next weekday as it would do in an ordinary year.

In Caesar's edict, the intercalary day was known as a *punctum temporis* (point of time), and anyone born that day had subsequent birthdays on February 23 (the day before); but lawyers then and in medieval times raised a number of arguments about its precise interpretation. Also, the Pontifices misinterpreted the edict and inserted the intercalation too frequently. The error arose because of the Roman practice of inclusive numbering, so that an intercalation once every fourth year meant to them intercalating every three years, because a bissextile year was counted as the first year of the next four-year period. This error continued undetected for 36 years, during which period 12 days instead of nine were added. The emperor Augustus made a correction by omitting intercalary days between 8 BC and AD 8. In consequence it was not until several decades after its inception that the Julian calendar came into proper operation, a fact that is important in chronology but is often forgotten.

Months of the Julian calendar

It seems that the months of the Julian calendar were taken over from the Roman republican calendar but were slightly modified to give a more even pattern of numbering. The republican calendar months of March, May, and Quintilis (July), which had each possessed 31 days, were retained unaltered. Although there is doubt about the details, changes may have occurred as follows. Except for October, all the months that had previously had only 29 days had either one or two days added. January, September, and November received two days, bringing their totals to 31, while April, June, Sextilis (August), and December received one day each, bringing their totals to 30. October was reduced by one day to a total of 30 days and February increased to 29 days, or 30 in a bissextile year. With the exception of February, the scheme resulted in months having 30 or 31 days alternately throughout the year. And in order to help farmers, Caesar issued an almanac showing on which dates of his new calendar various seasonal astronomical phenomena would occur.

These arrangements for the months can only have remained in force for a short time, because in 8 BC changes were made by Augustus. In 44 BC, the second year of the Julian calendar, the Senate proposed that the name of the month Quintilis be changed to Julius (July), in honour of Julius Caesar, and in 8 BC the name of Sextilis was similarly changed to Augustus (August). Perhaps because Augustus felt that his month must have at least as many days as Julius Caesar's, February was reduced to 28 days and August increased to 31. But because this made three 31-day months (July, August, and September) appear in succession, Augustus is supposed to have reduced September to 30 days, added a day to October to make it 31 days, reduced November by one day to 30 days, and increased December from 30 to 31 days, giving the months the lengths they have today.

Several scholars, however, believe that Caesar originally left February with 28 days (to avoid affecting certain religious rites in honour of the gods of the netherworld) and added two days to Sextilis for a total of 31; January, March, May, Quintilis, October, and December also had 31 days, with 30 days for April, June, September, and November. The subsequent change of Sextilis to Augustus thus involved no addition of days to the latter.

Divisions of the month

The Julian calendar retained the Roman republican calendar method of numbering the days of the month. Compared with the present system, the Roman numbering seems to run backward, for the first day of the month was known as the Kalendae, but subsequent days were not enumerated as so many after the Kalendae but as so many before the following Nonae ("nones"), the day called nonae being the ninth day before the Ides (from *iduare,* meaning "to divide"), which occurred in the middle of the month and were supposed to coincide with the Full Moon. Days after the Nonae and before the Ides were numbered as so many before the Ides, and those after the Ides as so many before the Kalendae of the next month.

There were no weeks in the original Julian calendar, but days were designated either *dies fasti* or *dies nefasti,* the former being business days and days on which the courts were open; this had been the practice in the Roman republican calendar. Julius Caesar designated his additional days all as *dies fasti,* and they were added at the end of the month so that there was no interference with the dates traditionally fixed for *dies comitiales* (days when public assemblies might be convened) and *dies festi* and *dies feriae* (religious festivals and holy days). Originally, then, the Julian calendar had a permanent set of dates for administrative matters. The official introduction of the seven-day week by Emperor Constantine I in the 4th century AD disrupted this arrangement.

Fixing of January as the first month

It appears, from the date of insertion of the intercalary month in the Roman republican calendar and the habit of designating years by the names of the consuls, that the calendar year had originally commenced in March, which was the date when the new consul took office. In 222 BC the date of assuming duties was fixed as March 15, but in 153 BC it was transferred to the Kalendae of January, and there it remained. January therefore became the first month of the year, and in the western region of the Roman Empire, this practice was carried over into the Julian calendar. In the eastern provinces, however, years were often reckoned from the accession of the reigning emperor, the second beginning on the first New Year's day after the accession; and the date on which this occurred varied from one province to another.

THE GREGORIAN CALENDAR

The Julian calendar year of 365.25 days was too long, since the correct value for the tropical year is 365.242199 days. This error of 11 minutes 14 seconds per year amounted to almost one and a half days in two centuries, and seven days in 1,000 years. Once again the calendar became increasingly out of phase with the seasons. From time to time, the problem was placed before church councils, but no action was taken because the astronomers who were consulted doubted whether enough precise information was available for a really accurate value of the tropical year to be obtained. By 1545, however, the vernal equinox, which was used in determining Easter, had moved 10 days from its proper date; and in December, when the Council of Trent met for the first of its sessions, it authorized Pope Paul III to take action to correct the error. Correction required a solution, however, that neither Paul III nor his successors were able to obtain in satisfactory form until nearly 1572, the year of election of Pope Gregory XIII. Gregory found various proposals awaiting him and agreed to issue a bull that the Jesuit astronomer Christopher Clavius (1537–1612) began to draw up, using suggestions made by the astronomer and physician Luigi Lilio (also known as Aloysius Lilius; died 1576).

The papal bull appeared in February 1582. First, in order to bring the vernal equinox back to March 21, the day following the Feast of St. Francis (that is, October 5) was to become October 15, thus omitting 10 days. Second, to bring the year closer to the true tropical year, a value of 365.2422 days was accepted. This value differed by 0.0078 days per year from the Julian calendar reckoning, amounting to 0.78 days per century, or 3.12 days every 400 years. It was therefore promulgated that three out of every four centennial years should be common years, that is, not leap years; and this practice led to the rule that no centennial years should be leap years unless exactly divisible by 400. Thus, 1700, 1800, and 1900 were not leap years, as they would have been in the Julian calendar, but the year 2000 will be. The bull also laid down rules for calculating the date of Easter.

The date of Easter; epacts. Easter was the most important feast of the Christian Church, and its place in the calendar determined the position of the rest of the church's movable feasts (see CHRISTIANITY: *Church year*). Because its timing depended on both the Moon's phases and the vernal equinox, ecclesiastical authorities had to seek some way of reconciling lunar and solar calendars. Some simple form of computation, usable by non-astronomers in remote places, was desirable. There was no easy or obvious solution, and to make things more difficult there was no unanimous agreement on the way in which Easter should be calculated, even on a lunar calendar.

Dependence on the Passover

Easter, being the festival of the Resurrection, had to depend on the dating of the Crucifixion, which occurred three days earlier and just before the Jewish Passover. The Passover was celebrated on the 14th day of Nisan, the first month in the Jewish religious year—that is, the lunar month the 14th day of which falls on or next after the vernal equinox. The Christian churches in the eastern Mediterranean area celebrated Easter on the 14th of Nisan on whatever day of the week it might fall, but the rest of Christendom adopted a more elaborate reckoning to ensure that it was celebrated on a Sunday in the Passover week.

To determine precisely how the Resurrection and Easter Day should be dated, reference was made to the Gospels; but even as early as the 2nd century AD, difficulties had arisen since the synoptic Gospels (Matthew, Mark, and Luke) appeared to give a different date from the Gospel According to John for the Crucifixion. This difference led to controversy that was later exacerbated by another difficulty caused by the Jewish reckoning of a day from sunset to sunset. The question arose of how the evening of the 14th day should be calculated, and some—the Quintodecimans—claimed that it meant one particular evening, but others—the Quartodecimans—claimed that it meant the evening before, since sunset heralded a new day. Both sides had their protagonists, the Eastern churches supporting the Quartodecimans, the Western churches the Quintodecimans. The question was finally decided at the Council of Nicaea, in 325, in favour of the Quintodecimans, and the Western church agreed. The Eastern churches decided to retain the Quartodeciman position, and the church in England, which had few links with the European churches at this time, retained the Quartodeciman position until Roman missionaries arrived in the 6th century, when a change was made. The dating of Easter in the Gregorian calendar was based on the decision of the Council of Nicaea, which decreed that Easter should be celebrated on the Sunday immediately following the (Paschal) Full Moon that fell on or after the vernal equinox, which they took as March 21. The council also ordered that if this Full Moon fell on a Sunday, the festival should be held seven days later.

Dominical letters

With these provisions in mind, the problem could be broken down into two parts: first, devising a simple but effective way of calculating the days of the week for any date in the year and, second, determining the date of the Full Moons in any year. The first part was solved by the use of a letter code derived from a similar Roman system adopted for determining market days. For ecclesiastical use, the code gave what was known as the Sunday, or dominical, letter.

The seven letters A through G are each assigned to a day, consecutively from January 1 so that January 1 appears as A, January 2 as B, to January 7 which appears as G, the cycle then continuing with January 8 as A, January 9 as B, and so on. Then in any year the first Sunday is bound to be assigned to one of the letters A–G in the first cycle, and all Sundays in the year possess that dominical letter. For example, if the first Sunday falls on January 3, C will be the dominical letter for the whole year. No dominical letter is placed against the intercalary day, February 29, but since it is still counted as a weekday and given a name, the series of letters moves back one day every leap year after intercalation. Thus, a leap year beginning with the dominical letter C will change to a year with the dominical letter D on March 1; and in lists of dominical letters, all leap years are given a double letter notation, in the example just quoted, CD. It is not difficult to see what dominical letter or letters apply to any particular year, and it is also a comparatively simple matter to draw up a table of dominical letters for use in determining Easter Sunday. The possible dates on which Easter Sunday can fall are written down—they run from March 22 through April 25—and against them the dominical letters for a cycle of seven years. Once the dominical letter for a year is known, the possible Sundays for celebrating Easter can be read directly from the table. This system does not, of course, completely determine Easter; to do so, additional information is required.

Golden numbers

This must provide dates for Full Moons throughout the year, and for this a lunar cycle like the Metonic cycle was originally used. Tables were prepared, again using the range of dates on which Easter Sunday could appear, and against each date a number from one through to 19 was placed. This number indicated which of the 19 years of the lunar cycle would give a Full Moon on that day. From medieval times these were known as golden numbers, possibly from a name used by the Greeks for the numbers on the Metonic cycle or because gold is the colour used for them in manuscript calendars.

The system of golden numbers was introduced in 530, but the numbers were arranged as they should have been if adopted at the Council of Nicaea two centuries earlier; and the cycle was taken to begin in a year when the New Moon fell on January 1. Working backward, chronologers found that this date had occurred in the year preceding AD 1, and therefore the golden number for any year is found by dividing the year by 19, then adding one to the remainder. If the result is zero, the golden number for the year is 19.

To compute the date of Easter, the medieval chronologer computed the golden number for the year and then consulted his table to see by which date this number lay. Having found this date, that of the first Full Moon after March 20, he consulted his table of dominical letters and saw the next date against which the dominical letter for that year appeared; this was the Sunday to be designated Easter. The method, modified for dropping centennial leap years as practiced in the Gregorian calendar, is still given in the English prayer book, although it was officially discarded when the Gregorian calendar was introduced.

The system of golden numbers was eventually rejected because the astronomical Full Moon could differ by as much as two days from the date they indicated. It was Lilius who had proposed a more accurate system based on one that had already been in use unofficially while the Julian calendar was still in force. Called the epact—the word is derived from the Greek *epagein,* meaning "to intercalate"—this was again a system of numbers concerned with the Moon's phases, but now indicating the age of the Moon on the first day of the year, and from which the age of the Moon on any day of the year may be found, at least approximately, by counting, using alternately months of 29 and 30 days.

Lunar and solar corrections

The epact as previously used was not, however, completely accurate because, like the golden number, it had been based on the Metonic cycle. This 19-year cycle was in error, the discrepancy amounting to eight days every 2,500 years. A one-day change on certain centennial years was then instituted by making the computed age of the Moon one day later seven times, at 300-year intervals, and an eighth time after a subsequent 400 years. This operation was known as the lunar correction, but it was not the only correction required; there was another.

Because the Gregorian calendar used a more accurate value for the tropical year than the Julian calendar and achieved this by omitting most centennial leap years, Clavius decided that when the cycle of epacts reached an ordinary centennial year, the number of the epact should be reduced by one; this reduction became known as the solar correction.

One advantage of the epact number was that it showed the age of the Moon on January 1 and so permitted a simple calculation of the dates of New Moon and Full Moon for the ensuing year. Another was that it lent itself to the construction of cycles of 30 epact numbers, each diminishing by one from the previous cycle, so that when it became necessary at certain centennial years to shift from one cycle to another, there would still be a cycle ready that retained a correct relationship between dates and New Moons.

For determining Easter, a table was prepared of the golden numbers, one through 19, and below them the cycles of epacts for about 7,000 years; after this time, all the epact cycles are repeated. A second table was then drawn up, giving the dates of Easter Full Moons for different epact numbers. Once the epact for the year was known, the date of the Easter Full Moon could be immediately obtained, while consultation of a table of dominical letters showed which was the next Sunday. Thus, the Gregorian system of epacts, while more accurate than the old golden numbers, still forced the chronologer to consult complex astronomical tables.

Adoption in various countries. The derivation of the term style for a type of calendar seems to have originated some time soon after the 6th century as a result of developments in calendar computation in the previous 200 years. In AD 463, Victorius (or Victorinus) of Aquitaine, who had been appointed by Pope Hilarius to undertake calendar revision, devised the Great Paschal (*i.e.,* Passover) period, sometimes later referred to as the Victorian period. It was a combination of the solar cycle of 28 years and the Metonic 19-year cycle, bringing the Full Moon back to the same day of the month, and amounted to 28 × 19, or 532 years. In the 6th century, this period was used by Dionysius Exiguus (Denis the Little) in computing the date of Easter, because it gave the day of the week for any day in any year, and so it also became known as the Dionysian period. Dionysius took the year now called AD 532 as the first year of a new Great Paschal period and the year now designated 1 BC as the beginning of the previous cycle. In the 6th century it was the general belief that this was the year of Christ's birth, and because of this Dionysius introduced the concept of numbering years consecutively through the Christian Era. The method was adopted by some scholars but seems only to have become widely used after its popularization by the Venerable Bede of Jarrow (673?–735), whose reputation for scholarship was very high in Western Christendom in the 8th century. This system of BC/AD numbering threw into relief the different practices, or styles, of reckoning the beginning of the year then in use. When the Gregorian calendar firmly established January 1 as the beginning of its year, it was widely referred to as the New Style calendar, with the Julian the Old Style calendar. In Britain, under the Julian calendar, the year had first begun on December 25 and then, from the 14th century onward, on March 25.

The Great Paschal period

Because of the division of the Eastern and Western Christian churches and of Protestants and Roman Catholics, the obvious advantages of the Gregorian calendar were not accepted everywhere, and in some places adoption was extremely slow. In France, Italy, Luxembourg, Portugal, and Spain, the New Style calendar was adopted in 1582, and it was in use by most of the German Roman Catholic states as well as by Belgium and part of the Netherlands by 1584. Switzerland's change was gradual, on the other hand, beginning in 1583 and being completed only in 1812. Hungary adopted the New Style in 1587, and then there was a pause of more than a century before the first Protestant countries made the transition from the Old Style calendar. In 1699–1700, Denmark and the Dutch and German Protestant states embraced the New Style, although the Germans declined to adopt the rules laid down for determining Easter. The Germans preferred to rely instead on astronomical tables and specified the use of the *Tabulae Rudolphinae* (*Rudolphine Tables*), based on the 16th-century observations of Tycho Brahe. They acceded to the Gregorian calendar rules for Easter only in 1776. Britain adopted the New Style in 1752 and Sweden in 1753, although the Swedes, because they had in 1740 followed the German Protestants in using their astronomical methods for determining Easter, declined to adopt the Gregorian calendar rules until 1844. Japan adopted the New Style in 1873; Egypt adopted it in 1875; and between 1912 and 1917 it was accepted by Albania, Bulgaria, China, Estonia, Latvia, Lithuania, Romania, Turkey, and Yugoslavia. The Soviet Union adopted the New Style in 1918; Greece in 1923.

Adoption of the New Style by Protestant countries

In Britain and the British dominions, the change was made when the difference between the New and Old Style calendars amounted to 11 days: the lag was covered by naming the day after September 2, 1752, as September 14, 1752. There was widespread misunderstanding among the public, however, even though legislation authorizing the change had been framed to avoid injustice and financial hardship. The Alaskan territory retained the Old Style calendar until 1867, when it was transferred from Russia to the United States.

CALENDAR REFORM SINCE THE MID-18TH CENTURY

The French republican calendar. In late 18th-century France, with the approach of the French Revolution, demands began to be made for a radical change in the civil calendar that would divorce it completely from any ecclesiastical connections. The first attacks on the Gregorian calendar and proposals for reform came in 1785 and 1788, the changes being primarily designed to divest the calendar of all its Christian associations. After the storming of the Bastille in July 1789, demands became more vociferous, and a new calendar, to start from "the first year of liberty," was widely spoken about. In 1793 the National Convention appointed Charles-Gilbert Romme, president of the committee of public instruction, to take charge of the reform. Technical matters were entrusted to the mathematicians Joseph-Louis Lagrange and Gaspard Monge and the renaming of the months to the Paris deputy to the convention, Philippe Fabre d'Églantine. The results of their deliberations were submitted to the convention in September of the same year and were immediately accepted, it being promulgated that the new calendar should become law on October 5.

The French republican calendar, as the reformed system came to be known, was taken to have begun on September 22, 1792, the day of the proclamation of the Republic and, in that year, the date also of the autumnal equinox. The total number of days in the year was fixed at 365, the same as in the Julian and Gregorian calendars, and this was divided into 12 months of 30 days each, the remaining five days at year's end being devoted to festivals and vacations. These were to fall between September 17 and 22 and were specified, in order, to be festivals in honour of virtue, genius, labour, opinion, and rewards. In a leap year an extra festival was to be added—the festival of the Revolution. Leap years were retained at the same frequency as in the Gregorian calendar, but it was enacted that the first leap year should be year 3, not year 4 as it would have been if the Gregorian calendar had been followed precisely in this respect. Each four-year period was to be known as a *Franciade.*

Weeks and *décades*

The seven-day week was abandoned, and each 30-day month was divided into three periods of 10 days called *décades,* the last day of a *décade* being a rest day. It was also agreed that each day should be divided into decimal parts, but this was not popular in practice and was allowed to fall into disuse.

The months themselves were renamed so that all previous associations should be lost, and Fabre d'Églantine chose descriptive names as follows (the descriptive nature and corresponding Gregorian calendar dates for years 1, 2, 3, 5, 6, and 7 are given in parentheses): Vendémiaire ("vintage," September 22 to October 21), Brumaire ("mist," October 22 to November 20), Frimaire ("frost," November 21 to December 20), Nivôse ("snow," December 21 to January 19), Pluviôse ("rain," January 20 to February 18), Ventôse ("wind," February 19 to March 20), Germinal ("seedtime," March 21 to April 19), Floréal ("blossom," April 20 to May 19), Prairial ("meadow," May 20 to June 18), Messidor ("harvest," June 19 to July 18), Thermidor ("heat," July 19 to August 17), and Fructidor ("fruits," August 18 to September 16).

The French republican calendar was short-lived, for while it was satisfactory enough internally, it clearly made for difficulties in communication abroad because its months continually changed their relationship to dates in the Gregorian calendar. In September 1805, under the Napoleonic regime, the calendar was virtually abandoned, and on January 1, 1806, it was replaced by the Gregorian calendar.

Soviet calendar reforms. When Soviet Russia undertook its calendar reform in February 1918, it merely moved from the Julian calendar to the Gregorian. This move resulted in a loss of 13 days, so that February 1, 1918, became February 14.

Modern schemes for reform. The current calendar is not without defects, and reforms are still being proposed. Astronomically, it really calls for no improvement, but the seven-day week and the different lengths of months are unsatisfactory to some. Clearly, if the calendar could have all festivals and all rest days fixed on the same dates every year, as in the original Julian calendar, this arrangement would be more convenient, and two general schemes have been put forward—the International Fixed Calendar and the World Calendar.

The International Fixed Calendar is essentially a perpetual Gregorian calendar, in which the year is divided into 13 months, each of 28 days, with an additional day at the end. Present month names are retained, but a new month named Sol is intercalated between June and July. The additional day follows December 28 and bears no designation of month date or weekday name, while the same would be true of the day intercalated in a leap year after June 28. In this calendar, every month begins on a Sunday and ends on a Saturday.

It is claimed that the proposed International Fixed Calendar does not conveniently divide into quarters for business reckoning; and the World Calendar is designed to remedy this deficiency, being divided into four quarters of 91 days each, with an additional day at the end of the year. In each quarter, the first month is of 31 days and the second and third of 30 days each. The extra day comes after December 30 and bears no month or weekday designation, nor does the intercalated leap year day that follows June 30. In the World Calendar January 1, April 1, July 1, and October 1 are all Sundays. Critics point out that each month extends over part of five weeks, and each month within a given quarter begins on a different day. Nevertheless, both these proposed reforms seem to be improvements over the present system that contains so many variables. (C.A.R.)

BIBLIOGRAPHY. An important book on both the development of the calendar and its calculation and possible reform is ALEXANDER PHILIPS, *The Calendar: Its History, Structure and Improvement* (1921). A shorter and more up-to-date reference is the section on the calendar in the *Explanatory Supplement to the Astronomical Ephemeris and the American Ephemeris and Nautical Almanac* (1961, reprinted with amendments, 1977). Also useful are FRANK PARISE (ed.), *The Book of Calendars* (1982), a general reference source with a number of conversion tables; and WILLIAM MATTHEW O'NEIL, *Time and the Calendars* (1975). LUDWIG ROHNER, *Kalendergeschichte und Kalender* (1978), discusses the history of Western calendars. VLADIMIR V. TSYBULSKY, *Calendars of Middle East Countries* (1979, originally published in Russian, 1976), examines modern calendars.

Babylonian: See references to special studies in E.J. BICKERMAN, *Chronology of the Ancient World,* 2nd ed. (1980). On astronomy and calendar, see OTTO NEUGEBAUER, *The Exact Sciences in Antiquity,* 2nd ed. (1957, reprinted 1969); and his chapter on "Ancient Mathematics and Astronomy," in the *History of Technology,* ed. by CHARLES SINGER *et al.,* vol. 1 (1954). On the later Babylonian calendar cycle, see RICHARD A. PARKER and WALDO H. DUBBERSTEIN, *Babylonian Chronology 626 B.C.–A.D. 75* (1956). Current bibliography is published in the quarterly review *Orientalia.*

Other Middle Eastern: (*Assyria*): HILDEGARD LEWY, *The Cambridge Ancient History,* 3rd ed., vol. 1, pt. 2, ch. 25 (1971); and, on the "week," see also *The Assyrian Dictionary,* vol. 5 (1956). Early Egyptian: See NEUGEBAUER (*op. cit.*); see also his *Commentary on the Astronomical Treatise* (1969); "The Origin of the Egyptian Calendar," *J. Near Eastern Stud.,* 1:396–403 (1942); and OTTO NEUGEBAUER and RICHARD A. PARKER (eds. and trans.), *Egyptian Astronomical Texts,* 3 vol. (1960–69). RICHARD A. PARKER, *The Calendars of Ancient Egypt* (1950), is a good source on the subject—all older material is out of date; his "Lunar Dates of Thutmose III and Ramesses II," *J. Near Eastern Stud.,* 16:39–43 (1957), is important for later lunar dates. H.E. WINLOCK, "The Origin of the Ancient Egyptian Calendar," *Proc. Am. Phil. Soc.,* 83:447–64 (1940), is also an important discussion.

Early Greek and Roman: For the *octaëteris,* see D.R. DICKS, "Solstices, Equinoxes, and the Presocratics," *J. Hellenic Stud.,* 86:26–40 (1966); see also his *Early Greek Astronomy to Aristotle* (1970). STERLING DOW and ROBERT F. HEALEY, *A Sacred Calendar of Eleusis* (1966), describes a calendar other than that of Athens. BENJAMIN D. MERITT, *The Athenian Year* (1961), contains a reconstruction of the Athenian civil years. JON D. MIKALSON, *The Sacred and Civil Calendar of the Athenian Year* (1975), includes useful bibliographical references. For water clocks, see OTTO NEUGEBAUER and H.B. VAN HOESEN, *Greek Horoscopes* (1959, reprinted 1978). WILLIAM KENDRICK PRITCHETT, *Ancient Athenian Calendars on Stone* (1963), is good for the Athenian calendar. See also his "Gaming Tables and I.G., I^2, 324," *Hesperia,* 34:131–147 (1965); and, with OTTO NEUGEBAUER, *The Calendars of Athens* (1947). Also useful are BICKERMAN (*op. cit.*); and ALAN E. SAMUEL, *Greek and Roman Chronology* (1972). For Roman calendars, see AGNES KIRSOPP MICHELS, *The Calendar of the Roman Republic* (1967, reprinted 1978); and PIERRE BRIND'AMOUR, *Le Calendrier romain* (1983).

Jewish: The oldest systematic and complete book on the present fixed Jewish calendar is the work of ABRAHAM BAR HIYYA (born c. 1065), known as Savasorda of Barcelona, that bears the title *Sefer ha-ʿIbbur.* A précis of this is contained in a section (ch. 6–10) in MOSES MAIMONIDES, *Sanctification of the New Moon,* trans. from the Hebrew by SOLOMON GANDZ, with an "Astronomical Commentary" by OTTO NEUGEBAUER (1956), and supplemented in the "Addenda and Corrigenda" by ERNEST WIESENBERG to MOSES MAIMONIDES, *The Book of*

Seasons (1961). These treatises from the *Code of Maimonides* are published as vols. 11 and 14 of the "Yale Judaica Series." Additional details of the Jewish calendar of both the rabbinic and sectarian varieties have been outlined by ERNEST WIESENBERG in "Calendar," and JACOB LICHT in "Sectarian Calendars," both in *Encyclopaedia Judaica,* vol. 5, pp 43–53 (1971).

Indian: The most complete account of the lunar–solar calendar of India may be found in "Indian Calendar," ch. 5 of the *Calendar Reform Committee Report* of the Government of India (1955). A good summary of the materials was published by JEAN FILLIOZAT in "Notions de chronologie," an appendix of the encyclopaedic work on Indian history and culture, *L'Inde classique,* by LOUIS RENOU and JEAN FILLIOZAT, vol. 2 (1953).

Chinese: The Chinese calendar is discussed in JOSEPH NEEDHAM and WANG LING, "Mathematics and the Sciences of the Heavens and the Earth," *Science and Civilisation in China,* vol. 3 (1959).

Pre-Columbian: The following are useful and authoritative references for the Mayan calendar: SYLVANUS G. MORLEY, *An Introduction to the Study of the Maya Hieroglyphs* (1915, reprinted 1975); and J. ERIC S. THOMPSON, *Maya Hieroglyphic Writing: An Introduction,* 3rd ed. (1971), the most complete and authoritative account. See also FLOYD G. LOUNSBURY, "Maya Numeration, Computation, and Calendrical Astronomy," *Dictionary of Scientific Biography,* ed. by CHARLES COULSTON GILLISPIE *et al.,* vol. 15 (1978); and MIGUEL LEÓN-PORTILLA, *Time and Reality in the Thought of the Maya* (1973). For the Mexican calendar: ALFONSO CASO, "El Calendario Mexicano," *Memorias de la Academia Mexicana de la Historia,* vol. 17, no. 1 (1958); *Thirteen Masterpieces of Mexican Archaeology* (1938, reprinted 1976); and *Los Calendarios prehispanicos* (1967). See also FRAY DIEGO DURÁN, *Book of the Gods, and The Ancient Calendar* (1971; originally published in Spanish, 1867), containing illustrated explanations of the Aztec calendar. Calvin and Calvinism

John Calvin, in French Jean Calvin or Cauvin (1509–1564), was the leading French Protestant Reformer and the most important figure in the second generation of the Protestant Reformation. His interpretation of Christianity, advanced above all in his *Institutio Christianae religionis* (1536 but elaborated in later editions; *Institutes of the Christian Religion*), and the institutional and social patterns he worked out for Geneva deeply influenced Protestantism elsewhere in Europe and in North America. The Calvinist form of Protestantism is widely thought to have had a major impact on the formation of the modern world.

This article deals with the man, his achievements, and the Calvinist tradition. For a further treatment of Calvinism, see PROTESTANTISM.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 827 and 961.

This article is divided into the following sections:

CALVIN

Life and works. Calvin was born on July 10, 1509, in Noyon, in Picardy, France, the son of middle-class parents. His father, a lay administrator in the service of the local bishop, sent him to the University of Paris in 1523 to be educated for the priesthood but later decided that he should be a lawyer; from 1528 to 1531, therefore, Calvin studied in the law schools of Orléans and Bourges. He then returned to Paris. During these years he was also exposed to Renaissance humanism, influenced by Erasmus and Jacques Lefèvre d'Étaples, which constituted the radical student movement of the time. This movement, which antedates the Reformation, aimed to reform church and society on the model of both classical and Christian antiquity, to be established by a return to the Bible studied in its original languages. It left an indelible mark on Calvin. Under its influence he studied Greek and Hebrew as well as Latin, the three languages of ancient Christian discourse, in preparation for serious study of the Scriptures. It also intensified his interest in the classics; his first publication (1532) was a commentary on Seneca's essay on clemency. But the movement, above all, emphasized salvation of individuals by grace rather than good works and ceremonies.

The influence of Renaissance humanism

Flight to Switzerland

Calvin's Paris years came to an abrupt end late in 1533. Because the government became less tolerant of this reform movement, Calvin, who had collaborated in the preparation of a strong statement of theological principles for a public address delivered by Nicolas Cop, rector of the university, found it prudent to leave Paris. Eventually he made his way to Basel, then Protestant but tolerant of religious variety. Up to that point, however, there is little evidence of Calvin's conversion to Protestantism, an event difficult to date because it was probably gradual. His beliefs before his flight to Switzerland were probably not incompatible with Roman Catholic orthodoxy. But they underwent a change when he began to study theology intensively in Basel. Probably in part to clarify his own beliefs, he began to write. He began with a preface to a French translation of the Bible by his cousin Pierre Olivétan and then undertook what became the first edition of the *Institutes,* his masterwork, which, in its successive revisions, became the single most important statement of Protestant belief. Calvin published later editions in both Latin and French, containing elaborated and in a few cases revised teachings and replies to his critics. The final versions appeared in 1559 and 1560. The *Institutes* also reflected the findings of Calvin's massive biblical commentaries, which, presented extemporaneously in Latin as lectures to ministerial candidates from many countries, make up the largest proportion of his works. In addition he wrote many theological and polemical treatises.

Protestantism in Geneva

The 1536 *Institutes* had given Calvin some reputation among Protestant leaders. Therefore, on discovering that Calvin was spending a night in Geneva late in 1536, the Reformer and preacher Guillaume Farel, then struggling to plant Protestantism in that town, persuaded him to remain to help in this work. The Reformation was in trouble in Geneva, a town of about 10,000 where Protestantism had only the shallowest of roots. Other towns in the region, initially ruled by their prince-bishops, had successfully won self-government much earlier, but Geneva had lagged behind in this process largely because its prince-bishop was supported by the neighbouring duke of Savoy. There had been iconoclastic riots in Geneva in the mid-1520s, but these had negligible theological foundations. Protestantism had been imposed on religiously unawakened Geneva chiefly as the price of military aid from Protestant Bern. The limited enthusiasm of Geneva for Protestantism, reflected by a resistance to religious and moral reform, continued almost until Calvin's death. The resistance was all the more serious because the town council in Geneva, as in other Protestant towns, exercised ultimate control over the church and the ministers, all French refugees. The main issue was the right of excommunication, which the ministers regarded as essential to their authority but which the council refused to concede. The uncompromising attitudes of Calvin and Farel finally resulted in their expulsion from Geneva in May 1538.

Calvin, oil painting by an anonymous master of the French school, *c.* 1550. In the Boymans-van Beuningen Museum, Rotterdam.

Calvin found refuge for the next three years in the German Protestant city of Strasbourg, where he was pastor of a church for French-speaking refugees and also lectured on the Bible; there he published his commentary on the Letter of Paul to the Romans. There too, in 1540, he married Idelette de Bure, the widow of a man he had converted from Anabaptism. Although none of their children survived infancy, their marital relationship proved to be extremely warm. During his Strasbourg years Calvin also learned much about the administration of an urban church from Martin Bucer, its chief pastor. Meanwhile Calvin's attendance at various international religious conferences made him acquainted with other Protestant leaders and gave him experience in debating with Roman Catholic theologians. Henceforth he was a major figure in international Protestantism.

Return to Geneva

In September 1541 Calvin was invited back to Geneva, where the Protestant revolution, without strong leadership, had become increasingly insecure. Because he was now in a much stronger position, the town council in November enacted his *Ecclesiastical Ordinances,* which provided for the religious education of the townspeople, especially children, and instituted Calvin's conception of church order. It also established four groups of church officers: pastors and teachers to preach and explain the Scriptures, elders representing the congregation to administer the church, and deacons to attend to its charitable responsibilities. In addition it set up a consistory of pastors and elders to make all aspects of Genevan life conform to God's law. It undertook a wide range of disciplinary actions covering everything from the abolition of Roman Catholic "superstition" to the enforcement of sexual morality, the regulation of taverns, and measures against dancing, gambling, and swearing. These measures were resented by a significant element of the population, and the arrival of increasing numbers of French religious refugees in Geneva was a further cause of native discontent. These tensions, as well as the persecution of Calvin's followers in France, help to explain the trial and burning of Michael Servetus, a Spanish theologian preaching and publishing unorthodox beliefs. When Servetus unexpectedly arrived in Geneva in 1553, both sides felt the need to demonstrate their zeal for orthodoxy. Calvin was responsible for Servetus' arrest and conviction, though he had preferred a less brutal form of execution.

The struggle over control of Geneva lasted until May 1555, when Calvin finally prevailed and could devote himself more wholeheartedly to other matters. He had constantly to watch the international scene and to keep his Protestant allies in a common front. Toward this end he engaged in a massive correspondence with political and religious leaders throughout Protestant Europe. He also continued his commentaries on Scripture, working through the whole New Testament except the Revelation to John and most of the Old Testament. Many of these commentaries were promptly published, often with dedications to such European rulers as Queen Elizabeth, though Calvin had too little time to do much of the editorial work himself. Committees of amanuenses took down what he said, prepared a master copy, and then presented it to Calvin for approval. During this period Calvin also established the Genevan Academy to train students in humanist learning in preparation for the ministry and positions of secular leadership. He also performed a wide range of pastoral duties, preaching regularly and often, doing numerous weddings and baptisms, and giving spiritual advice. Worn out by so many responsibilities and suffering from a multitude of ailments, he died on May 27, 1564.

Scriptural commentaries

Personality. Unlike Martin Luther, Calvin was a reticent man; he rarely expressed himself in the first person singular. This reticence has contributed to his reputation as cold, intellectual, and humanly unapproachable. His thought, from this perspective, has been interpreted as abstract and concerned with timeless issues rather than as the response of a sensitive human being to the needs of a particular historical situation. Those who knew him, however, perceived him differently, remarking on his talent for friendship but also on his hot temper. Moreover, the intensity of his grief on the death of his wife, as well as his empathic reading of many passages in Scripture, revealed a large capacity for feeling.

Calvin's facade of impersonality can now be understood as concealing an unusually high level of anxiety about the world around him, about the adequacy of his own efforts to deal with its needs, and about human salvation, notably including his own. He believed that every Christian—and he certainly included himself—suffers from terrible bouts of doubt. From this perspective the need for control both of oneself and the environment, often discerned in Calvinists, can be understood as a function of Calvin's own anxiety.

Calvin's anxiety found expression in two metaphors for the human condition that appear again and again in his writings: as an abyss in which human beings have lost their way and as a labyrinth from which they cannot escape. Calvinism as a body of thought must be understood as the product of Calvin's effort to escape from the terrors conveyed by these metaphors.

Intellectual formation. Historians are generally agreed that Calvin is to be understood primarily as a Renaissance humanist who aimed to apply the novelties of humanism to recover a biblical understanding of Christianity. Thus he sought to appeal rhetorically to the human heart rather than to compel agreement, in the traditional manner of systematic theologians, by demonstrating dogmatic truths. His chief enemies, indeed, were the systematic theologians of his own time, the Scholastics, both because they relied too much on human reason rather than the Bible and because their teachings were lifeless and irrelevant to a world in desperate need. Calvin's humanism meant first that he thought of himself as a biblical theologian in accordance with the Reformation slogan *scriptura sola.* He was prepared to follow Scripture even when it surpassed the limits of human understanding, trusting to the Holy Spirit to inspire faith in its promises. Like other humanists, he was also deeply concerned to remedy the evils of his own time; and here too he found guidance in Scripture. Its teachings could not be presented as a set of timeless abstractions but had to be brought to life by adapting them to the understanding of contemporaries according to the rhetorical principle of decorum—*i.e.,* suitability to time, place, and audience.

Calvin's humanism

Calvin's humanism influenced his thought in two other basic ways. For one, he shared with earlier Renaissance humanists an essentially biblical conception of the human personality, comprehending it not as a hierarchy of faculties ruled by reason but as a mysterious unity in which what is primary is not what is highest but what is central: the heart. This conception assigned more importance to will and feelings than to the intellect, and it also gave new dignity to the body. For this reason Calvin rejected the ascetic disregard of the body's needs that was often prominent in medieval spirituality. Implicit in this particular rejection of the traditional hierarchy of faculties in the personality, however, was a radical rejection of the traditional belief that hierarchy was the basis of all order. For Calvin, instead, the only foundation for order in human affairs was utility. Among its other consequences this position undermined the traditional one subordinating women to men. Calvin believed that, for practical reasons, it may be necessary for some to command and others to obey, but it could no longer be argued that women must naturally be subordinated to men. This helps to explain the rejection in Geneva of the double standard in sexual morality.

Conception of human personality

Second, Calvin's utilitarianism, as well as his understanding of the human personality as both less and more than intellectual, was also reflected in deep reservations about the capacity of human beings for anything but practical knowledge. The notion that they can know anything absolutely, as God knows, so to speak, seemed to him highly presumptuous. This conviction helps to explain his reliance on the Bible. Calvin believed that human beings have access to the saving truths of religion only insofar as God has revealed them in Scripture. But revealed truths were not given to satisfy human curiosity but were limited to meeting the most urgent and practical needs of human existence, above all for salvation. This emphasis on practicality reflects a basic conviction of Renaissance

Stress on practicality

humanism: the superiority of an active earthly life devoted to meeting practical needs to a life of contemplation. Calvin's conviction that every occupation in society is a "calling" on the part of God himself sanctified this conception. Calvin thus spelled out the theological implications of Renaissance humanism in various ways.

But Calvin was not purely a Renaissance humanist. The culture of the 16th century was peculiarly eclectic, and, like other thinkers of his time, Calvin had inherited a set of contrary tendencies, which he uneasily combined with his humanism. He was an unsystematic thinker not only because he was a humanist but also because 16th-century thinkers lacked the historical perspective that would have enabled them to sort out the diverse materials in their culture. Thus, even as he emphasized the heart, Calvin continued also to think of the human personality in traditional terms as a hierarchy of faculties ruled by reason. He sometimes attributed a large place to reason even in religion and emphasized the importance of rational control over the passions and the body. The persistence of these traditional attitudes in Calvin's thought, however, helps to explain its broad appeal; they were reassuring to conservatives.

Theology. Calvin has often been seen as little more than a systematizer of the more creative insights of Luther. He followed Luther on many points: on original sin, Scripture, the absolute dependence of human beings on divine grace, and justification by faith alone. But Calvin's differences with Luther are of major significance, even though some were largely matters of emphasis. Calvin was thus perhaps more impressed than Luther by God's transcendence and by his control over the world; Calvin emphasized God's power and glory, whereas Luther often thought of God as the babe in the manger, here among human beings. Contrary to a general impression, Calvin's understanding of predestination was also virtually identical with Luther's (and indeed is close to that of Thomas Aquinas); and, although Calvin may have stated it more emphatically, the issue itself is not of central importance to his theology. He considered it a great mystery, to be approached with fear and trembling and only in the context of faith. Seen in this way, predestination seemed to him a comforting doctrine; it meant that salvation would be taken care of by a loving and utterly reliable God.

Calvin and Luther

But in major respects Calvin departed from Luther. In some ways Calvin was more radical. Though he agreed with Luther on the real presence of Christ in the Eucharist, he understood this in a completely spiritual sense. But most of his differences suggest that he was closer to the old church than was Luther, as in his ecclesiology, which recognized the institutional church in this world, as Luther did not, as the true church. He was also more traditional in his clericalism; his belief in the authority of clergy over laity was hardly consistent with Luther's stress on the priesthood of all believers. He insisted, too, on the necessity of a holy life, at least as a sign of genuine election. Even more significant, especially for Calvinism as a historical force, was Calvin's attitude toward the world. Luther had regarded this world and its institutions as incorrigible and was prepared to leave them to the Devil, a far more important figure in his spiritual universe than in Calvin's. But for Calvin this world was created by God and still belonged to him. It was still potentially Christ's kingdom, and every Christian was obligated to struggle to make it so in reality by bringing it under God's law.

Attitude toward the world

Spirituality. Calvin's reservations about the capacities of the human mind and his insistence that Christians exert themselves to bring the world under the rule of Christ suggest that it is less instructive to approach his thought as a theology to be comprehended by the mind than as a set of principles for the Christian life—in short, as spirituality. His spirituality begins with the conviction that human beings do not so much "know" God as "experience" him indirectly, through his mighty acts and works in the world, as they experience but can hardly be said to know thunder, one of Calvin's favourite metaphors for religious experience. Such experience of God gives them confidence in his power and stimulates them to praise and worship him.

At the same time that Calvin stressed God's power, he also depicted God as a loving father. Indeed, although Calvinism is often considered one of the most patriarchal forms of Christianity, Calvin recognized that God is commonly experienced as a mother. He denounced those who represent God as dreadful; God for him is "mild, kind, gentle, and compassionate." Human beings can never praise him properly, Calvin declared, "until he wins us by the sweetness of his goodness." That God loves and cares for his human creatures was, for Calvin, what distinguished his doctrine of providence from that of the Stoics.

Calvin's understanding of Christianity is thus in many ways gentler than has been commonly supposed. This is also shown in his understanding of original sin. Although he insisted on the "total depravity" of human nature after the Fall, he did not mean by this that there is nothing good left in human beings but rather that there is no agency within the personality left untouched by the Fall on which to depend for salvation. The intention of the doctrine is practical: to reinforce dependence on Christ and the free grace of God. In fact, unlike some of his followers, Calvin believed in the survival after the Fall, however weak, of the original marks of God's image, in which human beings were created. "It is always necessary to come back to this," he declared, "that God never created a man on whom he did not imprint his image." At times, to be sure, Calvin's denunciations of sin give a very different impression. But it should be kept in mind that as a humanist and a rhetorician Calvin was less concerned to be theologically precise than to impress his audience with the need to repent of its sins.

Total depravity

The problem posed by sin was, for Calvin, not that it had destroyed the spiritual potentialities of human beings but rather that human beings had lost their ability to use their potentialities. Through the Fall they had been alienated from God, who is the source of all power, energy, warmth, and vitality. Sin, on the contrary, had exposed the human race to death, the negation of God's life-giving powers. Human beings thus experience the effects of sin as drowsiness when they should be alert, as apathy when they should feel concern, as sloth when they should be diligent, as coldness when they should be warm, as weakness when they need strength. Thus also, since the Devil, who seeks to drain human beings of their God-given spirituality, tries to lull them to sleep, God must employ various stratagems to awaken them. This helps to explain the troubles that afflict the elect: God threatens, chastises, and compels them to remember him by making their lives go badly.

The effect of sin also prevents human beings from reacting with appropriate wonder to the marvels of the world. The failure of spirituality is the primary obstacle to an affective knowledge that, unlike mere intellectual apprehension, can move the whole personality. Calvin attached particular importance to the way in which sin deadens the feelings, but spiritual knowledge renews the connection, broken by sin, between knowledge, feeling, and action. Thus God's spirit, in all its manifestations, is the power of life. Calvin's understanding of sin is closely related to his humanistic emphasis on activity.

As his emphasis on sanctification for the individual believer and on reconquering the world for Christ implies, Calvin's spirituality also included a strong sense of history, which he perceived as a process in which God's purposes are progressively realized. Therefore, the central elements of the Gospel—the Incarnation and Atonement, the grace available through them, the gift of faith by which human beings are enabled to accept this grace for themselves, and the sanctification that results—together describe objectively how human beings are enabled, step by step, to recover their original relationship with God and regain the energy coming from it. Calvin described this as a "quickening" that, in effect, brings the believer back from death to life and makes possible the most strenuous exertion in God's service.

Calvin exploited two traditional metaphors for the life of a Christian. Living in an unusually militant age, he drew on the familiar idea of the believer's life as a ceaseless, quasi-military struggle against the powers of evil both within the self and in the world. The Christian, in this conception, must struggle against his own wicked impulses, against the majority of the human race on behalf of the Gospel, and ultimately against the Devil. Paradoxically, however, Christian warfare consists less in inflicting wounds on others than in suffering the effects of sin patiently, that is, by bearing the cross. In Calvin's thought the metaphor for the Christian life as conflict thus takes on the added meaning of acquiescence in suffering. The disasters that afflict human existence, though punishments for the wicked, are an education for the believer; they strengthen faith, develop humility, purge wickedness, and compel him to keep alert and look to God for help.

The second traditional metaphor for the Christian life employed by Calvin, that of a journey or pilgrimage—*i.e.,* of a movement toward a goal—equally implied activity. "Our life is like a journey," Calvin asserted; yet "it is not God's will that we should march along casually as we please, but he sets the goal before us, and also directs us on the right way to it." This way is also a struggle because no one moves easily forward and most are so weak that, "wavering and limping and even creeping along the ground, they move at a feeble pace." Yet with God's help everyone can daily make some advance, however slight. Notable in this conception is a single-mindedness often associated with Calvinism: Christians must look straight ahead to the goal and be distracted by nothing, looking neither to the right nor left. Calvin allows them to love the good things in this life, but only within limits.

The progress of Christian life

Thus the Christian life is a strenuous progress in holiness, which, through the constant effort of the individual to make the whole world obedient to God, will also be reflected in the progressive sanctification of the world. These processes, however, will never be completed in this life. For Calvin even the most developed Christian in this world is like an adolescent, yearning to grow into, though still far from, the full stature of Christ. But, Calvin assured his followers, "each day in some degree our purity will increase and our corruption be cleansed as long as we live in the world," and "the more we increase in knowledge, the more should we increase in love." Meanwhile the faithful experience a vision, always more clear, of "God's face, peaceful and calm and gracious toward us." So the spiritual life, for Calvin as for many before him, culminates in the vision of God.

CALVINISM

Developments after Calvin. While Lutheranism was largely confined to parts of Germany and to Scandinavia, Calvinism spread into England, Scotland, the English-speaking colonies in North America, France, the Netherlands, much of Germany, and parts of central Europe. This expansion began during Calvin's lifetime and was encouraged by him. Religious refugees had poured into Geneva, especially from France during the 1550s as the French government became increasingly intolerant but also from England, Scotland, Italy, and other parts of Europe into which Calvinism had spread. Calvin welcomed them, trained many of them as ministers, sent them back to their countries of origin to spread the Gospel, and then supported them with letters of encouragement and advice. Geneva thus became the centre of an international movement and a model for churches elsewhere. John Knox, the Calvinist leader of Scotland, described Geneva as "the most perfect school of Christ that ever was on the earth since the days of the Apostles."

The appeal of Calvinism

Efforts to explain the appeal of Calvinism in social terms have had only limited success. In France it may have been primarily attractive to the nobility and the urban upper classes, in Germany it found adherents among both townsmen and princes, but in England and the Netherlands it made converts in every social group. It seems likely, therefore, that its appeal was based on its ability to explain disorders of the age afflicting all classes as well as on the remedies and comfort provided both by its activism and by its doctrine.

Having said this much, however, it is important to observe that the later history of Calvinism has often been obscured by a failure to distinguish between (1) Calvinism as the beliefs of Calvin himself, as discussed above, (2) the beliefs of his followers, who, though striving to be faithful to Calvin, modified his teachings to meet their own needs, and (3) more loosely, the beliefs of the Reformed tradition of Protestant Christianity, in which Calvinism proper was only one, if historically the most prominent, strand. The Reformed churches—in the 16th century referred to in the plural to indicate, along with what they had in common, their individual autonomy and variety—consisted originally of a group of non-Lutheran Protestant churches based in towns in Switzerland and southern Germany. These churches have always been jealous of their autonomy, and Geneva was not alone among them in having distinguished theological leadership. Huldrych Zwingli and Heinrich Bullinger in Zürich and Martin Bucer in Strasbourg also had a European influence, which combined with that of Calvin, especially in England, to shape what came to be called Calvinism.

The church in Geneva continued to venerate Calvin and aimed to be faithful to his teaching under his successors, first among them Theodore Beza, Calvin's chief lieutenant during the latter part of his life. But in the late 16th and early 17th centuries, in the atmosphere of what can be appropriately described as a Protestant "Counter-Reformation," Calvinism in Geneva underwent a change. Abandoning Calvin's more humanistic tendencies and drawing more on other aspects of his thought, Calvinism was increasingly intellectualized and came more and more to resemble the Scholasticism that Calvin had abhorred.

Under the influence of Aristotle the theology of Geneva became increasingly systematic. Faith, in this new atmosphere, was less a lively trust in God's promises than assent to a body of theological propositions. Especially the doctrine of predestination began to assume an importance such as had not been attributed to it before. Whereas Calvin had been led by personal faith to an awed belief in predestination, predestination, considered an "eternal decree" of God and a metaphysical necessity, now became the basis of faith.

Synod of Dort

Developments in Geneva illustrate what happened to Calvinism elsewhere. In 1619 they reached a climax at the Synod of Dort in the Netherlands, which spelled out various corollaries of predestination, as Calvin had never done, and made the doctrine central to Calvinism. Although the controversy that provoked this formulation was local, the synod was attended by representatives of Reformed churches elsewhere and assumed somewhat the same importance for them as the Council of Trent did for Roman Catholics.

In keeping with these developments Calvinist theologians, apparently finding Calvin's loose rhetorical style of expression unsatisfactory, began deliberately to write like Scholastic theologians, in Latin, and even appealed to medieval Scholastic authorities. The major Calvinist theological statement of the 17th century was the *Institutio Theologiae Elencticae* (1688) of Francois Turretin, chief pastor of Geneva. Although the title of his work recalled Calvin's masterpiece, the work itself bore little resemblance to the *Institutes;* it was not published in the vernacular, its dialectical structure followed the model of the great *Summae* of Thomas Aquinas, and it suggested Thomas' confidence in the value of human reason. The lasting significance of this shift is suggested by the fact that Turretin, in Latin, was the basic textbook in theology at the Princeton Theological Seminary in New Jersey, the most distinguished intellectual centre of American Calvinism, until the middle of the 19th century.

Historians of Calvinism have continued to debate whether these developments were essentially faithful to the beliefs of Calvin or deviations from them. In some sense they were both. Later Calvinism, though abandoning Calvin's more humanistic tendencies, found precedents for these changes in the contrary aspects of his thought. They were untrue to Calvin, however, in rejecting his typically Renaissance concern to balance contrary impulses. These changes, moreover, suggest the stage in the development of a movement that Max Weber called "routinization." It is the stage that comes after a movement's creative beginnings and, as a kind of reaction against the disorderly freedom of individual creativity, represents the quite different values of order and regularity. It is also relevant to explaining these changes in Calvinism that they occurred during a period of singular disorder, caused among other things by a century of religious warfare, which generally produced a longing for certainty, security, and peace.

Assessment. Calvin's influence has persisted not only in the Reformed churches of France, Germany, Scotland, the Netherlands, and Hungary but also in the Church of England, where Calvin was long at least as highly regarded as among those Puritans who separated from the Anglican establishment. The latter organized their own churches, Presbyterian or Congregational, which brought Calvinism to North America. Even today these churches, along with the originally German Evangelical and Reformed Church, recall Calvin as their founding father. Eventually Calvinist theology was also widely accepted by major groups of Baptists; and even Unitarianism, which broke away from the Calvinist churches of New England in the 18th century, reflected the more rational impulses in Calvin's theology. More recently Protestant interest in the social implications of the Gospel and Protestant neo-orthodoxy, as represented by Karl Barth, Emil Brunner, and Reinhold Niebuhr, reflects the continuing influence of John Calvin.

Calvin's larger influence over the development of modern Western civilization has been variously assessed. The controversial "Weber thesis" attributed the rise of modern capitalism largely to Puritanism, but neither Max Weber, in his famous essay of 1904, "Die protestantische Ethik und der Geist des Kapitalismus" (*The Protestant Ethic and the Spirit of Capitalism*), nor the great economic historian Richard Henry Tawney, in *Religion and the Rise of Capitalism* (1926), implicated Calvin himself in this development. Much the same thing can be said about efforts to link Calvinism to the rise of modern science; although Puritans were prominent in the scientific movement of 17th-century England, Calvin himself was indifferent to the science of his own day. A somewhat better case can be made for Calvin's influence on political theory. His own political instincts were highly conservative, and he preached the submission of private persons to all legitimate authority. But, like Italian humanists, he personally preferred a republic to a monarchy. In confronting the problem posed by rulers who actively opposed the spread of the Gospel, he advanced a theory of resistance, kept alive by his followers, according to which lesser magistrates might legitimately rebel against kings. Unlike most of his contemporaries, furthermore, Calvin included among the proper responsibilities of states not only the maintenance of public order but also a positive concern for the general welfare of society.

Calvinism has a place, therefore, in the development of liberal political thought. Calvin's major and most durable influence, nevertheless, has been religious. From his time to the present Calvinism has meant a peculiar seriousness about Christianity and its ethical implications.

BIBLIOGRAPHY. The most complete edition of Calvin's works is *Ioannis Calvini Opera quae supersunt omnia,* 59 vol. in 26, ed. by GUILIELMUS (JOHANN WILHELM) BAUM, EDUARDUS (EDUARD) CUNITZ, and EDUARDUS (EDUARD) REUSS (1863–1900; reprinted 59 vol. in 58, 1964). Supplementary material may be found in the series "Supplementa Calviniana: Sermons inédits" (1961–), which collects hitherto unpublished sermons, with 5 vol. published by 1988; and the *Registres de la Compagnie des Pasteurs de Genève au temps de Calvin,* ed. by ROBERT M. KINGDON and JEAN-FRANÇOIS BERGIER, 2 vol. (1962–64), a partial record of the deliberations of the Geneva Company of Pastors from 1546 to 1564, the first 2 vol. of a larger set, *Registres de la Compagnie des Pasteurs de Genève,* ed. by OLIVIER FATIO *et al.* The best English translation of *Institutio Christianae religionis* is *Institutes of the Christian Religion,* trans. by FORD LEWIS BATTLES, 2 vol. (1960). For selected other works of Calvin in English, see DAVID W. TORRANCE and THOMAS F. TORRANCE (eds.), *Commentaries,* 12 vol. (1959–72, reprinted 1976–88), on the New Testament; and DONALD K. MCKIM (ed.), *Readings in Calvin's Theology* (1984).

Studies of Calvin are numerous. For guidance to older works, see ALFREDUS (ALFRED) ERICHSON, *Bibliographia Calviniana* (1900, reprinted 1979); and WILHELM NIESEL, *Calvin-Bibliographie, 1901–1959* (1961). For literature since 1960, see the bibliographies ed. by PETER DE KLERK and published annually in issue no. 2 of *Calvin Theological Journal.* A recent scholarly biography of Calvin is T.H.L. PARKER, *John Calvin* (1975, reissued 1987). For a fuller account of his thought, see FRANÇOIS WENDEL, *Calvin: Origins and Development of His Religious Thought* (1963, reprinted 1987; originally published in French, 1950); and for Calvin in historical context, see WILLIAM J. BOUWSMA, *John Calvin: A Sixteenth-Century Portrait* (1988). ROBERT M. KINGDON, *Geneva and the Coming of the Wars of Religion in France, 1555–1563* (1956), deals with Calvin's interest in France. For later Calvinism, see ROBERT V. SCHNUCKER (ed.), *Calviniana: Ideas and Influence of Jean Calvin* (1988); and MENNA PRESTWICH (ed.), *International Calvinism, 1541–1715* (1985). For Calvinist political thought, see QUENTIN SKINNER, "Calvinism and the Theory of Revolution," in *The Foundations of Modern Political Thought,* vol. 2, *The Age of Reformation* (1978), pp. 189–358.

(W.J.Bo.)

Canada

The second largest country in the world in area (after the Soviet Union) but one of the most sparsely populated, Canada occupies roughly two-fifths of the North American continent. Its total area, including the Canadian share of the Great Lakes, is 3,849,672 square miles (9,970,610 square kilometres), of which 291,576 square miles (755,180 square kilometres) are inland water; also included are its adjacent islands, except Greenland, a self-governing part of the Danish kingdom, and Saint-Pierre and Miquelon, parts of the French Republic. Canada is bounded on the north by the Arctic Ocean, on the east by the Atlantic Ocean, on the south by 12 states of the United States, and on the west by the Pacific Ocean and the U.S. state of Alaska. The national capital for the 10 provinces and two territories of Canada is Ottawa.

Canada shares a 5,527-mile (8,895-kilometre) border with the United States. In longitude Canada extends from approximately 52° W to 141° W, a distance that spans six time zones. In latitude it extends from approximately 42° N to 83° N. With its vast Arctic and subarctic territories, Canada is often considered a country only of the far north. It can be noted, however, that the peninsula of southern Ontario juts deeply into the heartland of the United States, its southernmost point, Pelee Island, being south of 11 states of the United States. Canada has a strategic global location. It lies on great circle routes (the shortest line joining any two places on the globe) between the United States and Europe and, to a lesser degree, Asia. For this reason many international commercial air flights track across Canada.

Most of Canada's farmland and densely populated areas are located along a narrow strip that rims the U.S. border. In the highly urbanized areas of southern Ontario and Quebec, the population density compares with the more densely populated areas of the United States and Europe. More than 75 percent of Canada's population lives in urban centres.

Canada shares the largest sector of the North American continent with the United States, and there is considerable U.S. influence in Canada. It is apparent, in fact, to travelers crossing the border that the two countries are similar in many ways. The landscape does not change, and the buildings, farms, and dress are all comparable. Neither is there much variation in foods and the kinds of products available. Some differences do stand out, however. The type of government, the political organization, and the judiciary all display some marked contrasts, resembling British institutions rather than American. Education in Canada reflects both British and U.S. influence, although Quebec in particular shows some French adaptations. The French presence in Canada is a unique characteristic. More than three-fourths of Quebec's people have French as their primary language. The French character in Quebec is reflected in the architecture as well as the language. Throughout most of the rest of the country, the French influence is apparent in the dual use of French for place-names, product labeling, and street signs, in schools that teach in French, and in French-language radio and television programs. In addition, increased immigration from other European countries, Southeast Asia, and Latin America in the latter part of the 20th century has made Canada even more broadly multicultural. Added to the spectrum are the cultures of the native Indians and the Inuit, the former being far greater in number. Inuit, rather than Eskimo, is the name preferred by the latter and is the term of common use in Canada.

The name Canada, which is the official name of the country, is spelled the same in the country's two official languages, English and French. The word Canada is a derivation of the Huron-Iroquois *kanata,* meaning a village or settlement. The explorer Jacques Cartier used the name Canada to refer to the area around the settlement which is now Quebec city. Later, Canada was used as a synonym for New France, which included all the French possessions along the St. Lawrence River and the Great Lakes. After the British conquest of New France, the name Quebec was used for a while instead of Canada. The name Canada was restored after 1791, when Britain divided Quebec into the provinces of Upper and Lower Canada. In 1867 the British North America Act created a confederation of colonies called the Dominion of Canada. The word Dominion fell into disuse, but the name Canada has stood the test of time.

Canada has long been an influential member of the Commonwealth and has played a leading role in the organization of French-speaking countries known as Francophonie. Canada is a founding member of the United Nations (UN) and has been active in a number of major UN agencies and other worldwide operations. In 1989 it joined the Organization of American States (OAS).

The combination of physical geography and discontinuous settlement has led to a strong sense of regionalism in Canada, and popular regional terms often overlap. The Atlantic Provinces refers to all of the Appalachian region except the Quebec portion. If Newfoundland is excluded, the three remaining east-coast provinces are called the Maritimes. Quebec and Ontario are usually referred to separately but sometimes together as Central Canada; the West usually means all of the four provinces west of Ontario, but British Columbia may be referred to alone and the other three collectively as the Prairies, or Prairie Provinces; the Yukon and Northwest Territories are referred to as the North.

The article is divided into the following sections:

PHYSICAL AND HUMAN GEOGRAPHY

The land

RELIEF

In general terms, the landform structure of Canada can be considered as a vast basin more than 3,220 miles in diameter. The Cordillera in the west, the Appalachians in the southeast, the mountains of northern Labrador and of Baffin Island in the northeast, and the Innuitian Mountains in the north form its high rim, while Hudson Bay, set close to the centre of the enormous platform of the Canadian Shield, occupies the basin bottom. The western rim of the basin is higher and more massive than its eastern counterpart, and pieces of the rim, notably in the far northwest and in the south, are missing. The main lines of Canadian landforms continue well into the United States, intimately linking the geography north and south of the border. To create a nation from sea to sea, Canada had to forge transportation and communication links in an east–west direction, against the physiographic grain of the continent. The Canadian North remains one of the least settled and least exploited parts of the world. Canada can be divided into several physical regions, including the Canadian Shield, the interior plains, the Great Lakes–St. Lawrence lowlands, the Appalachian region, the Western Cordillera, and the Arctic Archipelago.

The Canadian Shield. By far the largest of Canada's physiographic regions, the Canadian Shield occupies about half of the total area of the country and is centred about Hudson Bay. It consists of ancient rocks folded by mountain-building movements and cut down by erosion until the area was reduced almost to a plain. It was warped and folded in places so that parts of it now stand much higher than others, especially around its outer edges. In the north the rim is about 7,000 feet (2,000 metres) above sea level, and fjords with walls from 2,000 to 3,000 feet high extend many miles into the mountain masses. South of Hudson Strait lie the Labrador Highlands, including the Torngat, Kaumajet, and Kiglapait mountains. Along the north shore of the St. Lawrence River in Quebec, the shield rim is a 2,000-foot escarpment—the Laurentide Scarp. The rim is almost imperceptible in southern Ontario, but in northern Ontario it rises again to almost 1,500 feet above the northern shore of Lake Superior. From Manitoba northwestward the shield edge is marked by a number of lakes.

Janet Foster/Masterfile

Nachvak Fjord in the Torngat Mountains, Labrador, the highest range in the Canadian Shield.

Formation of the landscape

Most of the shield itself is less than 2,000 feet above sea level. Its lack of hills of any size produces a generally monotonous landscape, but geologically recent glaciations have had a striking effect on the surface. By stripping off the top, weathered material, they roughened the surface into a type of rock-knob, or grained, landscape, with the hollows between the knobs or the troughs between the ridges occupied by enormous numbers of lakes. In other areas the glaciers deposited till or moraine on the surface and in still others left gigantic fields of erratics and boulders. Eskers—long, narrow ridges of deposits—stretch across the shield sometimes for more than 100 miles, marking the course of old, subglacial rivers. In still other places, deposits laid down by glacial lakes that have since drained away have given rise to extensive clay belts.

The interior plains. Surrounding the Canadian Shield are a number of extensive lowlands underlain by sedimentary rocks: the Arctic lowlands to the north, the Great Lakes–St. Lawrence lowlands to the south and southeast, and the interior, or western, plains to the west. The most extensive of these are the interior plains, which extend from the Arctic Ocean in the north to the United States border in the south and from the edge of the Canadian Shield in the east to the Rocky Mountain foothills in the west. Along the shield–interior plains boundary are a number of major lakes, three of which are larger than Lake Ontario: Great Bear, Great Slave, and Winnipeg.

In the southeast is the Manitoba lowland, with an elevation of less than 1,000 feet above sea level. It is underlain by lacustrine sediments of the glacial Lake Agassiz and is the flattest land in the interior plains. It includes Lake Manitoba and Lake Winnipegosis in addition to Lake Winnipeg. The fertile southern portion, known as the Red River valley, is covered with black clay and silt soils.

To the west of the Manitoba lowland, the land rises in two steps: the Saskatchewan plain (from 1,500 to 2,100 feet above sea level) and the Alberta plain (more than 2,500 feet above sea level). These plains are rolling landscapes of glacial deposits laid over an almost horizontal bedrock. In some areas the undulating plains are interspersed with ranges of low hills (glacial moraines) studded with kettle lakes and flat-bottomed, steep-banked valleys cut by glacial meltwater, now occupied by rivers such as the Assiniboine, Saskatchewan, and Qu'Appelle. Ponds called sloughs dot the landscape of both these plains. In Saskatchewan, the Cypress Hills rise 4,816 feet above the surrounding plain including that portion lying in Alberta, to the highest point in mainland Canada between the Rocky Mountains and Labrador.

The Mackenzie Lowlands, extending from the Alberta

The Mackenzie Lowlands

plain north to the Arctic Ocean, is a flat area covered with muskeg (bogs) and swamps. It is drained by the Mackenzie River.

The Great Lakes–St. Lawrence lowlands. The Great Lakes–St. Lawrence region comprises the peninsula of southern Ontario bounded by the Canadian Shield and Lakes Huron, Erie, and Ontario. It extends along the St. Lawrence River to the Atlantic Ocean. This is a much smaller region, but it is important for its high agricultural productivity, its intensive industrialization, and its high degree of urbanization.

The rolling landscape of the Great Lakes–St. Lawrence lowlands is composed primarily of glacial landforms: glacial lake bottoms and shorelines, till plains, moraines, drumlins, eskers, and giant spillways carved by glacial streams. In southwestern Ontario the Niagara Escarpment is the only significant exposed bedrock structure. This steep cuestaform ridge runs from Niagara Falls to the Bruce Peninsula west of Georgian Bay and on into Manitoulin Island. In southeastern Ontario the lowland is interrupted by a band of the Canadian Shield, the Frontenac Axis, which extends across the St. Lawrence River to form the Thousand Islands.

Northeast of the Frontenac Axis, the lowlands embrace the Ottawa valley and the St. Lawrence valley to a point some 70 miles downstream from Quebec city. During the last glacial period, this area was inundated by ocean water, known as the Champlain Sea, resulting in a very flat plain. The level plain is broken by the seven Monteregian Hills near Montreal. The westernmost of these is Mont-Royal in Montreal, about 820 feet high.

The Appalachian region. The Appalachian region extends from the eastern townships of Quebec (south of the St. Lawrence valley) northeastward to the Gaspé Peninsula and the Maritime Provinces, and on to the island of Newfoundland. The region consists of very old folded rock formations that have been eroded into low, rounded mountains dissected by valleys and interrupted by lowland areas developed on weaker rock formations. Three broad groups of highlands can be recognized. The highest mountains, with elevations exceeding 4,000 feet above sea level, are found in southern Quebec: Sutton, Notre-Dame, and Shickshock mountains. The highlands in New Brunswick and Nova Scotia are lower, and the hills have been dissected out of a plateau upland. The major portion of Newfoundland is also a dissected plateau, but along the east coast, the Long Range Mountains rise to more than 2,000 feet in elevation. The relatively small areas of lowland of the region extend along the seacoast and the major rivers.

Highland division of the Appalachian region

The Western Cordillera. The Cordilleran region comprises a series of mountain belts some 500 miles wide that flanks the Pacific coast of Canada. The great heights and angularity of the peaks (many of which rise to more than 10,000 feet) indicate that these are much younger mountains than the Appalachians. Signs of alpine glaciation are widely evident. In many places valley glaciers remain active, and snowcapped peaks are frequently hidden in the clouds. Some of the mountain slopes are so precipitous that they are bare of trees. Viewed from an airplane, the whole landscape seems to be an irregular sea of mountain ranges, trending in a north–south direction.

The Cordilleran region is composed of numerous mountain groups, the major ones of which are discussed here. The Rocky Mountains make up the eastern edge of the Cordillera from the Yukon border south to the 49th parallel, where they continue into the United States. They form the continental divide between eastward- and westward-flowing rivers and contain some of the most rugged and scenic landscape in North America. The highway between Banff and Jasper is particularly noted for its spectacular mountain scenery. The Rockies include 30 peaks more than 10,000 feet high, among them Mount Robson, which rises to 12,972 feet. Five of Canada's national parks are located within the Rockies, including Banff, which was established in 1885. Three major passes cut through the Rockies: the Yellowhead Pass, which is used by the Canadian National Railways, and the Kicking Horse Pass and Crowsnest Pass, which are used by the Canadian Pacific Railway. The Trans-Canada Highway is routed through the Kicking Horse Pass.

West of the Rockies

To the west the Rocky Mountains are bordered by a major valley about 15 miles wide and several thousand feet deep, known as the Rocky Mountain Trench. West of the Rocky Mountain Trench the Columbia Mountain system rises to peaks of more than 10,000 feet. The Columbia Mountains include, from east to west, the Purcell, Selkirk, and Monashee groups. Northwest of these are the Cariboo Mountains, world-famous for their helicopter alpine skiing. Between the Columbia Mountains and the Coast Mountains farther west is a broad region of interior mountains and plateaus. Although some of the surface of this region is fairly level, most of it has been dissected into mountains and hills.

The Coast Mountains are another group of high mountains, with several peaks rising to over 15,000 feet, including Canada's highest peak, Mount Logan, rising to 19,524 feet (5,951 metres) in the St. Elias Mountains. All along the coast there are spectacular fjords with precipitous cliffs that often rise 7,000 feet from the water. Off the coast is a chain of mountains that appear as a series of islands, the largest of which are Vancouver Island and the Queen Charlotte Islands. In the far north the main mountain groups are the Richardson, Mackenzie, Selwyn, and Pelly mountains. The rugged Cassiar Mountains stand just south of the Yukon border.

The Arctic Archipelago. The Arctic Archipelago is composed of thousands of islands north of the Canadian mainland. The southeastern islands are an extension of the Canadian Shield. The balance consists of two distinctive landform regions: the Arctic lowlands to the south and the Innuitian Mountains to the north. The Innuitians are geologically young mountains similar to the Western Cordillera, with peaks reaching 10,000 feet. Much of the Innuitian region is permanently covered with snow and ice through which mountain peaks occasionally protrude.

DRAINAGE

With just 1 percent of the world's population, Canada has some 9 percent of the world's supply of fresh water. Much of this water is stored in lakes and wetlands that cover about 20 percent of Canada's total area. About three-quarters of Canada's land area is drained by rivers flowing into the Arctic Ocean and the Hudson and James bays. The Arctic drainage basin is dominated by the Mackenzie River, Canada's longest river, which flows 2,635 miles from its source to its mouth. With its many tributaries, it drains 690,000 square miles. The St. Lawrence is the largest river flowing into the Atlantic Ocean. Its drainage basin includes the Great Lakes, forming an inland navigable waterway extending 1,900 miles into the heart of the continent. The longest Pacific-draining river that is wholly within Canada is the Fraser; the Yukon and Columbia rivers also flow to the Pacific.

The St. Lawrence River

The usefulness of Canadian rivers is limited by two factors: many flow through the northern part of the country, which is sparsely populated, and most of them are frozen over in winter. In the densely settled regions, pollution has further reduced the usefulness of the water. Almost all Canadian rivers are characterized by rapids and falls, many of which have been developed for hydroelectricity.

CLIMATE

Because of its great latitudinal extent, Canada has a wide variety of climates. The Pacific coast, like that of the U.S. Northwest coast, has a climate similar to that of England, with heavy precipitation and moderate winter and summer temperatures. The northern two-thirds of the country has a climate similar to that of northern Scandinavia, with very cold winters and short, cool summers. The central southern area of the interior plains has a typical continental climate—very cold winters, hot summers, and relatively sparse precipitation. Southern Ontario and Quebec have a climate with hot, humid summers and cold, snowy winters, similar to that of some portions of the American Midwest. All of Canada, except the west coast, has a winter season with average temperatures below freezing and with continuous snow cover.

Temperatures. Those parts of the country farthest from open water are the coldest, so that in the interior plains and in the North the winters are extremely cold. The lowest temperature ever recorded was −81° F (−63° C) at Snag in the Yukon. In July those parts of Canada farthest from open water are the warmest. Thus, west-coast Vancouver has an average January temperature of 37° F (3° C) and an average July temperature of 64° F (18° C), while on the interior plains Regina's average temperatures vary from −1° to 67° F (−18° to 19° C). The daily range of temperature is also less on the coasts than in interior locations. The highest temperature recorded was 115° F (46° C) at Gleichen in southern Alberta.

Impact of the Pacific and Rockies on precipitation

Rainfall. Humid air masses from the Pacific cause enormous quantities of orographic (mountain-caused) rain to fall on the coast and mountain areas. Several sites along the British Columbia coast receive annual precipitation in excess of 100 inches (2,540 millimetres). But British Columbia also receives much less precipitation in summer than in winter because low-pressure systems move on a more northerly track in summer and seldom cross the southern part of the coast. Vancouver has an annual average precipitation of 41 inches.

In the interior plains and the North (Arctic and subarctic), precipitation is seldom more than 15 inches a year; it drops as low as 2 inches at Eureka on Ellesmere Island. The west-coast mountains effectively keep marine air out, since the dominant movement of air is from west to east. Spring and summer are wetter than winter.

Ontario and Quebec have more rainfall than the interior plains because the air masses can pick up water vapour from the Great Lakes, Hudson Bay, the Atlantic Ocean, and the Gulf of Mexico. The average annual precipitation for Toronto is 31 inches (800 millimetres); for Montreal, 40 inches (1,020 millimetres). Because winters are not as cold as those in the interior plains, the air is less dry, and enough snow falls to make winter precipitation equal to that in summer. The Atlantic Provinces are wetter than those of Central Canada. Yearly rainfall, most of which is cyclonic in origin, is more than 50 inches in places and is fairly evenly distributed throughout the year. There are few thunderstorms, and the low Appalachian Mountains produce only a little orographic rainfall. In general, the rainfall on Canada's east coast is less than on the west coast because the prevailing wind is offshore.

Snowfall. Canada's snowfall does not follow the same pattern as rainfall. In the North and the interior plains, snowfall is light because cold air is very dry. The snow is hard and dry, falls in small amounts, and is packed down by the constant wind. The east and west coasts are areas of lighter snowfall because the ocean usually makes the air too warm for large quantities of snow to fall. The depth of snow increases inland from each coast, reaching maximums of about 240 inches in the Rocky Mountains and on the shores of the Gulf of St. Lawrence. Still farther inland, lack of moisture brings the depth of snow down again. Freezing precipitation may occur during the colder months in any part of the country, occasionally disrupting transportation and communication.

PLANT AND ANIMAL LIFE AND SOILS

Both landforms and climate affect the distribution of plants, animals, and soils. Ecologists recognize broad regions called ecosystems that are characterized by fairly stable complexes of climate, soils, and plant and animal life. The boundaries of these regions are not usually sharp lines on the landscape, but are broad transition zones. The discussion that follows concentrates on preagricultural, or natural, vegetation. In southern Canada only remnants of these ecosystems remain.

Vulnerability of tundra

Tundra. Tundra is the land type of the Arctic and subarctic regions. Tundra also exists above the tree line in the Western Cordillera, but the discussion here is generally confined to the northern tundra. With long cold winters, short cool summers, and low precipitation, the soils are thin or absent, and the vegetation is sparse. The tundra is the ecosystem most susceptible to environmental damage. Because of the small number of plant and animal species and the fragility of the food chains, damage to any element of the habitat may have an immediate chain reaction through the system. The permafrost is easily damaged by heavy equipment and by oil spills. The Inuit, who fish, hunt, and trap for a living, are directly affected by abuses of the ecology.

Tundra vegetation is quite varied, considering the climatic conditions. Although the rock deserts are almost devoid of vegetation, relatively fast-growing mosses often surround large rocks. In rock crevices such plants as the purple saxifrage survive, and the rock surfaces themselves may support lichens, some of the orange and vermilion species adding colour to the landscape. Lichen tundra is found in the drier and better-drained parts. Mosses are common, and some species may dominate the landscape to such an extent that it appears snow-covered. The heath and alpine tundra support dwarf, often berry-bearing shrubs, while the ground between usually is covered with a thick carpet of lichens and mosses.

The distinctive animals of the tundra are the seal and the polar bear, the latter feeding on seal; the musk-ox, caribou, and lemming, which feed on the tundra vegetation; and their predators, the Arctic wolf and white fox. Few birds make the tundra their year-round habitat, the great snowy owl and the ptarmigan being exceptions. Numerous birds that normally live in mild climates, however, often fly to the tundra for nesting. Two large birds that do this are the snow goose and the Canada goose.

The forest regions. Canada has several large and distinct forest zones, which blend into a number of transitional zones. The northern coniferous, or boreal, forest is the world's second largest area of uninterrupted forest; only the Soviet Union has a greater expanse of forest. With severe winters and a short growing season, there is a limited number of tree species. Among them the white and black spruce and white birch are common, and balsam, fir, and tamarack (larch) also have wide distribution. The boreal forest is an important source of pulpwood and also produces considerable lumber, but much of the northern area is too inaccessible for commercial lumbering.

Transitional zones

A vast transitional zone of mixed boreal and tundra growth connects the northern forest and the tundra region. The trees in this subarctic region, with its cold, dry climate, are small and of little commercial consequence. Underlaid with intermittent permafrost, its ecological balance is almost as delicate as that of the tundra.

Along the southern edge of the coniferous forest lie two other transitional zones. In the interior plains the forest merges with the grasslands to create an arc of aspen parkland, characterized by prairie vegetation dotted with groves of trembling aspen and other poplar species in low moist areas and along valley bottoms. East of the Manitoba–Ontario border is a band of mixed coniferous-deciduous forest that extends into the Great Lakes–St. Lawrence lowlands and into the Appalachian region. In addition to the species of the boreal forest, there are white pine, red pine, white cedar, and eastern hemlock. The deciduous trees include sugar maple, red maple, beech, red oak, and white ash.

Remnants of the only predominantly deciduous forest in Canada grow in the most southerly portion of the southwestern Ontario peninsula. This deciduous forest is an extension of the Carolinian forest zone of the United States, and in addition to the species it shares with the mixed forest, it contains species usually found much farther south, such as the tulip tree, sycamore, black and white oak, and several types of hickory.

The western forests

The forests of the Western Cordillera are complex, as might be expected from the strong relief and the sudden change in climate within relatively short distances. The subalpine forest, of Engelmann and white spruce and lodgepole pine, is characteristic of the slopes of the Rockies from about 4,000 feet up to the timberline. The forests of the Selkirk, Purcell, and Monashee mountains contain Engelmann spruce at higher elevations, merging with western red cedar and western hemlock on the lower slopes. On drier slopes Douglas fir is common. Typical of the ranges that traverse the rather arid interior plateau is a generally open forest of aspen and yellow pine interspersed with glades of grass. Douglas fir and lodgepole pine are found on higher slopes.

Pacific coastal forest

The forest of the Pacific coast, where steep slopes facing rain-bearing winds produce a high rainfall, is Canada's densest tall-timber forest. Abundant moisture, along with the long growing season, is conducive to the growth of evergreens with very hard wood, excellent for construction lumber. Douglas fir, western hemlock, and western red cedar are the outstanding trees; they grow to great height and thickness. Alder, cottonwood, and maple are subsidiary, along with western white pine. Dense stands of immense trees, their trunks rising to considerable heights, their crowns almost touching, give a grandeur to the forest.

Canada's forest soils are acidic, resulting in various degrees of leaching of minerals out of the topsoil, thus making them relatively infertile for agriculture. The degree of acidity and leaching is greater in the coniferous forest and less in the mixed and deciduous forest. With proper soil-management practices, the mixed and deciduous forest soils make good farmland.

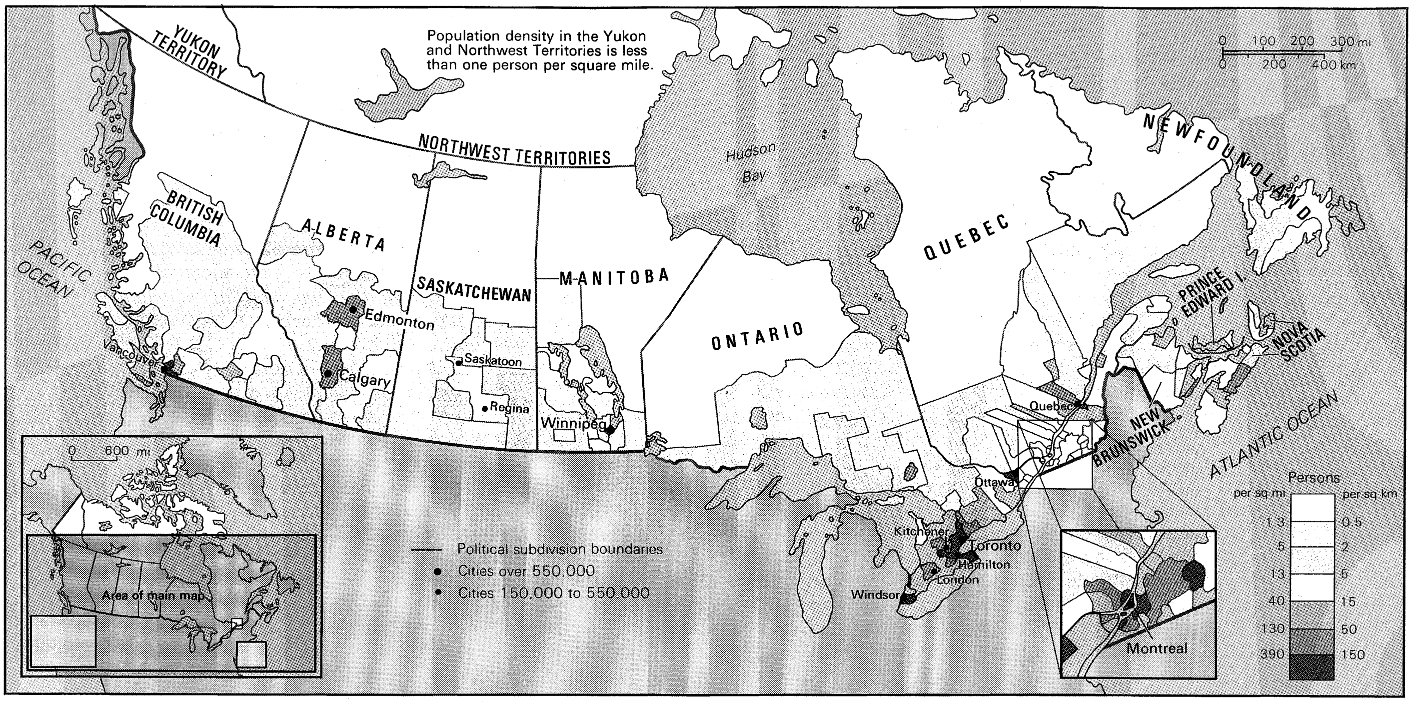
Wildlife regions correspond closely to the different forest zones. The subarctic supports large numbers of woodland caribou. The boreal forest includes nearly all species of mammals and birds recognized as distinctively Canadian. Among these are the moose, beaver, Canada lynx, black bear, wolf, snowshoe hare, and a variety of birds, including the Canada jay, blue jay, gray jay, raven, and crow. In summer the coniferous forest fills with scores of varieties of warblers and other small birds that go north to nest. Farther south the white-tailed deer thrives on the forest borders and partially cleared areas. There also are numerous smaller mammals, including the gray and red squirrels, mink, raccoon, muskrat, skunk, jackrabbit, cottontail rabbit, groundhog, and a variety of mice and moles. In southern Ontario the wild turkey, which disappeared because of hunting and reduction of its habitat, was reintroduced in the 1980s with some success. A wide range of wildlife species inhabit the Western Cordillera, with its wide variety of terrain and vegetation. Rocky Mountain sheep, mountain goats, elk, mule deer, and black bears are common in the southern mountains.

Grasslands. The southern portion of the interior plains is too dry for forests and gives rise to grasslands or natural prairies. Shortgrass with sagebrush and cactus make up the natural vegetation of the most southerly area. Farther north, where there is slightly more precipitation, there is a band of tallgrass prairie. At its northern limit the grasslands merge with the transitional parkland at the edge of the boreal forest. Today the grass area is small, crops having replaced grass in all but dry or hilly areas.

Fertile grasslands

With its high organic matter and mineral content, the grassland soils are among the most fertile in Canada. The best soils for crops are the dark brown to black soils of the tallgrass and parkland zone, the area of Canada that has become famous for wheat growing. The less fertile light brown soils of the shortgrass country tend to be very alkaline, and the predominant agricultural activities are dryland farming and grazing. Wind erosion is a serious problem in the prairies wherever the grassland has been converted to cultivated farmland.

Among the common animals of the grasslands are Richardson's ground squirrel and the pocket gopher, both of which damage young grain crops. They continue to proliferate despite predation by badgers, hawks, and owls and attempts at control by farmers. The first settlers to cross the Canadian prairies encountered enormous herds of bison (often called buffalo), but by the beginning of



Population density of Canada

the 20th century hunters had reduced their numbers to near extinction. Bison may now be seen only in wildlife reserves. With the bison gone, the mule deer and the pronghorn antelope are the remaining large animals on the shortgrass plain. Farm drainage projects and extended drought have greatly reduced the prairie's waterfowl habitat, causing a decline in their numbers.

SETTLEMENT PATTERNS

When the Europeans began exploring and developing resources in what is now Canada, they found the land sparsely populated by many different Indian peoples in the south and the Inuit in the north. The native peoples were primarily hunters and gatherers and often were nomadic. Because they were few in number, the native peoples made little impact on the natural environment; they harvested only the resources needed for their own consumption, and there were no large settlements. Even though the native peoples had lived in the area for thousands of years, the Europeans perceived that they had found a pristine country with rich resources that awaited exploitation.

Different groups of Europeans came at different times to develop and export the natural resources of fish, furs, forests, and minerals. With the development of each new resource, new settlements were established. Most of the settlements based on these resources remained small, however, and some of them disappeared when the resource was depleted. A few port cities—including the eastern cities of St. John's, Nfd.; Halifax, N.S.; and Saint John, N.B.—continued to grow, as they benefited from the export of successive resources. Montreal owed its early growth to the fur trade, but later it became an important entrepôt for the export of a succession of raw and processed materials and the import of manufactured goods from Europe. Later, Toronto and, on the west coast, Vancouver also grew quickly because of entrepôt activities. Winnipeg, Man., owed its early growth to its gateway role in the agricultural development of the interior plains.

Except for the port cities, Canada's most densely settled areas and largest cities have developed in the areas with good agricultural land. Thus, within a narrow strip of land along the U.S.–Canada border, making up about 10 percent of the total national area, live some 90 percent of the people. Intensive commercial agriculture in the Great Lakes–St. Lawrence lowlands gave rise to a dense network of villages, towns, and cities. Later, manufacturing and service industries reinforced population growth in this region, making it the urban and industrial heartland of Canada. Villages, towns, and cities also evolved from the agricultural industry in the western grasslands, but due to a lack of growth in the manufacturing and service industries, much less urbanization occurred. The development of the petroleum industry, however, did stimulate the growth of two large cities, Edmonton and Calgary in Alberta.

At the beginning of the 20th century, only one-third of the people of Canada lived in urban areas, but by the late 20th century about four-fifths of the population lived in communities of more than 1,000 people and more than one-half were in cities of 100,000 or more.

The growth of most of Canada's large cities on good farmland with an accompanying low-density pattern of urban sprawl has aroused considerable public concern about the urbanization of Canada's limited agricultural

George Hunter

Long, narrow strips of farmland, typical of French Canada, laid out along the roads in the St. Lawrence River valley, near Montreal, Que.

land resources. In the Niagara Peninsula of southwestern Ontario, an area with the best climate in Canada for the production of soft fruits and grapes, urbanization has destroyed about one-third of the fruit land. To prevent further reduction, the Ontario Municipal Board in 1981 delineated permanent urban boundaries and ordered that urban growth be directed away from fruit-growing areas.

Cultural diversity of settlement

Settlement did not proceed westward from an Atlantic beginning because permanent settlement was dependent upon agricultural land, and agricultural land in Canada occurs in patches, separated by physical barriers. Different patches were settled by people from various European countries, resulting in the diversity of cultures and settlement patterns across the country.

In the Appalachian region, farms are spaced along the roads at irregular intervals wherever there is cultivable land. In Quebec the first settlers laid off long, narrow lots from the shores of the Gulf of St. Lawrence or the St. Lawrence River into the interior. As settlement moved farther inland, roads were built parallel to the waterways, from which narrow lots extended on either side. The same pattern is seen in the Red River valley of Manitoba, where the early settlers were also French.

In Ontario and the eastern townships of Quebec, land subdivision was made with reference to a much more definite plan. The townships were more or less square, but the grid became irregular because it was started from a number of different points, each of which used a differently oriented base. In the prairies of the interior plains the grid is much more regular, partly as a result of the topography, partly because a plan for the subdivision of the whole region was laid out in advance of settlement.

The people

ETHNIC COMPOSITION

Canadians do not form a compact, homogeneous people. They are, rather, a collection of diverse national and cultural groups. In the strictly legal sense, there was no such thing as a Canadian citizen until the Canadian Citizenship Act came into force on Jan. 1, 1947.

Principal ethnic groups. About one-half of Canadians descend from one of the two founding nations, Britain or France. At the time of the first census of Canada (1871), about 50 percent of the population was British and 30 percent French. Since that time the proportion of Canadians of British and French origin has dropped to about 25 percent each. This decline has resulted from a reduction in the number of people coming from the United Kingdom and France and an increase in the number from other countries in Europe, Southeast Asia, and Latin America. Immigrant groups tend to retain their cultural identity in Canada largely because they have tended to settle in colonies. For example, Ukrainians have been attracted to the prairies, where the land and climate are similar to their homeland, and many Dutch have settled on the flat fertile farmland of southwestern Ontario, where they practice fruit and vegetable growing as they did in The Netherlands. Many Chinese, Portuguese, Greeks, and Italians have settled in specific sections of large cities, particularly Toronto, Montreal, and Vancouver.

Retention of cultural identity

Census data show that the mix of ethnic origins differs greatly from province to province. The proportion of people of British origin ranges from about 80 percent in Newfoundland to 5 percent in Quebec; the proportion of people of French descent ranges from about 80 percent in Quebec to less than 3 percent in Newfoundland, British Columbia, and the territories.

U.S. immigration. Canadian census data do not account for the number of Canadians whose forebears emigrated from the United States. There was heavy migration from the United States during and after the American Revolution (1776–83), when colonists who remained loyal to the British crown (known as United Empire Loyalists in Canada) moved to what is now the Maritime Provinces and southern Quebec and Ontario. By 1790 about one out of every six people in British North America was of U.S. origin. These people had been exposed to the ideas of the popular government and democracy that had evolved along the Atlantic seaboard. Their ideas of governmental institutions were blended in Canada with those of people who came directly from Britain. There was some migration from the United States to Canada during the 19th and 20th centuries, but during the same period there was more movement of Canadians to the United States, due to the generally higher U.S. standard of living.

Native peoples. It is estimated that, when Europeans began settling what is now Canada, there were only about 200,000 Indians and Inuit. For about 200 years after the first permanent European settlement, the native population declined somewhat because of European encroachment on their territory. High birth rates and improved medical care in the last half of the 20th century, however, have greatly increased the native population.

American Indian reserves

In Canada the word Indian has a legal definition given in the Indian Act of 1876. People legally defined as Indians are known as status-Indians. Indians who have chosen to give up their status rights or who have lost them through intermarriage with whites are called nonstatus Indians. Through treaties with the Canadian government, some 542 status-Indian bands occupy more than 2,250 reserves. The resources of these reserves are limited, and the majority of status-Indians have a standard of living below the Canadian average. The treaties and agreements about reserves apply only to a portion of the Indian people. Large tracts of land were never taken from the Indians by treaty, and various groups are negotiating land claims with the Canadian government.

The Inuit who inhabit the far north do not have any reserves and are not covered by any treaties. Their estimated population of more than 27,000 live in scattered camps and settlements of 25 to 500 people. In the latter part of the 20th century, mining, oil exploration and pipeline construction, and mammoth hydroelectric developments greatly affected their traditional way of living off the land. The worldwide decline in demand for furs greatly diminished their income, and they became increasingly dependent upon government social and welfare programs. Education and training programs were instituted to enable them to compete for employment.

LINGUISTIC COMPOSITION

The 1986 census of Canada reported that about 60 percent of the people identified English as their first language, while about 24 percent said that French was their mother tongue. Some 11 percent of Canadians reported a first language other than English or French; most of these indicated that they spoke another European language, while a smattering reported Asian and Middle Eastern tongues as their first language. English and French are both official languages of Canada. The language of the Inuit, called Inukitut or Inuttituut, has a number of variations.

RELIGIONS

More than 85 percent of Canada's population claim affiliation in some degree with either the Roman Catholic or a Protestant church. The major Protestant churches are the United Church of Canada, the Anglican Church of Canada, and the Lutheran Church. The balance of the population adhere to the Jewish, Eastern Orthodox, and other faiths or have no affiliation. In Quebec more than 80 percent of the population is Roman Catholic, and New Brunswick also has a Roman Catholic majority. The other provinces have Protestant majorities.

DEMOGRAPHIC TRENDS

Immigration

Traditionally Canada has sought to increase its population through immigration in order to expand the work force and domestic markets. The peak year of immigration in the 20th century was 1913, with more than 400,000 arrivals. Immigration was discouraged during the Great Depression of the 1930s, but after World War II tens of thousands of displaced persons from Europe were admitted, and in the 1970s and '80s large numbers of refugees from Europe, Asia, and Latin America were welcomed to Canada. Canada's immigration policy is nondiscriminatory regarding ethnicity; however, individuals with special talents or with capital to invest are given preference.

During the first two decades of the 20th century, the notable feature of internal migration was the movement from eastern Canada to the Prairie Provinces. Although British Columbia has continued to gain from migration since 1931, much of this has been at the expense of the Prairie Provinces. Alberta gained population from all across Canada during the oil boom of the 1970s. Saskatchewan has had more emigration than immigration since 1941. Ontario consistently has received far more people since 1941 than the other provinces, but most of this growth has been from immigration rather than interprovincial migrations. The Atlantic Provinces have lost about 300,000 people since World War II.

During the 20th century, natural increase, not immigration, was the major factor in Canada's population growth. Until 1961 the crude birth rate (live births per 1,000 population) remained in the high 20s, while the crude death rate (deaths per 1,000 population) declined from more than 10.6 in 1921 to 7.7 in 1961. The rate of natural increase slowed after 1961, however, because of a sharp drop in the birth rate accompanied by a slight decrease in the death rate. The rate of natural increase is much lower than the world average and is about the same as that of the United States and Australia. Canada has an aging population. The life expectancy is longer for Canadians than it is for the peoples of most other countries. The percentage of the Canadian population over 65 years of age more than doubled in the 20th century.

The economy

The early settlement and growth of Canada depended on developing and exporting natural resources. During the 20th century, manufacturing and service industries became increasingly important. By the end of the 1980s agriculture and mining accounted for less than one-tenth of Canada's labour force, while manufacturing stood at one-fifth and the service industry, including transportation, trade, finance, and other service industries, at about two-thirds. For many years Canada encouraged its manufacturing industries through protective tariffs on the import of manufactured goods. This high tariff policy resulted in the establishment of Canadian branch plants by many U.S. firms in order to supply the Canadian market. Another cornerstone of Canada's economic policy was the encouragement of economic development in slow-growth regions of the country by grants and subsidies. In the 1980s Canada began moving away from these two basic policies. Compliance with international rules on trade and the signing of a free-trade agreement with the United States (1988) reduced protection for the manufacturing industry. Funding for regional economic development programs was also scaled down.

Private-sector orientation

Canada's economy is oriented to the private sector, with only relatively few enterprises such as postal services, electric utilities, and some transportation services publicly owned. The agricultural industry is firmly private, although it has had to become dependent on government subsidies in order to compete with the highly subsidized agricultural industries of the European Economic Community (EEC) and the United States. Several marketing boards for specific farm commodities practice supply management and establish floor prices.

About one-third of Canada's labour force belongs to trade unions. Of this total, two-thirds belong to unions with international affiliations, mostly with unions in the United States. The Canadian unions tend to strive for wage parity with their counterparts in the United States. This causes labour–management tensions because Canadian productivity levels are generally lower than those in the United States, due primarily to smaller production runs.

RESOURCES

Minerals. Canada is rich in mineral resources. The vast Canadian Shield, with its masses of igneous and metamorphic rocks, contains numerous large deposits of iron ore and such other metallic minerals as gold, silver, copper, platinum, nickel, lead, zinc, titanium, cadmium, molybdenum, uranium, and cobalt. Metallic minerals are also found in the igneous and metamorphic zones of the Western Cordillera and the Appalachians. Although there are some metallic mineral and fossil fuel deposits in sedimentary rocks in the Western Cordillera and the Appalachians, the largest volume of coal and petroleum has so far been found in the interior plains of western Canada.

Farmland. According to the Canada Land Inventory only 8 percent of Canada's land area is suitable for crop production. About 80 percent of this cropland is in the western prairies, where long sunny days in summer and adequate precipitation combine to provide good yields of healthy grain crops. The widest range of crops, however, and the highest yields occur in southwestern British Columbia and southern Ontario.

Forests. Almost one-half of Canada's land area is covered with forest. The accessible portions of the huge coniferous forest zone provide abundant resources for lumber and pulp and paper. The most valuable forest region for timber production is the west coast, where the climate is conducive to the growth of giant trees with excellent-quality lumber.

Fish. Canada has rich fishing grounds off both the Atlantic and Pacific coasts. In 1977 Canada established a 200-mile fishing zone along both coasts to give the country more control over the management of its ocean fish resources. Off the Atlantic coast the continental shelf extends seaward for several hundred miles. The parts of the continental shelf with the shallowest water are known as fishing banks, where plankton, on which fish feed, thrive because the sunlight penetrates to the seafloor. The most important of these fishing banks is the Grand Banks of Newfoundland. Off the coast of the Maritime Provinces are found Bradelle Bank, Sable Bank, Georges Bank (shared with the United States), and a number of other fishing banks. On the Pacific coast the continental shelf is very narrow, but the numerous mountain streams are suitable for salmon spawning. In the rivers of the far north and in the Arctic Ocean there are abundant fish upon which large numbers of the native peoples depend for food. Fish resources in southern Canada declined significantly after the mid-20th century because of overfishing and pollution.

Grand Banks fishing grounds

Energy. Canada is richly endowed with hydroelectric power resources. It has about 15 percent of the world's total installed hydroelectric generating capacity. However, most of the suitable hydroelectric sites have already been developed, except in Quebec, which has huge hydroelectric potential in the James Bay area. Increasingly, Canada is turning to coal-fueled thermal energy or nuclear energy. Canada has vast coal reserves, particularly in the western provinces, except Manitoba, and in New Brunswick and Nova Scotia. Canada can almost meet its own petroleum needs and has a surplus of natural gas. The largest producing oil and gas fields are in Alberta, but potential reserves lie both in the Arctic and off the east coast. There are also large deposits of uranium.

AGRICULTURE, FORESTRY, AND FISHING

Agriculture. Although agriculture employs only about 5 percent of the Canadian labour force, it is a very important Canadian industry, producing large volumes of food for both the domestic and export markets and providing raw materials for the food processing industry and the food wholesale and retail industry. The trends in the industry are toward larger farm units, mechanized farm operations, specialization in fewer products, and the use of improved varieties, breeds, and farming methods.

There are distinctive types of farming across the country. The Prairies are known for grain (particularly wheat), oilseeds, and cattle grazing. Central and eastern Canada have a wider variety of crops and livestock, and farmers tend to specialize in either a particular cash crop or livestock type. Southwestern Ontario produces large amounts of corn (maize) for grain and soy and white field beans. Both southwestern Ontario and southwestern British Columbia produce a wide variety of fruits and vegetables. Dairying is important around all the major cities.

Forestry. Forest products form a larger part of Canada's export trade than do the combined exports of farm, fish, and mineral products. Canada is the world leader in the export of pulp and paper and also exports large amounts of lumber, mostly to the United States. British Columbia, Ontario, and Quebec are the leading provinces in the production of forest products. Canada's forest industry has to struggle constantly against the threats of fire, insects, and disease. Some control of insects has been afforded by aerial spraying of insecticides, but this practice also eradicates insect-eating birds and predator insects. Because forests have significant value in maintaining an ecological balance in the environment and also provide important recreational opportunities, the forest industry is increasingly held to account for environmentally damaging practices.

Environmental problems in forestry

Fishing. Canada catches only a very small percentage of the fish taken from the world's oceans, but it ranks first among countries in volume of fish exports. The exports are high because of Canada's relatively small population and quite low per capita fish consumption. In the Atlantic Provinces the fishing industry contributes significantly to the value of all goods produced in the region. Small coastal communities throughout the region are wholly or partly dependent on the fishing industry. The most important species caught on the east coast are cod, haddock, redfish, flatfish, turbot, pollock, flounder, sole, halibut, herring, mackerel, tuna, and lobster. In the Pacific coast fishery, salmon is the leading species caught, followed by herring, the two constituting most of the catch. On both coasts the Canadian government has established catch quotas for species and has negotiated international agreements toward preserving fish stocks and protecting the Canadian fishing industry.

INDUSTRY

Mining. Canada is one of the leading mineral producers in the world. In the late 1980s it ranked first or second in the world as a producer of uranium, zinc, nickel, potash, asbestos, gypsum, elemental sulfur, and titanium. It is also a major producer of iron ore, coal, petroleum, gold, copper, silver, lead, and a number of ferroalloys. Modern mining is not labour-intensive, so the industry employs a very small portion of the Canadian labour force. Related industries such as iron and steel and transportation, however, account for a much larger share of the labour force. Because Canada exports a large proportion of its mineral production, the mining industry is sensitive to world price fluctuations. In times of high world demand, prices rise and mining companies step up their production and open new mines; when the demand falls, production is cut, mines close, and workers are laid off. In single-industry communities, mine closings can result in ghost towns. Mining has been a key factor in developing Canada's northlands. In many areas, roads and railroads built to serve new mining operations have encouraged the subsequent development of forest and recreational resources. Unfortunately, development is often accompanied by environmental damage.

Manufacturing. Manufacturing accounts for about one-fifth of Canada's gross national product and labour force. Canada's iron and steel industry is modern and efficient and produces steel products for the manufacture of such durable goods as automobiles, mining equipment, and household appliances. After the Canada–U.S. Automotive Products Agreement, signed in 1965, the Canadian automobile industry expanded dramatically; automobile manufacturing was largely in branch plants of U.S. firms until the 1980s, when Japanese firms began building automobile factories in Canada. Also in the 1980s, the high technology and electronics industries experienced rapid growth. Although there is some manufacturing in all large cities, more than three-fourths of Canadian manufacturing employment is located in the Canadian heartland, which extends from Quebec city to Windsor, at the edge of the Detroit automobile-manufacturing centre.

Canadian automobile industry

Service industries. Service industries in Canada employ more people than all other industries combined. Among the fastest growing of Canada's service industries is tourism. Canadian and foreign travelers spend several billion dollars each year on transportation, accommodations, food, recreation, and entertainment as they travel in the country. By 1990 the tourist industry was providing employment for about 5 percent of Canada's total labour force.

FINANCE

Canadian financial services have developed relatively flexibly in response to the monetary needs of the economy. To operate in Canada, a commercial bank must be individually chartered by Parliament. Most normal central-banking functions are fulfilled by the Bank of Canada, which has substantial autonomy in the determination of monetary policy. The Bank of Canada implements its monetary policies through its relations with the 11 chartered (commercial) banks, which are at the centre of the financial system and rather highly developed. Although there are other financial institutions—credit unions, provincial savings banks, trust and mortgage-loan companies—the chartered banks remain the main financial institutions, even in some specialized activities. They are relatively free from controls on activities involving foreign exchange.

Canada has five stock exchanges, in Alberta, Montreal, Toronto, Vancouver, and Winnipeg. There is extensive interpenetration between Canadian and U.S. stock exchanges. In the bond market the role of government-sector borrowing traditionally has been dominant. The degree of foreign ownership of Canadian industry is very high, as much as 50 percent in the primary resource industries (except agriculture) and manufacturing. The largest portion of the foreign investment is from the United States.

TRADE

Canada's history has always been strongly associated with trading. In the early days, Canada's economic development was dependent upon the export of large volumes of raw materials. Over the years, raw materials have declined as a percentage of Canada's exports, while processed, fabricated, and manufactured goods have increased. By 1990 approximately 80 percent of Canada's exports were processed to some degree. Since about the mid-1970s, the leading Canadian exports have been automobiles and automobile parts, and other types of machinery and equipment, including such high-technology products as portable electrical transformers, computerized communication systems, and nuclear reactors. Fabricated metals and other materials and forestry products, including wood pulp and newsprint, are other important exports.

Canadian exports

The largest proportion of imports in Canadian trading history has always fallen within the manufacturing category. Automobiles and automobile parts lead the list of imports, followed by industrial machinery. Other significant imports are chemical products, textiles and clothing, and such foods as vegetables in the winter season and tropical and subtropical fruits and nuts.

Because the United States is so close and has a common language and similar life-style to that of the majority of Canadians, that country is Canada's chief trading partner. The 1988 free-trade pact between Canada and the United States further enhanced the volume of trade between the two countries. In the late 1980s some 75 percent of Canada's foreign trade was with the United States.

The dependence on U.S. trade in particular is not just a technical matter of market shares in imports and exports. In an overall sense, the degree of export dependence means that business trends in the United States feed back directly and quickly into the Canadian business sector. Changes in consumer tastes in the United States may have disproportionate effects on Canadian producers because to North American consumers it is a matter of almost no relevance whether, for example, their automobiles are produced in the United States or Canada.

Canada also retains strong ties with EEC and other traditional European trading nations, but newly emerging trading patterns may decrease somewhat Canada's dependence on its traditional trade partners. Foremost among these new patterns is that which has developed within the Pacific Rim. The growing Japanese market resulted in Japan's replacing the United Kingdom as the second largest market for Canadian exports by the mid-1970s. Since that time, exports to China, South Korea, and Australia have increased.

TRANSPORTATION

An efficient transportation system is essential to Canada because of its great size, the patchiness of its population distribution, and the need to move primary and manufactured goods over long distances to coastal ports.

Roads and highways. The populated sections of Canada are well traversed by highways and roads, but vast areas of the larger provinces and the territories that are sparsely settled are virtually without roads of any kind. Access to outlying settlements often is provided by roads built by logging, pulp and paper, and mining companies, although these are not generally available for public travel. The Trans-Canada Highway was opened officially in 1962, and it became possible to drive the entire length of the 4,860-mile route from St. John's, Nfd., to Victoria, B.C. Ferry connections extend the highway on both coasts. In the urban-industrial heartland, a four-lane highway links Windsor to Quebec city. Motor vehicles number more than one for every two inhabitants. Trucking as an industry has grown spectacularly since World War II.

The Trans-Canada Highway

Railways. Canada has one of the highest railway mileages per capita of any country in the world. The main railway networks, although connecting the Atlantic and Pacific coasts, are confined to the southern part of the country. Even in the west, where they extend farthest north, the transcontinental routes do not go farther north than Edmonton and Prince Rupert. North–south regional lines, however, reach Hudson Bay at Churchill, Man.; James Bay at Moosonee, Ont.; and central Labrador at Schefferville, Que.

Two great transcontinental systems operate almost all the railway facilities in Canada. The Canadian National Railways (CN) system, a government-owned body, is the country's largest public utility. The Canadian Pacific Railway Company (CP) is a joint-stock corporation. These systems, though highly competitive, still cooperate in many fields in which duplication of service would not be profitable. They are supplemented by a major north–south line on the west coast, the British Columbia Railway, and a number of regional railways to serve mining and timber resource developments in the north. Although thousands of railway miles have been retired, particularly in the Prairie Provinces, new railroads to northern resources have been constructed, leaving the total track mileage relatively unchanged.

The retirement of track miles is at least partly related to the major decline in the railway share of passenger transportation after World War II as automobile and airplane travel became dominant. In 1977 the Canadian government created VIA Rail, a crown corporation that assumed responsibility for most passenger trains. VIA Rail owns its trains, but it uses the tracks and other facilities of CN and CP. Even though VIA Rail introduced new equipment and improved services, it was not able to stem the tide of declining railway passenger travel. In 1989 its government subsidies were cut and many passenger routes discontinued, including, in 1990, transcontinental service. Most of Canada's railway passenger service is concentrated in the densely populated Windsor-to-Quebec city corridor. In 1967, GO Transit, an agency of the Ontario government, began operating commuter trains in the heavily urbanized area around Toronto. A similar commuter train operation began in the Montreal area in 1984.

Railway passenger traffic

Waterways. A large proportion of goods carried in Canada, in both domestic and international trade, uses water facilities for some part of its journey. The inland shipping routes are dominated by the St. Lawrence–Great Lakes waterway, which provides navigation for vessels of 26-foot draft to the head of Lake Superior, 2,342 miles from salt water. It includes the major canals of Canada. There are seven locks between Montreal and Lake Ontario; the Welland Ship Canal bypasses the Niagara River and Niagara Falls between Lake Ontario and Lake Erie with eight locks; and the Sault Ste. Marie Canal and lock link Lake Huron and Lake Superior. These 16 locks overcome a drop of some 582 feet from the head of the lakes to Montreal. The St. Lawrence Seaway accommodates all but the largest oceangoing vessels, making the upper St. Lawrence and Great Lakes area open to 80 percent of the world's maritime fleet. The main commodities shipped are grain from Thunder Bay on Lake Superior to St. Lawrence ports and iron ore to steel mills in both Canada and the United States.

On the west coast, large volumes of forest products are moved by tug and barge operations. On both the west and east coasts there is an extensive network of ferry services. Shipping is crucial to the development of the Canadian Arctic; it provides a means of transporting mineral resources to markets and bringing supplies to remote communities. In addition to ocean shipping to the Arctic, there is a barge service that transports supplies along the Mackenzie River all the way to its mouth.

By international standards, the Canadian merchant fleet is quite small. Most Canadian-registered merchant vessels operate on domestic routes; only a few Canadian-flag ships operate deep-sea routes. The Canadian Coast Guard ensures that all ships plying Canadian waters, including the Arctic waterways, meet the requirements of the Canadian Shipping Act and follow pollution-prevention procedures.

Airways. Vast distances, rugged terrain, and extreme variations in climate have shaped the development of civil aviation in Canada, and air transport is of tremendous importance. Two major airlines, Air Canada and Canadian Airlines, form the nucleus of Canada's domestic freight and passenger air service. Five major regional domestic air carriers operate other scheduled commercial services. More than 700 small airlines operate nonscheduled services, many of them to parts of Canada that are inaccessible by other means of transportation. Both Air Canada and Canadian Airlines operate international routes.

Major Canadian airlines

The Lester B. Pearson International Airport at Toronto is by far the busiest in the country, handling about 15 million passengers a year in the late 1980s. Montreal has two major airports, the newer one built in 1975 at Mirabel, some 20 miles north of the city.

Pipelines. Pipelines are a major element in Canada's vast transportation network. Growth has been so rapid since 1950, when pipelines were a negligible factor in intercity freight traffic, that oil and gas pipelines now account for about one-fourth of intercity freight ton-miles. Some of the world's longest oil and gas pipelines have been built to link the oil fields and gas fields of Alberta and Saskatchewan to major cities as far east as Montreal, and two major pipelines several hundred miles in length cross the Rocky Mountains and supply the lower mainland of British Columbia and the Pacific Northwest of the United States. The network is to be extended to facilitate transmission of oil and gas south from the Arctic.

Administration and social conditions

Canada is an independent federal parliamentary state, the head of which is the reigning monarch of the United Kingdom. The state was established by the British North America Act of 1867, which united the colonies of Nova Scotia, New Brunswick, and Canada into the provinces of Nova Scotia, New Brunswick, Quebec, and Ontario. Rupert's Land and the Northwest Territories were acquired from the Hudson's Bay Company in 1869, and from them Manitoba was created and admitted to the Confederation as a province in 1870; its extent was enlarged by adding further areas from the territories in 1881 and 1912. The colonies of British Columbia and Prince Edward Island were admitted as provinces in 1871 and 1873, respectively. In 1905 Saskatchewan and Alberta were created from what remained of the Northwest Territories and admitted to the Confederation as provinces. In 1912 the provinces of Quebec and Ontario were enlarged by adding areas from the Northwest Territories. In 1949 Newfoundland and its dependency, Labrador, joined the Confederation following a popular referendum. The Yukon Territory in 1898 was separated from the Northwest Territories. Thus, Canada now consists of 10 provinces and two territories, which vary greatly in size.

Development of the provinces

An act legislated by the British Parliament and proclaimed by Queen Elizabeth II on April 17, 1982, formally ended all vestiges of British control and made Canada responsible for all changes to its own constitution.

GOVERNMENT

The Constitution Act is not an exhaustive statement of the laws and rules by which Canada is governed. The constitution of Canada in its broadest sense includes other statutes of the United Kingdom; statutes of the Parliament of Canada relating to such matters as the succession to the throne, the demise of the crown, the governor-general, the Senate, the House of Commons, electoral districts, elections, and royal style and titles; and statutes of provincial legislatures relating to provincial legislative assemblies. Many of the rules and procedures of Parliament are not laid down in the Constitution Act but are established by convention and precedent, often that of the United Kingdom.

The preservation of both the English and French languages is safeguarded by the provision that either language may be used in all institutions (including the courts) of the Parliament and government of Canada and in all institutions of the National Assembly of Quebec, the legislature of New Brunswick, and their governments. The act also guarantees to Quebec the right to a Roman Catholic school system under Roman Catholic control and to exclusive jurisdiction over property and civil rights and safeguards preservation of the French system of civil law in the province. When the constitution was patriated to Canada in 1982, it was amended to include a Charter of Rights and Freedoms, which provides greater detail than the original charter. Further amendments of the constitution require agreement of the federal government and seven provinces that together represent 50 percent of the country's people. All the provinces approved the constitution except Quebec. The province of Quebec refused to approve the constitution because it infringed on its policy related to the restriction of the use of the English language, did not give Quebec a veto on future constitutional changes, and did not officially recognize Quebec as a distinct society.

Quebec's anti-Constitution Act stand

Federal legislative and executive authority. Federal legislative authority is vested in the Parliament of Canada, which consists of the sovereign of Canada, the Senate, and the House of Commons. The Senate has 104 members, who are appointed on a provincial basis and may hold office until they are 75 years of age. The 295 members of the House of Commons are elected by the people of Canada for maximum terms of five years. Each electoral district elects one member of Parliament to the House of Commons on a universal suffrage basis.

The Constitution Act divides legislative and executive authority between Canada and the provinces. The Parliament of Canada is assigned authority over control of the armed forces, the regulation of trade and commerce, banking, credit, currency and bankruptcy, criminal law, postal services, fisheries, patents and copyrights, the census and national statistics, the raising of money by taxation, and, in the field of communication, such matters as navigation and shipping, railways, canals, and telegraphs. In addition, the federal government is endowed with a residual authority in matters beyond those specifically assigned to the provincial legislatures and including the power to make laws for the peace, order, and good government of Canada. Both the House of Commons and the Senate must pass all legislative bills before they can receive royal assent and become law. Both bodies may originate legislation, but only the House of Commons may introduce bills for the expenditure of public funds or the imposition of any tax.

The personal representative of the crown in Canada, the governor-general, is appointed by the reigning monarch of the Commonwealth upon the advice of the Canadian government. The governor-general exercises the executive authority of the monarch in relation to the federal government. On the recommendation of responsible advisers, the governor-general summons, prorogues, and dissolves Parliament, assents to bills, and exercises other executive functions.

The leader of the party winning the most seats in a general election is called upon by the governor-general to form a government. He becomes the prime minister and generally chooses party colleagues from among the elected members to form the Cabinet. Almost all Cabinet ministers are also heads of executive departments of the government, for the work of which they are responsible to the House of Commons. The Cabinet is responsible for determining all important policies of government and securing the passage of such legislation, financial measures, and administrative provisions as their supporters may approve.

The Cabinet

The ministers of the crown, as members of the Cabinet are called, are chosen generally to represent all regions of the country and its principal cultural, religious, and social interests. Although they exercise executive power, they are collectively responsible to the House of Commons and can remain in office only so long as they retain the confidence of the House. The choice of the Canadian electorate not only determines who shall govern Canada but also, by deciding which party receives the second largest number of seats in the House, designates which of the major parties becomes the official opposition. The function of the opposition is to offer intelligent and constructive criticism of the existing government.

Canada has three major national political parties: Progressive Conservative, Liberal, and New Democratic. In political philosophy, the Progressive Conservatives tend to be slightly to the right, the Liberals in the centre, and the New Democrats on the left. Only the Progressive Conservatives and Liberals have formed national governments. From the 1930s to the 1980s, both the Progressive Conservatives and the Liberals became somewhat more liberal regarding social and health welfare policies and government intervention in the economy. In this way they continued to take votes from the more socialist-oriented New Democratic Party. Under the leadership of Brian Mulroney, who became prime minister in 1984, the Progressive Conservative government underwent a distinctly conservative shift, evidenced by the selling of crown corporations, deregulation of some industries, and the granting of tax advantages to corporations and the wealthy.

Provincial and territorial government. Similar political institutions and constitutional usages operate in the government of the 10 provinces as in that of the nation as a whole. In each province the sovereign is represented by a lieutenant governor appointed by the governor-general in council, usually for a term of five years. The powers of the lieutenant governor in the provincial sphere are essentially the same as those of the governor-general in the federal sphere.

The election of a legislative assembly and the conventions of Cabinet government operate as in the federal House of Commons. The legislature of each province is unicameral and its assembly is elected for five years. The provinces have powers embracing mainly matters of local or private concern such as property and civil rights, education, civil law, provincial company charters, municipal government, hospitals, licenses, management and sale of public lands, and direct taxation within the province for provincial purposes.

Provincial legislatures

The vast and sparsely populated regions of northern Canada lying outside the 10 provinces—Yukon Territory and the Northwest Territories—are administered by the federal government, but they have both elected representation in the House of Commons and a measure of local self-government.

Federal-provincial relations. A major part of Canada's constitutional development has occurred gradually through judicial interpretation and constitutional convention and through executive and administrative coordination at the federal and provincial levels of government. Through such devices, the national and provincial legislatures have been able to retain their separate jurisdictions over different aspects of the same matters. Regular meetings of first ministers are held to discuss federal-provincial jurisdictional issues. Only in such an approach can Canada achieve an accommodation that gives fair assurances to the aspirations of the provinces without disrupting the integrated national structure of the Canadian Confederation.

Of the provinces, Quebec has the most pronounced political aspirations. Only there are citizens of French origin in the majority. Their survival in Quebec as a distinctive and majority group is not difficult to explain in light of the historical constitutional guarantees. They have therefore developed a culture of their own that differs in many respects from that of the rest of Canada—and, indeed, from the rest of North America. The aims of politics for them have been not only material prosperity and liberty in the Anglo-Saxon sense but also ethnic survival. As a consequence they have tended to act as a unit in national matters and support whichever party is paying attention to their claims. The Quebec idea of a distinct society has led to strong movements in favour of political secession of the province from the Confederation. In 1976 Quebec elected a majority government of the Parti Québécois, whose major policy platform was "sovereignty association," a form of separation from Canada but with close economic ties. In 1980 Quebec voted the concept down.

At the national level efforts have been made to create a dual culture in Canada rather than simply preserve two cultures. Thus, the Official Languages Act of 1969 declares that the English and French languages "enjoy equality of status and equal rights and privileges as to their use in all the institutions of the Parliament and Government of Canada." Pursuant to this act, a commissioner of official languages was appointed to ensure compliance with the intent of the act.

Variations in municipal government

Local government. Because government at the municipal level falls under the jurisdiction of the provinces, there are 10 distinct systems of municipal government in Canada, as well as many variations within each system. The variations are attributable to differences in historical development and in area and population density. Thus, the legislature of each province has divided its territory into geographic areas known generally as municipalities and, more particularly, as counties, cities, towns, villages, townships, rural municipalities, or municipal districts. The county system as understood in Britain or the United States exists only in southern Ontario and southern Quebec. County councils are composed of representatives from rural townships, towns, and villages and provide a second level of services for the whole county. This two-tiered municipal government was first extended to urban areas when Metropolitan Toronto was established in 1953. A number of other highly urbanized areas in Ontario have since adopted a metropolitan or regional form of government to deal with common areawide problems. The more than 4,600 incorporated municipalities and local government districts in Canada have various powers and responsibilities suited to their classification. A municipality is governed by an elected council. The responsibilities of the municipalities are generally those most closely associated with the citizens' everyday life, well-being, and protection. In addition to local municipal government, there are numerous local boards and commissions, some elected and others appointed, to administer education, utilities, libraries, and other local services. The sparsely populated areas of the provinces are usually administered as territories by the provincial governments.

Justice. Canadian courts of law are independent bodies. Each province has its police, division, county, and superior courts, with right of appeal being available throughout provincial courts and to the federal Supreme Court of Canada. At the federal level the Federal Court has civil and criminal jurisdictions with appeal and trial divisions. All judges, except police magistrates and judges of the courts of probate in Nova Scotia and New Brunswick, are appointed by the governor-general in council, and their salaries, allowances, and pensions are fixed and paid by the Parliament of Canada. They cease to hold office at age 75. Criminal law legislation and procedure in criminal matters is under the jurisdiction of the Parliament of Canada. The provinces administer justice within their boundaries, including the organization of civil and criminal codes and the establishment of civil procedure.

Royal Canadian Mounted Police

Police and the military. The police forces of Canada are organized in three groups: the federal force, called the Royal Canadian Mounted Police (RCMP), the provincial police, and municipal police. The RCMP—or Mounties, one of Canada's best-known organizations—was established in 1873 for service in the Northwest Territories of that time. It is still the sole police force in the Yukon and Northwest territories, but it also has complete jurisdiction of the enforcement of federal statutes throughout Canada, which includes the control of narcotics. The maintenance of peace, order, and public safety and the prevention and investigation of criminal offenses and of violation of provincial laws are provincial responsibilities. Ontario and Quebec have their own provincial police forces, but all other provinces engage the services of the RCMP to perform these functions. Provincial legislation makes it mandatory for cities and towns and for villages and townships with sufficient population density and real property to furnish adequate policing for the maintenance of law and order in their communities. Most large municipalities maintain their own forces, but others engage the provincial police or the RCMP, under contract, to attend to police matters. In 1984 the Canadian Security Intelligence Service (CSIS) was created to replace the security service previously provided by the RCMP. The purpose of the CSIS is to conduct security investigations within Canada related to subversion, terrorism, and foreign espionage.

Matters relating to national defense, including the armed forces, are the responsibility of the minister of national defense. Canada's armed forces constitute a considerably lesser percentage of the Canadian labour force than do the armed forces of its allies in the North Atlantic Treaty Organization (NATO), and its defense spending is lower per capita than that of most of its allies. Military strength has never been central to Canada's national security efforts. Instead, it has worked through the United Nations at keeping peace and has formed strong alliances with the United States and NATO.

EDUCATION

Under the Constitution Act the organization and administration of public education are provincial responsibilities. The federal government is directly concerned only with the provision of education in the Yukon and Northwest territories, in Indian schools throughout Canada, for inmates of federal penitentiaries, for the families of members of the Canadian forces on military stations, and for the operation of three military colleges. In addition, it finances vocational training of adults and provides financial support to the provinces for the operating costs of postsecondary education.

Because each of the 10 provinces has the authority and responsibility for organizing its education system as it sees fit, policies and practices vary from province to province, but each has a department of education headed by a minister who is a member of the provincial Cabinet. In addition, Ontario has a Department of Colleges and Universities with a minister of its own. Most Canadian children have one year of kindergarten before they enter an eight-grade elementary school at age 6 or 7. At about 14 years of age, nearly 90 percent of those who entered grade one enter a regular four-year secondary school.

Higher education

Traditionally, a higher education was chiefly the preserve of universities. Now, although universities still account for about 60 percent of full-time students, postsecondary education is available in institutions without degree-granting status—regional colleges in British Columbia, institutes of technology in Alberta, institutes of applied arts and sciences in Saskatchewan, colleges of applied arts and technology in Ontario, and *collèges d'enseignement général et professionel* (community colleges) in Quebec.

Canada has more than 65 degree-granting institutions. They range from institutions with a single faculty and enrollments of a few hundred to institutions with many faculties and research institutes and more than 40,000 students, such as the Université du Québec (a multicampus university), the University of Toronto, and the University of British Columbia.

The oldest university in Canada, Laval, in Quebec, was founded during the French regime. Universities in English-speaking Canada were established after the American Revolution. University of King's College in Nova Scotia and what is now the University of New Brunswick were patterned after King's College (now Columbia University) in pre-Revolutionary New York City. Most other universities in pioneer days were begun by churches, but almost all have since become secular and almost entirely financially dependent on the provincial governments. In the 1960s Ontario established a number of new postsecondary institutions. One of the new universities, the University of Waterloo, has a cooperative program (alternating academic and work terms) and has gained an international reputation in mathematics, computer science, and remote sensing. There are no truly private universities in Canada. A somewhat unusual characteristic has been the system of "affiliated colleges" linked to a "parent" degree-granting institution even though separated from it physically. English is the language of instruction at most places, French in several, and a few are bilingual.

HEALTH AND WELFARE

Canada has a diversity of joint federal-provincial and local programs to meet the health and social needs of its people: health insurance; general public-health services, primarily of a preventive nature; services for specific diseases or disabilities, combining prevention, treatment, and rehabilitation related to general medical and hospital care; and welfare services. The health professions and voluntary agencies and institutions supply services, initiate new activities, and stimulate better standards. The federal government provides consultative, coordinating, and financial assistance. The federal Medical Care Act (1968) made provision for federal contributions to medical-care plans of participating provinces provided that such plans are comprehensive with regard to medical services, have universal coverage, are administered by a public authority, and allow portability of benefits between provinces. The federal Hospital Insurance and Diagnostic Services Act (1957) allowed for federal contributions to the costs of specified hospital services and now covers 99.5 percent of the insurable population of Canada. The federal government also has responsibilities for the administration of food and drug legislation (including narcotics control), quarantine, immigration and sick-mariners services, and the health and welfare of Indians, Inuit, and past and present members of the Canadian armed forces.

National health care provisions

There are a number of social security and social assistance programs. The universal Family Allowance Act, which now provides monthly payments to help support all dependent children up to the age of 18 years, has been a unique feature of the Canadian social security system since its inception in 1945. The Canada Pension Plan provides retirement, disability, and survivors' benefits. The Old Age Security Act provides a monthly pension to all persons 65 years of age or over, while the guaranteed-income supplement provides additional income for old-age pensioners. Financial aid is available under provincial or municipal auspices to persons in need and their dependents. The unemployment insurance system is financed by premiums paid by employers and employees, along with federal government contributions. To receive benefits, applicants must have been previously employed for a stated period and claim that they are actively seeking employment.

Cultural life

The culture of the English-speaking Canadian people is a blend of British and American influences; that of the French-speaking people blends French and American influences. In general, the way of life, family structure, cuisine, and dress are closer to those of the United States than to those of Britain or France. Canada has become a cultural mosaic in which immigrant groups have been able to retain much of their ethnic culture.

The British and French heritage, plus the influence of the United States, has led to broad diversity of artistic endeavour in Canada, a diversity further encouraged by groups of other national origins and a widely dispersed population. The major metropolitan centres have provided several focal points for artistic activity stimulated by a rapidly urbanizing society.

Since 1950 economic growth has provided all Canadians with greater means for the practice and enjoyment of the arts, and the influx of immigrants from many countries has increased both the audience and the pool of available talent. Most provincial governments provide some form of financial assistance for the arts and for cultural organizations within their borders; and some have advisory and funding councils for the arts. At the national level the Canada Council was established in 1957 "to foster and promote the study and enjoyment of, and the production of works in the arts, humanities and social sciences." It is funded by an endowment, by an annual grant from the federal government, and by private donations. The annual Governor General's Literary Awards, the preeminent literary prizes in Canada, have served to reward Canadian writers as well as to publicize Canadian literature through ceremonies held in various centres across the country.

LITERATURE

French literary heritage

The first truly Canadian literary works were written in French by explorers, missionaries, and settlers, and many of them became the inspiration of subsequent writings. Some were notable literature, such as Marc Lescarbot's *Histoire de la Nouvelle France* (1609). The first major contribution in English was made by Thomas Haliburton of Nova Scotia, with his *The Clockmaker; or, The Sayings and Doings of Samuel Slick of Slickville* (1836). The years following were also marked by some works that have become classics—William Kirby's *Golden Dog* (1877), Robert W. Service's *Trail of '98,* the humorous works of Stephen Leacock, and the long series of Jalna novels by Mazo de la Roche. Natural and vigorous French-Canadian writing was held back by a sense of isolation, strict Roman Catholicism, a small and relatively unsophisticated audience, and a tendency to favour academic and formal literary styles and themes. The 1940s witnessed the emergence of Canadian writers of the first rank. Hugh MacLennan established himself as a writer of international importance with *Barometer Rising* (1941) and *Two Solitudes* (1945), Thomas Raddall with *His Majesty's Yankees* (1942), and W.O. Mitchell with *Who Has Seen the Wind?* (1947). Gabrielle Roy's novel *Bonheur d'Occasion* (1945) was an immediate success, and *Le Survenant* (1945), by Germaine Guèvremont, placed its author in the forefront of French-language novelists, in both Montreal and Paris. Still later came the novels of Robertson Davies and the satires of Mordecai Richler. The French-Canadian novel, long handicapped by sentimentality and stilted prose, went beyond even hard realism into the psychological realm with Marie-Claire Blais's *La Bell Bête* (1959). In the 1960s and '70s other important authors, among them Margaret Laurence, Alice Munro, and Margaret Atwood, emerged to international prominence and made significant contributions on into the 1980s. In the 1980s Davies wrote a successful trilogy of novels, and Richler produced his most ambitious work, *Solomon Gursky Was Here* (1989). Although the growth of competent novel writing was the main feature of Canada's literary scene after World War I, the period saw marked changes in the work of Canadian poets. John McCrae's *In Flanders Fields* (1919) was the only important Canadian verse related to the 1914–18 conflict, but since then E.J. Pratt, Earle Birney, Irving Layton, Anne Hébert, James Reaney, Al Purdy, and Ralph Gustafson, among others, have attracted widespread attention.

VISUAL ARTS

Painting

From the beginning, artists in Canada have been greatly influenced by the art of their European roots. At the same time, Canadian painting has been successful in expressing a distinctive Canadian national identity. This has been particularly true of a long succession of artists who have portrayed Canadian locales and landscapes. In the 19th century Paul Kane, an immigrant from Ireland, traveled across Canada and painted numerous canvases depicting Canadian landscapes and the lives of Indians, fur traders, and missionaries, all rendered in a contemporary European genre style. During the same period, Cornelius Krieghoff, of German descent, painted more than 2,000 canvases of anecdotal scenes in Quebec. His paintings brought new dimensions to the Canadian scene and a colourful romanticism unsurpassed by contemporary artists. The first distinctively Canadian painting, free of Old World influences, is generally attributed to Homer Watson, an Ontario landscape painter of the late 19th and early 20th centuries. In the 1920s an assemblage of painters called the Group of Seven sought to develop a national form of painting, taking their inspiration from the Canadian landscape and the work in particular of the Canadian landscape painter Tom Thomson. A.Y. Jackson was among the best known of this group. Emily Carr, a contemporary of the Group of Seven, depicted Indians of the west coast and was heavily influenced by their art.

After the 1930s Canadian painters generally moved away from the landscape theme. In Quebec, where art tended to be more theoretical than in the other provinces, painting evolved through a number of movements. In reaction to automatism, Guido Molinari and Claude Tonsignant freed painting from its surrealism and directed it toward the concern of structure and colour. Similar trends occurred in Ontario, where a group called Painters Eleven, led by Harold Town and Jack Bush, moved from abstract expressionism to formalism.

Contemporary art in Canada is marked by a questioning of the nature of art, accompanied by experimentation and innovation. The resulting work ranges from the intensely personal to the public airing of concern about social and environmental issues.

Inuit sculpture and carvings

Although painting has received most of the attention in the art world of Canada, sculpture and the handicrafts have been in evidence since earliest times and only now are receiving adequate public attention. Prominent in sculpture exhibitions are stone carvings of the Inuit people, while among the most interesting of museum-guarded sculptures are the totem-pole carvings of the Indians of the west coast. In the European-derived cultures of Canada, the development of sculpture lagged behind that of painting. For centuries, sculpture meant carved figures made of wood, stone, or bronze. It was not until the 1960s that sculptors challenged the traditional notions of form, content, and technique. Artists such as Les Levine and Michael Snow were also painters, but their three-dimensional work established their reputations. By the 1970s and '80s there was established a new tradition of constructed sculpture in which abstract shapes were created from a variety of materials, including steel, aluminum, and plastic. Canadian sculptors were beginning to collaborate with architects in the design of public buildings. Architecture in Canada tends to be international in style, but some architects, such as Arthur Erickson and John Andrews, an Australian, have designed buildings of elegance that reflect truly Canadian influences.

GALLERIES AND MUSEUMS

Along with developments in the visual arts came the establishment of art collections and art galleries. The National Gallery of Canada in Ottawa, dating from 1880, includes not only the most extensive and important collection of Canadian art in existence but also collections built up along international lines to give an indication of the origins from which Canadian tradition is developing. It also circulates exhibitions to several hundred centres in the country each year. In addition, major cities have public art galleries, and many arts councils and university galleries house important collections.

Many museums in Canada keep Canadian historic artifacts on public display. There are several national museums on specific themes located in Ottawa, and almost every city and town has a local museum. The Royal Ontario Museum, Canada's largest museum, is visited by more than one million people annually. There are also many historic parks and monuments in Canada, the most ambitious being the 13,000-acre site around the reconstructed Fortress of Louisburg in Nova Scotia.

THE PERFORMING ARTS

There was a virtual explosion of musical activity in Canada in the second half of the 20th century. Choral music societies sprang up across the country. Opera grew, with Toronto, Montreal, and Vancouver having regular opera seasons and the Toronto-based Canadian Opera Company making extensive tours, often to remote parts of the country. Many cities have their own symphony orchestras, particularly those with Canadian Broadcasting Corporation (CBC) broadcast centres where musicians can be sustained by radio and television assignments. The symphony orchestras of Toronto and Montreal are internationally recognized. International acclaim has also been won by musical groups such as the Orford String Quartet, the Festival Singers of Canada, and the Canadian Brass.

Individual Canadian performers who have received world acclaim include the singers Maureen Forrester and Lois Marshall, the pianists Glenn Gould and Austrian-born Anton Kuerti, the guitarist Liona Boyd, and jazz musicians Maynard Ferguson and Oscar Peterson. Well-known popular and folk singers and songwriters include Gordon Lightfoot, Anne Murray, Gilles Vigneault, Bruce Cockburn, Leonard Cohen, and k.d. lang.

Dance

Canada can claim three top-ranking professional ballet companies: the Royal Winnipeg Ballet (founded in 1939), the National Ballet of Canada (founded in 1951), and Les Grands Ballets Canadiens (founded in 1957). Les Ballets Jazz de Montréal is a dynamic dance company that combines ballet technique and jazz music. The National Ballet is the largest and most widely traveled, touring across Canada, the United States, and Europe.

Canada's professional theatre evolved out of the amateur Little Theatre movement, which involved Canadian playwrights and performers and which developed a knowledgeable and appreciative audience. Several year-round repertory groups in the largest cities became professional. In 1953 the Stratford Festival was founded in Stratford, Ont., and it became an immediate success, drawing people from across Canada and the United States to see performances of Shakespeare's plays. Another celebrated summer theatre is the Shaw Festival at Niagara-on-the-Lake, Ont. The Blyth Festival in rural southwestern Ontario specializes in Canadian plays on rural issues. In Quebec during the 1960s and '70s, drama expressed the Québécois society's social and political aspirations. By the 1980s French Canadian theatre was again concerning itself with broader universal issues.

Although most Canadian amateur and professional musical theatre groups prefer to present Broadway musicals, Canadians continue to compose musicals on Canadian topics. The Charlottetown Festival produces Canadian shows exclusively. Charlottetown's most successful show, *Anne of Green Gables,* has been produced both in London and on Broadway.

The enthusiasm engendered by the success of theatre ventures set off a new Canadian determination to have professional theatre on a regular and nationwide scale. Spectacular new theatres were built across the country after 1958, among them Confederation Centre in Charlottetown (Prince Edward Island); Place des Arts (Montreal), National Arts Centre (Ottawa); O'Keefe Centre, St. Lawrence Centre for the Performing Arts, and Pantages Theatre (Toronto); the Centennial buildings of Winnipeg and Saskatoon; the Jubilee theatres of Edmonton and Calgary; and the Queen Elizabeth Theatre in Vancouver.

FILMMAKING

The National Film Board

The impact of television on the film production industry can be readily assessed by the fact that about three-quarters of the films produced as features, advertising, trailers, newsclips, and newsreel stories by Canada's private and governmental filmmaking agencies are for television. The National Film Board was established by the federal government in 1939 to produce films, filmstrips, and still photographs that reflect the life and thought of Canada and to distribute them both domestically and abroad. It has earned international acclaim for the imaginativeness as well as the artistic and technical excellence of its work, winning awards from film festivals around the world. In 1967 the federal government established the Canadian Film Development Corporation to foster and promote a feature-film industry through investment in productions, loans to producers, and grants to filmmakers.

RECREATION

Canadians, enjoying ever-increasing amounts of leisure time, are able to participate in a wide array of sports and other recreational activities.

Sports. Several of the sports played in Canada are derived from those of the indigenous peoples or the early settlers. Lacrosse, adopted as Canada's national game at the time of Confederation, was played by Indians in all parts of the country and adopted by later immigrants. By 1867 definite rules had been established, and the game had become organized. Ice hockey is also Canadian in tradition and leadership. It remains one of Canada's most popular winter sports. The original teams of the National Hockey League, established in 1917, were all Canadian. "Hockey Night in Canada" broadcasts, originating with Foster Hewitt on radio in 1931 and still carried by CBC television, is popular with millions of Canadians. Other team sports have been more strongly influenced by the recreational interests of the United States. The Canadian Football League (CFL) plays a football game only slightly different from that of the United States. The annual Grey Cup game that decides the CFL championship has become a national event and has the largest television audience of any Canadian sporting event. Two Canadian teams, the Montreal Expos and the Toronto Blue Jays, compete in United States professional baseball leagues. Winter sports widely enjoyed by Canadians, as both participants and spectators, include curling, ice skating, and downhill and cross-country skiing. From spring through fall, recreational activities include fishing, hunting, hiking, golf, and water sports.

National parks and historic sites. Canada's vast national park system, which extends to both coasts, began around the hot springs centred in Banff National Park in Alberta, established in 1885. Tourists and Canadian vacationers are attracted to the park sites throughout the year to view the striking natural scenery and to partake of the numerous recreational activities offered. Programs include guided tours, lectures, and films.

In 1919 the federal government established the Historic Sites and Monuments Board to advise on matters of national historic importance, with particular reference to commemoration or preservation. Most of the national historic parks are military or fur-trading forts, historic buildings, or reconstructions of historic buildings; most have museums. They range from the 13,000-acre site around the reconstructed Fortress of Louisburg in Nova Scotia to the boyhood home of former prime minister W.L. Mackenzie King and a reconstructed theatre of the gold-rush days in Dawson, Yukon Territory. Two are preserved Yukon riverboats. Each province has a similar preservation policy. In the west many of the marked sites, such as Head-Smashed-In Buffalo Jump in Alberta, recall the Indian period. Several provinces have restored or reconstructed pioneer communities. British Columbia's first provincial historic park was the restored gold-mining town of Barkerville. In Ontario, Fort Sainte-Marie, the headquarters of the Jesuit mission to the Huron Indians in the 17th century, has been restored.

Provincial preserves

PRESS AND BROADCASTING

Press. In every Canadian city there is a daily newspaper; in the largest cities there is usually more than one. Smaller towns are served by weekly newspapers. The trend in daily newspaper publication is toward chain ownership, but editorial policy is developed at the local level. The Toronto *Globe and Mail,* which calls itself Canada's national newspaper, is distributed six days a week across the entire country. Supporting the newspapers are two news-gathering agencies, the Canadian Press and the United Press International of Canada. Several hundred magazines are published in Canada, but most of the popular magazines that circulate in Canada are from the United States. *Maclean's* is a weekly Canadian newsmagazine.

The market for Canadian books is small by international standards, and thus Canadian publishers have had difficulty meeting foreign competition. Increasingly, Canadian book publishing has been taken over by foreign firms, primarily from the United States.

Broadcasting. In a huge country that includes groups of people of diverse origins separated by vast distances, broadcasting is not only important as entertainment but is also crucial for linking the various regions together to develop a sense of national community. It is for this reason that Canada has developed an elaborate structure and organization for delivering radio and television broadcasts. Canada was the first country in the world to use geostationary satellites for television broadcasting. The publicly owned Canadian Broadcasting Corporation (CBC) provides two national networks for both radio and television, one in English and one in French. The CBC also has a special northern shortwave radio network to provide broadcasts to the more remote Arctic settlements in both official languages as well as in Indian and Inuit-Aleut languages. In television broadcasting there is a second national network, the privately owned CTV, as well as several other private networks serving limited areas, such as Global TV in Ontario. Private radio and television stations usually are affiliated with one of the major networks. As a result, all Canadians have access to radio, and almost all have a choice of two Canadian television channels. Cable and satellite connections have also given Canadians access to U.S. television networks.

Canadian broadcasting regulation

Canadian broadcasting is regulated by the Canadian Radio-Television and Telecommunications Commission (CRTC). It authorizes the establishment of networks and private stations and specifies how much of the broadcast content must be Canadian in origin. The CBC has played an important role in developing Canadian talent in the entertainment world. Its music, drama, and documentary programs are considered to be of high quality.

(N.L.N./R.R.K.)

For statistical data on the land and people of Canada, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

The first inhabitants of the territories that now make up Canada were the Indians and the Eskimo, or Inuit. The former came from northern Asia across the Bering Strait, while the latter were part of the circumpolar dispersion of a race that lived along the edge of the Arctic ice. There were marked differences in cultural development among the Indians, whose population had reached about 200,000 at the beginning of the period of European exploration of the New World in the late 15th century. The west-coast Indians of British Columbia, for instance, tended to group in settlements, while those of the plains and eastern woodlands tended to follow a more migratory pattern. The Inuit were far fewer in number, and, although they lived in various-sized groups, they shared a common culture based largely on hunting. The Inuit group life did not necessarily evolve into a community pattern of life beyond that of the immediate family. For the prehistory of the North American Indians, see AMERICAN INDIANS; for that of the Inuit, see ARCTIC, THE.

Canada to 1867

The first Europeans to reach what is now Canadian soil were Norse explorers about AD 1000, as is recorded in the Icelandic sagas and recently confirmed by the archaeological discovery of a Norse site at L'Anse-aux-Meadows on the northern peninsula of Newfoundland. While the Norse made no lasting settlements, their voyages traditionally begin most general histories of Canada, largely because of their discovery of the northern route to North America.

The voyage of John Cabot

Only five years after the first voyage of Columbus, an Italian navigator, known to the English as John Cabot, sailed from Bristol in 1497 under the patronage of Henry VII of England by the northern route in an attempt to reach Cathay (China). His trip to a landfall generally accepted as having been on the east coast of Newfoundland was made so expeditiously that it is tempting to assume that he had the aid of local knowledge of the route and its winds, perhaps from Bristol fishermen accustomed to sailing in

Iceland's waters. Cabot, however, perished in an unknown manner with a large expedition in the following year.

THE SETTLEMENT OF NEW FRANCE

Jacques Cartier. The discoverer of the great entry to Canada, the St. Lawrence River, was the Frenchman Jacques Cartier. In 1534, in a voyage conducted with great competence, he explored the Gulf of St. Lawrence and claimed its shores for the French crown. In the following year, Cartier ascended the river itself and visited the sites of Stadacona (Quebec) and Hochelaga (Montreal). So favourable were his reports that the French king, anxious to challenge the claims of Spain in the New World, decided to set up a fortified settlement. Internal and European politics delayed the enterprise until 1541, when, under the command of the Lord de Roberval, Cartier returned to Stadacona and founded Charlesbourg-Royal just above Quebec. Cartier had hoped to discover precious gems and minerals, as the Spaniards had done in Mexico and Peru. But the mineral specimens he sent home were worthless, and "false as a Canadian diamond" became a common French expression. Disappointed in his attempt to reach the mythical "Kingdom of Saguenay," the reputed source of precious metals, Cartier returned to France after a severe winter, deserting Roberval, who had arrived in Newfoundland with reinforcements. Roberval also failed, and during the century only two subsequent attempts were made at exploiting the French claim to the lands of the St. Lawrence. The French claim remained; it had only to be made good by actual occupation.

Although French and English fishermen began to sail to the cold Atlantic waters off Newfoundland shortly after Cabot's discoveries, it was not until the early 1600s that France attempted to establish a permanent settlement in North America. That enterprise was based on the granting of fur-trade monopolies, because furs were in great demand in Europe and the Indians seemed eager to trade them for European manufactured goods.

Samuel de Champlain. In 1604 the French navigator Samuel de Champlain, under the Lord de Monts, who had received a grant of the monopoly, led a group of settlers from the St. Lawrence region to Acadia. He chose as a site Dochet Island in the St. Croix River, on the present boundary between the United States and Canada. But the island proved unsuitable, and in 1605 the colony was moved across the Bay of Fundy to Port Royal (now Annapolis, N.S.). The colony was to be a trading post and a centre of settlement, but the rugged, forested inlets of the Nova Scotian peninsula, the heavy forests of the St. John River, and the many bays and beaches of Cape Breton and Prince Edward islands made it impossible to enforce the monopoly of the fur trade against enterprising interlopers.

Foundation of Quebec

In 1608, therefore, de Monts and Champlain left Acadia and returned to the St. Lawrence. At "the place where the river narrowed" (Quebec), they built a "habitation" (*i.e.,* a fur-trading fort, or factory) to control the great river and to be the mart of its fur trade. Already in 1603 Champlain had noted that the Iroquois (or Huronian) Indians, whom Jacques Cartier had found there, had withdrawn from the St. Lawrence under pressure from the Algonquin Indians of the north country and Acadia. The French then became the allies of the Algonquin in the rivalry that began for control of the inland fur trade. In 1609, in accordance with this alliance, Champlain and three companions joined an Algonquin war party in a raid against the Mohawk, the easternmost tribe of the Iroquois League. The party ascended the Richelieu River to Lake Champlain. In an encounter with a Mohawk band, the firearms of Champlain and his men killed some Iroquois and panicked the remainder. This skirmish signaled the initial commitment of New France to the side of the Algonquin and the Hurons (who were Iroquoian but hostile to the confederacy) in the century-long struggle for control of the output of furs from as far away as the western Great Lakes. That commitment deepened in succeeding years. The conflict between the Iroquois and Hurons was based on trade rivalries that had existed since before European settlement. While French support went to the Huron, the Dutch, followed by the English, sided with the Iroquois.

The company of de Monts and his frequent successors, for whom Champlain remained the lieutenant in New France, had the obligation to bring out settlers, as well as the exclusive right, seldom enforced, to trade in furs. Their efforts at settlement were even less successful, partly because settlement was not easy in a country of heavy forests and severe winters and partly because the fur trade had little need of settlers beyond its own employees. The company, moreover, had scant funds to bring out and establish colonists on the land. Champlain did the best he could, and he also encouraged missionaries (first the Recollects [Franciscans], then the Jesuits) to come to Quebec to convert the Indians. His greatest interest, however, lay in exploration. Already in Acadia, in 1606 and 1607, he had surveyed the coast southward and westward to Stage Harbor, only to be rebuffed by hostile Indians.

In 1613 Champlain set out from Quebec to explore the upper St. Lawrence Basin. He passed Montreal Island, not settled since Cartier's time but used by traders who bypassed Quebec. In order to avoid the heavy rapids of the St. Lawrence, he ascended its great tributary, the Ottawa, only to be turned back at Allumette Island by the Algonquin middlemen who were trading for the furs of the Hurons and other people farther inland and who wished to retain that trade. At Allumette, Champlain, however, heard of the "inland sea" (Hudson Bay), the existence of which he had divined before he could have heard of Henry Hudson's discovery of it in 1610. Undaunted, he ascended the Ottawa again in 1615, traversed the Mattawa River, Lake Nipissing, and the French River to Georgian Bay, and turned south to "Huronia" (the land of the Hurons). He wintered with the Indians and went with a Huron war party to raid an Onondaga village south of the St. Lawrence. He was slightly wounded and the party was repulsed, but Champlain had once more confirmed the alliance of the French with the northern tribes and the Hurons against the Iroquois and, by the opening of the Ottawa route, had secured the midcontinent for the French fur trade.

Alliance against the Iroquois

The discovery of this inland, central region was perhaps Champlain's main achievement. He had no success, however, from 1616 to 1627 in maintaining the fur trade. The fault was not entirely his, for the enterprise in itself was very difficult. The coupling of trade and settlement was somewhat contradictory, and it was impossible to finance both out of annual profits, especially as the French government failed to uphold the monopoly.

The Company of New France. The French government was to supply more active support after the remarkable revival of royal power carried out by Cardinal de Richelieu in the 1620s. Richelieu sought to make French colonial policy comparable with that of England and the Netherlands, joint victors with France in the long struggle in Europe against Spain. These countries had found a means of both raising capital and enforcing trading rights through the medium of the joint stock company. Richelieu used his power to create such a company to exploit the resources and settle the lands of New France. This was the Company of New France, commonly called the "Hundred Associates" from the number of its shareholders. It was given broad powers and wide responsibility: the monopoly of trade with all New France, Acadia as well as Canada; powers of government; the obligation to take out 400 settlers a year; and the task of keeping New France in the Roman Catholic faith.

The company was chartered and its capital raised in 1627. The next year, however, war broke out with the English, who supported the French Protestants, or Huguenots, in their struggle against Richelieu. The war was mismanaged and inconclusive, but it gave a pretext for the Kirke brothers, English adventurers who had connections in France with Huguenot competitors of the Hundred Associates, to blockade the St. Lawrence in 1628 and to capture Quebec in 1629. For three years the fur trade was to be in the hands of the Kirkes and their French associates the brothers de Caën. It was a stunning blow to the new company and to Champlain, who was taken prisoner to England. At the same time, Acadia, already raided from Virginia in 1613, was claimed by Scotland. An attempt at settlement

The Scots in Nova Scotia

there was made by Sir William Alexander, to whom Nova Scotia (New Scotland) had been granted by the Scottish king James VI (after 1603, James I of England).

It is difficult to estimate the effect of the war on the policy of the Hundred Associates. Canada and Acadia were restored by the Treaty of Saint-Germain-en-Laye in 1632, and the company retook possession in 1633. On the surface all seemed to go smoothly. In 1633 Champlain returned as governor; the government and settlement of Acadia was farmed out to the vigorous Isaac de Razilly; the Society of Jesus assumed sole responsibility for the care of souls in Canada and for the conversion of the Indians. The fur trade was resumed, and the Trois Rivières settlement was founded in 1634 to control the Saint-Maurice River. Settlement began, but the company seemed unable to recoup the losses caused by the capture of Quebec and by the disruption of five years' trade and seemed unable to make profits that would both pay dividends and provide for the costs of settlement. The company remained the proprietor of New France until 1663, providing a succession of governors and other officials, but it never succeeded in meeting its obligations to colonize. Weary of its profitless task, the company leased the fur trade to private companies and then, in 1645, to a group of Canadian residents known as the Community of Habitants.

The character of French settlement. The fur trade was not the sole enterprise of New France. By 1645 settlers in Canada and Acadia were producing provisions for the fur traders and the annual ships. A characteristic mode of landholding, known as the seigneurial system, began to evolve; it was essentially a modified form of feudal French land law and justice. But the great partner and sometime rival of the fur trade was the missionary endeavour of the Jesuits. They had two obligations: (1) to keep New France Catholic by ministering to its people and excluding Huguenots and (2) to convert the Indians. The missionaries made the conversion of the agrarian Hurons their principal concern. Huronia was the hub of the inland fur trade. To make Huronia a Christian community would create a centre of Christianity and confirm the French commercial alliance with the Hurons and their Algonquin clients. French missionaries had already visited Huronia in the mid-1620s, and in 1634 the Jesuits resumed the mission, which thrived, at least outwardly, for 10 years.

Increased Iroquois hostilities

As the French-Huron alliance tightened, Iroquois hostility toward both parties increased. This was a case of traditional tribal trade rivalries being exacerbated by newer trade rivalries involving Europeans. The Iroquois sought to eliminate the Hurons and take complete control of the interior fur trade. They were able to obtain firearms from the Dutch in the Hudson River valley and launched ever more devastating raids on Huronia. The French tightly controlled the firearms trade with their Huron allies, putting the latter at a tremendous disadvantage. In 1648 and 1649 the Iroquois inflicted major defeats on the Hurons, virtually eliminating them as a major factor in the region.

These checks to both the fur trade and the missions, at least in terms of the intentions and hopes of 1627, were the result not only of bad luck and poor management but also of the economic conditions of New France, which depended almost entirely on the fur trade for profit. Settlement was unprofitable to both the company and the colonists. The population of New France, therefore, grew quite slowly, rising from an estimated 200 residents (*habitants*) in 1642 to perhaps 2,500 by 1663; and by no means were all of these farmers. The fur trade, however, was booming, borne up by the fashion of the beaver felt hat in Europe. The traders brought French goods to trade with the flotillas of canoes that carried the furs of the Ottawa and Great Lakes countries, which before 1648 were usually manned by Huron middlemen. This was the sole commercial enterprise of New France.

Royal control. New France, though a proprietary colony, was governed by the company, which appointed governors for Canada and Acadia, and a few dependent officers. The kings of France remained interested in the colony, both because of the vast potential wealth of the area and because the crown might have to resume the powers of government given to the Hundred Associates. Government was, in fact, very much what it would have been if the colony had been directly under the rule of the crown. In 1647 a council was established in New France that included the governor, the chief religious authority, the superior of the Jesuits, and the governor of Montreal. During the brief rule of the Community of Habitants, representatives (syndics) of the people of Quebec, Trois Rivières, and Montreal were consulted on local matters. This, however, was the nearest approach to anything like representative government. Government in New France, as in old, was authoritarian and paternalistic.

Colbert's reorganization

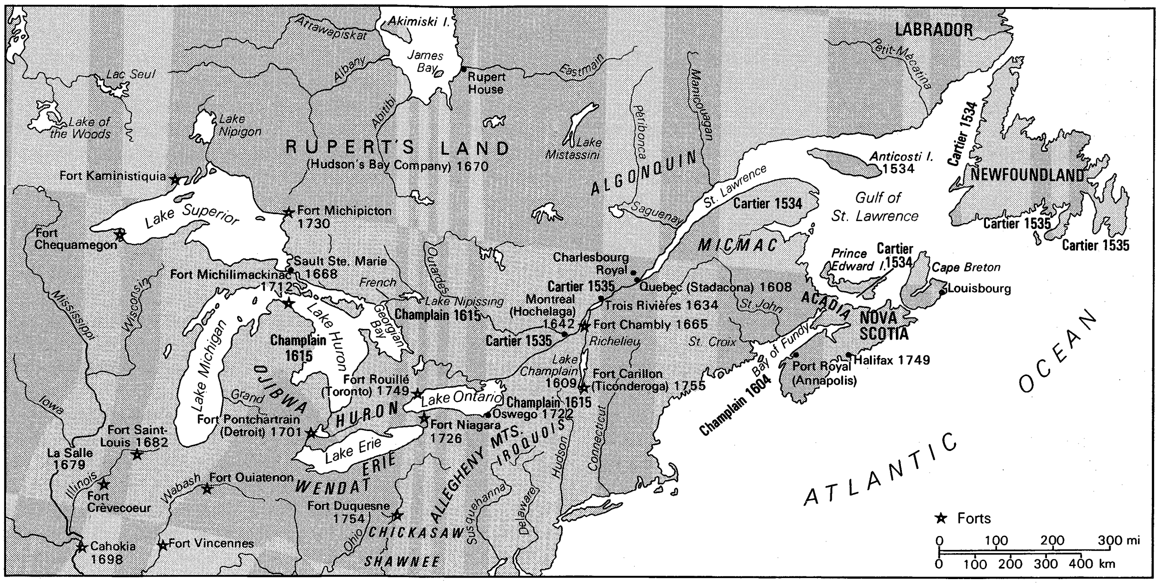
The assumption of power by Louis XIV, however, and the colonial ambitions of his great finance minister, Jean-Baptiste Colbert, led to a recasting of French colonial policy and of the government of New France. Colbert entrusted commercial policy to a new Company of the West Indies. Politically, he made New France a royal province, governed much like a province of France itself. It was to be governed by three persons: a governor, an intendant, and a bishop. The governor was the largely titular head of this triumvirate, although he was responsible for matters of defense and relations with the Indians. He was aided in his decision making by the Superior Council (first called the Sovereign Council), which was to advise him during the long periods when he had no communication with France. The intendant was responsible for internal matters, and the bishop administered mission work and the church. Both the intendant and the bishop were members of the council. Bitter rivalries were not unknown among these officials.

The general effect of Colbert's reorganization, however, was to give New France firm and rational government thereafter, strongly centralized and efficient for the times. The exception was Acadia. Torn by feuds among French rivals, claimed by England, and occupied by New Englanders eager to exploit its fishery, Acadia did not again become an effective part of New France until 1667–70.

The strength of the royal government was in inverse proportion to the weakness of a small and scattered population. Great efforts made by the first intendant, Jean Talon, did indeed bring some thousands of settlers, hundreds of them women, to New France in the 1660s and early 1670s. The population in 1666 reached 3,215; in 1676, about 8,500; thereafter, however, the population grew largely by natural increase, fortunately at a prodigious rate. Most of the population lived in the three towns (Montreal, Quebec, and Trois Rivières) and in seigneuries along the banks of the St. Lawrence between Quebec and Montreal. Scores of the men, however, went inland with the trading canoes, and some of these voyageurs remained inland permanently, marrying Indian women and fathering the métis, or people of mixed French and Indian blood.

The frontier of New France was not a broad front of advance but, rather, a penetration of the wilderness via the rivers in search of furs and strategic position. Alliances with Indians continued to be necessary, and those alliances were constantly challenged by the Iroquois, who controlled the region south of Lakes Ontario and Erie in the 1650s. Thus war with the Iroquois continued, as did the push into the interior, Louis Jolliet penetrating via the Mississippi River as far as the confluence with the Arkansas River.

The growth of Anglo-French rivalry. In the 1660s two voyageurs, Médard Chouart des Groseilliers and Pierre Esprit Radisson, exasperated by the high cost of the long haul back to Quebec and by the heavy tax on fur pelts, fled to New England. From there they were escorted to England, where in 1668 they persuaded a group of London merchants to attempt to gain the fur trade of the mid-continent by way of Hudson Bay. This led to the formation in 1670 of the Hudson's Bay Company, a late proprietary company that was given exclusive trading rights in all the territory draining into Hudson Bay. New France now found itself caught between the Iroquois, supported by the Dutch and English, to the south and the Hudson's Bay Company to the north. The Count de Frontenac, the governor of New France, after his arrival in 1672 made a vigorous push into the continental interior. Frontenac



New France, 16th–18th centuries.

had been directed to concentrate settlement in areas with easy sea access to France, but he defied those instructions in search of profits from furs. For this and other transgressions he was recalled in 1682.

The Treaty of Utrecht

Over the next three decades the French struggled—sometimes with success—to improve their strategic position in America. The British were almost completely expelled from Hudson Bay by 1700, while in the late 1690s Frontenac (who returned as governor in 1689) finally defeated the Iroquois, who sued for peace. Much of this success was lost, however, by the Treaty of Utrecht, which ended Queen Anne's War (1702–13) between the British and French in North America, as well as the War of the Spanish Succession. By that treaty France lost its claim to Hudson Bay, its hold on Acadia, and its position in Newfoundland. After Queen Anne's War there followed a generation of peace during which the governors of New France built a line of fortified posts: Louisbourg on Cape Breton Island, Chambly on the Richelieu River, Carillon (Ticonderoga) on the portage from Lake George to Lake Champlain; the trading posts of Niagara, Toronto, Detroit, and Michilimackinac extended the line to the west. At the same time, French priests and military emissaries kept the Acadians and the Indian allies of New France aware of their former ties with New France. The Acadians, claiming to be neutral, obstinately refused to take the oath of allegiance to the British crown.

For New France the early 18th century was a period of steady growth. French *défrichements* ("clearings") spread along the St. Lawrence between Quebec and Montreal; the iron forges at Saint-Maurice produced iron for Quebec stoves and even cannons; shipbuilding flourished. The colony nevertheless remained largely dependent on the fur trade, which, in turn, depended on keeping the west open. Access to the far west was frustrated, however, by the three Fox wars (1714–42), in which that tribe strove to close the Wisconsin portages to French traders. Then Pierre Gaultier de Varennes, Lord de La Vérendrye, turned the flanks of the Fox and Sioux by proceeding by way of Lake Superior and the Rainy River to the Lake of the Woods and the Red and Saskatchewan River country. There he found a new region for the French fur trade and also cut into the English trade in the area of Hudson Bay and the Hayes River.

King George's War

The expansion of New France in these years was challenged, however, by the outbreak of the War of the Austrian Succession in Europe in 1740. In America the war became known as King George's War (1744–48). Fighting broke out again in Acadia, on Lake Champlain, and among the English and French Indian allies in the country of the Great Lakes and the Ohio valley. It was a confused conflict of raids and reprisals marked by only one action of major significance—the capture of Louisbourg by an expedition from New England. Holding the St. Lawrence River valley, the Great Lakes, and the mouth of the Mississippi River, the French commanded the better strategic position in America. However, the English colonies, if having a less advantageous location, were far wealthier and more populous.

All this was perceived by Roland-Michel Barrin, Marquis de La Galissonière, the exceptionally able governor of New France (1747–49). He declared in a memorandum to the French court that New France must restore its position by a bold advance into the Ohio valley, which theretofore had not been claimed by New France or its Indian allies. His policy was adopted by his successors, and in 1749 Pierre-Joseph Céloron de Blainville led an expedition down the Ohio to claim the valley for France and to confine English colonists and their fur trade to the east of the Alleghenies. The British colonists, from New York to Virginia, immediately felt the threat to their trade, to their expansion, and to their settlement. In 1749 the Ohio Company was formed in London with English and American support, and the fortress of Halifax in Nova Scotia was built to counter the French fort at Louisbourg, which had been restored to New France by the peace of 1748 ending King George's War. In 1753 an American expedition under George Washington was sent to the Forks of the Ohio to make good the English claim.

The French and Indian War

The French and Indian War. The French had also been active on the Ohio and had opened a line of communication from Lake Erie to the Forks. The rivals clashed on the Monongahela, and Washington was forced to surrender and retreat. This clash marked the beginning of the Anglo-French war known in America as the French and Indian War (1754–63) and in Europe as the Seven Years' War (1756–63). England resolutely supported the colonies and sought to recover the Ohio valley by an expedition under General Edward Braddock in 1755. This, too, was bloodily repulsed on the Monongahela, and both sides then reinforced their colonies with regular troops. It was to be a war for empire; how sternly it was to be fought was made clear by the expulsion of the Acadians from Nova Scotia in 1755.

The French in America, cut off by British blockade, fought to hold the long line from the Ohio to the Bay of Fundy, counting on the results in Europe for a victory. Britain, however, while subsidizing and aiding Prussia, its only European ally, sought victory in America and sent across the Atlantic what was, for that century, an overwhelming body of regular troops in order to stiffen the militia of the American colonies. The first victories went to the French, who captured Fort Oswego and Fort William Henry in 1757 and sternly repulsed the British at Fort

Carillon (Fort Ticonderoga) in 1758. Then numbers and more skillful British generalship began to tell. In 1758 the British captured and razed Louisbourg. In 1759 Sir Jeffrey Amherst began a cautious but irresistible advance from Fort William Henry by way of Fort Ticonderoga to Lake Champlain. In the same year an expedition under General James Wolfe sailed up the St. Lawrence and besieged Quebec, which fell to the British after the celebrated Battle of the Plains of Abraham. Sir William Johnson took Niagara, and John Forbes took the Forks of the Ohio. New France was caught in cruelly closing pincers. In 1760 Amherst closed in on Montreal, and New France capitulated. By the terms of the Treaty of Paris in 1763, all French North America east of the Mississippi was ceded to Britain.

The British victory produced three major results: (1) The danger from New France to the American colonies was ended, thus weakening their dependence on Britain. (2) The British (largely Scots with some Americans) took over and expanded the Canadian fur trade. (3) Britain now possessed a colony populated almost wholly by persons of alien descent.

CANADA UNDER BRITISH RULE, 1763–91

The Royal Proclamation of 1763

The Quebec Act. At first New France was to be governed by the Royal Proclamation (Oct. 7, 1763); it declared the territory between the Alleghenies and the Mississippi to be Indian territory and closed to settlement until the Indians there could be subdued. New France was to become the colony of Quebec, with a royal governor who had the authority to call an assembly. However, the 70,000 French inhabitants of Quebec could neither vote nor sit in the assembly by virtue of their Roman Catholicism.

Few British Americans moved to Quebec (there were perhaps 500 migrants in all), and those who did were attracted primarily by the prospect of taking control of the fur trade. Their bourgeois mentality and their repeated demands for the "rights of Englishmen" tended to alienate the landed-gentry-based British officers who administered the colony. Among the latter was General James Murray, who was appointed the colony's first governor in 1763. Murray sympathized with the condition and difficulties of the French and ignored the demands of the recently arrived Protestants, especially the landed gentry called seigneurs, for an assembly, with the result that an agitation by the Protestants led to his recall. He was replaced in 1766 by General Guy Carleton, who was expected in Quebec to carry out the policy of the proclamation. Carleton, however, soon came to see that the colony was certain to be permanently French. He decided that Britain's best course was to forge an alliance with the elites of the former French colony: the seigneurs and the Roman Catholic church.

Carleton returned to England in 1770 to press his new policy for Quebec on the government of Lord North. The trouble the imperial government continued to have with the colonies to the south secured official acceptance of Carleton's policy. The result was the Quebec Act of 1774, by which the province of Quebec was expanded to include all the inland territory to the Ohio and the Mississippi. The new colony was given a governor and an appointed council. A change in the oath taken by officials, eliminating religious references, allowed Roman Catholics to hold political office. French was made an official language, along with English, and French civil law was restored, but with English criminal law. The Roman Catholic faith was recognized, the church was allowed to collect the tithes of the faithful, and the seigneurial system was endorsed.

Toward the French Canadians the act was liberal and conciliatory, but toward the American colonies it was menacing. To them it reestablished to the north and west an area despotically ruled, predominantly French and Roman Catholic, and with an alien form of land tenure.

American invasion of Canada

The influence of the American Revolution. Instead of intimidating the American colonies, the act helped push the Americans to open revolt. Indeed, the first act of the American Continental Congress in 1775 was not to declare independence but to invade Canada. The failure of that invasion ensured that the continent north of the Rio Grande would, on the recognition of American independence, be divided between the Americans and the British.

Not all American colonists had supported the cause of independence, and many had resisted it in arms. At the conclusion of hostilities, these loyalists had to make their peace with the new republic, as by far the greater part did, or go into exile. The refugees, known as United Empire Loyalists, were the object of considerable concern to the British government, which sought to compensate them for their losses and to assist them in establishing new homes. Some went to the United Kingdom, others to the British West Indies, but the majority emigrated to Nova Scotia or Canada. Nova Scotia, which to a great extent had been recently settled by American colonists, had not, except for an ineffectual rising or two, joined the revolting colonies. Overawed by British sea power and by the fortress of Halifax, Nova Scotians at first kept quiet, and later many of them even made fortunes privateering against American commerce. Easily reached by sea from New York, Nova Scotia became the chief refuge of the loyalists. Some settled in the peninsula itself, some in Cape Breton and in the separate colony of Prince Edward Island. A large number, however, settled along the St. John River, north of the Bay of Fundy. Dissatisfied with tardy government from Halifax, they promptly agitated for a government of their own, and equally promptly the new province of New Brunswick was created for them in 1784, with its own governor and assembly.

In Quebec the loyalists simply crossed the new frontier and settled along the St. Lawrence River. Their impact in Quebec was even greater than in Nova Scotia, resulting in a new province and, perhaps more importantly, the Constitutional Act of 1791. The loyalists who settled in Canada were for the most part quite different from those who went to what were soon to be called the Maritime Colonies. The latter had possessed an elite of government officials and professional men, often loyalist regiments with their officers and men, from the long-settled seaboard areas. The Canadian loyalists, however, were largely from upper New York, especially the Mohawk valley country, and were almost wholly simple frontier folk and recent immigrants, driven from their homes by neighbours who often used the Revolution to dispossess them of their lands; hence, the bitter fighting along the frontier and the long loyalist hatred in the new province for all things American.

Their coming transformed the character of the population of Quebec. That province had been given a government much like that of New France, except for the important office of intendant, and the province was in population almost wholly French, as it was in civil law. Most loyalists had one desire, to hold the land granted them in simple ownership, something the civil law of Quebec did not allow. Some of them—how many is uncertain—also wanted representative government, denied by the Quebec Act. Their representations reached London and were listened to with respect, as they were, after all, from people who had lost everything fighting for the crown.

Appeasement of the loyalists

The Constitutional Act of 1791. Their appeals caused a great problem for the British government. The measures taken in the Quebec Act to conciliate the French could not in honour or policy be withdrawn. Yet the loyalists could not be required to live under French civil and land law and without the representative assembly to which they were accustomed. One obvious answer was to divide Quebec into separate French and English provinces. The English province would have, of course, English common law and an assembly. The French province might have been left with the forms of government provided by the Quebec Act. But there had already been one revolution in America, and, by 1789, another had broken out in France. British statesmen felt that the former had occurred partly because Americans had not been granted the British constitution in its proper forms. The thing to do, therefore, was to give not only the new province but Quebec as well the British constitution in its entirety as far as circumstances might permit. The result would be, it was hoped, to assimilate the French population.

After a fiery debate in the British House of Commons, the Constitutional Act of 1791 gave the same constitution to the colonies of Upper and Lower Canada. Nothing that had been given the French in 1774 was revoked, but the form of government was changed to the familiar one of governor with his executive council, a legislative council, and an assembly elected on what was for the time a wide franchise. The result of this last provision was that the first assembly in 1792 had a majority of French members.

NATIONAL GROWTH IN THE EARLY 19TH CENTURY

Population trends. The coming of the loyalists changed the composition of the population of the British North American colonies by adding elements at once American yet profoundly attached to British institutions; it also increased the population by some 6,000 in the old province of Quebec. To these were to be added the unknown numbers of "late loyalists"—settlers, primarily land seekers, who arrived from the northern states as late as 1812. Some 80,000 came to Nova Scotia, although not all remained; of these, some 20,000 settled in what became New Brunswick, and a few hundred on Prince Edward Island.

The ethnic mixture

They added also to the growing diversity of the population of the colonies. In Newfoundland there were already the west country English and a growing number of Irish—a total of 26,505 in 1806. In Nova Scotia there were, in addition to New Englanders, loyalists, and Yorkshiremen, the Germans of Lunenburg and the Highland Scots of Pictou county and of Cape Breton Island—in all, an estimated 65,000 in 1806, with 2,513 on Cape Breton Island. New Brunswick had a population of about 35,000 in 1806, mostly loyalists or of loyalist descent, but already the southern Irish, drawn by the timber trade, were beginning to appear on the rivers of the north shore. Prince Edward Island, with a population of 9,676 in 1806, had some Acadians, some loyalists, some English, Scots, and Irish. In Upper Canada in 1806 the population numbered 70,718; in Lower it was estimated at 250,000 for the same year.

The first Canadian mosaic had taken shape as it was to remain for a century, a population of British, French, and German. The British element was to be steadily reinforced by northern English, coming by way of Liverpool, Highland and Lowland Scots, and southern and northern Irish. The result was the creation of a society in which religious liberty and a great measure of social equality were necessary for social cohesion and common effort.

Until 1815, however, the number of immigrants was small: Highlanders for Glengarry county in Upper Canada, disbanded soldiers in Lanark county south of the Ottawa River, and a straggle of Irish after the crushing of the rebellion of 1798. Nor did the numbers greatly increase after 1815; not until 1830 did the English, Scottish, and Irish begin to come to the British North American colonies in great volume. Afterward, thousands came each year. The British North American colonies became predominantly British in population, except in Lower Canada, a fact that was to determine the course of Canadian history for the next 100 years.

The Montreal fur traders. The redivision of the continent begun by the American Revolution had been intensified by rivalry in the fur trade. The French fur trade of Montreal had been taken over by British fur traders who conducted the trade with the aid of French experience and skill. The British supplied the capital, and the French voyageurs supplied the skill of canoeists and the knowledge of the country and the Indian. These "Montrealers" pushed the trade with great boldness southwest from Montreal, where they had persuaded the British government not to surrender the fur posts after 1783 on the ground that debts owing loyalists had not been paid by the United States. Thus, the trade of the lands lost by France in 1763 and by Britain in 1783 was kept tributary to Montreal rather than to New York and Philadelphia. The Montrealers also pushed the trade into the far northwest. By 1784 most of the Montreal traders to that region had combined in the North West Company, which dominated the trade from Montreal and seriously challenged the trade and legal monopoly of the Hudson's Bay Company. In the southwest, however, they were slowly squeezed out by the American government and by John Jacob Astor's American Fur Company. So the British traders pushed ever harder into the farthest northwest. In 1787 one partner, Peter Pond, gathered information about a great river that he was convinced flowed into the Pacific. In 1789 a young Scot, Alexander Mackenzie, followed that river, later named after him, to an outlet in the Arctic Ocean. It was a bitter disappointment, for Mackenzie had hoped to find a passage to the Pacific by which the high cost of bringing furs to Montreal could be avoided. In 1793 Mackenzie crossed what is now British Columbia to the Pacific at Bute Inlet. It was a great feat of exploration but did not lead to a route to the Pacific.

The North West Company

The War of 1812. The War of 1812 was to a large degree caused by the Anglo-U.S. rivalry in the fur trade. British traders and soldiers had supplied Indian tribes and afforded them moral support in their contest with the advancing U.S. frontier. Britain had surrendered the western posts by the Jay Treaty of 1794, but the cause of the Canadian fur trade and of the Indians remained the same—the preservation of the wilderness. Certainly, apart from single ship actions and privateering, the war was fought for the conquest of Canada and its elimination as an ally of the Indian. In the end, the war was a stalemate and closed with no concession by either side. It did, however, push back the Indian frontier, increase the breach between the United States and the British North American colonies, and confirm the U.S.-Canadian boundary.

That boundary had been fixed in 1783, by a line running from the mouth of the St. Croix River to the "high lands" dividing Quebec from Maine; then by the mountains between the St. Lawrence and Connecticut River valleys to the 45th parallel; by that line to the St. Lawrence; then by centre line of the river and the Great Lakes and the Pigeon and Rainy rivers to the northwest angle of the Lake of the Woods. The Treaty of Ghent in 1814 confirmed this, although the location of the Maine–New Brunswick boundary remained in dispute until the Webster–Ashburton Treaty of 1842. A convention in 1818 reduced the rights of U.S. fishermen along the shores of the Atlantic colonies and made the 49th parallel the boundary from the Lake of the Woods to the Rocky Mountains. Beyond, the Oregon Territory was to be jointly occupied for a period of 10 years, an occupation ended by the division of the territory, after some threat of war over the U.S. claim to the whole, by extending the 49th parallel to the Strait of Georgia in the Oregon Treaty of 1846.

The 49th-parallel boundary

The Rebellion of 1837. The colonies grew quietly but steadily after the War of 1812, aided by the development of the timber trade and shipbuilding and by increased immigration from the British Isles. The growth of population and social sophistication led to growth of a reform movement, stimulated by similar movements in Great Britain and the United States. The movement was essentially attempted to make the institutions of the colonies more popular and less the monopoly of the royal governors and the appointed and permanent councils. The rise of a middle class of professional men, especially lawyers and journalists, and the importance of religious liberty in a population so diverse in faith underlay this development. In the Maritimes the movement proceeded peaceably and constitutionally under the leadership of forceful but moderate reformers, such as Joseph Howe of Nova Scotia. But Upper Canada, under the leadership of the irascible Scots democrat William Lyon Mackenzie, was more militant. In Lower Canada, matters became much more serious for two reasons: one was that the political division was to a great extent a national split between English and French; the other was that the wheat farming of the habitants was primitive and dependent on new lands and exhausted both the fertility and the extent of the good soils. An economic depression in 1837 intensified political grievances and burst into open rebellion. A hasty and unplanned republican rising in Lower Canada was crushed by the British regular garrison and the militia.

The Union of Canada. The abortive rebellions, however, did dramatize the need to reform Canada's outmoded and constrictive constitution. The "Canadian question" became a leading issue in British politics. Lord Durham was sent out as governor-general with a royal commission to enquire into the causes of the troubles. Durham's stay in Canada was brief, but his enquiry was sweeping and his recommendations trenchant. Durham perceived that

The Durham Report (1839)

the colonies had stagnated and that, if they were to live side by side with the dynamic United States, they must be brought into the full stream of material progress. One political means to this end was union. Durham decided the time for the union of all the North American colonies had not yet come, but he did recommend the reunion of at least the two Canadas in order to realize the economic possibilities of the St. Lawrence valley. In Durham's view, union would also hasten the assimilation of the French, whom he saw as a backward people. Second, he adopted a proposal of certain Upper Canadian and Nova Scotian reformers for "responsible government." This would make the colonial executive responsible to the assembly and assure colonial self-government.

The British government refused an explicit grant of responsible government but did accept the proposal to unite the Canadas. In 1841 the United Province of Canada came into being under a new and dynamic governor, Charles Poulett Thomson (later Lord Sydenham). Although the French of Canada East (Lower Canada) outnumbered the English of Canada West (Upper Canada), both sections received an equal number of seats in the new legislature. This was done to facilitate assimilation of the French, but the French, led by such astute reform leaders as Louis Hippolyte LaFontaine, took advantage of divisions among the English-speaking legislators. They allied themselves with the reformers from Canada West to push for responsible government and to make themselves indispensable for governmental stability. In Britain the success of the Industrial Revolution led to the growth of free-trade liberalism and a desire to dismantle the colonial empire. The last British tariffs (the Corn Laws) were repealed in 1846, and colonial governors were instructed to implement a policy of responsible government. The policy received its first real test the following year, when the reform ministry headed by LaFontaine and Robert Baldwin of Canada West passed a law to compensate victims of the 1837 rebellions. Governor Elgin signed the law despite strong opposition from conservatives. In reaction a mob burned the parliament buildings in Montreal.

Achievement of responsible government

The British North American colonies, then, had achieved self-government by 1848; the next decade saw their laws and institutions remodeled to fit the individual needs of each colony. But, for Canada at least, the time was at hand for expansion. The British repeal of the Corn Laws had deprived the colonies of imperial protective tariffs. The Grand Trunk Railway, begun in 1853, was an attempt to draw the trade of the American Middle West down the St. Lawrence. The Reciprocity Treaty of 1854 in part replaced imperial with continental trade, and the colonies boomed. Economic growth was especially stimulated after 1862 by the American Civil War. When the U.S. government gave notice in 1864 that it wished to abrogate the treaty by 1865, it stimulated colonial politicians to seek unification of the British North American colonies to provide a substitute market. This move was also made necessary by a continuing political deadlock between conservatives and reformers in Canada, by growing fears of U.S. military power, and by a desire to annex the northwest. After the merger of the North West Company and the Hudson's Bay Company in 1821—a merger made necessary by their bloody rivalry—direct links between Canada and the west had been cut. In Canada West, however, a shortage of good agricultural land was forcing young men to leave for the United States to homestead, and demands grew to annex the northwest to provide room for expansion.

The first significant step toward union, later called confederation, was taken in Canada with the formation of the Great Coalition, a government that united Reform Party leader George Brown of Canada West with the Conservatives' John A. Macdonald of Canada West and George Étienne Cartier of Canada East. In September 1864 they attended a conference at Charlottetown, P.E.I., in which Maritime political leaders discussed Maritime union. They persuaded the Maritimes to postpone Maritime union and discuss confederation. At a conference called at Quebec (Oct. 10, 1864), an agreement was quickly reached on a general federal union; this agreement was immediately approved by the British government, which was eager to set the colonies up on their own and to be rid of its obligation to defend them inland from Quebec. There were hitches and failures; New Brunswick voted against union in 1865, then reversed itself in 1866; Prince Edward Island refused to enter until 1873; Newfoundland also refused and did not join Canada until 1949. But the Canadas and the British government applied quiet but strong pressure on the reluctant colonies. In 1867 the three colonies of Nova Scotia, New Brunswick, and the Canadas (now the provinces of Quebec and Ontario) were united under the British North America Act as the Dominion of Canada.

That act, with certain amendments, was the "constitution" of Canada until 1982. It was, in fact, retitled the Constitution Act of 1867 (pairing it in name with the Constitution Act of 1982). The act of 1867 provided constitutions, based on the British model, for the new provinces of Quebec and Ontario, confirmed the language and legal rights of the French, and above all provided for the division of power between the federal government and the provinces. The union was not, at its beginning, a truly federal one because the central government was given broad powers, not unlike those the British government had possessed over the colonies. In time, judicial interpretation and the growth of provincial rights made the union more truly federal. For the moment, however, a strong central government was needed in order to develop the northwest and the colony of British Columbia beyond and to build a railway to the Pacific that would bind the vast new territories to the original Dominion.

Canada from 1867 to 1920

THE DOMINION OF CANADA, 1867–1914

Purchase of Hudson's Bay Company territories

Section 146 of the British North America Act provided for the admission of Rupert's Land (the Hudson's Bay territory) to the new dominion. The first action taken by the federal government was to buy out the title of the Hudson's Bay Company. The negotiations for this purpose, assisted by the British government, were completed in the winter of 1868–69. Canada was to pay the company £300,000 for its title, and the company was to retain 5 percent of the Fertile Belt (land fit for agricultural settlement) and designated areas around its various posts. The Canadian government passed a provisional act for the government of the Northwest Territories, sent out a survey party to begin a land survey before settlement began, and appointed as governor William McDougall of Ontario.

The first Riel rebellion. The government unwisely regarded the acquisition of the northwest as a transaction in real estate with the Hudson's Bay Company. But the company was not the only power in the territory. There was the colony of Red River, and also the métis, who made up more than half the colony. The progeny of white fur-trader fathers and Indian mothers, the métis community was divided between English-speaking Protestant and French-speaking Roman Catholic elements. They had a semimilitary, semipolitical organization of their own. They had long thought of themselves as a new nation, neither European nor Indian but both, sharing the rights of one and the title to the land of the other. And behind them were the powerful Plains tribes—Plains Cree and the Blackfoot confederacy, buffalo hunters not under the influence of the Hudson's Bay Company. Canada had taken no account of the métis or Indians in effecting the transfer. It assumed it could take over from the company and then consider what should be done.

This policy was rendered impossible by Louis Riel, a métis educated in Montreal, who organized resistance in Red River to a transfer to Canada without the people of the northwest having a voice in the transaction. Riel, with the support of armed métis, seized control of Red River and forced Canada to postpone the transfer and to negotiate. The result was the creation in 1870 of the small province of Manitoba, with equality of the English and French languages and an educational system like Quebec's two systems of public confessional schools, Roman Catholic and Protestant. The implication was that the northwest was to be open to French institutions and language, as well as English.

That assumption was to be thwarted, however, by the extreme smallness of the new province, which amounted to little more than the Red River Settlement, and by the dominion's control of natural resources and of the still vast North West Territory. Riel's obstructionism did not block Canada's march to the west, and the dominion at once opened negotiations with delegates from British Columbia. That colony consisted of Vancouver Island (organized as a colony in 1849) and the mainland to the watershed of the Rockies, the latter having first been made a separate colony in 1858, when the gold rush along the Fraser River began, and united with Vancouver Island in 1866. The chief needs of the new colony were responsible government and connection with the east. Union with Canada might afford both, and in the negotiations the chief Canadian representative, George Étienne Cartier, promised both and more—in fact, a railway was to be begun in 2 years and finished in 10 (1881). Faced with such generosity, the Legislative Council of British Columbia could only accept. British Columbia became a Canadian province in 1871.

Addition of British Columbia

The transcontinental railroad. With the addition of British Columbia, Canada extended from Atlantic to Pacific. To maintain that area, however, and to ensure its independence from the United States, it was necessary to build a railway to the west coast. The effort to organize a company to undertake this enterprise, much greater than any railway yet built, was made in 1872. But Sir John Macdonald's government, charged with corruption in its dealing with the head of the new company, fell on the eve of the great depression of 1873. The railway thereafter could only be built piecemeal until Macdonald returned to power in 1878. An economically revived Canada, fortified with a new National Policy of tariff protection, incorporated the Canadian Pacific Railway in 1881, and the line was pushed ahead rapidly with government grants of land and money.

Even so, the railroad came to need new loans from Parliament, and its funds ran out as depression returned. Had it not been for the Riel Rebellion of 1885, which showed the need for the railway in moving troops, the last loan needed might have been refused. Despite the victory in the creation of Manitoba, many of the mêtis—finding life impossible with the influx of new settlers—sold their lands and trekked westward to the Saskatchewan River. Even there, they were followed by the government land survey. The buffalo herds were vanishing, and the railway would supersede transport by boat and cart, from which many of them earned their living. The Plains Indians, alarmed by the depletion of the buffalo and unhappy with the government's treaties, were also restless. The mêtis again organized to claim their rights as they saw them and sent for Riel, living in exile in Montana Territory, U.S. Riel returned and a new armed resistance was formed. Canada had to rush militia to the northwest. Here the new railway, though not quite completed, proved its worth. The troops were rushed out, the rebellion was suppressed, and the railway obtained the grant that enabled it to complete its track across the Canadian Shield and the Rockies. Riel, with several associates, was tried and, despite evidence that he was of unsound mind, convicted of treason, though with a recommendation for mercy. Macdonald, as minister of justice and prime minister, refused clemency. The last spike of the Pacific railway was driven on Nov. 7, 1885, nine days before Riel was hanged at Regina.

Reaction of Quebec

Canada had united its new territories with its old, but there was a fierce reaction in the French province of Quebec. Riel, who had not gained much French sympathy in 1870, was now viewed by nationalist French Canadians as a martyr to the cause of French Canadian rights. The result was the election by a narrow majority of a clerical-nationalist government in Quebec. This produced a reaction in Protestant Ontario, which, in turn, led in 1890 to the abolition of the confessional schools in Manitoba, where the Roman Catholic schools were almost wholly French-speaking. French Canadians thereafter fell back on the provincial rights of Quebec to maintain the rights of French Canadians—a reaction with serious consequences for the Canadian federation. The Conservative Party, which had lost Macdonald by death in 1891, fell from power in 1896 largely because of the Manitoba Schools Question. The Liberal Party, under the French Canadian Wilfrid Laurier, came to power by virtue of a large majority in Quebec. Canada, it seemed, was not to be governed without the support of Quebec, even though the west retained only traces (in the Northwest Territories) of French population and French rights.

The Klondike gold rush. In 1896 gold nuggets were found on Klondike Creek, a tributary of the Yukon River. A rush began in 1897 and swelled in 1898, as miners and adventurers poured in, mainly from the United States. The Klondike was, in fact, the most publicized of all the great rushes. It was the last of the great placer rushes and excited a world weary of depression with stories of the long climb up the Chilkoot Pass and of red-coated Northwest Mounted Police keeping law and order on the gold-rush frontier. Klondike gold, however, was probably the least important mineral discovery of this period. Far more significant for Canada's economy were the copper, lead, zinc, and silver deposits in the Kootenay region of southeastern British Columbia; the coal deposits of the Crowsnest Pass (bordering British Columbia and Alberta); and the gold, nickel, and silver beds of northern and northeastern Ontario and northwestern Quebec. These discoveries stimulated railway and town construction and brought thousands of permanent residents. In the decades that followed, prospectors traced the rich mineral deposits of the Canadian Shield westward from Ontario and Quebec, making major base metals discoveries as well as gold and silver, at Flin Flon, Man., in 1915 and finding rich deposits of radium at Great Bear Lake in 1930. By the 1930s, Canada had become a major mining country.

Increased agricultural base

The land rush in the west. At the same time, the land rush to the prairies widened the country's agricultural base by the settlement of Manitoba and the Northwest Territories. Their population rose from 419,512 in 1901 to 1,322,709 in 1911. Manitoba had already been enlarged westward and northward in 1881. The territories, governed by a governor and appointed council since 1876, had had elected members added to the council and began the traditional Canadian struggle, first for representative and then for responsible government. The latter, however, could only come with provincehood, and the demand arose for the creation of a province between Manitoba and the Rockies. The federal government responded after the election of 1904, and in 1905 not one but two provinces were created, Alberta and Saskatchewan. The provinces were roughly equal in area and extended north to the 60th parallel. A fierce political struggle arose over the question of French schools in the new provinces, and again the cause of French rights outside Quebec received a setback. There were to be separate schools in the Canadian sense of denominational schools supported by the taxes of members of a denomination—Roman Catholics in this case—but nothing like the dual confessional school system of Manitoba before 1890, or of Quebec. Once again the development of the west had disturbed the relations of English and French in Canada.

The Laurier era. For 15 years, Laurier's Liberal government reflected the acquiescent politics of prosperity and progress. Canada seemed at last to be entering on its own century, as the United States had done in the one just past. Nothing better exemplified the confident, easy mood of the Laurier years in Canada than the vast and extravagant railway expansion in response to the settlement of the west and the initial development of the mineral and forest wealth of the nearer, or middle, north. The Laurier government built one transcontinental railway from Quebec to a point east of Winnipeg; from there to Prince Rupert a well-subsidized Grand Trunk Railway of eastern Canada built a subsidiary line, the Grand Trunk Pacific. Not to be deterred by two transcontinental railways in a country that was yet little more than a narrow corridor from east to west, two Canadian private entrepreneurs, geniuses of their kind, William Mackenzie and D.D. Mann, built or bought the Canadian Northern bit by bit with lavish subsidies from provincial governments. By 1914 Canada had one long established coast-to-coast railway (the Canadian

Pacific) and two railway lines from Montreal to the Pacific toiling to complete their tracks in the Rocky Mountains. In such a wealth of easy capital and easy prosperity, governments were not likely to be defeated.

Yet two factors—one as old as Canada, one relatively new—were to disturb the smooth current of prosperity. The former was the never-quite-settled place of the French in an English Canada. The question had flared up in the creation of the new provinces in the west; it now arose over participation in Britain's wars, first the South African War in 1899, then World War I. The result was the growth of a new nationalist movement among French Canadian clerics and intellectuals, who made their voices heard in a new paper, *Le Devoir.* Their spokesman, insofar as a man so independent could speak for anyone but himself, was Henri Bourassa. The second factor was the impingement of the world on a Canada intensely absorbed in its own development and its own troubles. The two were to combine to end the Laurier regime and bring Canada, still troubled, into the world at large.

Foreign relations. Canada's contacts with the world in 1900 were almost wholly through Great Britain and the United States. Indeed, Canada's formal relations with other countries were conducted only through the British Foreign Office because Canada, as a colony, had no diplomatic status.

Relations with Britain

The dependence on Great Britain raised, after 1895, the question whether Canada might be expected, on its own decision, to take some part in Britain's imperial wars. The British colonial secretary Joseph Chamberlain was anxious that the dominion should at least be committed in principle to supporting the mother country. Laurier, at the colonial conference of 1897, remained silent on the issue; thereafter his stand was that the Canadian Parliament must decide whether or not Canada would take any action. When the South African War broke out in 1899, many English Canadians actively urged participation; but some French Canadians, led by Henri Bourassa, were actively opposed. A compromise was reached, by which Canada sent volunteers to serve under British command and with British pay, but the rift between French and English Canadians had been further exacerbated. Also, Britain's naval competition with Germany made Britain eager to have colonial help, preferably by contributions in money or by the colonies' assuming their own naval defense. Again, Laurier sought a compromise. In 1910 he established a Canadian navy, which in time of war, however, was to be placed under British command. The measure was bitterly opposed by the nationalists in Quebec, who argued that conscription in Britain's army would follow. Their clamorous opposition led to the defeat of the government candidate in a Quebec by-election, foreshadowing Laurier's fall from power in 1911.

Canada's relations with the United States were close and informed, but in the final analysis they were relations between states foreign to one another. There had been a long record of border disputes, the settlements of which were resented, rightly or wrongly, by Canadians. There were the perennial difficulties over fishing rights in the North Atlantic and the dispute in the 1890s over the sealing industry in the Pacific. The Fenian raids at the time of confederation symbolized another cause of strain, the Irish-American hatred of England and suspicion of Canada as a British colony. Matters were brought to a head in the dispute over the Alaskan panhandle boundary. The line laid down by treaty between Great Britain and Russia had not since 1867 been marked on the ground by the United States and Canada. It became an urgent issue in 1897 with the Klondike gold rush, as the principal access to the gold fields was through the panhandle, and the disputed territory might contain gold. Canada claimed a line that would have put the heads of major inlets in Canadian territory and so have given it, especially the port of Vancouver, free access to the Yukon Territory. The United States claimed a boundary that would have excluded Canada from the sea. A joint commission of Americans, British, and Canadians found in favour of almost the whole of the American claim, the one British jurist voting with the three Americans. The decision was bitterly resented in Canada, the action of the British member, Lord Alverstone, even more than that of the Americans. In fact, Canada's case was exceedingly weak, but the combination against it of the two powers with which alone Canada dealt made the country realize it must be prepared to look out for itself. Canadian nationalism in a new sense came into being.

U.S.-Canadian friction

Two results followed. One, neither quick nor dramatic but significant, was the creation of the Department of External Affairs in 1909, in preparation for Canadian handling of its own foreign affairs. The other was the cultivation of direct relations with the United States. From this followed the final settlement in 1910 of the long-vexed Atlantic fisheries issues and the creation of the Permanent Joint Commission on Boundary Waters in the previous year.

Relations between Canada and the United States were assuming a new guise, and with reason. The United States was beginning to turn to Canada as an outlet for investment and as a source of raw materials, particularly minerals and newsprint. An exchange of ideas began on a new scale, particularly in the ideas of the Progressive movement, which advocated a wide range of reforms to combat the growing social evils caused by industrialism. These ideas were influential on both sides of the border, in Canada sometimes more than in the United States, as in the creation of the publicly owned and operated Ontario Hydro-Electric Power Commission in 1906. To some degree these developments were upset by the Canadian election of 1911, when the Conservative Party under Sir Robert Laird Borden defeated the Laurier Liberals. Two issues largely dominated that campaign: Laurier's naval policy, which was stimulated by Britain's defense needs in Europe, and a reciprocal trade agreement with the United States. In Quebec the naval policy was denounced as imperialistic. Borden, backed by the business community and renegade Liberals, attacked the reciprocal trade agreement as a sellout of Canada's British birthright and won a convincing victory. This, however, by no means interrupted the growth of the Canadian-American relationship.

Accession of Sir Robert Laird Borden

Although burdened by demands for the distribution of patronage, Borden tried to institute more progressive policies after taking office. But foreign policy issues and defense questions dominated the first years of his government. He struggled to establish a policy of direct cash aid for Britain's naval building program in return for a voice in imperial policies that affected Canada. He was defeated by the Liberal-dominated Senate and rebuffed by the British. When World War I broke out in August 1914, Canada was almost totally unprepared.

CANADA IN WORLD WAR I

At the outbreak of World War I, Minister of Militia and Defence Sir Samuel Hughes scrapped the carefully laid plans for a mobilization of the existing militia and, instead, launched a direct appeal to the men of Canada. Canada was just emerging from a deep recession, and tens of thousands of British-born young men with no work and with patriotism in their hearts rushed to the colours. An initial contingent of 33,000 men sailed for England in October 1914 to lay the foundation for the creation of the First Canadian Division. In April 1915 the Canadians saw their first major action in the Second Battle of Ypres, where they were among the first Allied troops to be gassed. As more volunteers came forward, Borden increased the authorized force levels. By the spring of 1917, four Canadian divisions, constituting the Canadian Corps, were in the field, with a fifth division in England. The entire corps fought together for the first time in April 1917, when it distinguished itself in the Battle of Vimy Ridge in northern France. This force not only earned an enviable record as a fighting force; it was the first authentic expression of Canada in the world. Its strength and reputation meant that Canada could not be treated as a mere colony. The cost to Canada was high. Out of approximately 625,000 who served, about 60,000 were killed in action and another 173,000 were wounded. The Canadian Corps won many battle honours, but its role in history was to ensure Canada that "voice" in imperial and international affairs for which Borden had asked in vain in 1912.

The Canadian war effort

At home, the war effort was scarcely less impressive. Canadian foodstuffs and raw materials were of first importance in maintaining the western Allies. No less important were the millions of shells turned out by Canadian factories. In fact, the war was a significant step forward for Canadian industry, which had to learn complicated mass production techniques and apply them to the manufacture of everything from wooden shell crates to training aircraft. The rapid growth of the munitions industry created an acute labour shortage that brought increased female participation in the industrial work force. It also promoted the growth of labour unions. At the same time, the accelerated demands of the war economy brought high inflation, which the government was unable to control despite increasingly interventionist policies. Strikes and lockouts grew to crisis proportions by the last year of the war.

At the start of the war, Borden had envisaged an essentially voluntary war effort: employers were urged to treat their workers fairly, workers were urged to curb wage demands, producers were urged to keep price increases down, and men were urged to enlist. As the war dragged on, more and more English Canadians began to view the war as a Canadian national war effort, not simply as another British war in which Canadians were taking part. By 1917 the government was trying to regulate many facets of Canadian economic life. It nationalized bankrupt railways. It introduced income taxes. It controlled some commodity prices. And in the spring of 1917 it introduced compulsory military service—conscription—in response to a growing manpower crisis in the Canadian army. Conscription tore Canada apart. French Canada had never been enthusiastic about the war, and many fewer French Canadians volunteered for military service than did English Canadians. To make matters worse, French nationalist feeling had been reawakened by new troubles with respect to the use of the French language in schools in French districts in Ontario and Manitoba. French Canada, led by Laurier, opposed conscription but was overridden by the formation of a Union government—almost wholly English in personnel—and in the wartime election of 1917. But Canada was divided as it had not been since 1837.

Despite this rift at home, the entry of Canada into the world of nations went ahead. In 1917 the British government under Prime Minister Lloyd George formed an Imperial War Cabinet, of which the prime ministers of the dominions were members, to conduct the war and to plan the peace. In reality, if not yet in name, the British Commonwealth of Nations had come into being. This was recognized by Article IX of the Imperial War Cabinet in 1917, which stated that the British Empire was made up of self-governing nations as well as colonies, with India in a special position. Henceforth, it was hoped, a common policy would be worked out by government conferences in peace as well as war.

Canada since 1920

CANADA BETWEEN THE WARS

The labour–farmer revolt

Turmoil at home. During the war discontent had increased in virtually every region of Canada and in almost all of its social classes. When the fighting ended, patriotic constraints on demands for change disappeared, and organized labour and the farmers mounted a revolt that swept across Canada. In 1919 the Conservative government of Ontario was turned out by a farmer–labour alliance led by the United Farmers of Ontario. United Farmers governments were elected shortly afterward in Alberta (1921) and Manitoba (1922). In federal politics the agrarian-based Progressive Party in the 1921 election became the second largest party in the House of Commons. The agrarian revolt was marked by demands for farm price supports and regulation of the grain and transportation industries. At heart, however, it was aimed at curtailing the growth of the power of the cities.

A labour revolt paralleled the uprising on the farms. The virtual doubling of union membership across Canada during the war and the failure of the Borden government to control inflation stimulated militancy. There was an upsurge of industrial unrest despite governmental efforts to impose peace. In 1919 the unrest peaked with a six-week general strike that paralyzed Winnipeg and sparked sympathetic strikes across Canada. The Winnipeg General Strike was crushed by a federal government gripped by a hysterical fear of revolution. By 1921 the labour revolt had subsided, partly because of federal intervention, partly because of the onset of an economic turndown that brought increased unemployment and a virtual collapse of union power.

Commonwealth relations. As a result of their efforts during the war Canada and the other dominion powers demanded separate signatures to the treaties with the defeated countries and won at least the right to sign as members of a British Empire Panel. They also demanded and got, despite the doubts of the United States and France, membership in the newly organized League of Nations. Thus, Canada finally became a full-fledged member of the community of nations.

Canada followed an isolationist policy between World Wars I and II. This was mainly a consequence of the return to government in 1921 of the Liberal Party, now more than ever dependent on French Canadian support. French Canadians were themselves isolationist, and they strengthened the general disposition of Canadians to express their new national feelings by the completion of autonomy in the empire and by resuming their material development as a North American country. The new prime minister, W.L. Mackenzie King, and his government were firmly nationalist and isolationist, as was made very clear by their prompt refusal to back the United Kingdom's policy in Turkey in 1922. This, in effect, ended the hope of a common imperial policy. Instead, there would be conference, consultation, and sharing of information, but freedom of action.

The Balfour Report of 1926

King was primarily motivated by his desire to maintain national unity. He knew that a close relationship with Britain would remind French Canadians of the conscription crisis, and he was determined not to split Canada over questions of foreign policy. He was a willing partner in efforts by the Union of South Africa and the Irish Free State to weaken the formal ties of empire—efforts that culminated in the Balfour Report of equality of status at the 1926 Imperial Conference. That report was embodied in the 1931 Statute of Westminster. The statute ended all legislative supremacy of the Imperial Parliament over the dominion parliaments and made them, when they proclaimed the Act, sovereign states sharing a common crown. The Commonwealth had become a legal reality and Canada an independent nation.

Canada's new independence was reflected by its establishment of its own foreign service. Canadian ministers were appointed to Washington, D.C., in 1927 and to Paris and Tokyo in 1928 and 1929, respectively. (In the United Kingdom and Canada, officers called high commissioners played much the same role after 1928, although the office was to some degree political and not just diplomatic.)

The Great Depression. The quest for international equality was to some degree obscured by the onset of the Great Depression. With an economy largely dependent upon the export of farm products and raw materials, Canada suffered severely during the depression period from 1929 to 1939. The Liberal Party, except for a brief interval in 1926, had been in power since 1921. In the general election of 1930, the Conservative Party, led by R.B. Bennett, succeeded in winning the election—partly because the King government had refused to give federal funds to the provinces to combat unemployment and give relief, and partly because Bennett promised to blunt the effects of the depression by protective tariffs. If the attitude of King was old-fashioned and not up to the needs of the times, so were the election promises of Bennett. The depression was so far-reaching in its effects that only drastic measures could lessen its impact and begin the process of recovery.

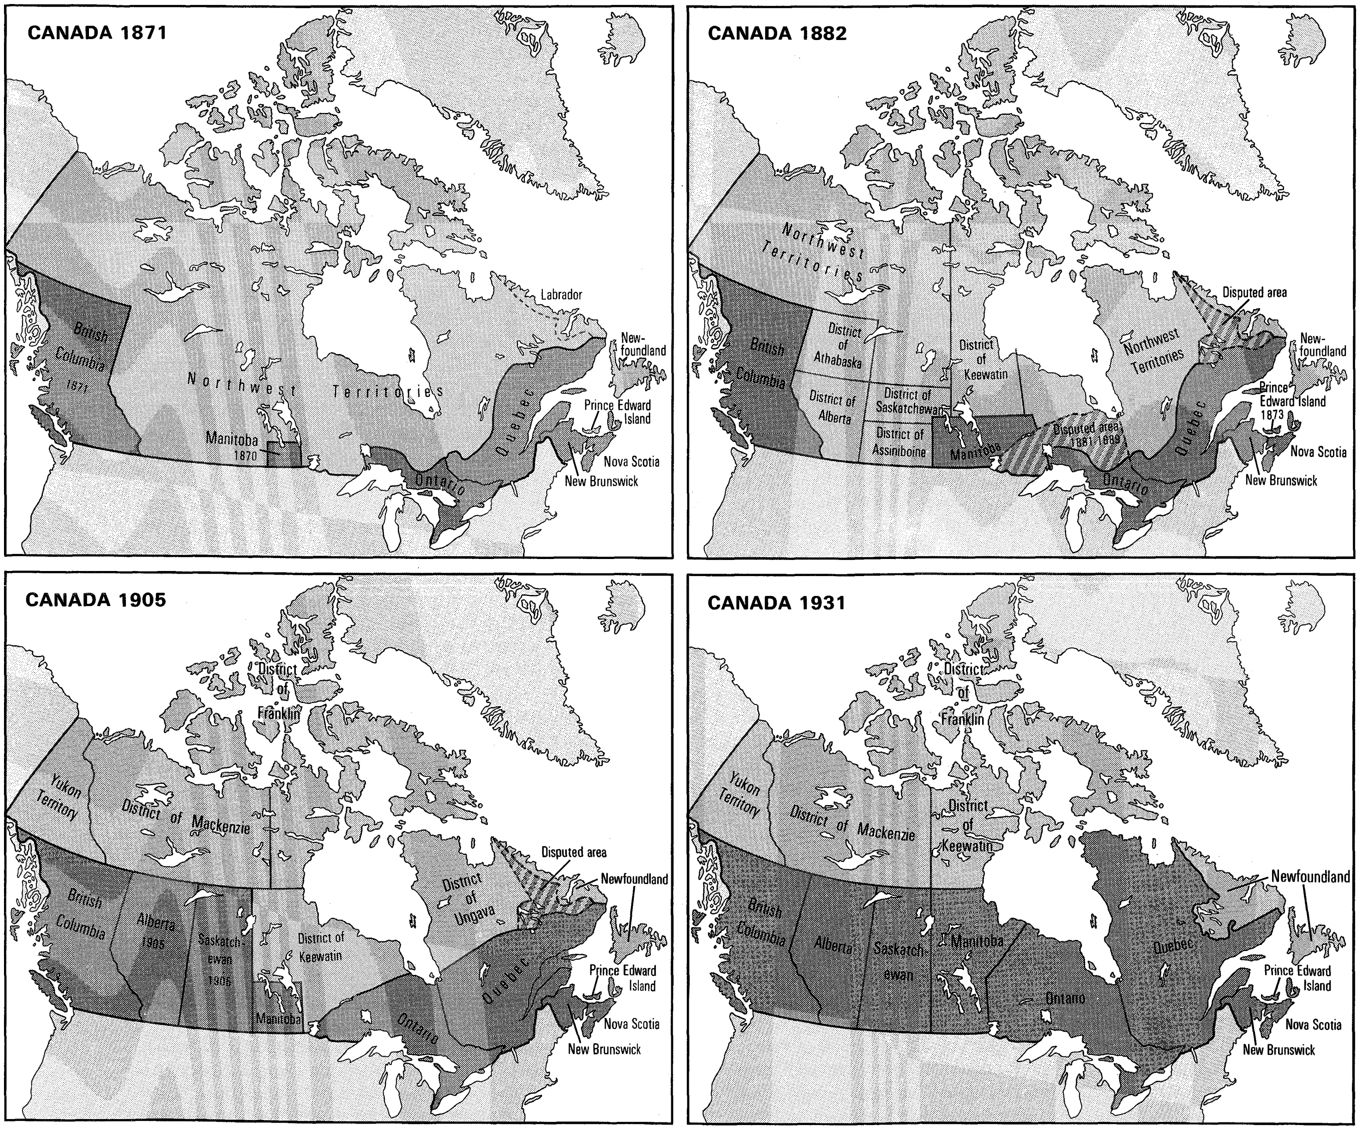
The Bennett government did little to increase the already high tariffs that had been in effect under the Liberals, but it did stiffen the application of customs regulations. The Conservatives also sought relief for Canadian producers by reviving an old dream of Joseph Chamberlain that the

The Imperial Economic Conference

empire should have a common tariff policy. The obstacle created by Britain's policy of free trade had ended with the modification of that policy in the 1920s. Political imperialism had ended, but perhaps commercial imperialism would be revived. Prime Minister Bennett arranged an Imperial Economic Conference at Ottawa in 1932. The national interests of the representatives made agreement difficult, but all countries were desperate. The dominions badly needed the British market for their foodstuffs and other primary products, and Britain itself could not afford to ignore protected markets in the dominions. The Ottawa Agreements were a series of preferences given by Commonwealth countries to one another, to some degree at the expense of producers in other countries, particularly the United States.

The depression, however, merely intensified. Canada had known widespread unemployment in the mid-1870s and in the immediate postwar years. But an economy still predominantly agricultural had largely, if painfully, absorbed the unemployed. In 1921, however, supremacy began to pass from agriculture to industry, and from countryside to city, and the trends thereafter were rapid. The cities had now to provide for mass unemployment, and Canadian municipalities were required by law yet unfitted in financial resources to furnish welfare and relief. The municipalities had therefore to turn to the provinces for aid; the weaker provinces had to turn to the federal treasury. Thus, not only was the economy being dragged down to unexampled levels of prices and production, but the very framework of government was threatened in the poorer provinces. What happened in Newfoundland, where responsible government was replaced by administration by a commission aided with British funds, came close to happening in the prairie provinces. The brighter side of the picture was that the mining industry of Ontario and Quebec kept the revenues of those provinces comparatively good, and so the greater part of the country remained in a condition to maintain the federal revenues and make possible the support of the weaker provinces. Confederation had never been more important.

Prime Minister King might refuse to aid the provinces in 1930, before the second great slump of the depression, but his successor had no such choice. Prime Minister Bennett's own remedies—stiffened protection and imperial preference—could only act slowly at best. But conditions were drastic by 1931, aggravated by unprecedented drought on the prairies. Bennett began, on entering office, to advance federal funds to the provinces for relief works. The provinces had already come to the financial aid of their municipalities, and a relief system was worked out for the unemployed. But all the means of aid that were employed ended with the giving of relief; the government still looked for recovery from the depression. The rise of parties with more fundamental solutions than relief therefore began. One was the Co-operative Commonwealth Federation, a party socialist in theory if pragmatic in fact. Another was Social Credit, a movement urging the payment of social dividends to fill the gap between the costs



Canadian political development, 1871–1931 of production and the cost of purchase. There was even a small Fascist Party in Quebec, as well as a splinter group led by Paul Gouin, a Liberal rebel, which in 1936 joined with Maurice Duplessis's Conservatives to make up the Union Nationale, which became a nationalist "Quebec First" party. Disquieting findings of a Price Spreads Commission and the growing desperation of the farmers led Bennett to listen favourably to praise of the New Deal in the United States. Perhaps personally convinced, certainly politically desperate, in 1935 he had his last Parliament enact a Canadian New Deal. It quite failed to remove the resentment his government had provoked during its years of office, and the Liberals returned to power easily.

The Reciprocity Treaty of 1936

King, despite some advanced ideas in his youth, believed Bennett's New Deal was unconstitutional, as the courts in 1937 found most of it to be. King and his government believed that the way to end the depression was to stimulate international trade. The Ottawa Agreements, of course, remained in force. Canada, however, availed itself of the U.S. policy of more liberal trade agreements, resulting in what was called the Reciprocity Treaty of 1936. Reciprocity and imperial preference were reconciled. In the long run, U.S.-Canadian trade was to grow to enormous proportions, but for the time being the depression continued, as did the drought.

The Liberal government did concern itself with the devastation wrought by the depression on government finances. In 1936 an official inquiry made by the newly created central Bank of Canada revealed that the Prairie Provinces were at the end of their economic rope. A distinguished Royal Commission was set up to inquire into the allocation of revenues between the federal and provincial governments. The resulting report in fact amounted to a comprehensive study of the constitutional and financial development of government in Canada, and of how the depression had revealed its weaknesses. The federal government, with unlimited power to tax, lacked the power to spend on needed issues; the provinces possessed the necessary constitutional power but, except for Ontario, their financial resources were inadequate. The commission in 1940 recommended the assumption by the federal government of provincial debts, a scheme of federal unemployment insurance, and a reallocation of revenues between the two levels of government, on the principle that all provinces had the means to maintain a national level of governmental and social services. The first two were done, relieving the credit of the provinces and strengthening the federal government, but on the latter there was no agreement, as it involved a redistribution of income between wealthier central Canada and the Maritimes and the Prairies. At that time both Ontario and Quebec were strongly provincialist and resisted redistribution.

Canada's policy toward Hitler

Growing international tension. Even domestic distress was to some degree submerged in the second half of the 1930s by the worsening outlook in international affairs. The external interests of Canada shifted from the development of the Commonwealth to the fate of the League of Nations and the first shocks of aggression in Asia and Europe. Canada was too preoccupied with its own affairs up to 1935 to take great note of Japanese aggression in Manchuria or the rise of Hitler in Europe. By that date, however, the fate of the League of Nations, clearly threatened by unprovoked aggression, drew more and more attention. From 1936, King supported the French and British policy of appeasement, refused to make any public commitments to aid Britain in the event of war, and declared that Parliament would decide Canada's course if and when fighting broke out. He did this even though he knew that strong ties of culture, emotion, and nationality still bound most English Canadians to Britain and that these ties would inevitably bring Canada into war on Britain's side. He said as much to Hitler in a visit to Germany in 1937. His plan, however, was to put commitment off to the last possible moment so as not to alienate French Canada until war had actually begun.

CANADA IN WORLD WAR II

When the Parliament of Canada voted on the declaration of war against Germany on Sept. 9, 1939, only a very few members voted in opposition. This unanimity, however, rested on the assumption that there was to be a "limited liability" war effort that would consist mainly of the supply of raw materials, foodstuffs, and munitions and the training of Commonwealth air crew, mainly for the Royal Air Force. Canadian males were to be actively discouraged from serving in the infantry, which was expected to take high casualties, and few infantry units were planned. If this plan were followed, King and other government leaders reasoned, conscription would be unnecessary. King and the leader of the Conservative Opposition had both pledged themselves to a "no conscription" policy even before the war began.

Increased Canadian involvement in the war

The expulsion of the British from Europe and the fall of France in May and June of 1940 totally changed the circumstances. Canada's overseas allies had fallen or were in danger of doing so, and it immediately concluded an agreement at Ogdensburg with the United States for the defense of North America. Moreover, Canada now stood in the forefront of the war. After England, it was now the second most powerful of Germany's adversaries. The emphasis on supply had to give way to an emphasis on combat forces. Necessarily, the question of the allocation of manpower, including compulsory service overseas, came to the fore and was made more urgent by the Japanese attack on Pearl Harbor in December 1941. King, resolved at almost all costs to avoid a repetition of the Anglo-French cleavage, had to recognize the changed situation by holding a national plebiscite in 1942 to free him from his pledge and allow conscription if necessary. It was strongly carried in English Canada but heavily defeated in Quebec. Thereafter, compulsory service for home defense was enforced, while overseas service remained voluntary until the last year of the war. Then in 1944 unexpectedly great casualties in Normandy led to a "conscription crisis" and the ordering of 16,000 home defense men overseas. The gulf of 1917 between English and French, reopened in 1942, was deepened.

Not only was Canada's war effort in World War II far more massive than that in World War I, it also had a much more lasting impact on Canadian society. By the end of the war, more than 1,000,000 Canadians (about 50,000 of whom were women) had served in the three services. Casualties were much lower than in the previous war, with approximately 42,000 killed or having died in service and 54,400 wounded. The Royal Canadian Air Force provided an entire group (6th Group) for the Royal Air Force's Bomber Command, and the five Canadian divisions were united in the First Canadian Army under Lieutenant-General H.D.G. Crerar. Canadians saw action in battles as far afield as Hong Kong, in December 1941, and the invasion of Normandy, in June 1944, when Canada was assigned one of the five invasion beaches.

The domestic war effort was no less significant. Canada hosted, and paid much of the cost of, the British Commonwealth Air Training Plan, which trained more than 100,000 Commonwealth air crew. Canadian factories turned out everything from rifles to Lancaster heavy bombers, and Canadian scientists, technicians, and engineers worked on the latest weapons technology, including the atomic bomb, for which Canada supplied the uranium ore. Canadian foods, direct cash contributions to Britain, and munitions for the Allies, including the Soviet Union, contributed to the overall war effort.

Unlike the situation during World War I, the government intervened in almost all aspects of Canadian life to regulate the war effort, ensure a smooth flow of men and materials, and curtail inflation. Agencies such as the Wartime Prices and Trade Board and the National War Labour Board marked a massive growth in the federal government that brought a surge of government spending and a vast increase in the civil service. Toward the end of the war the King government launched Canada into the era of social welfare spending and Keynesian economics with a major veterans' benefits program, family allowances, farm price supports, compulsory collective bargaining, and a national housing program. It would undoubtedly have gone even further than it did in 1945 and 1946—it was considering a national health insurance plan—but for the opposition of provincial governments headed by Ontario and Quebec. Despite that opposition, however, the war produced a significant shift of power toward Ottawa.

POSTWAR CANADA

U.S. and British relations

International commitments. The most significant outcome of the war for Canada in its foreign relations was the relative decline of Britain and the emergence of the United States as the world's foremost economic and military power. Canada's relations with Britain remained unchanged; those with the United States became closer. The creation of the Permanent Joint Board on Defence in 1940 was a significant harbinger of that shift. For the first time in its history, Canada coordinated its defense planning with the United States.

Canada's shift in orientation from Britain to the United States did not come all at once and did not progress without hitches. In early 1948, for example, King balked at concluding a free-trade agreement with the Americans. But given Britain's growing economic, political, and military weakness, and the rise of the United States to superpower status, it was inevitable. It posed a major dilemma for Canada, especially in the Cold War era: how to safeguard Canadian sovereignty while integrating Canada more and more into the United States' economic, diplomatic, and military spheres of influence, especially when Canada shared to a considerable degree the U.S. view of the postwar world. One answer was to avoid bilateral arrangements with the Americans where possible and to involve Canada in multilateral organizations such as the United Nations, where U.S. influence would be somewhat diffused. Most informed Canadians welcomed the United Nations, and the Canadian government took a vigorous part in its creation. But King, mindful of his own lifetime battle to remove Canada from the trammels of British imperialism, was dubious of a world to be dominated by the great powers. His advisers, for their part, wanted to find some way for Canada to play a significant role in the world. The government therefore advanced the concept of a status of "middle power"—that is, a state strong economically if not militarily. Members of the United Nations should function appropriately, according to their capacities. The idea in practice meant that Canada should concern itself mainly with economic policy in world affairs and with aid to developing countries.

Similarly sensible was the Canadian decision to use its considerable knowledge of nuclear fission not for military purposes but exclusively for peaceful and economic ones. Canada, in short, wanted—as in 1918—to get back to its original peaceful character and to resume its own development, this time in the world at large. That desire, however, was just a dream in a world increasingly split between East and West, between supporters of democratic capitalism and partisans of communist totalitarianism.

Canada and the Cold War

Although the Cold War was born in Europe, primarily in the failure of the wartime Allies to decide the fate and future of Germany, Canada was involved from the very start when in September 1945 the defecting Soviet cipher clerk Igor Gouzenko revealed extensive Soviet spying operations in Canada and the United States. These revelations, combined with Soviet intransigence at the United Nations and Soviet aggressiveness in central and eastern Europe—particularly the communist coup in Czechoslovakia and the Berlin blockade—convinced Canadian leaders of the malevolent nature of Soviet communism.

As the Cold War intensified, the idea of a regional agreement for the defense of western Europe against Soviet pressure or attack was taken up. Devoted supporters of the United Nations in Canada as elsewhere were dismayed, for they felt that regional agreements militated against the global purposes of the general organization. The Canadian government, nevertheless, supported the United States' proposal for an alliance of North Atlantic powers. Yet Canada insisted that this alliance should not be purely military, but also political and economic. The minister of external affairs, Lester B. Pearson, pressed strongly for the adoption of that principle. It was accepted in Article 2 of the North Atlantic Treaty Organization (NATO) in 1949, sometimes referred to as the "Canadian article." The article, however, has had little notable effect. Whether that is a comment on a Canadian lack of realism or the lack of percipience in others, it remains evidence of the outlook and intent of Canadian foreign policy and of informed Canadian opinion at the time. Canada as a member of NATO also, for the first time in its history, assumed serious peacetime military commitments, maintaining out of its armed forces an infantry brigade and 12 air squadrons and contributing ships to the naval forces of NATO until 1969. Then a change of emphasis in foreign policy led to a reduction, much criticized by its NATO allies, of the Canadian contribution.

The Korean War

Just as NATO was a test of Canada's seriousness in entering world affairs, so, too, was the Korean War of 1950, which also tested Canada's relationship with the United States. When that country decided to assist South Korea in resisting invasion by the forces of North Korea, the question for Canadians was: Was this an endeavour to uphold the peace settlement that had divided Korea at the 38th parallel of latitude, or was it simply part of a U.S. crusade against communism? In the latter, few Canadians had any interest—not even French Canadians, for all their Roman Catholic heritage. The government decided that it was the former, and military and naval contingents from Canada served with the U.S. and UN forces.

More significant was the fact that informed Canadian opinion was already markedly diverging from the opinion of the majority of Americans on the subject of the new communist regime in China and would have approved recognition of it as the government manifestly supported by the Chinese people. But the government, though sympathetic, thought it wise not to challenge U.S. opinion on an issue in which no major Canadian interest was at stake. Most important, from a practical standpoint, was the economic outcome of the Korean War, which ended any possibility of a postwar depression—expected but not experienced from 1945 to 1950—and helped launch Canada on its extraordinary development in the 1950s.

U.S.-Canadian relations. The policy of the Liberal government (in power since 1935), wartime cooperation, and the close interconnections between the two economies had brought the two neighbours into a more intimate relationship than ever before. The United States, with British power and influence ended in Canada, no longer had intermittent designs on that country and had dropped the language of Manifest Destiny. Most Canadians were persuaded that the development of economic relations did not necessarily carry with them political relations that would end in annexation. The two nations, then, accepted and took one another for granted. In that development, however, there were certain dangers. Americans, including the U.S. government, were accused by Canadians of taking Canada for granted in the sense of being unaware of and indifferent to Canadian sentiments and changes. Canadians, in turn, were apt to claim both a special standing with the United States and independence of it. None of this was ultimately of great importance, but two new trends were to prove significant. One was the growth of "continentalism," a special relationship not provided for in the theory of national independence—except perhaps in the joint commissions, such as the Permanent Joint Commission on Boundary Waters and the Ogdensburg Declaration, in which the parties met as legal equals and in which the fundamental assumption was that both, when in agreement, would contribute a proportionate share of their population and wealth to the common undertakings. The second was the unequal rate of economic and technological development, especially after 1950. The United States, leader of the world in industrial capacity and technology, was nearing the limits, subject to strategic reserves, of its natural resources. Canada, within the inner defense orbit of the United States, had many such resources undeveloped and available. The interest of the United States was, therefore, to have assured access to these resources as they were developed, largely with U.S. capital. This, however, tended to keep Canada a primary producer and a country of relatively low employment and low income. Its national development and its hope of educational and cultural development called for the continued growth, un-

The United States and Canadian resources der Canadian law and control, of its secondary industry. Yet its provinces—owners of the natural resources of the country, except for those controlled by the Northwest Territories—were driven by the need to secure revenue and to satisfy the popular demand for development, and thus were eager to alienate their resources to foreign, usually U.S., investors. This disparity of aim made U.S.-Canadian relations, if much better diplomatically than in the days of territorial expansion and boundary settlements, much more subtle and complicated than ever before. Something of this lay behind Lester Pearson's warnings in the mid-1950s that henceforth those relations would be more difficult. It appeared also in the conclusion of a study prepared in 1965 by Livingstone Merchant, U.S. ambassador to Canada, and A.D.P. Heeney, Canadian ambassador to the United States, that U.S.-Canadian relations could best be handled by "the practice of quiet diplomacy"—that is, with a minimum of public discussion.

A third element of difficulty in U.S.-Canadian relations, which became more apparent in the late 1960s and early 1970s, involved the fact that the main thrust of Canadian policy was to support the United Nations, in which Canada might evade subordination to the great powers. It did so by its peacekeeping efforts (Canadian troops, for instance, served with the United Nations in Egypt after the Suez crisis of 1956) and in cultivating the developing countries and those, such as India, that attempted to play a neutral role between the United States and the Soviet Union in the Cold War. To do this, Canada had the advantage of being at once a materially advanced country and also a small nonimperialistic one. But Canada's special relations with the United States continued and expanded. One notable example of joint action was in the Distant Early Warning System against surprise aerial attack, largely based in the Canadian Arctic. Another was the North American Air Defense Command (Norad) arrangement of 1957 for the defense of North America against aerial and missile attacks, in which elements of the Royal Canadian Air Force were placed under U.S. command. How could Canada be at once an influential, because uncommitted, power to the Third World and an ally, even for limited purposes, of the United States? The opinion increased that it could not, and after the election of Pierre Elliott Trudeau as prime minister in 1968 this attitude began to affect Canadian foreign policy. Canada's contribution to NATO and Norad began to be whittled down in the Defence White Paper of 1970. At the same time, relations with the Soviet Union were improved, and in 1970 diplomatic recognition was extended to the People's Republic of China. Concurrently, however, the stress on aid to developing countries and the idea of Canada as an intermediary with the Third World were played down. The emphasis shifted to more domestic aspects of foreign policy: control of pollution in coastal waters, extension of Canadian fishing rights, and especially to confirming Canadian sovereignty in its Arctic islands and their icebound waters, a concern not much in evidence since the early years of the century. Yet in all these changes the special relationships with the United States remained unchanged, rooted in the facts of neighbourhood and common interest.

Recognition of the People's Republic of China

Canada and the Commonwealth. If the special ties with the United States waxed during these years, the historic ones with Great Britain waned. It cannot be said that this was willed or decided by either party. It was the outcome of the developing circumstances. The traditional ties remained—the common crown; the parliamentary system of government; the desire for much the same kind of world; the same pragmatic, unideological temperament and outlook. Cordial relations between the two governments remained, consultation continued. Canada had, however, achieved the kind of world it wished to inhabit, with the creation of the Commonwealth; Britain, charged with the task of liquidating its empire, began to find the Commonwealth a burden and an embarrassment. Even imperial preference failed of its purpose; Canada exported more to Britain and imported more from the United States, while Britain exported less to Canada. Like relations who have moved apart, each knew it could call on the other at need, but each was going its own way with little to call them together. The British phase of Canadian history, which had begun with the great British immigration of the 1830s, seemed to have ended.

Post-World War II Commonwealth membership policy

The reverse was true for the Commonwealth of Nations during the 1950s and '60s. Canada, as one of the principal creators of the Commonwealth in the early 1930s, had a special if largely sentimental interest in it. But the Commonwealth had consisted of self-governing nations, and, thus, those dependent parts of the British Empire, including India, that were not self-governing, or not wholly so, had not been members of the Commonwealth. With the rapid achievement of independence in most parts of the empire after World War II, a process of which Canadians in general approved, the new nations could choose to leave the empire entirely, or to apply for membership in the Commonwealth. Burma (Myanmar) chose the former course, India the latter. But India had also become a republic in 1947. How could a republic be part of an association bound together by allegiance to a common crown? Suddenly the Commonwealth was seen as an association that might bridge the differences of race and culture in freedom as the empire had done by power. It was agreed among the members of the Commonwealth that republics could be members if they chose to accept the king as "head" of the Commonwealth. Canadians, as members of a republican hemisphere, were perhaps particularly happy to agree, and certainly because the proposal fitted well with their desire to cultivate the widest possible associations, especially with the new and developing nations. Canada, perhaps somewhat smugly, saw a possible role for itself as an intermediary between the old members of the Commonwealth and the new.

Canada's relationship with the Third World

That Canada might, in some sense, play such a part was revealed by the Suez crisis of 1956, a great strain for the Commonwealth as well as for world peace. Australia and New Zealand, for example, were disposed to sympathize with the strategic concern of the United Kingdom, while India was dismayed and angered by what it saw as an act of concerted aggression. Canada, led by Lester Pearson, was able to intervene between a wrathful and humiliated United Kingdom and a righteously angry India, enabling the contestants to save face to some extent and preserve the integrity of the Commonwealth.

The Canadian role of disinterested friend was also played in the crisis in Commonwealth affairs precipitated by the apartheid policy of the Union of South Africa. To a multiracial association such as the Commonwealth, South Africa was not only an anomaly but a reproach. Yet a basic rule of the Commonwealth was that of nonintervention in the domestic affairs of members. The issue of South Africa's racial policy came to a head in the Commonwealth Conference of 1960, at which certain members sought to have South Africa expelled. The United Kingdom, Australia, and New Zealand deplored this violation of the rule of nonintervention. Canada again tried to play the role of impartial intermediary, but when that failed, voted for expulsion. In short, Canada's Commonwealth policy was normally that of supporting the nonwhite members, as later in the matter of economic sanctions against the white regime in Rhodesia (now Zimbabwe).

That was a defensible policy, if pursued realistically and for the purposes of mediation, and even if it led to some feeling against Canada in the United Kingdom. But in 1961 another issue was to arise at the Commonwealth Conference in Accra, Ghana, that raised some question of the whole future of the Commonwealth: the possible entry of the United Kingdom into the European Common Market. For it to do so would mean, if not the ending, at least the diminution of the imperial preferences, which since 1932 had given the Commonwealth a material as well as a sentimental basis. The Canadian delegates professed to be appalled by the prospect and spoke strongly against it as a betrayal of the Commonwealth. But in view of Canada's favourable economic position in trade with Britain, this attitude seemed to the British selfish and unacceptable. Britain was, in fact, not to join the market until 1973, by which time Canada, then under a Liberal government, chose merely to wish Britain well and to look out for Canadian trade with the market as best it could.

Britain and the Common Market

But Britain's entry meant that the Commonwealth would be less and less a matter of material ties and more and more one of tradition and sentiment.

Ideally, perhaps, Britain might, like France, have sought to bring its Commonwealth partners into some form of economic association with the market, as it was to do with New Zealand and the African and West Indian members, heavily dependent on the British market for the sale of their primary produce. But industrialized members such as Australia and Canada, with their economic ties with the United States, had relatively little such dependency, and the members of the market were firmly opposed to their becoming even associated members. There was no hope of a special relationship in that respect. Canada therefore would have to stand on its own, economically as well as diplomatically.

Franco-Canadian affairs. That Canada was regarded in Europe as being at once on its own and also an economic, if not a military, dependency of the United States was revealed by the course of Franco-Canadian relations in the 1960s. France was, of course, as much as Britain a mother country of Canada. Yet practically nothing to reveal that fact had happened since the cession of New France in 1763. Relations between France and French Canadians had been strained by the Seven Years' War. The British regime was watchful against all but private correspondence. Then the French Revolution, particularly its attack on the Roman Catholic church, caused further friction between France and French Canadians. What influence there was was private and literary. There had been readers of the philosophes in New France, and in Quebec French books and ideas were always sure of at least a small audience. Nothing was done officially and formally, however, until the 1850s, when the Second Empire of Napoleon III, Catholic and expansive, took note of French Canada. Not only did the frigate *La Capricieuse* visit Quebec in 1855 but, in 1859, a French consul general was appointed to Quebec, and a form of diplomatic relations began (and continued thereafter). Little more came of this rapprochement. French Canada's true ties abroad were with Rome, not with Paris.

The "Quiet Revolution"

All this changed a century later, particularly after the "Quiet Revolution" began in the province of Quebec with the election of a Liberal government led by Jean Lesage. All changed because French Quebec had wholly changed.

One result was to alter decisively relations between French Canada and France. The former suddenly found an interest in French history, French ideas, and the place of France and the French language in the world. French Canadian students went to French universities, teachers were exchanged, and some liaison developed between the press of the two countries. All this the Department of External Affairs both noted and welcomed. Canada and France had exchanged ministers in 1928 but as between foreign countries.

A warming of established relations proved to be by no means enough, however, either in Quebec or in France. Perhaps the main object of the Quiet Revolution was to arouse and make flourish French culture and the French spirit in Quebec. To do so was not a matter of diplomacy, as generally practiced, or of commerce, but of cultural affairs, for which Quebec had already set up a government ministry. The urgent spirit of the new Quebec was profoundly dissatisfied with the way Ottawa dealt with such matters in the Canadian embassy in France. Quebec began to establish what might be called quasi-diplomatic relations between France and Quebec and had constitutional grounds for thinking it might do so. The federal government could not make treaties with foreign powers on subjects coming under the jurisdiction of the provinces. Cultural affairs, Quebec claimed, were educational, a provincial matter, and therefore Ottawa could not conclude treaties in cultural matters. It followed that Quebec ought to be free to develop its own cultural relations with France and, indeed, all Francophone countries. The matter was difficult and is of continuing concern in Quebec.

De Gaulle's 1967 visit

The second result arose from the personality of President Charles de Gaulle of France. De Gaulle made it his particular role to restore French prestige in a world dominated by the "Anglo-Saxon" powers after World War II. De Gaulle encouraged the informal and then formal relations between the republic and Quebec. He was the first international statesman (unless one counts the flurry of interest shown by Napoleon III) to recognize Quebec for what it is, an island of French speech and culture in an Anglo-Saxon sea. His interest and that of the new nationalists of Quebec happily coincided. Moreover, de Gaulle had been rebuffed, largely because of U.S. influence, in two attempts to deal with Canada: first, in the attempt to sell French aircraft to Air Canada in 1964, and second, in an attempt to buy uranium from Canada in 1965 without giving assurance that it would not be used for military purposes. De Gaulle therefore saw in Quebec an occasion to raise French prestige in the world, and in Canada a chance to separate that country from what he regarded as American domination. He visited Quebec in the summer of 1967 and received an extraordinarily emotional reception. There, in an apparently calculated move, he took the opportunity to encourage Quebec *separatisme,* and in a speech in Montreal he created a furor by repeating the slogan of the French separatists: "Vive le Québec Libre!" De Gaulle was gently but directly rebuked on the spot by Mayor Jean Drapeau of Montreal, his official host, and firmly by the Canadian government, then under the administration of Lester B. Pearson, and he returned to France in customary grandeur. His *bêtise* (foolishness), however, was possible because there was a separatist movement of growing strength in Quebec.

Domestic developments. In many significant ways, World War II had been a watershed in Canadian history. The role of the federal government as engineer of national economic growth had been considerably strengthened. Yet there were complications and difficulties.

One problem was rooted in the expectations of Canadians for a better postwar world. When close to a million veterans reentered civilian life, they married, began to raise children (this was the start of the "baby boom" in Canada), and went on a buying binge. After all, Canadians had not really been able to enjoy themselves since the start of the Great Depression in 1929. That buying binge put tremendous pressure on Canada's balance of payments with the United States, because much of what Canadians were buying was built in the United States. It also added to inflationary pressures that stimulated industrial unrest, especially in 1945 and 1946. Organized labour had virtually doubled in size during the war; the unions were ready and willing to demonstrate their new strength, with major auto, steel, and transportation strikes.

King retired as prime minister and leader of the Liberal Party in 1948, and the mantle of leadership passed to Louis Stephen Saint Laurent, a Quebec lawyer whom King had brought into the government in 1941. Saint Laurent continued most of the domestic policies of his predecessor but was much more an activist in foreign policy. His time in office coincided with the intensification of the Cold War in the late 1940s, which brought an increase in defense spending. This, and opposition from provincial governments, eventually forced him and his government to curtail plans to expand existing social programs or to introduce such new ones as a national health insurance scheme. Saint Laurent was a popular leader, especially in Quebec, and was aided by a strong cabinet team and an effective civil service. He won major victories in the 1949 and 1953 federal elections, reinforcing the notion that the Liberals were somehow "the government party" destined to govern Canada forever.

Postwar prosperity. In the 20 years after 1950 Canada enjoyed growth and prosperity such as it had never known before. Not only did its old primary industries thrive, but Canada also embarked on a new phase of industrial development. In this, Canada was only moving with the greater industrial powers, especially the United States; the significance lay in it now being able to move in such company. The result was the development of electronic, aeronautic, nuclear, and chemical engineering on a great scale and the transformation of industrial Canada. Much of the growth, however, was also simple enlargement of earlier estab-

New mineral discoveries

lished industry, such as steel production. New sources of minerals were, indeed, part of the boom of the 1950s. Not only Labrador iron but also newly discovered deposits of radium, petroleum, and natural gas gave Canada resources it had theretofore had only in comparatively small supply. Mining investment also provided an excellent example of two matters of primary importance: first, how much the greater part of Canadian economic growth had come to be financed by American capital, largely in the form of direct investment and American ownership of the plant and control of operation, and, second, how foreign investment, largely American, aided by the American demand for Canadian materials, made the Canadian boom possible. Investment from abroad was, of course, eagerly sought, especially by the provincial governments, and Canada prospered both because of it and because of the resulting advanced technology and management. Nonetheless, Canadians were of two minds about U.S. investment. Many undoubtedly agreed with Saint Laurent's minister of trade and commerce, Clarence Decatur Howe, that the more U.S. investment in Canada the better. But others were uneasy over the growth of U.S. control over Canadian businesses and over the obvious partnership between Howe and American enterprises. Nowhere was this unease more apparent than in the House of Commons when, in May 1956, Howe tried to ram through a bill to finance a trans-Canada natural gas pipeline scheme, mostly backed by U.S. capital. The opposition created an uproar that politically weakened Howe and Saint Laurent.

Ethnic minorities. Much of the new economic development took place in Canada's northlands and had some part in ending the nomadic hunting life of the forest Indians and the Inuit of the Arctic shores and islands. This contact between the Canadian government and the Indians signaled a new dilemma that Canada faced in trying to deal equitably with its aboriginal peoples. After 1945 it was apparent that the old system for administering Indian affairs was not enough and that the system was itself collapsing. The poverty and disease of many reserves were a reproach to Canadian policy and humanity. The health care provided was greatly improved, and in 1959 the Indian Act was amended to increase opportunities for Indian influence on decisions affecting them. The métis, equal to whites according to the law, while in fact often treated as status-Indians, played an important part in the growing protest. The federal government took note by granting the franchise to all Indians in 1960, and several provinces followed suit.

Improved Indian relations

Large-scale immigration after World War II challenged Canada's social structure. First displaced persons, then people leaving war-devastated Europe, and then those coming to share the prosperity of Canada in the 1950s constituted the greatest immigration Canada had known. A majority of the immigrants were from Europe, many from southern Europe, particularly Italy, Greece, and Portugal; and almost all went into industrial cities in the east. As a whole the movement marked a new phase in the development and character of Canadian society. By 1961 the percentage of Canadians of British and Irish descent had fallen to 43.8 and of French descent to 30, while the percentage of persons of other descents had risen to 26.4. Moreover, most newcomers to Quebec chose to speak English and not French and to join the English culture. This stimulated the growing nationalism in Quebec.

Internal politics. The Pipeline Debate of 1956 revealed the malaise that was gripping the Liberal government after 21 uninterrupted years in power. Saint Laurent, though still personally popular, appeared to be old and tired. It was widely believed that he was losing his grip on the reins of government. Howe's actions during the Pipeline Debate, many felt, were an indication that he and other Liberal leaders had truly come to believe in their divine right to govern. The time was right for a new and dynamic Conservative leader, John George Diefenbaker, to end the decades of Liberal rule. A powerful orator, Diefenbaker challenged Canadians to open up the north, diversify their international trade, and end corrupt Liberal rule. In 1957 he was elected with a minority government, and the following year he won the largest parliamentary majority in Canadian history up to that time. During Diefenbaker's term of office, however, there was a major recession. He had to face the strains of an unsuccessful British attempt to enter the European Economic Community (Common Market); of relations with the United States during its Cuban missile crisis, in which Canada was not consulted and yet was expected to take part in the air defense of North America; and of a domestic struggle over the installation of nuclear warheads in Canada and their use by the Canadian NATO contingent. Internal dissension brought the Diefenbaker government down to a minority government in 1962 and to defeat in 1963. The Liberal government that followed was led by Lester B. Pearson, who had been chosen party leader following the 1957 election. Pearson included many talented men and women in his Cabinet, but many of them were also inexperienced. He initially set out to launch "one hundred days of decision," but he was stopped short when his finance minister, Walter Gordon, was forced to withdraw from his first budget controversial proposals to reduce U.S. investment in Canada. This and other blunders and scandals seemed to dog Pearson during his entire five years in office. Nevertheless, though he never achieved a majority government (he sought just that in a federal election in 1965), his government was one of the most productive in Canadian history. Under Pearson, Canada gained a national flag, a national social security system (the Canada Pension Plan), and a national health insurance program and granted federal public servants the right to free collective bargaining. While accomplishing all this, however, Pearson was also hampered by the rise of nationalism and separatism in Quebec, and he announced his retirement in 1967, to be succeeded in 1968 by Pierre Elliot Trudeau.

The Diefenbaker government

The origins of French separatism. The cause of the movement for a special status for Quebec within confederation, or a new form of association on the basis of equality with English Canada, or complete independence as a sovereign nation, was the belief, shared by a growing number of Quebec intellectuals and labour leaders, that the economic difficulties of Quebec were caused by confederation and could only be ended by altering, or ending, the ties with other provinces and the central government. In part it was the outcome of the perennial desire of Québécois to have their own state, as in a sense they had from 1791 to 1841. In part it was a continuation of the minority of French Canadian opinion that had opposed confederation in 1867. It was also a continuation of that sense of minority grievance stimulated by the execution of Riel, given substance by the Manitoba Schools Question, and given voice in the nationalism of Jules-Paul Tardivel and Henri Bourassa.

Origins of French nationalism

Yet French Canadian nationalism was also the outcome of profound economic and social changes that had taken place in Quebec since about 1890. Until that time French Canadians had lived by agriculture and seasonal work in the timber trade. The middle-class French of Quebec and Montreal acted as intermediary between their humbler countrymen and the English masters of commerce and industry. The coming of hydroelectric power and the woodpulp industry as a result of the successful national policy of protection in creating Canadian manufacturing plants in Quebec and Ontario created a labour force that brought French Canadians as workers into the cities, particularly Montreal. The rate of growth of the French Canadian population and the lack of good workable land outside the narrow St. Lawrence and Richelieu valleys contributed to the rush to low-paying jobs in urban industries and to the growth of slums, particularly in Montreal. By 1921 Quebec was the most urbanized and industrialized of all Canadian provinces, including Ontario, which remained, however, the most populous and the wealthiest. The Quebec government, devoted to the 19th-century policy of laissez-faire, recklessly encouraged industry and did little to check its worst excesses. With few exceptions the new enterprises were owned and directed, in the English language, by English Canadians or by U.S. businesses. It was a kind of second conquest of Quebec.

At the same time it destroyed the myths by which French Canada had survived: that of the Roman Catholic mission to the New World, and the cult of agriculture as the basis of virtuous life. Ever more Québécois had to make their way as best they could in quite a different world, in which the old values were mockeries and the obstacles not to be overturned by the old powers of endurance.

This clash of old and new came to a head in the last years of the regime of Premier Maurice Duplessis. A Conservative who became leader of the new Union Nationale Party formed during the Great Depression, he came to power in 1936, was defeated in 1939, but returned in 1944, and remained in office until his death in 1959. Duplessis, after 1944, wielded unequaled power in Quebec. Anglo-Canadians and U.S. big business furnished him the money he needed for political purposes; he in return preserved in the province a free enterprise system that would have done credit to a government before 1850. In the political miasma he created, all possibility of reform, all political integrity, seemed to be stifled.

Yet they were not. The fight against conscription in 1944 lifted Quebec politics out of the rut of place and favour. In 1949 the prolonged and bitter fight of the asbestos workers gave young idealists, one of them Pierre Elliott Trudeau, a chance to combine with labour in a struggle for a free society of balanced interests. Over the decade intellectuals began a searching analysis of Quebec politics and society in modern terms, often French and American as well as English Canadian.

The successors of Duplessis

When Duplessis died, it was a deliverance. Even his successors in office, Paul Sauvé and Antonio Barrette, seemed like reformers and to some degree were. But in the election of 1960 Jean Lesage and the Quebec Liberal Party made themselves the political vehicle of the new outlook and tried to carry out a Quiet Revolution—that is, to bring in much needed reforms before demands became revolutionary. They did much, both to assist the power of the province against the federal government and to transform Quebec society from clerical to secular and from 19th-century laissez-faire to positive, if not socialist, politics. Politically, indeed, they did too much for the taste of the rural areas of Quebec, and the party was defeated by the Union Nationale in 1966.

In the years that followed, the extremes widened in Quebec, and the elements of opinion began to crystallize. The Liberal Party was federalist; it held that the reforms needed in Quebec could be obtained within the federal system. So, at bottom, did the Union Nationale, but, as a mainly conservative party, it had to stress the importance of remaining Québécois and of obtaining greater provincial power. To the left of the traditional parties, however, opinion ranged from a demand for a special status for Quebec to the demand for separation and independence. The truth was that an active minority of Montrealers had passed far beyond the concept of constitutional reform, and in the process, of course, they broke with Trudeau and the Liberals. No social revolution (which, in their opinion, Quebec desperately needed) was possible, they believed, without independence. From their efforts came the Parti Québécois with a platform of secession from confederation. Under René Lévesque, a former Liberal, they won 24 percent of the popular vote in the election of 1970, but the Liberals, by reasons of the antiquated distribution of electoral districts, won 72 seats out of a total of 95. Constitutional reform was to be tried once more.

The growth of terrorism

Still other social revolutionaries, inspired by refugees from Algeria and by the Cuban example, began to practice terrorism. Bombings began in 1963 and continued sporadically. This mode of action most French and English Canadians felt was "un-Canadian," but it illustrated both the social ills of Quebec and the ties of the French intellectuals with the world outside Canada. In October 1970, with the kidnapping of James Cross, of the British consular service, and Pierre Laporte, minister of labour in Quebec, who was murdered, the government of Quebec called in the federal government for help, and the War Measures Act was proclaimed. The usual civil liberties were suspended, some 500 people were arrested, and troops were moved into Quebec. Few convictions followed—except those accused of the murder of Laporte—and public opinion in Canada, including Quebec, which in the majority approved the invocation of the act, began to wonder if the action had been too drastic.

The Trudeau years. *Domestic policies.* Pierre Elliot Trudeau, a member of Lester B. Pearson's Cabinet, moved in to fill the leadership void after Pearson's decline. He was a strong federalist who in 1968 won a decisive victory in Canada and Quebec. Whatever historians of Canada may decide as to the events and character of the years after 1968, it is certain that the political history of those years will be dominated by Trudeau. His government was highly personal. His ideas were clear, precise, and inflexible. His beliefs had the certainty of dogma. Never before had Canada been governed by a prime minister of personal assurance bordering on the arrogant and flavoured by the autocratic.

This influence of one man on the political life of Canada arose from two circumstances. One was the uncertainty introduced into Canadian politics by the rise of separatist feeling in Quebec. The other was the national feeling that Canada as a whole must take its own constitution and remake it to fit the circumstances of the late 20th century. Trudeau seemed superbly equipped to deal with both. He was a strong and convinced federalist, opposed flatly to separatism. He was a constitutional lawyer, acclaimed as an expert in constitutional understanding and reform. At the same time, he was impeccably French, the answer to the need of the Liberal Party for a French leader and to that of Canada for a French champion of the federal union.

Official Languages Act

As such Trudeau was free to complete Pearson's work in providing for a bilingual and bicultural Canada. To do this, his government introduced the Official Languages Bill in 1968 and issued the instructions under the resultant act, supported by all parties, which prepared the way for a bilingual federal civil service and for the encouragement of the French language and culture in Canada. (Similar encouragement was given to other ethnic cultures.) This was the foremost legislation of Trudeau's early years in office and was meant to begin a new relationship between the English and French in Canada.

Trudeau's government was also a government conducted, steered, and delicately attuned by the results of polls. Trudeau's personal aides ignored Canadian history and constitutional conventions; their eyes were fixed on the new political methods of the United States. Out of this personal and pollster government was to come a new constitutional concept, the doctrine of the personal constitutional mandate of the prime minister, a mandate measured by the life of Parliament, which had come only to reflect the image of a presidential prime minister.

Trudeau's special concern to maintain the unity of Canada and the good relations of English and French Canadians became the specialty of the Liberal Party in Quebec, both federal and provincial. Under a new leader, Robert Bourassa, the provincial Liberal Party in 1970 swept back into office. It was strongly committed to maintaining the federal system and to demonstrating the benefits of that system for Quebec. Compared with its electoral success and energetic policy of large investment and rapid economic development, the actions of the Parti Québécois seemed those of a petulant minority. The Bourassa government was at the same time strongly provincial and determined to make Quebec's viewpoint known and, if possible, prevail. Thus when the second of Trudeau's tasks taken over from Pearson, the reform of the constitution, had been, as it seemed, completed in the "Victoria charter" put before a meeting of the federal and provincial governments at Victoria, B.C., in 1971, Bourassa claimed a special position for Quebec. Despite agreement by all the other provinces, Quebec at the last moment withdrew its assent, and the path of constitutional reform was blocked.

At the same time a certain *folie de grandeur* led the province and the city of Montreal into enormous public expenditures. The chief result was that the Olympic Games of 1976 cost about $1.5 billion. Such recklessness augured ill for the federalist party of Quebec.

In grandiose expenditure, however, Quebec did no more than lead the way. The Trudeau government, following a policy of heavy public expenditure initiated by Pearson (and emulated by all the provinces), entered on a program of economic growth based in the first instance on government direction and expenditure. Government revenues (and, usually, deficits) rose to unprecedented proportions of the national income.

The French economy's coming of age

It was during the Trudeau years, however, and sometimes despite the policies of the Trudeau government, that the Canadian economy came of age. Canada continued to be a major supplier of foodstuffs and raw materials to the world during the boom decade of the 1970s, but Canadian secondary industry surpassed the primary industries as employers of people and exporters of products.

The west benefited greatly during the boom years. The products of mines and forests, on which the economy of British Columbia was so dependent, found ready markets at high prices in the United States and the Pacific Rim countries. One of the world's largest ocean coal depots, Roberts Bank, was built near Vancouver to expedite the shipment of British Columbian coal to Japan. Saskatchewan potash and uranium commanded premium prices during these years, and international demand for wheat, beef, and other farm products brought prosperity that matched the inflation-generated increase in land values. No province benefited more than Alberta, however, where escalating world oil prices brought wealth previously unimaginable and a tremendous land and construction boom—along with runaway inflation—in Edmonton and Calgary.

The increase in the price of oil and a rise in the price of natural gas sparked exploration in frontier areas such as the Beaufort Sea and the Arctic Archipelago. Some of this was aided by a variety of federal grant incentive programs and carried out by a joint federally and privately funded consortium, Panarctic Oils Ltd. Fearing that foreign capital would permanently dominate the Canadian oil industry, the Trudeau government created the integrated, crown-owned Petro-Canada in 1975.

In central Canada prosperity kept pace. The Canada–United States Automotive Products Agreement (Autopact), concluded in 1965, finally began to pay dividends as U.S.-owned carmakers began to build new assembly plants in Ontario and Quebec. Soon tens of thousands of new jobs were created in the automobile and the auto parts industry, and Toronto quickly passed Montreal as the financial capital of Canada. Although much of Atlantic Canada was still mired in poverty, it too experienced a taste of prosperity as foreign auto and tire plants began to locate there to take advantage of Autopact.

All of this growth came at a price: inflation. By the mid-1970s the Trudeau government was becoming preoccupied with the fight against rising prices and the wage increases that usually followed. In this it was in step with most of the Western industrialized countries. In 1975 the federal government created the Anti-Inflation Board and imposed wage and price controls for a three-year period. The move had the general support of business but incensed the labour movement, which called for a day of protest—actually a national general strike—in October 1976.

Foreign affairs. In 1970 the Trudeau government issued a major statement defining its foreign policy. Three major aims were presented: preservation of Canada as an independent political entity, maintenance of expanding prosperity, and constructive contribution to human needs.

Relations with China

In 1970–72 Canada reduced the number of its military and civilian personnel and military bases in Europe while remaining within NATO. Canada established diplomatic relations with the People's Republic of China on Oct. 13, 1970; ambassadors were exchanged the following year, and an exchange of consuls and most-favoured-nation trading arrangements were agreed upon in 1973. Canada also sought closer relations with the Soviet Union and the European Economic Community and played a more active role in the United Nations. Canada maintained its commitment to the North American Air Defense Command (Norad), but in 1975 regional responsibility was reorganized to include only Canadian territory within Canada's jurisdiction. In 1981 the Norad agreement was renewed, and its name was changed to North American Aerospace Defense Command.

Protection of Canada's economy led to adjustments in relations with the United States. In 1970 Canada increased the price of petroleum and natural gas sold to the United States, and in 1974 a plan to gradually reduce those sales and end them by 1982 was announced. This action was taken to protect domestic supplies of fossil fuels in the face of increasing prices of imported oil used in the eastern provinces. In 1978 Canada initiated purchases of new airplanes and other military equipment to better defend its borders and fulfill its international commitments.

In accordance with the third aim of its foreign policy—to contribute to human needs—Trudeau's government pursued a policy promoting the international control of nuclear weaponry. In 1972 Canada and the United States signed the Great Lakes Water Quality Agreement to control pollution of the lakes.

In and out of power. By the late 1970s the glamour of the Trudeau regime was wearing off, and the policies his government had pursued were falling into confusion. The bilingual policy was found to have been pushed beyond the brink of tolerance in English Canada and was hastily truncated before even the remodeling of the federal civil service was completed. The assertion of a strong central federal government was shocked by the sudden electoral victory of the Parti Québécois in Quebec provincial elections in November 1976. The grounds of its victory were the corruption and mismanagement of the Bourassa government, but the party was committed to separation, at least in the form known as sovereignty-association. Attempts to amend the constitution had failed, apparently beyond hope of recovery.

Growth of provincial government

The reasons for this slow but powerful reversal of much that a brilliant prime minister had stood for could be found in the enormous expansion of skill and power in provincial governments. There had been a steady widening of provincial jurisdiction (especially in the field of welfare), an expansion of revenues and expenditures, and a growing sense of local importance partly nurtured in the constitutional device of the federal-provincial conference. The provinces for the first time in 1975 spent more of the national product than the federal government did. The federal government had now become less powerful than the provinces acting collectively. These were more and more inclined to act collectively as more and more of them came to have Conservative or opposition governments—9 out of 10 by the fall of 1978.

Although Trudeau had won a solid majority in the 1968 federal election, much of his power base in western Canada, Ontario, and the Atlantic Provinces began to dissolve soon after. His almost constant preoccupation with Quebec and Quebec-related issues, combined with his seeming lack of sympathy with regional concerns, eroded his popularity. He was reelected only with a minority in 1972 and was forced to rely on the social democratic New Democratic Party to govern. Although he was able to refashion a majority in 1974, his victory was as much a result of dissatisfaction with the Conservative opposition as it was an indication of his popularity. In fact, the next five years witnessed a drastic decline in Liberal popularity. Trudeau's wage and price controls alienated organized labour. His advocacy of greater government intervention in the economy alienated business. His constant efforts to impose Ottawa's will on the provincial governments disturbed voters in Atlantic Canada and the west. He waited as long as he could, but in May 1979 the required election was held, and Conservative leader Joe Clark took power with a minority government.

Clark was the youngest Canadian prime minister ever—he was not quite 40 years old when elected. His youthful inexperience showed all too plainly in the months that followed. One of his major policy blunders turned out to be a promise made during the election to move Canada's embassy in Israel from Tel Aviv to Jerusalem. When he undertook to keep that promise after the election, an uproar led by federal bureaucrats and business leaders who feared an Arab boycott of Canada forced him to reverse himself. Perhaps his most serious mistake, however, was his attempt to increase the federal gasoline tax as a means of increasing Ottawa's share of the windfall oil profits that had flowed from the rise in energy prices and of promoting conservation of gasoline. When Clark's budget containing the tax was voted down in December 1979, his government was defeated. In February 1980 Trudeau was reelected with a majority, even though he had contemplated stepping down as Liberal leader after his defeat the previous May. Trudeau quickly consolidated his power and took up where he had left off. His continued opposition to separatism was evident when he took an active part in the May 1980 referendum in Quebec called by the Parti Québécois government in an effort to secure a provincial mandate to negotiate sovereignty-association—a watered-down form of independence—with the rest of Canada. That intervention helped tilt the balance against the pro-separatism forces.

The Canada Act

Following the referendum, the Trudeau government renewed its efforts to secure for Canada possession of and authority over its own constitution. The issue centred on the Constitution Act of 1867, which could be amended only by the British Parliament on Canada's behalf. The issue was complicated by the need to adopt an amending process acceptable to the federal government as well as to the 10 provinces. On Dec. 2, 1981, an amending process and a bill of rights (Charter of Rights and Freedoms) were accepted by all except Quebec. Nevertheless, the British Parliament approved the resolution on March 25, 1982; and Queen Elizabeth II on April 17, 1982, issued a proclamation making Canada fully independent and designating Canada's constitutional document the Canada Act. Canada retained its status as a member of the Commonwealth. Quebec, however, would not accept the new document without wording that would give that province a special status on the basis of its French heritage.

The patriation of the constitution and the adoption of a charter of rights was a political triumph for Trudeau and the culmination of a career-long campaign to put civil rights and liberties in Canada above the reach of legislatures. Trudeau's economic performance in his last years in power was somewhat less of a success. Canada suffered greatly in the worldwide recession of 1981–82, but the impact was made worse by Ottawa's failure to control its spending and its miscalculation in anticipating that future increases in energy prices would help pay its bills. That expectation was the basis of the National Energy Program (NEP), introduced in the fall of 1980, which was designed to speed up the "Canadianization" of the energy industry and vastly increase Ottawa's share of energy revenues. The NEP sparked a war with the energy-producing provinces, especially Alberta, chased private investment capital out of Canada, and drastically reduced exploration for conventional oil and gas. When oil prices declined, NEP policies made the recession even deeper in Alberta than virtually anywhere else in Canada.

In 1984 Trudeau resigned and was succeeded as head of the Liberal Party and as prime minister by John Turner. Turner immediately called for elections to be held in September; at that time the Progressive Conservative Party gained a parliamentary majority in a landslide victory. Party leader Brian Mulroney became prime minister. Mulroney's approach to government was, in most respects, very different from that of Trudeau. In federal–provincial relations he sought to avoid the bitterness and rancour that had marked Trudeau's dealings with the provincial premiers. Accords were negotiated with Newfoundland and Alberta that ended the crisis over federal energy policy and dismantled the NEP. In November 1984 the finance minister, Michael Wilson, announced that the government would adopt a new approach to economic and fiscal matters to encourage private, including foreign, investment, to bring down the national debt, to review social programs, and to sell Crown corporations (*i.e.,* privatization). It was in this last area that the most progress was made.

The government's pledge to reduce the national debt was not fulfilled. No major social programs were ended, and, although some savings in government expenditures were put into effect, the deficit was in fact controlled through major tax increases.

The Meech Lake accord

Two major initiatives marked the government's first period in office: a constitutional agreement with all 10 provinces known as the Meech Lake accord, designed to bring Quebec's agreement to the Canada Act of 1982; and the Canada–U.S. free-trade agreement. The Meech Lake accord was concluded in the spring of 1987, but response for ratification from some of the provinces was slow. Newfoundland's and Manitoba's refusal to ratify the accord by the June 23, 1990, deadline was a severe blow to Mulroney and created a new crisis on the issue of Quebec separatism.

Mulroney was more successful with the free trade agreement. Negotiated with the United States over a period of two years, the agreement was signed by Mulroney and U.S. President Ronald Reagan in January 1988. It easily passed through the U.S. Congress but was the object of bitter debate in Canada. In the federal general election held in the fall of 1988, Liberal opposition leader John Turner accused Mulroney of selling out Canada's birthright and mounted a major assault on the agreement. Free trade was virtually the only issue in that election, which Mulroney won with a reduced mandate but with his majority intact. On Jan. 1, 1989, the free trade agreement went into effect. (W.L.M./D.J.Be.)

ATLANTIC PROVINCES

New Brunswick

A Canadian province located on the eastern seaboard of the North American continent, New Brunswick is Canada's most forested province and also its only officially bilingual one, French and English having equal status. It was one of the four original provinces making up the national confederation in 1867. Together with Nova Scotia and Prince Edward Island, it forms the regional grouping known as the Maritime Provinces. While New Brunswick has contributed heavily to the national life of Canada, it is one of the smaller provinces and has always occupied a lesser role in the national economy. Its beautiful forests, rivers, lakes, and seashore—attractions for tourists, hunters, and sports fishermen—have remained relatively unspoiled. The province has a roughly rectangular shape, about 210 miles (340 kilometres) from north to south and 185 miles (300 kilometres) from east to west, and it has an area of 28,355 square miles (73,440 square kilometres). It is bounded on the west by the U.S. state of Maine, on the north by the province of Quebec, on the east by the Gulf of St. Lawrence and the Northumberland Strait, and on the south by the Bay of Fundy. The latter water bodies are separated by the narrow neck of the Chignecto Isthmus, which joins New Brunswick to Nova Scotia. Chartered by King George III, the province was named after the royal House of Brunswick, and its capital, Fredericton, for King George III's son.

PHYSICAL AND HUMAN GEOGRAPHY

The river system

The land. The land rises abruptly and in some places spectacularly out of the Bay of Fundy in the south and undulates northward in a series of rolling hills and rocky outcroppings. Plains and flatlands are limited to sea-level marshlands in the southeast, river valley floodplains, and low-lying lands adjacent to the beaches of the east coast. There are no true mountains, although ranges of rugged and sometimes steep hills run east–west a few miles above the Fundy coast and in the north-central part of the province, where the highest elevation is Mount Carleton at 2,690 feet (820 metres). This hilly landmass is cut in every direction by an extensive river system. The St. Croix follows the southwestern boundary. The 418-mile- (673-kilometre-) long St. John, with its numerous tributaries, drains the entire northwestern, central, and south-central parts of the province. The high tides of the Bay of Fundy reverse the rapids at the river's mouth at Saint John and raise the level of the lower river for up to 95 miles (150 kilometres) inland. Additionally, a number of lake-size arms branch off the lower St. John on its eastern side, the largest of which is Grand Lake, about 60 miles (100 kilometres) inland. The eastern part of the province is drained by the Restigouche River in the north, the many branches of the Miramichi in the north-central area, and the shorter Petitcodiac in the southeast. Spring flooding has always been common in many of the rivers. The majority of soils are acidic and low in nutrients. Most of the well-drained soils would be classified as podzols or luvisols. Almost all cultivable soils have moderate to severe limitations that restrict the range of crops or require special conservation practices.

Climate. Clearly distinguishable seasons characterize the climate. Winters are snowy and cold, and summers mild and pleasant. The fall is particularly spectacular, with alternating cold nights and sunny warm days turning deciduous foliage into a blaze of colour contrasting against the solid dark greens of the conifers. Temperatures at Fredericton range from an extreme low of −35° F (−37° C) to an extreme high of 99° F (37° C). In January the mean daily temperature is 15° F (−9.2° C), and in July 67° F (19.3° C). Temperatures are more moderate in the southern coastal regions. Normal annual rainfall is 32 inches (825 millimetres), and snowfall averages about 114 inches (2,900 millimetres); annual precipitation amounts to about 43 inches (1,100 millimetres).

Forested hills rising behind a small farm near Waterford, N.B.

Plant and animal life. Forests cover about 90 percent of the province, and coniferous trees commonly found in north temperate climates—such as balsam fir, red and black spruce, pine, and hemlock—constitute the principal growth. Deciduous stands, especially along the river valleys, consist of sugar and red maple, trembling aspen, and yellow and white birch. Wild blueberries and cranberries are found commonly on thin soils, especially in southwestern areas. The forests support substantial herds of white-tailed deer, moose, and small animals, such as porcupines and raccoons. A regulated hunting season occurs in the fall of the year. Several rivers are famous for their Atlantic salmon, while trout, bass, and pickerel also attract sport fishing. Whale watching near the western islands of the Bay of Fundy has become popular. The rivers and coasts lie in the eastern flyway of numerous migrating birds, best seen in early to mid-spring and late summer.

Towns

Settlement patterns. Settlement began on the coastline and rivers, where early settlers followed fishing and agricultural pursuits. Small towns tended to spring up along the river systems, which supported sawmills and general stores. Saint John, an all-season ocean port situated at the mouth of the St. John River, has been the largest city from earliest times. Moncton in the southeast emerged in the late 19th century as a railroad and distribution centre. Fredericton, the capital and an administrative, educational, and commercial city, is near the geographic centre of the province. Bathurst, Campbellton, and Edmundston in the north are small bilingual cities with French-speaking majorities, all developed on the basis of the pulp and paper industry. In the 1950s the Canadian Armed Forces established Base Gagetown, covering several thousand acres between Fredericton and Saint John, and they built the modern town of Oromocto for army personnel.

The people. The English-speaking majority consists largely of the descendants of American loyalist, Scottish, Irish, and English settlers of the 18th and 19th centuries, and it is concentrated in the southern and western parts of the province. The French-speaking minority, which has grown to about one-third of the population, consists of the descendants of 17th-century Acadian settlers augmented by French Canadians from Quebec, and it is concentrated in the northern and eastern counties. In addition, the province's first inhabitants, the native Indians, remain in small numbers on federally administered reserves along the east coast or in the St. John valley, or they have been assimilated into neighbouring communities. A handful of blacks are largely descendants of loyalist slaves. In the 20th century, small contingents of eastern European, Dutch, German, Italian, and South and East Asian immigrants added a multicultural dimension, mostly in the larger urban areas. Roman Catholics outnumber Protestants, who are mostly of the Baptist, United, Anglican, Pentecostal, and Presbyterian denominations.

Out-migration

Population growth was relatively slight in the late 20th century. A steady out-migration of young adults, drawn by the employment opportunities and higher salaries of central Canadian cities, continued to characterize the society. Within the province, cities became the employment centres, although the common practice of commuting from rural homes or from suburban areas prevented significant urban population growth.

The economy. New Brunswick has a resource-based economy based largely on forestry, mining, and fishing. Tourism, agriculture, small-scale manufacturing, and a growing service sector provide balance and diversity. Employment levels, however, are subject to seasonal variation, and the economy remains dependent on federal government programs. Such programs support the provision of economic infrastructure such as in transportation and communication and have contributed substantially to the development of up-to-date amenities and services comparable to those found elsewhere in Canada. Real economic growth tends to be above the regional average, reflecting expansion in mining and electrical power exports.

Agriculture. Only 20 percent of the landmass of the province is suitable for agriculture, and less than 6 percent is actually under cultivation. Small family farms remain the most numerous type among the fewer than 3,600 farms, but their numbers are dwindling and thousands of acres of previously cultivated land are returning to forest. The largest farms specialize in the leading cash crops, dairy products and potatoes, the former concentrated in south-central and southeastern areas and the latter in the upper St. John River valley. Both benefit from large-scale food processing plants in their respective areas. Poultry, cattle, hogs, eggs, maple products, and blueberries represent other significant items. Truck farming is concentrated near the southern cities, such as in the lower St. John valley, where floodplains possess the richest soils. They represent about 2 percent of the provincial landmass. Provincial policy focuses on soil conservation and improved drainage to increase production.

Forestry and fishing. The forest industry is the province's largest, and pulp and paper production represents its largest single component. Several cities and towns, mostly in the north, depend on large pulp and paper mills as their major employers. Sawmills are widespread. The forests supply the material for lumber, plywood, chipboard, fuel, and Christmas trees and provide a wide range of jobs in related fields.

North Atlantic fishing areas

Fishing and fish processing continue to be important in the provincial economy, employing numerous workers in the main fishing areas, including the Bay of Fundy, the Northumberland Strait, and the Gulf of St. Lawrence. Lobster, crab, scallops, herring, cod, mackerel, and a variety of other North Atlantic species make up the bulk of the catch. The industry is a volatile one, subject to seasonal and longer-term shifts in fish stocks, foreign competition, weather conditions, and credit availability; it has thus become highly dependent on government regulation and support. In the late 20th century the development of aquaculture expanded the fisheries with hatcheries producing salmon, trout, mussels, and oysters.

Mining and energy. The discovery in New Brunswick of rich deposits of zinc and potash in the second half of the 20th century elevated the importance of mining in the provincial economy. The northeast, especially around Bathurst, produces zinc, copper, lead, silver, and peat moss. A lead-smelting operation is at Belledune, a port near Bathurst, and potash is found near Sussex. Nationally, the province ranks high in the production of antimony, bismuth, potash, peat, zinc, silver, and lead. Coal, gypsum, and sulfur are also significant.

Industrial development was spurred by the vigorous expansion of electrical power generating capacity by the New Brunswick Electric Power Commission, the provincially owned utility. Hydroelectric developments along the St. John River system were supplemented by coal- and oil-fired steam generating units and by the construction of a nuclear power station at Point Lepreau southwest of Saint John. A power grid links the New Brunswick utility with all the neighbouring provinces and states and permits the export of excess capacity.

Transportation. At Saint John, a modern ocean port and the province's largest industrial centre, oil refining, shipbuilding, and papermaking are major employers. The city's port facilities are able to handle container ships, and they play an important role in exporting Canadian goods, especially in winter months when traffic on the St. Lawrence Seaway is curtailed. Moncton and Saint John remain major transportation and communication centres despite the reduced importance of railroads, and Moncton has emerged as an important regional distribution centre. Regional and national airlines provide regular service to all the larger cities, and a modern bus service links most urban centres. Highway traffic tends to be heavy on routes linking the other Maritime Provinces with Central Canada and the United States.

Administration and social conditions. The provincial government follows the constitutional forms of a Canadian province within the framework of the Canadian constitution. The one-chamber legislature at Fredericton has 58 members, while the executive consists of the premier and a cabinet of about 20 members. The three national political parties are active, but only Liberals and Progressive Conservatives have formed governments; the New Democratic Party established a small foothold in the late 20th century.

Education

Public education is free and includes 12 grades of elementary and high school. The system, unique in Canada, is administered by separate English and French sections of the provincial Department of Education and is assisted by locally elected school boards with limited authority. Teachers negotiate their salaries with the province, which raises and distributes funds to school districts on the basis of equality so that all areas of the province enjoy similar standards. All universities receive public funding. The University of New Brunswick (established in 1785, one of Canada's oldest) operates from its main campus in Fredericton, which it shares with the Roman Catholic St. Thomas University; a second campus is in Saint John. The University of Moncton is French-speaking. Mount Allison University, privately funded in part, is in Sackville. There are several trade and technical schools.

The province has a network of modern hospitals, the largest of which are regional hospitals with specialized facilities and equipment. Hospital and medical care are both publicly funded and are supported by a provincial sales tax. Social services are administered by the provincial government, and the same standards apply provincewide. A provincial housing authority plans and develops projects for low-income families and for the elderly. Health, education, and social welfare programs are all heavily dependent on federal financial support.

Cultural life. Culture is shaped by the predominance of the two largest linguistic groups, English and French. Ethnicity remains a strong determinant of cultural activity in some areas, as in the annual Irish festival held at Newcastle near the Miramichi River, the blessing of the Acadian fishing fleet at Caraquet, and Loyalist Days in Saint John. Summer festivals and fall fairs retain the flavour of the past and the traditions of the province's early settlers. Popular tastes in music include Irish, Scottish, and Acadian folk idioms and their North American "country" derivatives.

Fine arts

The fine arts are distinguished by some outstanding work in painting, choral singing, and creative literature. Saint John artists of the 1930s and '40s, such as Miller Brittain and Jack Humphrey, produced striking social commentaries in their depictions of depression and war, while painters at Mount Allison University led the way in the 1960s in the development of a widely recognized regional group of magic realists. Regional and provincial music festivals encourage music performance among youth. Fredericton maintains its claim to be the poet's corner of Canada with the publication of the literary magazine *The Fiddlehead* and the work of Fred Cogswell and others, carrying on a tradition first established in the late 19th and early 20th centuries by Bliss Carman and Sir Charles Roberts, arguably the founders of Canada's first school of poetry. Antonine Maillet, Acadian novelist and playwright from Bouctouche, achieved international recognition for her writing in French, which strikingly reveals the 17th-century idiom and structure of the language as spoken by today's Acadians.

Several institutions provide leadership in the arts. Theatre New Brunswick and the University of Moncton promote drama. The Beaverbrook Art Gallery in Fredericton houses an excellent small collection of British paintings of the past three centuries, and in several towns there are other public and private galleries featuring mostly regional work. The New Brunswick Museum in Saint John, the oldest in Canada, contains archival treasures from the province's past, while two historic reconstructions—King's Landing Historical Settlement near Fredericton and Acadian Village near Caraquet—depict rural life of the past century. Such historic sites as Fort Beauséjour National Historic Park near Sackville remind visitors of the Indian, French, and British roots of the province. A provincial agency fosters cultural activity. Scholars rely on university libraries, the archives of the New Brunswick Museum, the Provincial Archives in Fredericton, and the centre for Acadian studies at the University of Moncton. Municipal libraries are widespread.

Recreation

Recreational activities fall into two groups, winter and summer, with greater emphasis on the former. Skiing, hockey, and curling dominate in winter. Summer recreation focuses naturally on water: Boating, fishing, and swimming flourish in a province that abounds with lakes, rivers, and accessible seashore, including miles of clean sandy beaches along the east coast. Golf, tennis, and hunting are also popular, while two national parks—Fundy on the rugged coast of the Bay of Fundy (featuring the world's highest tides) and Kouchibouguac on the Northumberland Strait—and several provincial parks provide camping, bird-watching, hiking, and other outdoor pursuits.

Several major daily newspapers circulate in the province. Among the leading English-language dailies are the *Telegraph-Journal* and *Evening Times-Globe* (Saint John), the *Gleaner* (Fredericton), and the *Times-Transcript* (Moncton). The main French-language daily is *L'Acadie Nouvelle* (Caraquet). Television broadcasting derives from three main sources, the Canadian Broadcasting Corporation (CBC), CTV Television Network, and Radio-Québec. Cable and pay TV are also available. French- and English-language radio stations broadcast throughout the province.

HISTORY

The French were the first Europeans to lay claim to the province, part of a larger region that they called Acadia (French: Acadie), which was inhabited by Algonquian-speaking Indians of the Micmac, Malecite (Maliseet), and Passamaquoddy tribes. The British took over in 1713, expelled or dispersed most of the French-speaking Acadian settlers in 1755 (many of whom eventually returned), and governed the area as Nova Scotia until 1784, when New Brunswick was established as a separate province with its present boundaries.

St. John River valley settlement

The first English-speaking settlers, from New England, moved into the St. John River valley and founded the town of Maugerville in 1762. But it was the influx of some 14,000 loyalist refugees from the American Revolution, mostly from New York and its vicinity, that created the pressure for separate provincehood. The loyalist city of Saint John became Canada's first incorporated city in 1785, and smaller settlements were established in the St. John and St. Croix valleys.

After early problems of adjustment the loyalist communities of New Brunswick began to prosper. Underlying the improved economy was the British decision in 1808 to grant preferential tariffs to the timber resources of its North American colonies, a move made when Napoleon's blockade cut off the Baltic supply of shipbuilding materials to the British. For New Brunswick, with its limited agricultural lands but widespread forests, this historical incident provided an opportunity that helped usher in the so-called age of wood, wind, and water, an era of prosperity based on timber exports and shipbuilding. A Reciprocity Treaty with the United States in 1854 and the demand created by the U.S. Civil War further stimulated trade.

Politically, the province moved slowly toward a more democratic system. Government in the first generation was dominated by a loyalist elite supported by British imperial authority. Responsible home government was granted by Britain in 1848. Political parties emerged in the 1850s, organized largely along ethnic lines and prompted by the prohibition issue. With its economic success and political independence, New Brunswick entered confederation with Canada in 1867 only reluctantly.

Confederation, however, coincided with the collapse of the age of wooden ships, and New Brunswickers found themselves scrambling over the next 100 years to rebuild their economy on a new foundation. Railroads and national tariffs helped in the development of manufacturing, such as in cotton textiles, but the province suffered from the pull of the urban growth areas of Quebec and Ontario. By the 20th century, New Brunswick required federally subsidized freight rates, and it argued, along with other Maritime Provinces, for federal financial assistance, which, after the mid-1900s, it obtained.

Liberal program of the 1960s

Meanwhile, a modern party system emerged in which, until the 1970s, the old elements of ethnicity and religion continued to be significant. Liberals and Progressive Conservatives alternated in government at fairly regular intervals. In the 1960s, a Liberal equal opportunity program revolutionized the delivery of health, justice, education, and social services by abolishing counties as administrative units and by centralizing funding and administration at the provincial level. Unique in Canada, the system met strong early resistance, but it continued under the subsequent Conservative government and won acceptance, especially in less prosperous rural and northern areas, as a means of equalizing services in all parts of the province.

New Brunswickers think of their province, with its two languages and cultures, as a microcosm of Canada. Moreover, the province's small size and its reliance on federal government transfers tend to promote support for nationalistic approaches on constitutional and political matters. Even in the late 20th century, the province retained qualities of its rural and small-town past.

(W.S.MacNu./S.E.P.)

Newfoundland

The most easterly part of North America, the Canadian province of Newfoundland is composed of the island of Newfoundland and a larger mainland sector, Labrador. It is Canada's newest province, having joined the confederation only in 1949. The island, named the New Found Land by 15th-century explorers, has an area of 43,548 square miles (112,790 square kilometres) and lies athwart the Gulf of St. Lawrence. It is separated from Labrador by the narrow Strait of Belle Isle and from Nova Scotia by Cabot Strait. Labrador, with an area of 113,101 square miles (292,930 square kilometres), is bordered to the west and south by the province of Quebec. Newfoundland's position on the Atlantic gives it strategic importance in transportation and communications. Its capital city, St. John's, for instance, is closer to the coast of Ireland than it is to Winnipeg. Of perhaps greater significance are the great fish stocks inhabiting the Grand Banks to the east and south of the province, which spurred the development of numerous communities stretched along 10,000 miles (16,000 kilometres) of deeply indented, wave-battered seacoast. These fisheries have been the single most important factor in shaping the history and character of the land and its people.

PHYSICAL AND HUMAN GEOGRAPHY

Geologic characteristics

The land. *Relief.* Newfoundland and Labrador must be treated as two separate physiographic regions. The island, roughly triangular in shape, is part of the Appalachian geologic province of North America, in which the landforms run from southwest to northeast and are characterized by continental drift, volcanic action, crustal deformation, ice erosion, and deposition. These forces have produced a highly complex geologic structure with Precambrian rocks of ancient Europe and Africa on the east, newer Appalachian rocks on the west, and the bed of the ancient ocean squeezed up between them. On the west coast the land rises abruptly from a narrow coastal plain to a plateau with a maximum height of 2,651 feet (808 metres) that slopes away to the northeastern coast with its many headlands, islands, and bays. The plateau is gently undulating and dotted with thousands of lakes and ponds, numerous streams, and rivers, including the Exploits, Gander, and Humber. The coastal terrain is hilly and rugged. The southern coastal areas have numerous bays, fjords, and offshore islands.

Labrador is geologically part of the Canadian Shield, which comprises some of the world's oldest rocks. Although most of the rocks are Precambrian igneous and metamorphic formations, the Labrador trough, in the west, contains softer sedimentary deposits and includes some of North America's most extensive iron ore deposits. In the far north the Torngat Mountains rise abruptly from the sea to a height of 5,320 feet. The interior is like a giant saucer dotted with lakes and dissected by rivers that break through the eastern saucer rim to discharge into the Labrador Sea. The indented coastline has countless offshore islands, fjords, and coves; exposed and barren headlands; and relatively lush river valleys.

Most of the province shows the effects of continental glaciation during the Pleistocene Epoch. Thus, the material that lies underneath the thin layer of today's soil is generally glacial debris or marine sediments exposed by postglacial uplift. Nevertheless, the watersheds of the larger rivers contain deeper surface deposits that support the growth of excellent forest stands, and the province has pockets of arable mineral soils that support agriculture. Interrupted drainage systems throughout Newfoundland island have created extensive peat bogs.

Temperatures

Climate. In general, Newfoundland has cold but not severe winters and warm to cool summers. The mean July temperature of the coast ranges from 40° F (4.4° C) in northern Labrador to 59° F (15° C) on the island's south coast. In the southern interior the July mean is just above 60° F (16° C). January means in the southern portion of the island are above 20° F (−6.7° C), on the coast of Labrador approximately 10° F (−12.2° C) and 0° F (−17.8° C) in the south and north, respectively, and in interior western Labrador about −15° F (−26° C). Extreme low temperatures in southern Newfoundland rarely reach 0° F, but in western Labrador readings below −40° F (−40° C) are not uncommon. The annual precipitation varies from 55 inches (1,397 millimetres) in the southern parts of the island to about 17 inches (432 millimetres) at Cape Chidley. In the northern regions, as much as half of the annual precipitation occurs as snow. In the south, the snowfall usually accounts for only 20 percent of the total precipitation.

Mid-latitude storms, moving across Canada and up the Atlantic seaboard, have a pronounced effect on Newfoundland's climate. Warm air drawn in on the southern side of the disturbances contributes to the high precipitation in the southern part of the island. Northeasterly and easterly winds prevailing in advance of each storm blow across the cold Labrador Current, keep coastal summers cool, and impede the coming of spring. Northwesterly winds, following in the wake of each storm, carry in cold Arctic air that forces temperatures even lower than the latitude and marine location would suggest. To the south the cool air of the Labrador Current mixes with the warmer air over the Gulf Stream to produce frequent dense fogs, which are most common over the Grand Banks and along the south and southeast coasts.

Plant and animal life. With the exception of the tundra of northern Labrador and the barren reaches of higher altitudes and of some coastal regions, much of the province is forested. The principal species are conifers, of which balsam fir and black spruce are the most abundant. In most parts of the province, but particularly on the island, conifers are mixed with such deciduous species as the paper and yellow birches and a wide variety of hardwood shrubs. The best stands of forest occur in areas of deep and well-drained soils, while in less-favoured areas much of the forest growth is stunted. In others, repeated fires and subsequent erosion have created barrens that produce a great variety of small woody plants.

The moose is the most plentiful of the large wild animals found on the island, where they outnumber the herds of woodland caribou. In Labrador the case is reversed. Both, however, are outnumbered by herds of harp and hooded seals, who migrate along the coasts of the province. Other species include the black and polar bears, Arctic and red foxes, beaver, lynx, and the range of small fur-bearing animals common to the northern coniferous forests and the tundra of northern Labrador. Whales, now protected, are commonly seen throughout the summer as they feed and disport themselves in coastal waters.

Birdlife

Vast colonies of seabirds, notably murres, Atlantic puffins, northern gannets, petrels, and eider ducks, inhabit the offshore islands and headlands. Several species of gulls and terns are ubiquitous, and substantial breeding populations of black ducks and Canada geese are maintained, together with lesser populations of other ducks. Migratory shore and wading birds frequent the coast seasonally. Upland game birds include ptarmigan, grouse, and snipe, while such birds of prey as the osprey and bald eagle are common.

Settlement patterns. *The Avalon Peninsula.* Newfoundlanders see their province as comprising nine regions, distinct in their natural settings and human imprint. The most densely populated part of the island, the Avalon Peninsula on the southeast coast, contains the capital city, St. John's, the adjacent city of Mount Pearl, a number of smaller towns such as Conception Bay South, Harbour Grace, Carbonear, Trepassey, and Placentia, and a host of small villages typically located at the edge of the sea. These villages offer suitable harbours and such essentials as wood and fresh water, but most particularly afford ready access to near-shore fishing grounds. The neat and brightly painted houses, surrounded by small gardens and meadows, are generally of frame and timber construction, as are the adjacent stores, stages, wharves, and slipways. The helter-skelter arrangement of houses and other domestic buildings and of gardens, meadows, pastures, and woodlands suggests a delightfully picturesque and romantic nonconformity. Only after about 1950 was the idea of town planning introduced.

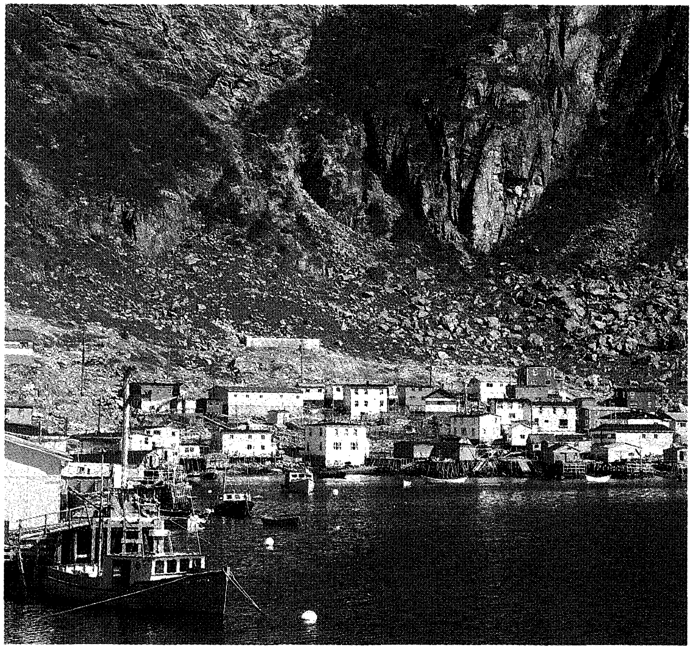
The east and northeast coast. Northward from the Avalon, along the coast rimming Trinity, Bonavista, and Notre Dame bays, the landscape is softened. The headlands and islands are still barren, but in the bays and estuaries the size and variety of the forest cover attest to deeper soils. The rocky shoreline is interrupted by stretches of sandy beach, and the fishing village occasionally is replaced by a farming community. Many islands shield the mainland from the worst effects of the northeasterly winds and create hundreds of miles of virtually landlocked waters. Many old communities such as Fogo, Bonavista, and Twillingate developed in the more exposed locations, where the exigencies of the fishery demanded that they be built. These are being outstripped in growth by the newer towns located in more favourable settings, such as Clarenville, Lewisporte, and Springdale, which have become important distribution centres.

Long Range Mountains

The Great Northern Peninsula. The Great Northern Peninsula stretches northward toward the Labrador coast. On the west, the Long Range Mountains, rising abruptly from a narrow coastal plain dissected by numerous fjords and rivers, offers spectacular scenic attractions. On the eastern slope of the Long Range are stands of commercial forest. Settlements along the coast are somewhat more widely spaced than in other regions. The principal towns include the important fishing centre of Port au Choix and the town of St. Anthony.

The west coast. The west coast region stretches southward from Bonne Bay, at the base of the Great Northern Peninsula, to Cape Ray on the Cabot Strait. The northern section is well forested, while from St. George's Bay to the Codroy Valley is the province's best agricultural land. The principal population centres are Corner Brook, a city based on a large pulp and paper complex, and Stephenville, originally developed in conjunction with a U.S. air base that was later converted into a centre for light industry and also became the site of a pulp and paper mill.

Sherman Hines/Masterfile



François, a fishing village on the rugged south coast of the island of Newfoundland.

The south coast. The most spectacularly rugged section of the island's coastline is probably the south coast, stretching from Cape Ray eastward to Fortune Bay. Here, the land generally rises abruptly from the sea, forming numerous embayments separated by rocky peninsulas. The rivers are short and turbulent, but the head of Bay d'Espoir, the site of a major hydroelectric project, and the rivers and valleys that enter it are well forested. Many small settlements that once dotted the coast have been abandoned, and the population is now centred in fewer but larger communities such as Channel-Port-aux-Basques at the western extreme of the region; it is a major port of entry for mainland Canada.

The Burin Peninsula. Almost all settlement is coastal and directly related to the fishery. The larger towns, Marystown, Burin, Grand Bank, and Fortune, are all major deep-sea-fishing ports and centres for the fresh-fish-processing industry. St. Lawrence produces Canada's total supply of the mineral fluorspar, an important agent in metallurgy.

The island interior. The interior is largely uninhabited. The pulp and paper industry fostered the development of such towns as Grand Falls, Windsor, and Bishop's Falls, while international air traffic made Gander into a major service centre for the whole northeast coast.

Coastal and western Labrador. Labrador is composed of two very different regions. The coast south of the Hamilton Inlet is settled with scattered fishing villages. The area north of the inlet has five permanent settlements with predominantly native Indian and Inuit populations. The largest town is Happy Valley-Goose Bay, which developed around a military airfield. In western Labrador the twin mining towns of Labrador City and Wabush are modern, well-planned, and prosperous; they form the centre of an industry that produces more than one-half of Canada's iron ore. Churchill Falls is the site of one of the world's greatest hydroelectrical developments, supplying power to Quebec and indirectly to the northeastern United States. Game fishing is a major activity.

The people. Considerably less than one-half of 1 percent of the population is aboriginal. A tiny population of Inuit (Eskimo) and North American Innu (Montagnais-Naskapi) occupy four or five villages on the northern coast of Labrador, retaining their original languages and a portion of their ancient cultures. On the island, the indigenous Beothuk are extinct, but a small Micmac community still exists.

Dominance of British peoples

The greater part of Newfoundland's people represent an extraordinarily homogenous group. About 95 percent of them trace their origin to the southwestern counties of England or to the southwestern region of Ireland. A small number trace their ancestry to other English and Irish counties, Scotland, Wales, the Channel Islands, or the coasts of Normandy and Breton in France. More than 98 percent of the people are English-speaking. Historically, social groups have been defined along denominational rather than linguistic or ethnic lines. The three principal denominations are Roman Catholic, Anglican, and United Church of Canada.

From the beginning of settlement, Newfoundland was a staging point for further emigration, and, in the 20th century particularly, there has been a large emigration to the United States and to other parts of Canada. Within the province the trend toward urbanization has been accelerated by government policy to reduce the costs of services by centralizing population. More than half the population is urban, nearly half of which live in the metropolitan areas of St. John's and Corner Brook.

The economy. Newfoundland's economy has traditionally been based on exploitation and export of natural resources. The economy is still resource-oriented although rapidly becoming more complex. Secondary manufacture is growing, and service and communications-related industries have expanded even more rapidly. Historically, the fisheries were Newfoundland's chief industry, and until the early 20th century they were virtually the only industry. The fisheries, although having diminished comparatively as a source of provincial wealth, remain the largest employers of labour and continue to be the main economic base for hundreds of coastal villages and towns. Agriculture is of little significance.

Resources and industry. The mineral resources of the island and of Labrador have become the largest contributor to the gross provincial product. The growth of mineral production has largely arisen from development of the immense iron ore reserves of Labrador, although other minerals, such as copper, lead, zinc, gold, asbestos, and gypsum, are also important. Significant offshore oil and gas deposits are a potential source of wealth. World demand for newsprint and other paper products has encouraged the rapid exploitation of the forests of black spruce, a wood suited to that manufacture.

Energy potential

Newfoundland's power requirements are met chiefly through the capture of its vast hydroelectric resources, particularly those of Labrador. However, the province of Quebec, which lies between these power sources and the markets in the more populous regions of North America, has denied Newfoundland access to transmission routes except under certain stringent conditions. Thus, virtually the entire yield of the vast Churchill Falls development is sold at bargain prices to Quebec and then resold by that province at a profit.

Fisheries and agriculture. Modern technology has changed the nature of the fisheries. For centuries the industry revolved around codfish, caught in inshore waters and salted or dried primarily by small family-run facilities for domestic and international markets. Today, while the inshore fishery, processing chiefly turbot, plaice, and redfish, is still the economic and social backbone of rural Newfoundland, the greatest part of the total catch is processed in large plants located strategically along the coast. Secondary processing is assuming an increasingly important role. Agricultural products, consisting mostly of vegetables, fruits, and livestock, are marketed locally, and most of the foodstuffs consumed must be imported.

Transportation. Until the end of the 19th century, virtually all communication among the coastal settlements was by sea. A narrow-gauge railway was built during the 1880s from St. John's to Channel-Port-aux-Basques along a route that touched the major bays. Subsequently, branch lines were developed to serve population centres and to connect with coastal steamships that carried passengers, freight, and mail to the villages not served by the railway. That railway has been abandoned, and the province now has only a single line that carries freight from Labrador to the Gulf of St. Lawrence. Elsewhere, rail has been replaced by road. A section of the Trans-Canada Highway crosses Newfoundland island more or less following the old rail line, while secondary roads link virtually every settlement on the island. Except for a short section along the Strait of Belle Isle and a gravel highway from Happy Valley-Goose Bay to Esker, most Labrador communities are still without road connections to their neighbours; the construction of landing strips for light aircraft has made possible some regularly scheduled air services. More recently work has been completed on a highway that links Labrador City and Wabush with the road network of Quebec. The island is linked to mainland Canada by ferries operating between Channel-Port-aux-Basques and Argentia on the south coast and North Sydney, N.S. National, international, and regional air service is provided by various lines.

Connections with the mainland

Administration and social conditions. In most ways, administrative organization and social conditions in Newfoundland are typical of those in other Canadian provinces.

Government. Under the terms of union with Canada, Newfoundland is represented in the Canadian Parliament by six senators and seven members of the House of Commons. The provincial government, completely autonomous in those areas reserved to its jurisdiction by the Canadian Constitution, consists of a lieutenant governor representing the crown and a unicameral legislature of 51 members elected by universal suffrage. The government is organized on the British parliamentary model. The executive council, or Cabinet, is chosen from among the elected members of the party representing the majority in the House of Assembly. Between 1949 and 1972 the Liberal Party won every election, with the opposition Progressive Conservative Party unable to win more than a few electoral districts. The Conservatives finally won power in the latter year, supported by a new generation who had not been involved in the great confederation debate and who were disillusioned with Liberal leadership and their policy of resettlement and centralization of many small coastal communities. In the election of 1988 the Liberals were returned to power with a substantial majority of electoral seats, although the Conservatives had won a small majority of the popular vote. The New Democratic Party (NDP) has never been a significant factor in Newfoundland.

Local government was slow to evolve in Newfoundland. Not until 1888 was the first municipal government elected in St. John's, and the next town council was not created until 1938. By the late 20th century, most communities were incorporated as towns or as components of rural district organizations. Elected councils are empowered to levy taxes and, under the aegis of the provincial Department of Municipal Affairs and Housing, are responsible for the management of local concerns.

Education. Newfoundland's educational system is a mixture of state and church activity. Historically, educational services were provided by the churches, which were permitted to retain administrative controls even when the government assumed the major financial burden. The rights thus acquired were enshrined in the provincial constitution, the provincial Department of Education being divided into five denominational divisions. In 1969 the Department of Education was reorganized: school districts were consolidated, school boards were reduced, and denominational services were integrated. The individual denominations, however, continue to maintain their own administrative offices and are responsible for certain functions. Vocational, technical, and trade schools are nondenominational in character and are operated by the provincial government. Founded as Memorial University College in 1925, the Memorial University of Newfoundland, in St. John's, is the province's single university. Nondenominational and managed by an autonomous board of regents, it has become one of Canada's larger universities with professional schools and research programs, some directly related to Newfoundland's physical and sociological environment.

Educational consolidation

Health and welfare. The provincial government administers virtually all health services, which are free to all residents. With few exceptions, members of the medical profession participate in the Medical Care Plan. Newfoundland differs from most other Canadian provinces in that few private agencies exist to provide services to the aged and children and to the variously disadvantaged. Almost all such services are provided by the provincial government. This reflects both the recent development of municipal institutions, the great dispersal of settlement, and the small population of most communities. The police force that serves St. John's is, in theory, responsible for the whole of the province. They are assisted outside St. John's by the Royal Canadian Mounted Police.

The same problems of population distribution and geography also combine to keep the cost of living somewhat higher and wage rates somewhat lower than in other parts of Canada. However, an inherent factor within a standard of living is the somewhat intangible notion of quality of life. Thus a cash income that statistically indicates subsistence below the poverty level might represent a comfortable living to a Newfoundland fisherman owning his own home, fishing equipment, and premises.

Cultural life. The insularity of Newfoundland and the isolation of hundreds of small communities have combined to preserve distinctive cultural characteristics that have long since disappeared in the land of their origin. Thus, a most distinctive feature of Newfoundland is the local speech, which preserves much of the flavour of its West Country origins in 17th-century England. Over several centuries it has been modified only by the influence of the Irish who at one time constituted half the total population. But there is really no such thing as a Newfoundland accent, for there are almost as many dialects as there are bays. The differences between these dialects and "standard English" are not merely in accent but in vocabulary, in sounds, and in syntax.

Folk culture

Though isolation produced distinctive language patterns and usages, it created as well the necessity for local entertainment. This factor, perhaps in combination with the Irish traditions of bards and minstrels, encouraged the development of the art of the storyteller and the preservation and creation of an immense body of folk music and song. Indeed, Newfoundland has been categorized as a living archive of folklore, folktale, and folk song. With a few notable exceptions, Newfoundlanders have not been exceptionally productive in the visual arts. But about 1970 painting and printmaking began to flourish, giving rise to a number of commercial galleries where there had been none. At the same time there was a renaissance of professional theatre, an institution that had nearly succumbed with the advent of television.

A provincial museum and archives in St. John's is maintained under the auspices of the Department of Culture, Recreation, and Youth. Smaller museums and cultural centres are located in other major towns throughout the province. Memorial University also serves as a centre of culture, promoting the arts through a variety of programs.

Recreational activity in Newfoundland is mostly related to the province's abundant and well-preserved natural scenery and wildlife, an endowment that serves both local and tourist interests. The province maintains a generous amount of parkland and preserves, including the magnificent Gros Morne National Park, and its history is reflected in such places as L'Anse Aux Meadows, the only authenticated Viking site in the hemisphere.

Publishing

Publishing was slow developing in Newfoundland. But in recent decades this field has also opened up, based primarily on a resurgence of interest in the local tradition and idiom. St. John's has always been well served by newspapers, although the score or more that appeared during the 19th century and flourished for various periods of time have now been replaced by the daily *Evening Telegram* and two Sunday papers, the *Express* and the *Telegram.* The *Western Star* is published in Corner Brook, and several weeklies serve other smaller communities. Radio broadcasting has been widespread since the 1930s, and the first television station was established on the island in 1955. The two Canadian television networks have stations in St. John's, and cable television is available.

Newfoundland's distinctive culture has begun to recede before the impact of mainstream North American influences, including the increase in the amount of radio and television transmission and the influx of large numbers of professional people. A particular and pressing care is to preserve the distinctive elements of the folk culture as a vital force in the province's life.

HISTORY

The official discoverer of Newfoundland was the Genoese-Venetian navigator Giovanni Caboto, better known to history as John Cabot, who reached the island in 1497 while sailing under the English flag. The Grand Banks doubtless had been known to fishermen earlier, but Cabot's enthusiastic reports opened the way for international rivalries over the region. Early in the 16th century, English, French, Basque, and Portuguese fishermen were contesting for catches; by 1600 England and France were the chief rivals for Newfoundland.

Early restrictions on settlement. Several attempts made at colonization during the 17th century met the hostility of the English fishermen and, after 1634, of the English crown. In 1699 Parliament prohibited settlement of the island except as necessary to maintain the cod fishery. This remained the basic governing directive for Newfoundland for more than 150 years, during which time the island became virtually a private fiefdom ruled by commercial fishing interests.

The rationale for this policy was twofold. First, under the prevailing concepts of international trade, the fishing of the Grand Banks remained a mother-country industry rather than that of a colony, with definite economic advantages accruing to England. Second, the region was looked upon as a "nursery for seamen," a training ground for the crews that were to maintain England's maritime superiority into the distant future. This latter idea also led the French in 1662 to found Placentia on the southeast coast as a base of operations. From Placentia the French destroyed every English settlement on the island in actions that took place in 1696, 1705, and 1708. Treaties in 1713, 1763, and 1783, the latter marking the armistice ending the American Revolution, recognized British sovereignty but granted French fishermen the right to land and dry their catches along portions of the northern and western coasts. This "French shore problem" remained a thorny one for the islanders until 1904.

French raids

During the 17th and 18th centuries the island's population increased despite repressive legislation, the denial of property rights and social services, and a particularly vicious judicial system managed by the captains of fishing vessels. Britain found it necessary to appoint a naval governor in 1729 and to establish a proper judicial system in 1792. Both governor and court remained only for the summer fishing season, however, and not until 1824, with the appointment of a resident governor and council, was a settled colony finally acknowledged.

In 1832 local agitation led to the addition of a popularly elected assembly. In 1855 the island was granted full responsible government after a campaign that reignited a bitter underlying sectarianism. As the hold of the transient fishermen over the island's life weakened toward the end of the 18th century, many of the prosperous fishermen settled in as merchants, and government office-holders increased in number. Large groups of labourers were imported for the cod fishery, 11,000 coming in the peak year of 1814–15 alone. These immigrants, mainly Irish Catholics, continued to stand for the rights of fishermen and servants against the new and largely Protestant middle class, creating a sectarian spirit that persisted in Newfoundland's political life well into the 20th century.

Toward confederation. Between 1864 and 1869, Newfoundland was involved in discussions leading to Canadian confederation. The idea of confederation, however, was rejected at the polls both then and after negotiations were reopened in 1895. New radical social policies were heralded with the formation of the People's Party by Edward Morris in 1907 and the Fishermen's Protective Union by William Coaker in 1908. The political rivalry of Morris and Coaker was submerged in the common efforts of World War I.

For nearly 150 years, rights to the coasts of Labrador, an ill-defined geographic entity, were a hotly debated issue. By 1826, British tribunals had given Newfoundland jurisdiction over the Atlantic face, Canada over the coasts on the Gulf of St. Lawrence. However, the inland boundaries and administration of Labrador were to remain unsettled until 1927, when Newfoundland was awarded the huge inland region in a definition that said that the "coasts" reached to the headwaters of rivers emptying eastward into the Atlantic Ocean.

The depression that afflicted the Western world after 1929 completely overwhelmed Newfoundland's already struggling economy, which had been overtaxed by the war and by the cost of building a transisland railway. In 1934 Newfoundland's government was reformed as a commission appointed by and responsible to the government of the United Kingdom. The commission was finally able to reestablish the colony's finances on a firmer foundation.

Confederation contested

Following World War II a national convention was elected to recommend possible forms of future government to be voted upon by the people. The convention failed, however, to recommend anything beyond a continuation of the existing government or a return to the pre-1934 constitution. The British government, nevertheless, added the confederation question to the ballot. The first of two referenda held in 1948 was inconclusive; the second gave a clear majority to confederation. On March 31, 1949, Newfoundland entered the Canadian Union.

Through the 1950s and '60s Newfoundland underwent changes as modern technology transformed industry and the nature of employment. Family-run operations were replaced by large fisheries and canneries, and a steady migration took place from smaller villages to the industrial towns. Population growth was rapid. Economic recession in the 1970s and '80s affected the province, although the impact of high unemployment was somewhat offset by social programs. The discovery of rich offshore oil and gas fields promised new wealth. (L.H./Ed.)

Nova Scotia

One of the four British colonies federated into the Dominion of Canada in 1867, Nova Scotia comprises the peninsula of Nova Scotia, Cape Breton Island (separated from the mainland to the southwest by the narrow Strait of Canso), and a number of small adjacent islands. The total area is 21,425 square miles (55,490 square kilometres). Along the 17-mile- (27-kilometre-) wide Chignecto Isthmus, which seems to thrust the peninsula into the Atlantic Ocean, runs the province's only land boundary, with New Brunswick to the west. Two arms of the Gulf of St. Lawrence, Northumberland and Cabot straits, separate it, respectively, from Prince Edward Island on the north and Newfoundland on the northeast. To the east lies the Atlantic and to the southwest the Bay of Fundy. Halifax is the capital.

Nova Scotia—with New Brunswick and Prince Edward Island—is one of Canada's Maritime Provinces, and both its past and its present are tied closely to the maritime life of fishing, shipbuilding, and transatlantic shipping. It was the site, in 1605, of the first permanent North American settlement north of Florida, established by the French. Among the legends that pervade the province is that told by the U.S. poet Henry Wadsworth Longfellow in his tale *Evangeline,* an account of the deportation in 1755 of the French inhabitants by a fearful British governor. The province's contemporary life retains some of the feeling of 17th-century Acadie, or Acadia, the Micmac Indian name adopted by the French for the region before Scottish colonists implanted their own name of Nova Scotia.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief, soils, and drainage.* Nova Scotia's five upland regions reach a maximum height of more than 1,700 feet (520 metres) above sea level in the Cape Breton Highlands. The most important lowlands lie along the Bay of Fundy and the Minas Basin, in the southwest and along the Northumberland Strait. Many of the tens of thousands of acres of marshland in the west created by the tremendously high tides of the Bay of Fundy have been turned to agricultural use by dikes, which were begun in the early 18th century by the Acadian French.

Nearly 90 percent of Nova Scotia's landmass is unsuitable for agriculture. Most of the southern peninsula rests upon acidic granite, and a large part of Cape Breton Island is mountainous, forested terrain of acidic and metamorphic rock. Podzolic soil dominates, with some gray wooded soil mainly along the Northumberland Strait. In a few pockets where clastic sedimentary rock, mostly sandstone, underlies the soil—as in the Annapolis Valley, along parts of Northumberland Strait, and at Cobequid Bay—the land supports orchards and field crops.

More than 3,000 lakes and hundreds of short rivers and streams either have been impounded by, or have cut

through, the irregularly high and low landscapes. The best known of the lakes, Bras d'Or on Cape Breton Island, which is saline, is connected to the Atlantic through three short channels. Many intruding heads of land make the lake's 424 square miles a geographic complexity.

Climate. Over its 350-mile length, Nova Scotia has a modified continental climate, comparable to that of northern Europe. Rarely does the temperature exceed 88° F (31° C) or fall below 14° F (−10° C) anywhere in the province. At Halifax International Airport the average July temperature is 65° F (18° C), and the average January temperature is 23° F (−5° C). Yearly precipitation at that station averages about 59 inches (1,500 millimetres), including some 107 inches (272 centimetres) of snow. The southwestern and southern shores of Nova Scotia have both milder and wetter climates than the rest of the province. Rainfall varies from 55 inches (1,400 millimetres) in the south, where fog may occur on as many as 90 days, to 40 inches elsewhere.

Plant and animal life. Forests occupy about 78 percent of the land area. About one-fifth of the woodland is held as crown land. Softwoods are by far the most numerous, led by species of balsam, spruce, hemlock, and pine; birch and maple make up most of the hardwoods. Animal life includes such game species as deer and moose and, among the birds, partridge, pheasant, and duck. Trout and salmon are common freshwater game fish; tuna is a favourite of deep-sea fishermen.

Settlement patterns. Subsistence living on family farms has been characteristic of Nova Scotia agriculture. Along the coasts many families living on marginal land have combined farming with fishing for lobsters and groundfish; in other areas farming and lumbering are often combined. Mixed farming and dairying are carried out in the fertile lands of Guysborough and other eastern counties, as well as on the Chignecto Isthmus and along the Fundy shore. Though apples, grapes, and pears are also found in other sections, the Annapolis Valley orchards, dating back three centuries, are the most productive. More efficient land use and increased mechanization have reduced the number and increased the size of farms while improving production and income. About 6 percent of the people live on farms, and another 40 percent are nonfarm rural dwellers.

In the 19th century, as steamships replaced schooners, the outports dwindled. Coal and steel and textile industries drew workers to Sydney and Halifax, but some smaller towns continued enterprises like boatbuilding, woodworking, and food processing. Internal population movement has been toward the Halifax–Dartmouth area, where there is employment in the shipyards, naval dockyard, construction industries, and assembly plants.

The people. When Europeans arrived in the 16th and 17th centuries, Micmac Indians greeted them. This seminomadic tribe ranged over the Maritime Provinces and into the Gaspé Peninsula and later spread to Newfoundland and New England. Their Algonquian language is reflected in such Nova Scotia place-names as Musquodoboit, Pugwash, and Shubenacadie. Of 14,000 Micmac Indians in Nova Scotia, more than 3,000 live on reservations.

Ethnic components of the population

About one-eighth of Nova Scotia's people are descended from the Acadian French, who were allowed to return from exile after the British took French Canada in 1763. Most of the remaining seven-eighths are descended from settlers from the British Isles, both English and Scottish. Acadian communities are now located around Yarmouth along St. Mary's Bay and on Cape Breton Island. New England planters resettled the Minas Basin after 1755, and British Empire loyalists founded Shelburne in 1783 and helped to populate Halifax. Yorkshiremen settled in Halifax county. Scottish Highlanders tended to settle in the Northumberland Strait counties and Cape Breton Island. Also in the 18th century some Ulstermen, including migrants from New Hampshire, established farms in the Truro and Onslow districts. Later Irish came in family groups by way of Newfoundland and directly from Ireland and settled in and near Halifax. German immigrants in the 1750s founded the seaport of Lunenburg, and others came a century later. Other minorities include small numbers of Dutch, Italians, and Hungarians, who have immigrated since World War II. More significant are the black communities near Halifax and Shelburne, dating from the days of the West Indian slave trade.

English is the only spoken language of more than 90 percent of the people. Few Nova Scotians remain who have French as their only spoken language, but nearly 8 percent of the people are bilingual. More than one-third of the people are Roman Catholics; among the Protestant denominations the United Church of Canada is the largest, followed by Anglicans and Baptists. Since 1960 immigration into Nova Scotia has not been numerically significant, but emigration of both the undertrained and the well-educated has continued.

The economy. Nova Scotia's diversified economy still relies heavily on maritime activities. It embraces some international and many local resource-based manufacturers housed in industrial parks. Essential to industrial development have been such crown corporations as the provincial Industrial Estates Limited and the federal Cape Breton Development Corporation. The federal Atlantic Canada Opportunities Agency assists with incentive grants mainly for small and medium-sized businesses. In addition, federal equalization payments help to compensate the province for above-average unemployment rates and substandard total and per capita incomes. Most of the labour force is employed in service industries.

Farm products

Agriculture and fishing. Farming has focused on dairy products, livestock, poultry and eggs, and fruit. Extensive forestry resources supply large pulp and paper mills, numerous sawmills, and expanding industries in Christmas trees and maple syrup.

The catching, processing, and exporting of fish continue as major Nova Scotian industries. Canada's stock-conservation and surveillance policies in the internationally recognized 200-mile coastal zone ensure that Nova Scotia's fisheries will remain productive. For fishermen from 250 harbours, lobster and cod are the most lucrative catches, but scallops, haddock, and herring are also important. Aquaculture has shown considerable promise.

Industries. Mining is another major industry in Nova Scotia. Coal is the leading mined product, and some 70 percent of the province's energy needs are met through thermal coal. Salt and anhydrite production also meet a wide demand, and the provincial gypsum deposits yield 75 percent of Canada's supply. There are also significant supplies of barite and construction materials, such as sand and gravel. A profitable tin mine has operated in East Kemptville since 1986. Upgraded mills in Sydney and Pictou manufacture selected steel products. Near Sable Island tested reserves offer promise of large quantities of oil and natural gas for export. The continent's first tidal energy project, completed in 1984 near Annapolis Royal, harnesses the tides of the Bay of Fundy to enhance the province's hydroelectric energy output.

More than one million tourists annually stimulate Nova Scotia's economy with cash and jobs generated for about 7 percent of the work force. Also significant for the provincial economy are four Canadian Forces bases: Halifax, Cornwallis, Shearwater, and Greenwood.

Transportation. Shipping remains a major enterprise in Nova Scotia. Point Tupper accommodates the world's largest oil carriers, and Halifax, a railroad terminus and year-round port, has facilities for all types of vessels, including huge container ships. Other transportation needs are served by a network of paved highways, by a rapidly growing trucking industry, which is partly displacing rail service, and by an international airport at Halifax and several smaller airports. Ferries operate between Nova Scotia and ports in New Brunswick, Prince Edward Island, and the U.S. state of Maine.

Branches of government

Administration and social conditions. *Government.* Nova Scotia's governmental structure is similar to that of all Canadian provinces. A lieutenant governor appointed by the federal government serves as representative of the crown. The premier, who is the leader of the party in power in the provincial parliament, selects his cabinet from among his colleagues. The judiciary is federally appointed, while government employees are recruited through a nonpolitical civil service. Provincial income is derived from two virtually equal sources: the federal government and various provincial taxes and fees.

Since confederation there have been two major political parties in Nova Scotia, the dominant Liberals and the Conservatives (now the Progressive Conservatives); the New Democratic Party has had little success.

Education. The nondenominational system of compulsory, free public education, dating from the mid-19th century, consolidated the many rural school districts into fewer, larger, and more efficient districts during the 1970s. Considerable emphasis is placed on commercial and vocational training at the secondary as well as the college level. Dalhousie University (founded 1818) in Halifax is perhaps the best known of the institutions of higher learning, though a number of Roman Catholic and other private institutions offer diversified curricula. Agriculture, social work, and teacher training are among the specialized areas served by specific institutions. St. Francis Xavier University, in Antigonish, has attracted international interest in its adult-education programs.

Health and welfare. In 1969 Nova Scotia joined the federal Medical Care Program. The premium is paid from the province's general revenues, and insured services include all medically necessary procedures. The province provides facilities for mental health, dental care, tuberculosis control, and other public-health services. Nova Scotia's welfare services are similar to those in other provinces, covering old age assistance, allowances for the blind and disabled, social assistance, social development, child welfare and adoptions, and service to unmarried mothers. The Department of Public Welfare operates institutions for mentally retarded children and for delinquent youth and supervises some private institutions.

Cultural life. Its geographic position has kept Nova Scotia somewhat removed from the mainstream of Canadian life, centred in Ontario and Quebec. The improvement of transportation, however, and the growing impact of the nationwide communications media have brought the province closer to the mainstream, enhancing a modern life-style in the province and eroding some features of traditional Nova Scotian life. Nevertheless many areas of the mainland peninsula and of Cape Breton Island retain an unretouched image of the past.

Preservation of traditional cultures

Scottish culture is particularly vigorous in Nova Scotia. Pictou county alone has several bagpipe bands, while St. Francis Xavier University offers courses in Celtic studies, and the Gaelic College in St. Ann's, Cape Breton, fosters piping, singing, dancing, and handicrafts. Clan gatherings take place annually at the Gaelic College to celebrate the Gaelic Mod, a festival of Highland folk arts. Each summer individual and community arts are taught at Tatamagouche, and an Acadian festival is held at Clare. Other popular attractions include the annual Nova Scotia Military Tattoo and the Atlantic Winter Fair.

The Neptune Theatre and the Art Gallery of Nova Scotia are major cultural assets. Halifax is the centre of repertory drama, and the universities have their own theatre productions. Resident and visiting painters work in such south shore communities as Mahone Bay, Lunenburg, and Peggy's Cove. Woodcarving, pottery making, hooking, and weaving are also pursued.

Impressive historic sites include the restored fortress of Louisbourg, Champlain's habitation at Port Royal, and the Halifax citadel. Also of interest are the Breton Highlands National Park and the Alexander Graham Bell National Historic Park and a museum at Baddeck and the Grand Pré memorial in the Annapolis Valley. Provincial parks are under continual development, and accommodations and recreational facilities are increasing.

HISTORY

In the 17th and 18th centuries Nova Scotia experienced instabilities of colonization, struggles for power originating in the rivalries between London and Paris, and migratory and military pressure from the colonies to the south that were to become the United States. The territory passed back and forth between France and England until 1713, when the French, retaining Cape Breton Island and other areas, began construction of the powerful Louisbourg fortress. Halifax was founded in 1749 as a counterbalance and populated with some 4,000 British settlers. In the 1750s the French Acadians, who refused to swear allegiance to the British crown, were expelled.

Offers of free land attracted immigrants from the British Isles and New England; the latter group helped to secure the first elected assembly. By the time of the American Revolution, New Englanders constituted roughly one-half of Nova Scotia's population; though they tried to remain neutral, four delegates attended the Continental Congress in Philadelphia. During the Revolution and after, some 35,000 loyalists immigrated to the province. Meanwhile, Prince Edward Island had split off from Nova Scotia in 1769, and New Brunswick followed in 1784; Cape Breton Island was reunited with Nova Scotia in 1820. In 1848 Nova Scotia became the first British colony to exercise the prerogative of government responsible to the people through their elected representatives. Despite economic and political opposition, confederation with Ontario, Quebec, and New Brunswick was carried out in 1867.

The Prince Edward Island and Nova Scotia split

As a separate British colony, Nova Scotia prospered from its forestry, fisheries, and shipbuilding for the first two-thirds of the 19th century. Under the Reciprocity Treaty of 1854, the north–south flow of commerce and Nova Scotia's normal market and supply source in New England seemed secure. Nova Scotia benefited further from the increased demand for duty-free natural products during the U.S. Civil War. The Canadian tariffs on manufactured goods, the alleged pro-Confederate sentiments of Britain and Canada, and the protectionist pressures of some states in the victorious North led to the nonrenewal of reciprocity in 1866 and the levying of further protective tariffs by both nations. Canada also lost the preferential treatment by Britain previously granted under colonial policy. Railways, meanwhile, were changing continental traffic patterns, and Canada and the U.S became rivals for the east–west inland trade. Canada's tariffs, intended both to protect its own manufactures and to assist in financing its railways from coastal ports to Central Canada, did not assure the province of year-round commerce, because transportation costs to the distant population centres were so high. Nova Scotia's prospects were further set back as iron steamers replaced the wooden sailing vessels that had been the pride and chief industry of the province. The steamers usually bypassed Nova Scotian ports for those in the United States, and even the lucrative trade with the West Indies dwindled. Also, the opening of the western provinces to settlement tended to drain the older regions of some vigorous elements of the population and to deprive them of investment capital and other resources.

By the last decade of the 20th century Nova Scotia's diversified economy and extensive natural resources had the potential to expand business and reduce unemployment. The 1989 Canada–United States free-trade agreement was regarded as a benefit to the province's fisheries and to its shipping and energy sectors, and continuing federal assistance was a vital factor in the maintenance of social and economic programs. There was, at the same time, a general agreement among the political and social institutions that Nova Scotia should continue to advance technologically but with a minimal sacrifice of traditional human values.

Agreement on technological growth

Prince Edward Island

The original Micmac Indian metaphor Abegweit—popularly translated "Cradled on the Waves"—aptly describes the slender crescent of land in the Gulf of St. Lawrence, known since 1799 as Prince Edward Island (P.E.I.). During the French regime (1720–58) it was called Île Saint-Jean, but when the British took over they first Anglicized the name to Saint John's Island, then attempted to call it New Ireland, and finally named it for the Duke of Kent, commander of the British forces in North America. In 1867 Prince Edward Island became the seventh, and smallest, province of Canada. The name of its capital, Charlottetown, commemorates the wife of King George III.

Curving from North Cape to East Point, the island is about 140 miles (225 kilometres) long, ranging from 2 to

40 miles (3 to 65 kilometres) in width. It lies between 46° and 47° N latitude, and 62° and 64° W longitude. On the south the Northumberland Strait separates the island by at least nine miles from the mainland provinces of Nova Scotia and New Brunswick. There are three counties: Prince, Queens, and Kings. The land area is 2,185 square miles (5,660 square kilometres).

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and soils.* Numerous streams, bays, and tidal estuaries indent the irregular coastline. On the north side the bays are generally blocked by dunes, but on the east and south there are good natural harbours. Along the 1,100 miles of shoreline, red sandstone cliffs average about 20 feet (6 metres) in height but occasionally exceed 50 feet (15 metres). Most of the island is within 5 miles of the sea or a tidal inlet, and no spot is more than 10 miles from salt water. Water pollution has not been extensive, but effluents from processing plants, pesticides, erosion, oil leakage, and sedimentation have seriously degraded some water resources.

Bill Brooks/Masterfile

Red sandstone cliffs along the Gulf of St. Lawrence at Cavendish Beach, on the north coast of Prince Edward Island.

The landscape ranges from rolling hills in central Queens county to level stretches in western Prince county. The highest elevation is 466 feet (142 metres) above sea level in Queens county. The soils, classed as podzols, rest on a sandstone base and are low in plant nutrients and high in acidity. On more than half the island, the red, sandy loam is suitable for cultivation.

Highest elevation

Climate and plant and animal life. The province has a relatively mild climate. The average mean temperature is 42° F (6° C), and the mean annual precipitation is 40 inches (1,016 millimetres).

Forests cover two-fifths of the island. The original stands were mainly deciduous, but coniferous trees are now much more common. Besides the native birch, maple, pine, and spruce, foreign species include linden, horse chestnut, black walnut, and European mountain ash. Tall trees line town streets as well as country lanes.

Prior to European settlement, moose and caribou roamed the island, as did black bears up to the early 20th century. Wildcats were exterminated, but foxes and snowshoe hares endured, and the nearly depleted beaver has been reintroduced. Mink, weasels, and muskrats are numerous. The coyote and the prolific skunk are unwelcome invaders. The ruffed grouse is a native bird, but ring-necked pheasants and Hungarian partridges are imports. Canada geese and brant are regular migrants. Cormorants are increasing, while black ducks are diminishing. Island rivers support such fish as trout, perch, and salmon. There is an active wildlife conservation program.

Settlement patterns. Despite its largely rural character, Prince Edward Island is the most densely populated province in Canada. Population growth has been most apparent in the urban areas of Charlottetown and Summerside. The smaller towns, such as Souris, Kensington, and Tignish, have exhibited little change. Family farms are increasing in size but decreasing in numbers. Kings county is the least populated area.

The people. More than three-fourths of the residents are descendants of early settlers from the British Isles: Highland Scots, Englishmen, and both southern and Ulster Irish. Other ancestral strains include several hundred loyalists, who settled after the American Revolution, and about 30 Acadian families, recorded in the census of 1765, who are the progenitors of several thousand present-day French-speaking island residents. Many original settlement patterns can still be traced in place-names and family names. The Acadians mostly live south of Rustico, near Cape Egmont, and west and north of Cascumpeque Bay. Since 1945 a number of Dutch families, as well as a sprinkling of Americans, Belgians, Lebanese, and Germans, have settled in Prince Edward Island.

The Acadians

Roman Catholics make up the largest religious denomination, followed by United Church members, Presbyterians, Anglicans, and Baptists. English is the predominant language of the island; relatively few residents speak only French. Bilingualism is encouraged, however, by an optional French immersion program in the schools, and classroom instruction in French is available.

The economy. A fertile soil and temperate growing season favour agriculture; the island's location makes it a base for lobster, shellfish, and groundfish (cod, hake, flounder, and redfish) operations; and its sandy beaches, warm waters, and other tourist amenities attract hundreds of thousands of summer visitors. Despite the success of these major industries, the provincial economy has lagged appreciably behind national averages for productivity, employment, and per capita income. Limited resources, distance from large markets, high transportation costs, and the nation's highest electric-power rates all hamper industrial enterprise.

During the late 20th century, federal-provincial agreements enabled the province to institute a series of reforms aimed at assisting the people to create viable economic enterprises for themselves. These included full exploitation of agriculture; development of tourist facilities; better use of forest assets; improvement of fisheries; expansion of manufacturing; public investment in housing, health, and welfare services; and the extension of programs of education and training. The reforms resulted in upgraded living standards, but with the growing dependence on government assistance and a strain on provincial resources.

Agriculture and fishing. Agriculture continues to serve as the economic base. The traditional primary crop is potatoes; turnips, hay, and grains are also grown. Dairying is a major industry, and there is some cattle and hog raising. Tobacco is grown in the eastern part of the island, and the raising of fur-bearing animals is pursued in the western part. Private woodlots yield both hardwood and softwood for lumber, pulpwood, and fuel.

Fishermen depend primarily on the lobster catch, but oysters, clams, and scallops are also important. A secondary industry is the harvesting of Irish moss (a seaweed) for its carrageenan, an extract with several commercial uses. Also lucrative are catches of cod, haddock, tuna, and mackerel. Onshore plants process and freeze sea products; several aquaculture enterprises are established.

Irish moss production

Industry. Industrial development is encouraged by the P.E.I. Lending Authority. Shipping frozen fried potatoes, green vegetables, and berries is now a leading business activity. Food processing has evolved from many small local plants into a few large enterprises. More than 600,000 visitors each summer contribute to the island's economy and social life.

Transportation. Transportation problems have always challenged islanders. Cars and trucks having effectively displaced trains as passenger and freight carriers, the Canadian National Railway in 1989 abandoned its rail services on the island. A year earlier a plebiscite favoured the construction of a fixed crossing linking the island and New Brunswick. Regular ferry services between the island and the mainland provinces are maintained, and Canadian Airlines and Air Canada fly daily routes between Charlottetown, Toronto, Montreal, and centres in the Atlantic region. Potatoes, pulpwood, and other products are shipped from ports on the island's south and east coasts.

Administration and social conditions. The provincial government consists of the lieutenant governor and an Executive Council chosen from the 32 members of the Legislative Assembly. The premier heads the ministerial Executive Council, whose responsibilities include education, agriculture, fisheries, tourism, industry, natural resources, and health and welfare.

The province is represented in the federal Parliament by one member from each of four electoral districts: Cardigan, Hillsborough, Malpeque, and Egmont. Four Senate appointments also are allotted to the province.

The Department of Education administers public education from primary grades through senior high school by means of five regional school boards.

Holland College, an institute of applied arts and technology, and the University of Prince Edward Island were both chartered in 1969, replacing two institutions that originated more than a century earlier, Prince of Wales College and St. Dunstan's University. The main campuses are in Charlottetown, but extension courses are offered in other island communities. In 1983 the Atlantic Veterinary College was established within the provincial university.

The Health Services Commission administers the provincial plan for universal medical care. Provincial agencies govern housing and pollution control.

The Charlottetown cultural centre

Cultural life. Charlottetown is the main centre of culture. Both amateur and professional productions are presented at the Confederation Centre of the Arts, which adjoins historic Province House in that city. This complex contains a large auditorium, art gallery and museum, children's theatre, various studios, shops, and a public library.

Other communities benefit from the Prince Edward Island Museum and Heritage Foundation, with its network of regional facilities and cultural programs. The public library system has community branches and a mobile service. Several art galleries and small theatres operate outside Charlottetown. A multicultural festival is presented annually, and there are regional folk festivals, exhibitions, plowing matches, fiddling contests, and highland games. The annual music festival attracts thousands of participants from the schools of the province. The Evangeline district has a reconstructed Acadian Village, a cultural centre, and a museum. Throughout the island such handicrafts as weaving, pottery making, and woodworking are encouraged.

Facilities and programs for sports and recreation are abundant. Every sizable community has an ice-skating rink; and golf courses, baseball and soccer fields, and basketball courts are scattered throughout the island. All major sports are organized into leagues, and island athletes compete in regional and national meets. Harness races are run year-round and culminate in the Gold Cup and Saucer event in August.

HISTORY

Before the European explorations, Micmac Indians from the mainland used the island for fishing, hunting, and some planting in the warmer seasons. Present-day descendants of these Indians subsist mainly on a small island in Malpeque Bay on the north shore.

Legend suggests that John Cabot, the English-sponsored Genoese-Venetian explorer, may have seen the island in 1497, although historians credit its discovery to Jacques Cartier, the French navigator, in June 1534. Claimed for France in 1603 by Samuel de Champlain, the first governor of French Canada, it was not colonized until 1720, when 300 settlers from France established Port la Joie at the entrance to the harbour of Charlottetown. In addition, fishermen and trappers from the French-speaking mainland colony of Acadia established several other small communities on the island. The French regime lasted only 38 years until the British occupied the island in 1758, dispersing more than 3,500 of the settlers.

Awarding of lots to proprietors

The island was formally ceded to Great Britain in 1763, and six years later the colony was separated from Cape Breton and its first governor was appointed. Under British administration the island was surveyed and divided into three counties, each with a township and "royalty," and 67 lots or townships of about 20,000 acres each. In 1767, proprietors, who were expected to promote settlement, were awarded 64 of these lots by ballot, and for the next century absentee-landlord problems beset the colony. Representative government was granted in 1851, and the Land Purchase Act of 1875 ended the controversial land tenure system. By 1900 the population reached 100,000.

In 1864 a conference called to discuss the Maritime Provinces' union prepared the way for the confederation of all the Canadian provinces. This Charlottetown Conference was the forerunner of the Quebec Conference of 1867, which actually resulted in the founding of the Dominion of Canada. Prince Edward Island has thus been known as the "Cradle of Confederation," even though it did not finally join the union until 1873, when forced to do so by severe financial troubles. Resourceful politicians then persuaded the federal government to make concessions that enabled the province to purchase the lands still held by foreign proprietors and resell them to resident farmers; to assume the debt of the island railway; and to obtain assurance of continuous communication with the mainland. Despite these advantages of confederation, the economy of Prince Edward Island remained chronically depressed and dependent on federal assistance through most of the 20th century. (B.O.'G.)

CENTRAL PROVINCES

Ontario

Ontario, the second largest province of Canada in area, occupies the strip of the Canadian mainland lying between Hudson and James bays, on the north, and the St. Lawrence River–Great Lakes chain to the south. Bordered to the east by the province of Quebec and to the west by Manitoba, it covers a total area of 412,581 square miles (1,068,580 square kilometres) and is the most populous Canadian province, representing more than one-third of Canada's total population.

Ontario is also the nation's wealthiest province, having a substantial share of the country's natural resources and its most mature and diversified industrial economy. It is at once Canada's economic pacemaker and a major force in national politics. Some Ontarians call it the "Empire Province," while to those Canadians living outside its boundaries, its preeminent position and the influence of Toronto, the provincial capital, and Ottawa, the national capital, have constituted a not infrequent source of regional resentment.

PHYSICAL AND HUMAN GEOGRAPHY

The forests of the north

The land. *Northern Ontario.* Ontario is composed of two regions of widely different character: northern and southern Ontario. Northern Ontario, as usually defined, lies north of a line drawn from the confluence of the Mattawa and Ottawa rivers southwest to the mouth of the French River on Georgian Bay. Most of the region's 350,000 square miles is part of the ancient Canadian Shield, characteristically marked with a profusion of lakes and rivers, muskeg (bogs), and densely forested, rocky, and rugged terrain. A low plateau, it is generally no more than 1,500 feet (450 metres) above sea level, although it contains the highest point in the province, Ishpatina Ridge, which rises to 2,274 feet (693 metres) west of the Montreal

River. Although the region has always been an obstacle to transportation and communication, its rich mineral deposits, huge forest reserves, and the hydroelectric power potential of its swift rivers have made it a major source of the province's contemporary wealth.

The vegetation is that of the boreal (northern, mountain) forest and includes the black and white spruce, jack pine, tamarack, poplar, white birch, and balsam. The soils of the region, apart from peat, consist largely of brown podzolic (mineral-covered, leached) soils unsuitable for agriculture, except for two clay belts in the Timiskaming and Cochrane farming areas. The region contains parts of two major drainage basins—that of the Great Lakes to the south and of Hudson Bay to the north—separated by a band of higher land running from Lake of the Woods to Kirkland Lake. Major rivers of the northern system are the Severn, the Winisk, and the Albany, while the major rivers in the southern system are the Ottawa and French. Both Hudson Bay and James Bay are bordered by sparsely forested lowlands less than 500 feet above sea level, and, at the northern limit of the province, there is a band of tundra along Hudson Bay.

The climate varies from that of the districts close to the Great Lakes, which are frost-free on more than 100 days a year, to the harsh climate of the Hudson Bay area, where the frost-free period may be as short as 40 days. At Thunder Bay on Lake Superior the mean temperature in January is 5° F (−15° C) and in July 64° F (18° C), the annual precipitation is 28 inches (712 millimetres), and the annual snowfall 84 inches (213 centimetres).

Southern Ontario. Covering less than 10 percent of the area of the province, southern Ontario contains land of gentle relief; its lowest area on the Ottawa River is only 150 feet above sea level, and its highest point—on Blue Mountains south of Georgian Bay—is just over 1,770 feet. The east is divided from the rest of the region by an extension of the Canadian Shield, known as the Frontenac Axis. This crosses the St. Lawrence River east of Kingston and forms the Thousand Islands region. Along the southern edge of the shield lies a series of beautiful lake districts—including the Muskoka Lakes, the lakes of the Haliburton Highlands, and the Rideau chain—which are the province's best-known resort areas. The most dramatic feature of the landscape is the Niagara Escarpment, running from Niagara Falls to the Bruce Peninsula; roads and rail lines pass through its notched valleys, and a nature trail runs along its length. The landforms of southern Ontario were shaped by glacial action, and most of the region consists of gently rolling plains. Both the Ottawa–St. Lawrence lowlands of eastern Ontario and the lands at the western tip of the Ontario Peninsula are, however, quite flat. Glaciers left over most of the region a fertile, gray-brown podzolic soil, although sand plains are also found north of Lake Erie and along the eastern Lake Ontario shore. Rivers of the region are short, draining into the Great Lakes from the Western Ontario Upland and from the Oak Ridge Moraine north of Lake Ontario. Eastern Ontario, however, is drained chiefly by tributaries of the Ottawa River.

The Niagara Escarpment

The original natural vegetation of the area consisted of hardwood forests with great stands of white and red pines on the lighter soils, but during the 19th century land clearing and lumbering removed most of the original forest cover. Since the 1880s, the provincial government has engaged in farm woodlot and reforestation programs.

The climate of the whole region is generally favourable to agriculture, although considerable local variation exists. The eastern section, away from the moderating influence of the lakes, tends to be cooler and more humid than the southern and southwestern zones. Ottawa receives 34 inches of rain and 86 inches of snow yearly, as compared to Toronto's 31 inches of rain and 54 inches of snow. The mean temperature in January for most of the southern region is about 25° F (−4° C), and for July, about 72° F (22° C). The Ottawa valley, however, has means of 13° F (−11° C) and 69° F (21° C).

Pollution. In both regions of the province, industrialization and urbanization have created problems of pollution, the most acute of which are the polluted waters of Lake Erie and the polluted air of the Toronto urban complex. Air and water pollution associated with the mining and pulp and paper industries of the north has also emerged, and increasing concern has been expressed about the presence of mercury in some northern lakes and rivers. The resort region is also endangered because of the high concentration of cottagers.

Settlement patterns. In northern Ontario, settlement has little agricultural base and is largely connected with major industries and transportation routes. Thunder Bay is located at the head of the Great Lakes navigation system and is the transshipment point for western wheat. Sudbury is the centre of a major mining area, as are such communities as Timmins, Kirkland Lake, and Geraldton. Sault Ste. Marie is both an important lake-navigation port and a centre of large steel and paper industries.

Urban growth

Agricultural settlement is more frequent in southern Ontario, where many farms are family-owned. Fields and townships are laid out in a square grid pattern, with roads one mile apart. In areas of French settlement, however, the long, narrow fields typical of French Canadian strip farming may be seen. Villages originally grew up at water-power sites, convenient distribution points, and around early garrison centres. Kingston, the first important town, combined these advantages.

Urban growth has been confined almost entirely to the south-central and southwestern parts of the province, except in Ottawa, the national capital, in the east. The Toronto metropolitan complex—the so-called "Golden Horseshoe"—sprawls along the Lake Ontario shore from Oshawa to St. Catharines and includes the major port and industrial city of Hamilton. Metropolitan Toronto is Canada's largest city, with a hinterland that embraces not only much of the province but a good part of the country. It has a phenomenal rate of growth. Other important urban concentrations in western Ontario include Windsor, London, and Kitchener-Waterloo.

The people. Until the end of the War of 1812, Ontario was peopled chiefly from the United States, by loyalists, frontier farmers, and Quakers and Mennonites from Pennsylvania—the latter forming a nucleus for German settlement in Waterloo County. For the remainder of the 19th century most of the immigrants were Protestants from the British Isles, although both Irish and Scottish Catholics came in large numbers. The first wave of British immigration, between 1815 and 1850, altered the original American character of the province. The second phase of European immigration, from 1896 to 1914, included sizable numbers from Germany, Scandinavia, Russia, Poland, the Ukraine, and Italy. Their arrival coincided with the first great mining discoveries in northern Ontario, and, as a result, the composition of that region's population became much less British in character than the remainder of the province. After World War II, Ontario's immigrants were mainly attracted to the industrial areas of the province, being drawn by the demands of a rapidly expanding economy. Although people from the British Isles still formed the largest single group, they were no longer in the majority, and the cities of Ontario became more cosmopolitan. Roman Catholics have become the largest single religious denomination; they are followed by members of the United Church and Anglicans.

Immigration from Europe

There are no Inuit (Eskimo) indigenous to Ontario, and the small Indian population is almost exclusively rural. Blacks first arrived as slaves to loyalist immigrants and, in the 19th century, as escaped slaves from the southern United States. Immigration continued during the 20th century, especially from Detroit, Mich. The black population is also small and is concentrated largely in Toronto, where most are probably of West Indian origin.

As well as immigration from abroad, Ontario has benefited from population movements within Canada. Approximately one-fourth of the net migration into Ontario came from other parts of the country. After Newfoundland joined the confederation in 1949, Newfoundlanders began to move to Ontario in increasing numbers, and there has been a continuing movement from Nova Scotia and New Brunswick. There are a few hundred thousand French-speaking Canadians living in Ontario, who were drawn from Quebec since the 19th century by the lumber industry and railroads of the north, the farms of the east, and the Cornwall industrial area. Ottawa contains the largest concentration of French Canadians, and there are sizable communities in Windsor, Toronto, and the Niagara Peninsula.

Emigration

Balanced against large-scale immigration is the fact that, as with Canada as a whole, there has long been substantial emigration from the province. As early as the 1850s, Ontarians were attracted by the westward movement in the United States, and outflow to the south has been important ever since. In the 20th century, much concern has been caused by what appears to be a disproportionate loss of professionally and technically skilled people to the United States. Similarly, many thousands of Ontarians have migrated to the Canadian West.

The result of the relationship between immigration and emigration is that natural increase has been the more important cause of population growth. The vital statistics (*i.e.*, the birth rate and death rate) and the rate of population growth for Ontario have been roughly the same as the Canadian rates for most of the 20th century. The provincial population more than doubled in the first half of the 20th century and doubled again during the next 30 years. The province is overwhelmingly urban, with 82 percent of its citizens living in cities and towns.

The economy. Ontario's strategic central location with respect to the Canadian provinces, its proximity to U.S. markets and coal supplies, its cheap power, its large and skilled labour force, its abundant natural resources and diversified transportation system, and its general attractiveness to both domestic and foreign investment, have made its economy the most productive in Canada. As with all mature economies, the bulk of employment and output is concentrated in the manufacturing and service industries, the latter having grown particularly fast in the later 20th century.

Federal economic policy remains the chief agent of control acting upon the private sector, but the provincial government has played an increasingly important role. In 1962 the province was divided into 10 economic regions for planning purposes, and the provincial government stimulated industrial research and development with various programs. Industrial disputes are regulated by the Ontario Labour Relations Board.

Agriculture. Ontario is one of the major agricultural regions of Canada. The most important cash crop is tobacco, but most farms are concerned with dairying or livestock. As a result of this specialization, corn (maize) acreage has expanded, though it is still necessary to import corn from the United States for livestock feed. The Niagara Peninsula and the Holland Marsh north of Toronto are the chief fruit- and vegetable-producing regions, while Kent and Essex counties in southern Ontario are the chief corn- and soybean-producing areas.

Thomas Kitchin/First Light

Mining and forestry. Ontario is Canada's leading mining province. The province mines a large percentage of the world's nickel; this metal alone accounts for more than one-fourth of the total value of metal production. Copper production is the second most important metal, followed by uranium, zinc, gold, iron ore, platinum, and silver.

Although the forest products industry does not rank with agriculture and mining in terms of value of production, it is still one of the most important branches of the industry in Canada. Pulp and paper manufacture and fabricated wood products dominate the industry in Ontario. Commercial fishing was once concentrated in Lake Erie, but heavy pollution in that and other lakes sent the commercial fishing industry into decline. Sport fishing continues to be important for local residents and tourists. The main fish caught include yellow perch, pike, smelt, white bass, whitefish herring, and chub.

Sport fishing

Manufacturing. Ontario is the leading manufacturing province in Canada, employing almost half of the country's workers and generating the same proportion of the total value of production. Historically, this preeminence derived from the milling, farm implement, furniture, and textile industries of the 19th century. The Canadian protective tariff of 1878 encouraged a domestic steel industry at Hamilton and the location of many American branch plants in the province. Other leading industrial products include automobiles, textiles, processed foods, industrial machinery, electrical goods, farm implements, chemicals, rubber and synthetics, aircraft, and furniture.

Ontario and Quebec are Canada's leading provinces for petroleum refining. Conventional thermal power and hydropower together account for more than one-half of Ontario's electrical energy, and nuclear power accounts for the remainder.

Transportation. Bulk cargoes, chiefly consisting of mining and forestry products and prairie grains, are moved to the United States or overseas by the Great Lakes–St. Lawrence waterway system. Seagoing carriers bring imports from abroad by the same route. Toronto's port activity declined after the opening of the St. Lawrence Seaway.

The basic road pattern, laid out in the 1790s, is an east–west highway from the Quebec border to Windsor and a north–south expressway from Toronto. The Ontario section of the Trans-Canada Highway runs for 1,400 miles from Montreal through Ottawa to the Manitoba border. Capital and maintenance costs are high because the region's heavy snowfall and extreme temperature range make constant repairs necessary.

Ontario is crossed by two transcontinental lines and is bisected by one provincially owned railroad with its northern terminus at Moosonee on James Bay. Although there has been a reduction in passenger mileage in southern Ontario due to lack of revenue, this region's rail network—centred on Toronto—is Canada's most elaborate.

Toronto is also the focus for the province's air traffic. Its International Airport is now the country's largest and is a main centre of operations for both domestic and international flights. Other important airports are located at Ottawa, London, Sault Ste. Marie, and Thunder Bay.

Administration and social conditions. *Government.* The provincial government consists of the lieutenant governor, appointed by the governor-general in council, whose functions are purely formal; the Executive Council, or Cabinet; and the elected Legislative Assembly. The province is represented in the federal government by 24 senators and 99 elected members of the House of Commons. Manhood suffrage, except for Indians living on reservations, has been in effect since 1888. Women were given the vote in 1917, and in 1954 Indians were enfranchised.

Rural political domination

Since 1963, urban constituencies elect the majority in the legislature, but rural areas are still overrepresented. The Cabinet is headed by the premier (frequently called prime minister in Ontario) and tends to be dominated by rural interests. Northern Ontario is habitually underrepresented, as is the province's Roman Catholic population.

Ontario has three political parties—the Progressive Conservatives, the Liberals, and the New Democratic Party. The latter, founded in 1961, represents an amalgamation of the Co-operative Commonwealth Federation and sections of the trade-union movement. Stability and one-party dominance, however, have long been the mark of Ontario politics. The changing character of Ontario society has the potential to alter the tradition of one-party rule, but as long as three parties are competing for votes it seems an unlikely possibility.

Municipal government in Ontario consists of elected township and county councils in rural areas and of elected councils in cities and towns. Urban growth, the demand for enhanced services, and the movement of taxpayers to the suburbs promoted the federation of the city of Toronto and its 12 suburbs in 1954. The 13 components retained their existence as political entities, but certain general powers and responsibilities were transferred to a second tier of government. In 1965 the federation was adjusted, subsequently being composed of the city proper and five boroughs with roughly equal populations. These changes brought an efficient centralization of public services, enhanced the borrowing capacity of the municipality, and created a uniform tax system. Similar regional governments were instituted for Ottawa–Carleton in 1969 and for Niagara in 1970.

Education. Education costs have risen sharply because of increased enrollment in elementary and secondary schools and increased assistance to higher education. Undergraduate and graduate schools are rapidly expanding, and several universities, though legally autonomous, receive both operating and capital grants from the Department of University Affairs, which has a measure of control over university planning, intake, and curricula. The province has also established a number of community colleges and colleges of applied arts and technology to provide postsecondary technical education. Major universities, in addition to the University of Toronto, include Queen's University at Kingston, McMaster University at Hamilton, and Carleton University at Ottawa.

Health and welfare. In the field of social legislation, the province has entered into important shared-cost arrangements with the federal government. An Ontario Health Insurance Plan, for example, provides comprehensive medical insurance to all residents and is free for those with no taxable income.

Poverty among Indians, marginal farmers, and city dwellers is of continuing concern, but the proportion of the population on welfare has remained fairly constant at a relatively low level. Real wages have risen steadily and exceed the national average for manufacturing and other industrial personnel. The cost of living, however, is high compared to most of the other provinces, and substantial discrepancies exist between male and female wages, although legislation is now in force against some forms of such wage and job discrimination.

Cost of living

Cultural life. Toronto tends to dominate the province's cultural activities, although its preeminence is by no means exclusive. The first notable school of Canadian painting—that of the Group of Seven—was founded there in the 1920s. The capital city is the centre of Canada's English-language theatre, as well as the headquarters of national radio and television broadcasting. The city supports two symphony orchestras, two choirs, national opera and ballet companies, and many art galleries and museums.

Cultural institutions are also growing in other urban centres. Ottawa has the National Arts Centre, a symphony orchestra, museums, and art galleries. London is developing an artists' colony, while Stratford is already established as a fine dramatic arts centre and site of the annual Stratford Festival. The latter, which opened in 1953 in this pleasant western Ontario town, has had a substantial impact upon the cultural life of the province. There is also an annual George Bernard Shaw Festival at Niagara-on-the-Lake. Upper Canada Village near Morrisburg is a recreation of a 19th-century Ontario community, and Fort Henry at Kingston and Fort George at Niagara-on-the-Lake have been preserved.

HISTORY

The earliest known inhabitants of the Ontario region included the agricultural Huron, Tobacco, and Erie tribes of the south and the hunting groups of the Algonquin, Ojibwa, and Cree of the north. The French explorer Étienne Brûlé was the first known European to travel among them, doing so on an expedition to the Ottawa River in 1610–11. He was shortly followed by Samuel de Champlain and other French explorers, fur traders, and missionaries. The southern tribes were dispersed when the Iroquois destroyed the Jesuit mission at Fort Sainte-Marie in 1648–49, and France established Fort Frontenac (present-day Kingston) in 1673 to begin the military protection of its westward-spreading fur empire. When Canada was ceded to Great Britain in 1763, however, no French colonization had taken place, except for a small farming settlement in the Detroit area.

The Quebec Act of 1774 established Ontario as part of an extended colony ruled from Quebec. During the American Revolution the region was a base for loyalist and Indian attacks upon the American frontier, and in 1784 it was settled by approximately 10,000 loyalists and those of the Iroquois tribes who had fought for the British. The Constitutional Act of 1791 divided Quebec colony into Lower Canada, with a French majority, and the new loyalist province of Upper Canada. Upper Canada received representative government; provision was made for the support of the colonial administration and an established church by substantial land endowments called the Crown and Clergy Reserves.

Early European settlement

John Graves Simcoe, the vigorous first lieutenant governor of Upper Canada, supervised the introduction of English legal and local government practices, laid out the land-granting pattern, supported the construction of trunk roads, and fixed the capital at York (now Toronto). His policy of welcoming massive immigration from the United States was a source of tension between the newcomers and the established anti-U.S. loyalists, a rift that deepened during the War of 1812.

From 1815 to 1841 the province was dominated by a conservative coalition that was known as the "Family Compact" because it was alleged to be an elite tied together by family relationships. The coalition favoured the Anglican church and the Crown and Clergy Reserve system. Reformers demanded responsible government, and in 1837 a radical minority led by William Lyon Mackenzie attempted an unsuccessful revolt.

In 1841 the provinces of Upper and Lower Canada were united, and Upper Canada became known as Canada West. Responsible cabinet government was achieved with the formation of the Robert Baldwin–Louis Hippolyte Lafontaine ministry in 1848, and the present system of municipal government and the province's educational system were created. The 1850s brought the railways, the beginnings of industrialization, and the emergence of Toronto as a commercial rival for Montreal.

Political deadlock and the impetus of the new Ontario economy contributed to the movement for Canadian political union. Canadian federation—achieved in 1867—was brought about in large part by such Ontario politicians as the Conservative John A. Macdonald and the Liberal George Brown. Canada West became the province of Ontario, and the capital was located at Toronto. For a generation Ontario's government was headed by Oliver Mowat, the Liberal premier who won a boundary dispute with Manitoba that doubled the size of Ontario and confirmed the supremacy of provincial governments within their constitutionally assigned powers.

Location of the capital at Toronto

In the 20th century the chief concern of Ontario's governments has been the fostering of economic growth. The province has been transformed into a multicultural society engaged in a highly industrialized economy. With the harnessing of Niagara Falls in 1882, Ontario entered into an energy revolution that also encompasses the power potential of the north, the St. Lawrence River, and uranium-generated thermal power. Since 1914 there have been major discoveries of minerals, as well as expansion of the forest products industry. Tied to the emergence of the northern natural resources, the rise of manufacturing in southern Ontario was spurred by the two world wars to the production of a surplus for export. The provincial government has also been concerned with the growth of services for its burgeoning population. (S.F.W./Ed.)

Quebec

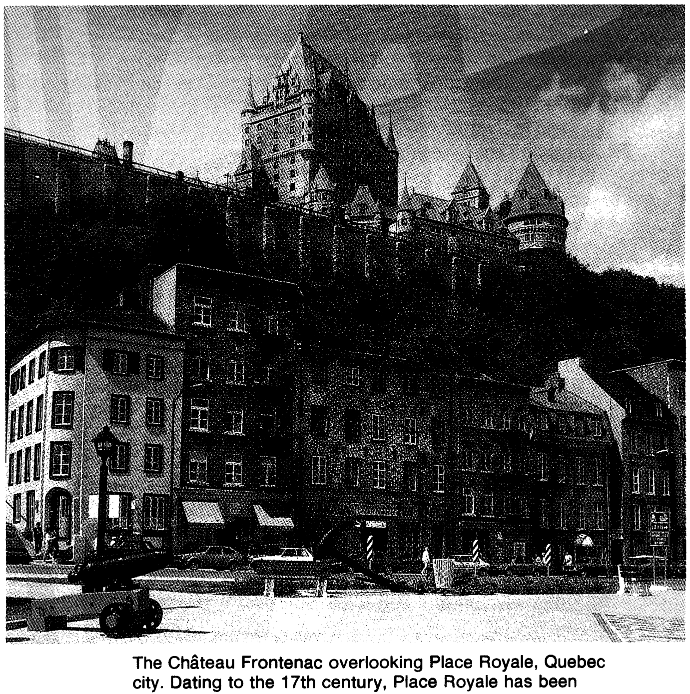
The Province of Quebec (French: Québec), with a total area of 594,860 square miles (1,540,680 square kilometres), is the largest Canadian province in size and is second only to Ontario in population. Its capital, Quebec city, is the oldest city of Canada; and its metropolis, Montreal, is the second largest city in Canada. It is bounded on the north by Hudson Strait and Ungava Bay, on the east by Labrador, on the southeast by the Gulf of St. Lawrence and New Brunswick, on the south by the United States (Maine, New Hampshire, Vermont, and New York), and on the west by Ontario and Hudson Bay.

To understand present-day Quebec, however, one must see the province against a background that goes back to the creation of the French colony in North America during the 16th century. Most observers would agree that the single most important theme in Quebec's history since the British acquisition of New France in 1763 has been the continuous attempt to achieve an accommodation between the numerically dominant French-speaking population and the economically dominant English-speaking one. Whatever changes in geographic size or political institutions have taken place in the province, life in Quebec has always been marked by a collective effort to maintain a distinct French-speaking society. This characteristic in the second half of the 20th century was at the core of debates over the federal structure of all Canada.

Creation of modern Quebec province

The present Province of Quebec was created in 1867, after being the colony of New France for more than two centuries until it was ceded to Britain in 1763. Named the Province of Quebec between 1763 and 1791, it then became the Province of Lower Canada until 1841, and then the District of Canada East until 1867. During these earlier periods its geographic boundaries were changed arbitrarily, and only in the 20th century, with the reacquisition of the northern part of Quebec, did it acquire its present size. Even today, however, there are problems about the eastern boundaries, because no Quebec government has accepted a 1927 decision of the British Privy Council to award Labrador to Newfoundland.

George Hunter



The Château Frontenac overlooking Place Royale, Quebec city. Dating to the 17th century, Place Royale has been largely restored to its appearance during the time of the French regime.

Quebec's size and its boundaries are not the most important influences on its life. The province was profoundly marked by 18th-century wars between France and Britain over their North American territories and by difficulties between the two linguistic groups since 1763, creating tensions that the social, economic, and political institutions of Canada and of Quebec have been unable to resolve. Because only in Quebec, New Brunswick, and at the level of the federal government is French an official language, French Canadians have felt that they are threatened as a minority group in Canada. In the past, control by the English minority in Quebec of most economic activities of the province had generally led to exclusion of the French Canadians from opportunities of economic advancement. In Quebec, where they constitute about 82 percent of the population, they maintain that the situation remains discriminatory.

Although people of goodwill on both sides have tried to find a lasting solution, the economic and social inequalities have created a growing nationalism among French Canadians and a feeling among some of them that only the separation of Quebec from Canada can solve their problems. Events since the late 1960s have shown, however, that neither extreme nationalism nor separatism is accepted by the majority of French speakers who live in Quebec, although there was a resurgence of nationalism in 1990.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Quebec is a sort of "land's end," almost separated from the rest of Canada by Hudson Bay and Hudson Strait. Beginning in the 1960s, provincial maps issued by the Quebec government reflected its long-standing territorial dispute with the federal government by not showing the Labrador boundary, thus including the whole of the North Atlantic coast down to the Gulf of St. Lawrence as part of the province.

The Canadian Shield

Geographic regions. Quebec usually is divided into three major geographic areas that reflect its main geologic structure: the Canadian Shield (also called the Laurentian Shield), the populated plains of the St. Lawrence lowlands, and the Appalachians. The Canadian Shield covers about 80 percent of Quebec, comprising the entire region north of the St. Lawrence lowlands. Beginning at the foothills of the Laurentians (Les Laurentides), the oldest mountain range in the world, it runs northward to the Hudson Strait. The Shield is composed of three main subdivisions: the Laurentians, covered with trees, which have become a natural playground for summer and winter activities; the taiga, a region of stunted trees farther north; and the tundra, in which a continuously frozen ground, or permafrost, allows no trees to grow and where summer enlivens only reindeer moss and a few dwarf birches.

The fertile zone of Quebec and the most densely populated is the plains of the St. Lawrence lowlands, while the Appalachian region is composed of hills and plateaus, more or less undulating and rising to the higher mountain ranges in the United States. This region includes the Eastern Townships (the area south of the St. Lawrence lowlands) and the Gaspé Peninsula.

Climate has been a major factor in determining plant and animal life. The vegetation zone gradually moved northward after the glaciation period. North of the 56th parallel the treeless Arctic tundra is characterized by lichen, mosses, and peat bogs. In it live the polar bear, fox, and Arctic hare. Southward, between the 56th and 52nd parallels, is the taiga, with trees in sheltered areas and herds of caribou that sometimes number in the thousands. South of the 52nd parallel is a forest of spruce, fir, and pine, and in the St. Lawrence and the Ottawa river valleys are forests of maple, ash, beech, and oak. These forests and the rivers and lakes in and around them abound in animal life, including hundreds of bird species, more than 100 freshwater fish species, and numerous sea mammals in the St. Lawrence estuary.

Drainage. The landscape of Quebec is laced with thousands of lakes and rivers, which amount to a freshwater area of some 71,000 square miles. The St. Lawrence, which cuts across southern Quebec from west to east, is one of the world's greatest waterways. Among its tributary rivers are the Ottawa, the Saguenay, the Saint-Maurice, and the Manicouagan.

Climate. Quebec's climate is often extreme, sometimes severe. In Fort-Chimo, on Ungava Bay, the temperature ranges from an average of −11° F (−24° C) in January to 52° F (11° C) in July. In the south in Sherbrooke, it varies from a January average of 14° F (−10° C) to a July average of 68° F (20° C). Temperature changes may be as great as 30° F (17° C) in less than 24 hours. The period in which the snow remains on the ground differs from an average of 12 to 13 weeks on the Montreal plain to 23 weeks on the north coast of the St. Lawrence. The same variations exist for days without frost, Montreal having an average of 140 days without frost, the far north fewer than 80 days.

Patterns of human settlement

Settlement patterns. For all practical purposes, the inhabited part of Quebec is limited to the St. Lawrence lowlands and parts of the Appalachians and the Laurentians. More than 80 percent of its population lives within an area 200 miles long and 60 miles wide, one of the highest concentrations in Canada. About 80 percent of all Québécois live in towns, a very small number are classified as rural farmers, and the balance of the population is scattered in forestry, fishing, mining, and other types of activity in small settlements. The historical movement of the population in Quebec has been from large numbers of scattered, diversified settlements to an increasing concentration in urban areas. The shortage of fertile land suitable for cultivation prevented the development of a truly agricultural economy.

The rural settlements that existed during and after the period of French control were limited to the shores of the St. Lawrence, forming a continuous line between the urban centres of Montreal and Quebec city. Outside of Quebec city, Trois-Rivières, and Montreal, the land was divided into long, narrow, individual strips. A house was built at the end of each of these strips, on the side of the road that led to the towns, thereby forming a type of ribbon development. Rural Quebec had no villages until the end of the 18th century, and most rural parishes were created during the 19th. As each road became fully settled, a parallel road was opened farther inland, a process that was repeated until the whole of the St. Lawrence lowlands was occupied. This system of colonization, in which houses were located equidistantly along a road, allowed for maximum density in settlement, but it was not suitable for agricultural activities.

The very rapid urbanization of the province in the 20th century did not imply, therefore, the breakdown of a traditional peasant society. Although relatively isolated rural and fishing settlements existed on the north coast of the St. Lawrence and mining and foresting settlements in the Laurentians or in northern Quebec, these communities did not create any distinctive "folk" type of society that would have given a dominant cultural orientation to French Canada.

The future of Quebec was for a time linked with the development of the Canadian Shield, which contains one of the world's largest reserves of minerals. The first area to be developed in the 20th century was around the Noranda–Rouyn area, which is noted for copper, zinc, lead, gold, and silver. Continued demand for copper resulted in the opening up of new mines in Chibougamau and in Labrador, where large deposits of iron are located. Outside the shield, copper is mined at Murdochville in Gaspé, while the Eastern Townships supply nearly two-thirds of the Western world's output of asbestos.

Cheap waterpower, abundant raw materials, relatively low labour costs, and dense concentration of population in the St. Lawrence lowlands have been the main factors behind the development of industries in Quebec. The process began with the building of textile mills in the Eastern Townships, but industry gradually was concentrated in the Greater Montreal area.

Because of the present distribution of the population, Quebec can be thought of as divided between Greater Montreal, with more than two-fifths of the population, and the rest of the province. Although there are other fairly large cities in the province, such as Ottawa-Hull, Quebec, Chicoutimi-Jonquière, and Trois-Rivières, this division represents the basic structure of Quebec society. The dichotomy is most evident when outlying areas of Quebec are compared with Montreal. The Gaspé Peninsula is the poorest and least urbanized region; nearly one-fifth of its population earns its living through agriculture, and, in the summer months, tourism becomes the major source of income for the population.

Dichotomy of Quebec society

The people. Because the distribution of the various ethnic groups is the single most important factor in Quebec's social, economic, and political life, past and future trends must be taken into account. In the years of French colonization, from 1608 to 1760, only some 10,000 French came over to settle on the shores of the St. Lawrence. The approximately 60,000 persons who were "ceded" to Britain in 1763 were practically all Canadian-born, and most of them traced their descent through several generations of habitants, the name given to those born in New France.

The high birth rate among habitants explains the growth of French Canada. Between 1700 and 1760, the average yearly rate of birth was between 54 and 62 per 1,000 inhabitants, while the death rate was relatively low for the time: between 24 and 40 per thousand. After 1763, this extremely rapid natural growth of the population continued, and from 1800 to 1850 the total number of French Canadians increased from about 100,000 to 1,000,000.

The very favourable conditions for population growth ceased gradually to operate during the 19th century, however, for the fertile lands around the St. Lawrence were fully occupied, and increasing difficulties were encountered in maintaining satisfactory economic conditions for family life. French Canadians began a migration to the United States and other parts of Canada that between 1840 and 1940 is said to have taken one million persons from Quebec. Although efforts were made to open new rural areas in more northerly Quebec, the harsher conditions of life limited the new settlements. Trends were, in fact, away from rural settlements, and the new industries attracted an ever larger number into the towns. By the beginning of the 20th century, the birth rate had been reduced to about 38 per 1,000, while the death rate still hovered around 20 per 1,000. From then on, both figures declined steadily, especially the death rate. By the late 20th century, both the birth and death rates were slightly less than the national rates.

Other types of demographic changes have also been taking place. Demographers from the University of Montreal, for instance, have identified a long-term decline in the number of French-speaking Québécois, especially in the Montreal area. This trend is contributing to the gulf between Montreal and the rest of Quebec, with the result that most of the linguistic legislation prepared by the Quebec government is increasingly difficult to apply equitably to Montreal and to the rest of the province. Quebec society's rates of divorce, suicide, and illegitimate birth are among the highest in Canada.

American Indian population

The Indian population of Quebec has grown to more than 33,000, distributed among 39 different reserves and Indian communities. Some 5,400 Inuit live in northern Quebec. Inuit and Indian affairs in Canada are under federal jurisdiction, but, with the transfer of certain responsibilities to the province, a Direction Générale of northern Quebec has been created by the Quebec government to provide services for the Inuit population. Since establishment of this department a debate has developed between the federal and provincial governments over the responsibilities of each toward the Inuit.

Another distinctive characteristic of Quebec has been its religious homogeneity. During the period of New France, Roman Catholicism was the official religion. After 1760, freedom of religious practice was authorized by the British government. As the English population grew, so did Protestantism. Following the potato famine in Ireland in the mid-19th century that forced many Irish to migrate to Canada, the number of Roman Catholics in Quebec also increased. Many marriages took place between the Irish and the French Canadians, and today many persons in Quebec who have French as their mother tongue have Irish names. With the coming of such new immigrant groups as the Italians after World Wars I and II, the proportion of Roman Catholics again increased and at one time reached a peak of 88 percent. For a long period, religion was a basic mode of differentiation among the various groups; today this is not so, and it has ceased to be a factor in Quebec's political life. Other ethnic groups in Quebec include eastern Europeans, Portuguese, Greeks, Haitians, and Asians, particularly from Southeast Asia.

The economy. Until after the middle of the 20th century Quebec was considered to be largely an agricultural society, but the occupational concentration is now in industrial and service activities, indicating that Quebec has followed the general trend of industrialization in Canada. Within the major corporations, banks, or branches of multinational companies that operate in Quebec, a number of French-speaking Québécois have achieved high-ranking positions. Promotion, however, has been generally slow even in the nationally owned Canadian National Railway or Air Canada, both of which have their headquarters in Montreal. This problem has been an increasing point of social and political contention in the province.

Resources. Because of continuing difficulties in surveying the land, it is not yet known how extensive Quebec's natural resources are. Considerable mineral deposits are known to exist, however. Between 1910 and 1970, mineral production increased 100 times in gross dollar value (not accounting for inflation). This rather spectacular development was due to the discovery of extremely large iron-ore deposits in northern Quebec. Geologists estimate that these deposits are among the largest in the world. Two new towns were created in the north as a result, Schefferville and Gagnon; and a large port, Sept-Îles, was developed. Quebec also has reaped many economic benefits from the iron-ore fields of neighbouring western Labrador. Much of the ore extracted from the Labrador fields is shipped to nearby Quebec towns for processing. Other important minerals extracted in the province include gold, asbestos, clay, lime, sand and gravel, and stone.

Minerals, water-power, and forestry

Another of Quebec's major economic resources is electric power. With the nationalization of all electric power in Quebec in 1963, Hydro-Québec became the largest producer of electricity in Canada. Besides its more than 70 hydroelectric plants, Hydro-Québec has many thermal and nuclear plants. In 1967 the Research Institute in Electricity, the first organization of its kind in the world, was created near Montreal.

Forestry is the third great economic resource of Quebec. It is estimated that forests with economic potential cover about 295,000 square miles, more than three-fourths of which is exploited. Only about 42,000 square miles of forests are privately owned, accounting for about two-fifths of the annual timber cut. The remaining timberlands are public and under government management.

Agriculture. The concentration of population in the southern part of Quebec developed historically in response to the potential of the fine level soils of the lowlands and the undulating moraine-covered plateaus of the Appalachian region. The lowlands are used largely for animal feed, particularly hay, for dairy cattle. Tobacco is grown on the sandy soils of the Joliette area, vegetables in the area of muck soil south of Montreal, and apples on the slopes of the Monteregian Hills. The region of the Eastern Townships is another dairying centre, although only half the land in the area is cleared. Maple sugar and maple syrup provide additional income. The Gaspé Peninsula and the Canadian Shield region, with the exception of the western clay belt and the Lac-Saint-Jean Depression, provide only limited opportunities for agriculture.

Furs and fisheries. The fur trade has played a part in the economy of Quebec since the beginning of the French regime and is still important today in Ungava. Mink easily ranks first in production while other species include beaver, fox, lynx, otter, and chinchilla.

Maritime fisheries are important in the Gaspé Peninsula, the north shore, and the Magdalen Islands. The Quebec Department of Industry and Commerce operates a network of cold-storage plants. Principal species include cod, herring, redfish, lobster, and salmon.

Regression in the economy

Industry. A number of unfavourable factors affect Quebec's economy, and such areas as textiles have definitely regressed. Slowdowns have been recurrent in the pulp and paper, food and beverages, and construction industries and in other related services. The per capita income has also lagged significantly behind that of Ontario, the other highly industrialized province. A significant proportion of Canada's organic and inorganic heavy chemicals is produced in Quebec. The province is a leader in petroleum refining, with major production in the Montreal region, and Quebec's furniture industry is the oldest in Canada. The industrial core of the province is Greater Montreal, where some 7,000 plants account for most of Quebec's manufacturing output. Montreal is a leading producer of aircraft, railway locomotives, leather footwear, and chemical and pharmaceutical products; other industries include flour milling, tobacco, brewing, and distillery.

Transportation. Quebec is fully integrated in the general transportation system of Canada and of North America. Except in northern Quebec, neither climate nor distance are serious problems. The major handicap in the development of transportation is the low population density of the regions outside the urban area of the St. Lawrence valley and the restricted flow of goods and persons to the north.

The transportation system is largely oriented on the basis of the geographic position of Montreal, the major crossroads for moving persons and goods in and out of Quebec, whether by road, water, or air. Montreal has two international airports, one in Dorval and another in Mirabel. Quebec city also accommodates international passengers. The internal air traffic for Quebec province is provided by two companies. Montreal is both a major ocean port and, by virtue of the St. Lawrence Seaway, which allows ships to travel a total of 2,300 miles from the North Atlantic to the ports of the Great Lakes, a major inland port as well.

The railway system of Quebec is practically restricted to the St. Lawrence Plain, with a few branch lines of the two major Canadian companies. Three privately owned railways transport iron ore from northern Quebec.

Administration and social conditions. *Government.* Quebec's administrative system can be defined as government through parliamentary democracy. An elected unicameral National Assembly is the equivalent of the parliamentary institutions of other Canadian provinces; its second chamber was abolished in 1968. A lieutenant governor represents the British monarch. The Executive Council, or Cabinet, is headed by a prime minister who is responsible to the National Assembly for all legislation within provincial jurisdiction. The Executive Council has responsibility for preparing legislation for the National Assembly. The administration follows the parliamentary principle that a prime minister and his Cabinet will remain in power as long as the prime minister is able to command a majority in parliament.

Branches of government

An unusual characteristic of Quebec is its administration of justice. Although its Department of Justice, as in other Canadian provinces, has a dual responsibility for criminal and civil laws, the civil law of Quebec is different from that in the other Canadian provinces. It follows the civil code of the French rather than the English common law followed by the rest of Canada. Quebec also has its own provincial police, La Sûreté Provinciale du Québec, who have taken over this responsibility from the federal Royal Canadian Mounted Police. Although the economy is shared with an English-speaking minority, political life has for some time been dominated by French-speaking Canadians. From 1936 to 1976 the parliamentary government was in the hands of either Union Nationale or the Liberal Party, both controlled by politicians of French descent. In 1976 a new separatist-minded party, Parti Québécois, won control and, until they were ousted in 1985, fought a continuing battle against its Anglophone citizens and against the federal power in Ottawa.

Education. Nothing shows more clearly the complex nature of Quebec than its educational system. Organized originally along religious and linguistic lines and largely privately financed, it has become, for all practical purposes, a public system since 1964 under the provincial Department of Education. Larger sums are spent each year on education. Although the religious dichotomy between Protestants and Roman Catholics has been maintained, it is largely along linguistic lines that the separation continues. A problem causing tensions is the growth in the number of English-speaking pupils, while, because of the low birth rate, the number of French-speaking pupils at the elementary level is decreasing. The law permits parents to choose the language of education, and increasing numbers of persons are choosing English.

Higher education

Organized on the normal structure of preschool, elementary, secondary, and college–university levels, the educational system has created the Colleges of General and Professional Studies, which act as two-year pre-university-level institutions. There are three English-speaking and four French-speaking universities; of the latter, the University of Quebec has numerous remote campuses, including those at Montreal, Trois-Rivières, and Chicoutimi.

Health and welfare. The provincial government has an integrated system of health and social services. More than 200 hospitals are under government administration to serve the health care needs of the people. Social assistance is available for the indigent, the elderly, dependent children, and others in need. Although sharing with the rest of Canada one of the world's highest standards of living, Quebec has a larger proportion of unemployed and persons on social security than the Canadian average. The cost of social aid is one of the highest among provincial governments in Canada. This situation is explained by the fact that age, health, level of education and training, and similar factors place a higher percentage of the population below the requirements of a modern industrialized society. In the late 20th century the Quebec government developed minimum-wage legislation, reorganized its health service, and introduced universal medicare.

The relation among economic development, social conditions, and educational level remains one of the basic causes of the political tension between French and English, on the one hand, and between the federal and the provincial governments, on the other. Although Quebec has transformed some of its institutions in order to meet the difficult demands of an industrial society, the changes are yet too recent to be able to determine whether they will improve the present situation permanently.

Cultural life. In many ways, Quebec is a smaller plural society within the larger pluralism of Canada: that is to say, it is nearly as difficult to define the cultural identity of Quebec society as it is to define that of Canada as a whole. Although a minimum of overall linguistic identity does exist in French Canadian life in Quebec, there are also many cultural differences between its French-speaking groups in east Montreal and similar groups in such smaller centres as Abitibi, Lac-Saint-Jean, Gaspé, or the Eastern Townships. Regional variations heightened by immigration have produced a sociocultural fragmentation that in part explains the differences in political votes, religious behaviour, and even the quality in the use of the French language. Furthermore, there are class–cultural differences and a strong elitist tradition explaining the high social status of such professions as medicine, law, the clergy, and business management. Even the new middle class of French Canada, which has appeared since the development of urban industrial society, is more politically aggressive in Montreal than in Quebec city, for the obvious reason that in Montreal their socioeconomic status is most difficult. Because of the cultural variations within Quebec, it is often difficult and sometimes impossible to obtain unanimity in political decisions that touch cultural or educational questions.

Debate over Quebec's cultural identity

While claims of a unique French-speaking culture, based on certain traditions brought from France, go back to the 19th century, a debate exists as to the exact nature of Quebec's cultural identity beyond the simple fact of dominant use of the French language. In many ways cultural values have been called up in an attempt to create a distinctive society. This is reflected in the government's fostering of a "Quebec" national culture, which was largely nonexistent when French-speaking Québécois used to call themselves French Canadians. Cultural values have thus been a sign of political identity as much as, or more than, the expression of long tradition.

To ensure the continuation of this Québécois identity, the Quebec government has created a number of institutions aimed at fostering cultural life. Foremost among these institutions is the Ministry of Cultural Affairs, which is responsible for improving the quality of the language used and for stimulating cultural, literary, and other artistic activities. Created in 1961, it was the first of its kind in North America. It not only gives direct financial aid to such state cultural bodies as museums and helps more than 60 theatrical, ballet, and musical companies, but it also has contributed for a number of years to book publishing and to public libraries for book buying. One of the major responsibilities of the department is to develop cultural links with other French-speaking countries. Another of its activities has been the development of regional cultural centres within Quebec to foster regional cultural life. Another institution created by the Quebec government in its efforts to stimulate French-language cultural development is Radio-Québec, founded in 1968 to develop cultural and educational programs. In 1969 its scope was broadened to take in television as well, and it was renamed Quebec Broadcasting Bureau. Radio-Canada and the TVA Network also broadcast in French as well as English. There are French- and English-language daily newspapers, the French-language papers being more numerous by far. The largest dailies of both languages are published in Montreal.

Besides the official cultural institutions, Quebec possesses an extremely large number of private artistic organizations, ranging from theatre companies to filmmaking. The most spectacular cultural development in Quebec, however, has been that of the *chansonniers,* who represent a cross between poets and songwriters. Their popularity, especially among the younger generation, arises from the fact that their songs reflect the present search for cultural and political identity. The *chansonniers* are involved frequently in political activities and are identified largely with the nationalist movement. Music and painting also share in this artistic revival, as does literature.

HISTORY

When in 1534 the French explorer Jacques Cartier landed at present-day Gaspé and took possession of the land in the name of the king of France, he brought with him the traditions of mercantile expansion of 16th-century Europe to this land where Indians and Inuit had been living for some thousands of years. There is a debate among historians, however, as to when the real history of Quebec should begin. Because the Province of Quebec as a political and geographic entity was created by the proclamation of 1763, the notion is sometimes also advanced that its real history should start with the capitulation of the French army in 1760, although Quebec city was founded in 1608.

Problems of political identity

The various definitions given by historians are not simply semantic questions, for they contain diverse assumptions concerning the political identity of the Quebec government. For example, there is a political tradition among French Canadians that the government of Quebec is also the government of the French Canadian people, and, therefore, they are heir to what was New France. The 1966–67 *Annuaire du Québec* (*Québec Yearbook*) states this claim most clearly:

> Quebec is a state with limited responsibilities that belongs to the Canadian Federation as a province. It is also the national state of the French-Canadians and exercises its governmental prerogatives, in the areas of its responsibilities, on the majority of the heirs of those who colonized New France.

To this, some authorities have replied that the territories covered by New France and those now included in the Province of Quebec cannot be equated. Although New France began with the founding of three cities—Quebec city in 1608, Trois-Rivières in 1616, and Montreal in 1642—it finally included territories that extended west in what is now the United States to the Ohio and Mississippi rivers. Even if the British government, by the Quebec Act of 1774, did in fact include practically all the territories of

New France in the new Province of Quebec, this situation lasted only briefly.

Some English-speaking historians assert that the Quebec Act created what is now Quebec as well as the practice of trying to fuse British and French institutions in the new political entity. The new British colony was, thus, to be administered by a governor and a council, using British criminal law and French civil law. Whatever the British government intended, however, when the composition of Quebec's population gradually changed as a result of increasing English-speaking immigration, it became increasingly difficult to carry out a policy that could give satisfaction to both the English- and French-speaking groups. In 1775, the year the American Revolution broke out, Quebec city was besieged by American troops, and Montreal was occupied. When peace was restored in 1783, the loyalists who had fled from the United States were settled west of Ottawa River, in what became the province of Ontario. This was the beginning of the basic geographic dichotomy in Canada between French and English. In 1791, Canada was split into Lower Canada (Quebec) and Upper Canada (the future Ontario).

Beginnings of ethnic inequities

Furthermore, although throughout the province the rural population remained overwhelmingly French, Montreal became the domain of the English merchants, who were bitterly anti-French. The metropolis of Canada was to have an English-speaking majority until the middle of the 19th century, and, even after that, it took nearly a century before French speakers gained control of its economic life. Discrimination existed between the two groups not only in economic, political, and religious activities but also in such other fields as education. Gradually, two different educational systems came into being. English-speaking McGill University was opened in 1821, but it was not until 1852 that the French-speaking Quebec Seminary, founded in 1668, became Laval University.

During the first part of the 19th century, the causes for conflict between the two groups increased with the rapid growth of the English-speaking population in Canada. The English merchants of Montreal tried in 1822 to obtain an Act of Union that would have united Lower and Upper Canada and given them an English-speaking majority in the country as a whole. The reaction against this attempt among French Canadians was strong and prepared the way for the 1837 rebellion. This rebellion, the first major manifestation of political nationalism among French Canadians, was led by Louis-Joseph Papineau, whose Patriote Party became a centre for radical politics. After the rebellion was put down, the British government sent out the Earl of Durham to investigate; his report, published in 1839, offended French Canadians by referring to them as a people without a history or culture and by characterizing the situation in Lower Canada as "a war between two races." The report also suggested the setting up of responsible government in Canada as a solution to the tensions between the two groups. In 1841 a new Act of Union joined the provinces of Upper and Lower Canada, and, in 1867, the British North American Act created the confederation of Canada by the federation of the four provinces of Nova Scotia, New Brunswick, Quebec, and Ontario.

From then on, French Canadian nationalism became a permanent feature of Canadian as well as Quebec politics. Doctrines of papal supremacy over national authority introduced the idea of the religious mission of French Canadians in North America. Under the leadership of such men as Henri Bourassa and the abbé Lionel Groulx, the province evolved its special vocation as the "political home" of French Canadians, and the government of that province assumed special responsibility for the defense of French culture. This situation also resulted in the doctrine of provincial autonomy that was used by Prime Minister Maurice Duplessis between 1936 and 1957.

Revival of nationalism and separatism

French Canadian nationalism also led to the "quiet revolution" of the Liberal government under Jean Lesage, who took office in 1960, and to the not-so-quiet revolution of a terrorist group known as the Front de Libération du Québec (FLQ), which was responsible for sporadic violence and the murder in 1970 of Quebec's labour minister, Pierre Laporte. The creation of the Parti Québécois in 1970 brought into being a new forum of Quebec nationalism, one that is no longer strictly French Canadian: it has English-speaking members as well as members of other ethnic groups, and its advocacy of separation from Canada is based on issues of economic and social development. In 1976 the party won the general elections and control of the provincial parliament, under the premiership of René Lévesque. In a referendum held in May 1980 the Quebec electorate rejected the opportunity to negotiate with the national government for sovereignty-association status (see above *Canada since 1920*). In elections held the following year the Parti Québécois maintained its majority in the provincial parliament, but in 1985 it was defeated and a Liberal Party government was installed. From that time the appeal of the political ideology of separatism declined steadily, although some revival occurred in 1990 when the Meech Lake accords, which would have recognized Quebec as a distinct society, failed to be ratified by the Canadian Parliament. (P.Ga.)

PRAIRIE PROVINCES

Alberta

Alberta, sparsely populated but possessing rich resources and beautiful scenery, is the most westerly of the three Prairie Provinces occupying the continental heartland of western Canada. With a land and freshwater area of about 255,285 square miles (661,190 square kilometres), it remains one of the most attractive of the underpopulated areas of the globe.

Location and general character

Following the earliest explorations of fur traders, the settlement of its plains and parklands led to the rapid development of agriculture. Subsequent exploitation of rich oil, gas, coal, and timber resources has led to further population growth, with steadily increasing urbanization and industrialization. The scenery of the mountain parks in the west is internationally renowned.

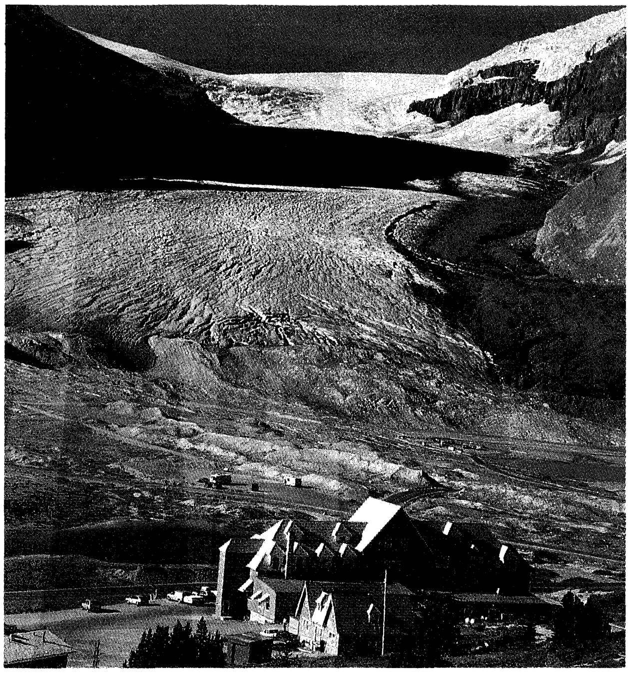
Relative isolation from the more populous eastern regions of the nation has slowed the development of industries needing mass markets. However, natural routes to the north have made Alberta the major jumping-off point for development of the Arctic.

Alberta is 756 miles (1,216 kilometres) in extent from north to south, and 404 miles (650 kilometres) across at greatest width. To the east, the 110th meridian is the boundary with its prairie neighbour Saskatchewan. Its western boundary with British Columbia is formed by the 120th meridian and the crest of the Rocky Mountains. Northward, beyond the 60th parallel boundary the adjoining Northwest Territories slopes to the Arctic Ocean, while the 49th parallel in the south forms the international boundary between Alberta and the state of Montana in the United States. Freshwater surfaces cover about 6,485 square miles (16,800 square kilometres) of the province. Alberta was established as a district of the Northwest Territories in 1882 and was enlarged to its present boundaries on becoming a province in 1905. The provincial government has its seat in Edmonton.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* Along the southwest border, Mount Columbia (12,294 feet [3,747 metres]) is the highest of 26 magnificent peaks reaching above 11,000 feet. Beyond the narrow foothills, soft rocks form an undulating plateau falling from over 3,000 feet to under 1,000 feet in the northeast, where the ancient rocks of the Precambrian shield outcrop. Outliers of higher ground include the Cypress and Swan hills and the Caribou Mountains.

The Columbia Icefield is the source of two major Alberta rivers, the Athabasca and the North Saskatchewan. The first flows northeast to the Lake Athabasca–Lake Claire



The Athabasca Glacier on the Columbia Icefield in the Rocky Mountains, Jasper National Park, Alta.

Alec Pytlowany/Masterfile

complex, where it is joined by the Peace River. The Slave River drains the area north toward the Arctic Ocean, and the lowest point in the province (573 feet) occurs in its valley.

Southern drainage system

Apart from a small area drained by the Milk River into the Missouri, the south of the province is dominated by the Saskatchewan River system. The Oldman, Bow, and Red Deer rivers combine to form the South Saskatchewan, which flows east with the North Saskatchewan toward Hudson Bay. Many of the rivers flow through deeply incised valleys, in which the eroded, barren landscapes known as badlands may develop. Those of the Red Deer are famous for their rich deposits of dinosaur remains.

Climate. Alberta has a continental climate, with more sunshine than any other Canadian province. Winters are dry, sunny, and cold, though in the south the Chinook winds, which comprise warm, dry airflows of Pacific origin descending the western slopes of the Rockies, may raise temperatures by 40° F (22° C) in 10 minutes. Summers are warm and wetter (except in drought years), with occasional destructive hailstorms and tornadoes, the latter having increased in frequency in the 1980s. Edmonton's mean and extreme temperatures are, in January, 5° F and −57° F (−15° C and −49° C), while in July they are 63° F and 95° F (17° C and 35° C). Annual precipitation averages 18 inches (466 millimetres), about half of it falling between June and August.

Plant and animal life. Chernozems—rich brown and black soils with a deep humus layer—underlie the prairies and parklands. Blue grama and other grasses dominate the prairie area in the south, although cacti, tumbleweeds, and sagebrush are more conspicuous; few trees grow naturally outside river valleys. The transitional parklands have aspen bluffs, increasing in size until forest dominates. The less fertile gray-wooded soils known as podzols underlie the extensive mixed and coniferous forests of the foothills and the north, where various combinations of aspen, white spruce, jack and lodgepole pines, and balsam fir are found. Black spruce and tamarack grow over accumulations of organic peat in extensive bogs. Engelmann spruce and subalpine fir are important trees in the mountain forests. The wild rose, Alberta's provincial flower, is widespread.

Meadowlarks and pronghorn are conspicuous on the prairies, and badlands support rattlesnakes, horned lizards, and scorpions. White-tailed deer and coyotes are familiar in parkland areas, while the great horned owl, the provincial bird, rears its young in vacated crows' nests. The northern forests house a wealth of fur bearers and big game, including the moose, wapiti, caribou, and black bear. Gray jays visit campsites, and loons are heard on the many lakes. Mountain goats, bighorn sheep, and grizzly bears, together with Clark's nutcrackers and golden eagles, are characteristic of the mountains, while rivers and lakes throughout the province support trout, whitefish, and pike; ducks nest by every slough. Examples of most habitats and some threatened species receive partial protection in national and provincial parks, wilderness areas, and ecological reserves. The endangered peregrine falcon, however, also flys among the high-rise buildings of Edmonton and Calgary.

Threatened habitats

Settlement patterns. The agricultural southeast is fairly uniform, though with considerable variations in landscape, farming practice, and density of settlement, while the isolated Peace River block forms a basically agricultural area to the northwest. The broad strip of forested foothills is much visited for hunting and other recreational purposes, utilizing the network of forestry roads. Some parts of the northern forested area are little changed from fur-trading days, with a scattered population of trappers and fishermen. The road network is advancing, however, and the province is committed to the development of pulp mills there. The mountain national parks each have small permanent populations and many visitors.

The square pattern of the Dominion land survey dominates much of the rural landscape. The survey established townships with 36 sections, each one mile square. From the air, the resulting great square fields can be seen spreading from horizon to horizon, while on the ground the straight roads seem to stretch endlessly.

Homesteading introduced some individuality into this pattern: log huts, elegant frame buildings, and modern houses were often occupied successively on the same farm and may still survive, although rural depopulation has caused abandonment of many dwellings. A network of dugouts and irrigation canals provides water in dry areas. Also, Indian reserves, presurvey settlements, and the communal farms of some religious groups make their own distinctive contributions to the landscape.

Groups of highly visible grain elevators, set at intervals along the railways, are characteristic sights in the province. Most villages have grown up around such a group, often only on one side of the railway track. A grid street plan and frame houses are typical, along with small shops, a hotel, and several churches.

Most urban centres gain character from their often splendid settings rather than from outstanding buildings. Such settlements as Peace River, in a spectacular river valley, and Drumheller, among extensive badlands, are noteworthy but not untypical. Most towns have a basically rectangular grid pattern, perhaps elongated along river frontage or a railway.

Each of Alberta's major cities serves a large rural area: Lethbridge and Medicine Hat, the southwest and southeast, respectively; Grande Prairie, the Peace River country; and Red Deer, the central region. Edmonton and Calgary have a much wider influence. Each is developing the high-rise buildings and expressways characteristic of cities in more populated centres, while retaining enough parkland to remain an attractive place to live.

Varied ethnicity

The people. In terms of national and cultural origins, Alberta is one of the most varied of the Canadian provinces. The early settlement around the turn of the century, as well as immigration following World War II, contributed to this diversity. Persons of British origin or descent are the most numerous, followed by Germans, Ukrainians, Scandinavians, French, and Dutch. The Indian population constitutes about 3 percent, and there are also Polish, Austrian, Russian, Chinese, Japanese, Lebanese, Vietnamese, and other ethnic elements. There are about 20 religious denominations, with the Roman Catholic, the United Church of Canada, and the Anglican Church of Canada predominating. Other groups include Mormons, Mennonites, Hutterites, and Muslims.

This human mosaic has provided a valuable cultural legacy for Alberta. This has found expression in festive occasions, costumes, the performing and fine arts, and in handicrafts. In domestic and religious architecture, this heritage is evident in areas of ethnic concentration such as the regions north and east of Edmonton; the Nikka Yuko centennial garden in Lethbridge; and the Hutterite settlements around the province.

The most densely populated area of Alberta is the central and southwestern portion, east of the foothills. The lowest density, averaging about one person per square mile, is in the northern portion of Alberta, the foothills and the mountain regions, which, together, occupy about three-quarters of the province. Alberta's population growth leveled off because of the economic slowdown of the 1980s, but rural depopulation continues.

The economy. *Resources.* Alberta holds the bulk of Canada's known fossil fuels. Oil and gas occur widely, and major deposits of heavy crude oil are being exploited in the Lloydminster, Cold Lake, and Fort McMurray regions. Alberta produces about 90 percent of Canada's natural gas and crude oil and a significant proportion of its coal. Fluctuations in world oil prices seriously affect the economy. Other mineral resources include sands, gravels, bentonite, clay, limestone, salt, phosphates, and sodium sulphate; sulphur and helium are produced along with the natural gas.

Forests cover more than one-half of the surface of the province. Aspen, birch, white spruce, and pines are the principal commercial species and are exploited for lumber, plywood, and pulp.

Industrial ecology problems

Most of the province has an abundance of lakes and rivers, a considerable number of which are exploited for irrigation and hydroelectric power. The ecological damage caused by these developments, weighed against the economic gains, has caused widespread controversy. Also significant as a resource are Alberta's wildlife and spectacular scenery, which, in combination with historic cultural attractions, form the basis of an expanding tourist industry.

Agriculture, forestry, and fishing. Although fisheries and furs remain important in the undeveloped areas of the province, several million acres (some irrigated) are under crops, mostly wheat, followed by barley, hay, and oats. There is increasing diversification, with rapeseed (canola), flaxseed, sugar beets, potatoes, rye, and mustard becoming important. Cattle, including dairy cattle, are also significant, together with swine, sheep, and poultry.

Industry. Natural resources are largely developed by private industry, controlled by the Canadian and provincial governments through legislation and regulations. Much of the industry is managed and financed outside Canada. Extensive government research aids resource development, and practical assistance is provided to agriculture.

Major manufacturing industries are foods and beverages, petroleum and chemical products, metals, transport equipment, and wood and paper. During the 1980s there also was considerable development of high-technology industries in such fields as computers, telecommunications, and medical equipment. Construction is linked to the development of gas and oil resources but also includes a proportion of residential building.

Transportation. Southern Alberta communications are dominated by east–west routes that thread the few mountain passes and spread over the plains. There are good communications south into the United States, and from Edmonton air and surface routes fan out to serve the Arctic from Alaska to the northern Canadian islands. The Athabasca and Slave rivers are active in the carrying of freight to the Arctic. The east–west Canadian Pacific and Canadian National railways have a network of branch lines serving agricultural and northern areas. Oil and gas pipelines link Alberta to markets as far away as Quebec and California. Alberta's major highways include the Trans-Canada and Yellowhead east–west routes and the Mackenzie and Alaska highways to the north and northwest.

Air transport has been used in development of northern resources since 1921; in the late 20th century there were elaborate air charter services as well as scheduled regional, national, and international services. Edmonton and Calgary have international airports.

Administration and social conditions. *Government and politics.* The Canadian Constitution and the Alberta Act (1905) provide the constitutional framework for the province. In line with other Canadian provinces, Alberta has a lieutenant governor (functioning as representative of the British monarch), an elected legislative assembly, and an executive council. The lieutenant governor is appointed by the federal government for a five-year term. The premier heads the executive council, which is responsible for administering laws and appropriations approved by the legislature. From 1935 to 1971 the Social Credit Party was dominant. The Progressive Conservative Party thereafter revived to lead the province, with Liberals and New Democrats forming a large opposition.

The Mounties

There is no provincial police force. The Royal Canadian Mounted Police is under contract to the province and to some municipalities, while in others there are municipal police forces. Correctional and rehabilitation services are provided under federal and provincial jurisdiction.

Municipal administration takes a variety of forms, appearing as cities, towns, villages, counties, municipal districts, and improvement districts (special areas). Mayors, councils, and school and hospital boards are elected, while the major sources of municipal revenue are the property tax, the local-improvement tax, and the business tax. Substantial grants are nevertheless made by the provincial authorities, although some municipalities derive additional revenue from the operation of utilities.

Education. Education is on a 12-grade system and includes a large but separate Roman Catholic school system, tax-supported. The province outlines the school curriculum and maintains general supervision of the elementary and secondary school systems, but administration is through elected school boards. The School Foundation Program Fund, pooled from provincial grants and local property taxes, provides funds—distributed back to the school boards—for the school systems.

Universities are located in Edmonton, Calgary, Lethbridge, and Athabasca, the latter specializing in distance education, a system of off-campus learning. Institutes of technology in Calgary, Edmonton, and Stony Plain provide extensive vocational training. A network of community and agricultural colleges supplement the system. Financial assistance for students is obtainable through the Alberta Students Assistance Board.

Health and welfare. The Alberta health insurance plan and the Alberta hospitalization benefit plan provide for health services through payment of an annual premium but with subsidies for low-income families. The Alberta Blue Cross plan and private insurance plans provide for certain supplementary hospital, drug, and other services, while mental hospitals are provided under a special provincial act. The costs of social assistance programs are borne jointly by federal, provincial, and municipal authorities.

Cultural life. Although the province is young, interest in preserving its heritage and fine arts is strong. The Cultural Development Branch of the provincial government gives practical aid and encouragement in all fields through such programs as performing-arts tours and exhibitions, leadership training programs and workshops in all phases of performing and expressive arts, consultative services, and financial assistance.

Folk tradition

The arts. The early artistic history of the province is largely one of rich oral folklore, although a major Icelandic poet, Stephan G. Stephansson, lived near Markerville, and his house is now a historic site. Since the 1940s a limited number of noteworthy artists (all immigrants to the province) have emerged, including the painter Illingworth Kerr and such writers as W.O. Mitchell and Rudy Wiebe. Interest in cultural heritage and the arts has increased rapidly since the 1960s, and Calgary, Edmonton, and Banff exhibit a rich and diverse artistic life with thriving communities of artists in all fields, many of national and some of international recognition.

Cultural institutions. A network of museums and historic parks now interpret the natural, historic, and artistic heritage of the province. The Provincial Museum of Alberta was opened in Edmonton in 1967. The Glenbow-Alberta Institute in Calgary has important collections of history and art, and the Tyrrell Museum of Palaeontology in Drumheller is the world's largest fossil museum, with particularly fine displays of dinosaurs. The latter operates in association with Dinosaur Provincial Park near Brooks, the first World Heritage Site to be designated for its fossil resources. Head-Smashed-In Buffalo Jump, another World Heritage Site near Fort MacLeod, features a buffalo jump that was used for 6,000 years. Other notable institutions include the Ukrainian Cultural Heritage Village east of Edmonton, the Crowsnest Ecomuseum, Calgary Zoo, and Edmonton's Space Sciences Centre and Art Gallery.

The performing arts are served by the Jubilee auditoriums in Edmonton and Calgary and the Calgary Centre for the Performing Arts, which are used by local symphony orchestras and opera and ballet companies, and by the Citadel Theatre complex in Edmonton. A lively performance scene exists in less formal settings, with major folk and jazz festivals, Edmonton's Fringe Theatre Festival, and a host of theatre and other groups performing outdoors, and in a variety of small theatres and adapted buildings. Smaller centres are served by provincial educational television and radio. Support for many of the arts is provided by the internationally renowned Banff Centre for Continuing Education, the Provincial Department of Culture and Multiculturalism, and a number of independent funding agencies.

Recreation. Alberta has the largest area devoted to national parks of any province in Canada. The national parks and several provincial parks are heavily utilized for such recreational activities as downhill and cross-country skiing, mountaineering, camping, hiking, and birdwatching. Ethnic and Indian arts and crafts are featured at such annual events as the Banff Indian Days, the Calgary Stampede, the Edmonton Heritage Festival, and many local fairs and rodeos. Ice skating and curling are important sports during the long winters, and professional ice hockey and football are extremely popular. The 1988 Winter Olympics, held in Calgary, centred world attention on the city and the province. (R.O.H./D.A.E.S.)

Traditional cultural and sporting events

HISTORY

The area now known as Alberta has been inhabited by various Indian groups for at least 10,000 years. European explorers first appeared in the 1750s as the fur trade expanded across western North America. Two rivals, the Hudson's Bay Company and the North West Company, began building trading posts in the last quarter of the 18th century along the major northern rivers, most notably the Athabasca, North Saskatchewan, and Peace. From 1821, when the companies merged, until 1870, when this region was transferred to the Dominion of Canada, the Hudson's Bay Company controlled and governed the area, which was populated by Indians, the métis, and a few European fur traders, missionaries, and settlers.

After 1870, settlement in southern Alberta began, based on a ranching economy. The Indian tribes had been decimated by European diseases and the disappearance of the buffalo, their main source of livelihood. The signing of treaties relegated the remaining Indians to reservations, but not before the abuses of unscrupulous whiskey traders had hastened the creation of the North West Mounted Police. In 1874 they established Fort Macleod and laid the bases of Canadian law enforcement in Alberta.

The Dominion Lands Act of 1872, which provided low-cost homesteads, the building of the Canadian Pacific Railway, which reached Calgary in 1883, and vigorous promotional campaigns brought an influx of settlers from eastern Canada, the United States, and Europe. By 1901 the population had reached 73,000, and by 1911 it had ballooned to 374,000. The development of earlier-maturing and more disease-resistant varieties of wheat made crop farming less risky and, in northern areas, newly feasible. Subsequently a wheat-based economy expanded throughout most of the arable parts of the province.

Responsible government developed gradually from 1875, when the North West Territories Act went into effect, until 1897, when a fully responsible legislative assembly was elected. Made a district of the Northwest Territories in 1882, Alberta was enlarged to its present boundaries in 1905 when it was made a province of Canada, although crown lands and natural resources remained under federal control until 1930. Edmonton, as the capital and distribution centre, grew rapidly, as did other urban centres. Calgary boomed with the discovery of oil at Turner Valley in 1914. Medicine Hat and Lethbridge, the latter a coal-mining area since 1869, developed into large distribution centres. Railways spread over most of the province, increasing agricultural development and providing a ready market for the province's vast coal deposits.

Aspects of economic growth and instability

During World War I the growth of population and the economy slowed. A postwar slump in wheat prices was a major factor leading to agrarian political discontent and the election success of the United Farmers Party of Alberta in 1921. During the 1920s the economy improved and population again increased, but the depression of the 1930s had a devastating effect. In 1935 the Social Credit Party, with a new monetary policy, was elected and retained power for 36 years. Not until World War II did the economy begin to recover. The discovery of oil at Leduc in 1947, as well as discoveries of other oil and natural gas deposits, brought Alberta prosperity, which lasted until the world drop in oil prices brought on the recession of the early 1980s. (R.B.D.)

Manitoba

Lying midway between the Atlantic and Pacific oceans, Manitoba became the fifth province of Canada when it was admitted to the confederation in 1870. Manitoba straddles the boundary between the prairie and central Canada. It has a large agricultural sector and a topography similiar to those of the provinces of Saskatchewan and Alberta; it also has a mixed economy, an urban orientation, and a multiethnic character, all of which resemble Ontario's. While other areas of the Canadian west have experienced economic cycles of boom and bust, Manitoba has maintained a steadier pace, missing sudden growth spurts and escaping abrupt collapses. Similarly, the province's political and cultural life has largely avoided the extremes that tend to characterize western Canadian society.

A relatively stable society

The province's name comes from an Indian word meaning "the god who speaks." More than two-fifths of its land area is forested. Its 250,947 square miles (649,950 square kilometres) contain 39,224 square miles of water, and, of its more than 38,500 lakes, Lake Winnipeg is the 13th largest in the world. The province is bounded on the north by the Northwest Territories, on the northeast by Hudson Bay, on the east by Ontario, on the south by the U.S. states of Minnesota and North Dakota, and on the west by Saskatchewan. Winnipeg, the seventh largest Canadian city, is the capital.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and soils.* Extreme southern Manitoba is part of the Saskatchewan plain, a land of rich, level prairies and rolling pastures. The Manitoba Lowland to the north is the basin that once held glacial Lake Agassiz, remnants of which include Lake Winnipeg (9,416 square miles), Lake Winnipegosis (2,075 square miles), and Lake Manitoba (1,785 square miles). Upland plateaus, wooded river valleys, limestone outcrops, forests, and swamps mark the area that is drained by the Red and Assiniboine rivers into Lake Winnipeg.

To the north and east of the lowland is the geologically ancient Canadian Shield, an area of rocks, forests, and rivers. It covers three-fifths of the province and is drained by the Nelson and Churchill rivers into Hudson Bay. The Hudson Bay Lowland extends 100 miles (160 kilometres) inland as a flat plain of tundra and boglike muskeg. Soil conditions change from north to south. In the fertile zone black soils suitable for farming dominate, although there are occasional large sandy areas. North of this region, lower-quality black soil and gray-wooded soils are found. Soil in the shield, generally not suitable for agriculture, is characterized as gray wooded, podzol, and peat. Manitoba's Western Upland is on the Saskatchewan border. The Riding, Duck, and Porcupine mountains form the Manitoba Escarpment, whose highest point is Baldy Mountain at 2,727 feet (831 metres).

Temperature extremes

Climate. Manitoba has a moderately dry climate with sharp seasonal temperature changes. Temperatures of −40° F (−40° C) are not uncommon in any part of the province; summer days of 100° F (38° C) are not unusual in the southern regions. Average daily temperatures at Winnipeg range from 8.8° F (−12.9° C) in January to 79.7° F (26.5° C) in July. Average lows vary from −8.7° F (−22.6° C) in January to 56.8° F (13.8° C) in July. Annual precipitation varies from 14 inches (355 millimetres) in the north to 22 inches (560 millimetres) in the southeast, with about two-thirds of it falling between May and September. Snow typically covers the ground from November to April in the south, longer in the north.

Plant and animal life. The southern part of the province was once covered by open grasslands, most of which has been converted into farmland. The southern plains are relatively treeless, except for the river valleys, where stands of aspen, oak, willow, and poplar are common. Manitoba's more than 148,000 square miles of forest include open parklands of ash, Manitoba maple, elm, and oak in the south, becoming a mixed broad-leaved and coniferous forest to the north and west, and true northern coniferous forest in the higher latitudes. Trees in the north include white and black spruce, jack pine, aspen, white birch, and tamarack. The Hudson Bay lowlands have willow and spruce, as well as moss, lichens, and sedges.

Caribou, Arctic fox, marten, wolf, otter, lynx, red squirrel, and mink live in the northern forests; deer, moose, cougar, elk, black bear, beaver, weasel, raccoon, red fox, coyote, and muskrat inhabit the more southerly areas. Polar bears roam along Hudson Bay. Grouse, prairie chicken, and other game birds live in the uplands, and millions of geese and ducks breed in Manitoba's sloughs and ponds. Fish include bass, pickerel, sauger, pike, trout, and whitefish. Beluga whales inhabit Hudson Bay.

Settlement patterns. Manitoba's countryside has an older, more settled look than the other Prairie Provinces. The development of the Red River colony in the 19th century gave the early province a distinctly rural character. The rapid settlement of the agricultural lands between 1870 and 1914 and subsequent expansion into the Interlake and northwest areas maintained the rural dominance. During World War II, however, the rural–urban balance tipped. Since that time, the depopulation of rural Manitoba has continued apace, and Winnipeg and the province's network of smaller urban centres have grown accordingly.

Secondary towns

Other than Winnipeg, the province's main towns are Brandon, an industrial and agricultural centre serving the southwest; Thompson, a nickel-mining and nickel-processing town in the northern forest; The Pas, a trading and communications centre on the Saskatchewan River; Flin Flon, a mining centre near the Saskatchewan border; Churchill, a transshipment centre and port on Hudson Bay; Dauphin, a regional service town in west central Manitoba; and Selkirk, the centre of commercial fishing and water transportation on Lake Winnipeg.

The people. *Population composition.* Manitoba is home to a number of native peoples, including American Indian groups such as the Assiniboin and Ojibwa in the south, the Cree and Chipewyan in the north, and Inuit on the Hudson Bay coast. The native peoples have occupied the region for thousands of years, although historically there have been considerable population shifts. In addition, their numbers were greatly reduced as a result of exposure to European diseases, particularly smallpox. The métis (people of mixed ancestry, chiefly French and American Indian) developed a unique plains culture in the early 19th century. The early agricultural settlement in the Red River colony attracted a number of Scottish and Irish farmers. Nonnative settlement grew rapidly between 1870 and 1900, as a result of improvements to river and rail transportation. Immigration from Central Canada and, after 1900, from Europe continued until World War I. Manitoba's population declined during the depression in the 1930s and World War II but grew steadily thereafter, largely through natural increase.

Manitoba is noted for its ethnic diversity. There are numerous ethnic enclaves within the city of Winnipeg. The north end of town retains a strong Ukrainian character, and St. Boniface has one of the largest French Canadian communities outside Quebec. French Canadians established a number of communities south of Winnipeg, Germans settled in south-central Manitoba, and a sizable Icelandic settlement developed around Gimli, on the shores of Lake Winnipeg. The current population is more than 40 percent British, with significant ethnic minorities that include Germans, Ukrainians, French, native peoples, and Poles. The Roman Catholic and United churches are the largest religious denominations, although there are substantial numbers of Anglicans, Ukrainian Catholics, Greek Orthodox, Lutherans, and Mennonites, plus smaller groups.

In- and out-migration

Demographic trends. Mainly because of its faltering late 20th-century economy, there has been a steady out-migration of young people and professionals to other provinces. Manitoba's population growth rate stagnated during the late 1970s and early 1980s; the province enjoyed a slight net in-migration in the mid-1980s, but growth slowed again in the last part of the decade.

The economy. *Resources.* Manitoba has a range of resources to draw upon, allowing it to diversify its economic base. The province has more than 12 million acres (5 million hectares) of land in agricultural use, a huge network of streams, rivers, and lakes with considerable potential for irrigation and hydroelectric development, massive stands of timber, significant fish and game resources, and numerous mineral deposits, including nickel, copper, gold, lead, silver, cadmium, and zinc. Oil and natural gas have been found in the southwest, particularly around Virden, although the fields are relatively small.

Agriculture, forestry, and fishing. Agriculture remains an important sector of the Manitoban economy. Climate and soil types limit agricultural production; some marginal areas, including the Interlake District, have been farmed for several generations with little success. While much of the agricultural production is grain for export, a sizable market gardening sector has developed in the lands bordering the Red and Assiniboine rivers. In addition, poultry, hogs, and cattle are raised through the southern districts of the province. Wheat remains the province's main crop; others include barley, rapeseed (canola), flaxseed, and rye. Manitoba produces a variety of specialized crops, such as sugar beets, sunflowers, corn (maize), canning vegetables, and potatoes.

Foresty dominates northern Manitoba's economy. More than one-fourth of the province's landmass supports valu-

E. Otto/Miller Comstock Inc.

able timber, although there has been some devastation from forest fires. Manitoba also has a specialized commercial fishing industry. Much of the fishing is done on the major lakes—Winnipeg, Manitoba, and Winnipegosis.

Industry. Manufacturing has overtaken agriculture as the largest sector of the province's economy. The traditional industries—meat packing, flour milling, lumber, pulp and paper, printing, and clothing—have been supplemented by more advanced processing and manufacturing. Food processing and distilling remain important, as do nickel and copper ore smelting and the manufacture of aeronautical systems, computers, electrical equipment, and a variety of other products.

Major industrial plants

Among Manitoba's major industrial establishments are a nuclear-research plant in Pinawa, an integrated forest-products complex in The Pas, a nickel-processing complex in Thompson, a pulp mill in Pine Falls, and a fertilizer plant in Brandon. Most of Manitoba's non-resource-based industrial capacity is located in Winnipeg. Manitoba Hydro, the government-owned utility, has been developing a number of large power stations along the Nelson and Saskatchewan rivers. Hydroelectric power is supplemented by coal-fired thermal plants at Brandon and Selkirk.

Winnipeg, once the commercial centre for western Canada, remains a major financial centre, home to the Winnipeg Commodity Exchange and other financial institutions. The growth of government services has also contributed to the expansion of the Manitoba service sector. Tourist travel grew steadily in the 1980s.

Transportation. Because of its location, Manitoba has long been a focus for transportation activity. The construction of transcontinental railways after Manitoba joined the confederation stimulated much development in the region. In outlying areas, branch lines are being abandoned as roads are built and passenger traffic declines. The province has an extensive network of major highways running east to west (including the Trans-Canada Highway) and north to south, supplemented by secondary gravel roads.

Winnipeg is a major hub for air travel; scheduled flights carry travelers to major Canadian centres and the United States, while nonscheduled operators provide service throughout isolated areas of Manitoba.

Churchill, a railway port and former military base on the shore of Hudson Bay, provides a short, direct sea route to Europe. The port is open for only 10 weeks in late summer, however. Waterborne freight traffic plys Lake Winnipeg in summer, and isolated northern communities and logging and mining camps are served by sled trains and vehicles designed for winter roads.

Administration and social conditions. *Government.* Manitoba derives its authority from the Canadian Constitution and the Manitoba Act of 1870. The lieutenant governor of Manitoba, appointed by the (federal) governor-general in council, represents the crown; the duties of this office are largely honorary and ceremonial. The functioning head of the government is the premier. The unicameral legislature sits for five years or until dissolved by executive action.

Executive branch

Municipalities are incorporated by the province, and local administration is under provincial control. Each municipality is governed by a council headed by a mayor or reeve. Districts are governed by provincial administrators, but there are no counties. Greater Winnipeg, consolidated into a single administrative unit in 1972, has an elected mayor and council. Provincial policing is handled by the Royal Canadian Mounted Police.

Education. Elementary, secondary, technical, and vocational schools and universities are a provincial responsibility. Schools are administered by elected local or larger-unit boards under supervision of the Department of Education and are financed by government grants and local taxes. After French-speaking Manitobans fought for their linguistic rights, the availability of French as a language of instruction was reinstated.

Manitoba has three universities. The University of Manitoba in Winnipeg is the major academic institution and home to most professional schools. The University of Winnipeg, noted for its Institute of Urban Studies, is a major cultural centre in downtown Winnipeg. Brandon University is small but noted for its music school and native studies program. Vocational schools are based in Winnipeg, The Pas, and Brandon.

Health and welfare. The people of Manitoba enjoy a relatively high standard of living and access to a wide range of government services. Sanitation and water-delivery systems protect against outbreaks of disease and are part of an extensive public health and safety service. The province supervises medical and hospital insurance programs and provides all Manitobans with free medical insurance. Manitoba has an extensive hospital network, with most specialized services available in Winnipeg or in regional centres. The province also maintains a substantial social welfare infrastructure.

Cultural life. Manitoba's diverse population has created a rich and varied cultural life. Ethnic groups—European, Asian, and native peoples—maintain vigorous attachments to their traditional cultures through schooling, dance, art, music, and crafts. The province's cultural diversity is not uniform. Winnipeg exhibits a variety of cultures, while the towns and villages of the southwest have a strong, uniformly British tradition. Ethnic enclaves throughout the province reflect the pattern of initial settlement. Manitoba is noted for its efforts to retain minority languages.

Cultural institutions
